Exploration of Errors. When a student presented a revised proof that had some mathematical errors, Dr. Jones would invite the student to discuss the revision. An example of this was shown in Amy’s revised proof presentation of the following statement: “Prove: For all integers x and y, if $x + y$ is odd, then $x \neq y$." In her revised proof, Amy initially wrote the contrapositive statement as, "There exist some integers x and y such that $x = y$.” In response to this alteration, Dr. Jones posed the question, "Why did you change the quantifier?" This inquiry prompted Amy to reconsider her choice regarding the quantifier. After careful thought about the quantifier and statement, Amy concluded that altering the quantifier was not necessary when applying the contrapositive. Dr. Jones confirmed the validity of Amy's explanation regarding the equivalence of the contrapositive statement. In summary, when a student struggled fixing a proof error, Dr. Jones would start the proof reconstruction process, which might include verbal guidance or an explicit conversation-based reconstruction.

Summary and Discussion

Dr. Jones' approach to assessing oral proof presentations combined flexibility and thoroughness. Dr. Jones occasionally granted success without follow-up questions for authentic and fluently presented valid proofs. However, she frequently asked follow-up questions to confirm understanding, even when proofs appeared correct These queries focused on the logical structure or the reasoning behind revisions. These inquiries helped gauge student comprehension, considering any resources were allowed. When alternative solutions are available, Dr. Jones would highlight this and occasionally provide explanations or walk students through the proof's reproduction. She also gave students opportunities to correct errors through questions or prompts to extract missing information or initiated discussions to encourage self-identification and correction of the proof errors.

Oral follow-up questions revealed a key insight: constructing a correct proof does not necessarily imply a deep grasp of the foundational concepts it relied on. These thought-provoking questions played a pivotal role in preparing students to actively participate in discussing the "why" behind the proof, delving into the rationale and reasoning that support their revisions and the validity of their proofs. This active engagement, in which students defended their arguments, fostered an increased awareness of the meta-discursive rules inherent in constructing a mathematical proof. Encouraging students to articulate and justify their thought processes helped them understand the fundamental principles and logical connections in mathematical proofs, improving their overall communication skills in this context.

Dr. Jones' assessment method aligns well with the conceptualized commognitive process "of becoming able to have mathematical communication" (Sfard, 2007, p. 573). Through revisions and oral presentations, students not only share their proofs but also actively engage in the written and oral communication to deepen their understanding of proofs. This study highlights the effectiveness of oral follow-up assessments in improving communication skills and shifting the focus from acquiring knowledge to expressing mathematical concepts sufficiently.

The act of verbally explaining ideas during the oral follow-up sessions allows students to become involved in an authentic mathematical conversation which promotes mathematical discourse and think critically when responding to questions related to their proof productions. Moreover, through follow-up questions, the students will learn that they need to be responsible to defend every statement presented in their proof narrative. This promotes the metalevel learning on substantiation in their mathematical proofs.

As a final remark, we observed that this assessment method also offers a valuable teaching and learning platform, allowing Dr. Jones to guide students in error identification and proof reconstruction on a one-to-one basis, which is highly effective for learning. Beyond assessing proof productions, the oral assessment encourages mathematical discourse and discussion, promoting deeper understanding and knowledge enrichment. Furthermore, it prioritizes proof comprehension over construction, with discussions shifting from correcting construction errors to probing comprehension when students present correct proofs, thereby facilitating a more comprehensive assessment of students' mathematical understanding.

The Problems with “Any” and “All”: How Language Impacts Student Meanings for Quantified Variables

Morgan E. Sellers
Colorado Mesa University

This study investigates undergraduate students’ meanings for quantified variables, and how the language of a mathematical statement impacts their meanings. I conducted 3-day exploratory teaching interviews with eight students from transition-to-proof and advanced calculus courses (four from each course). Over the course of the three days, I presented students with a variety of statements from calculus in order to test how both and language and mathematical content might impact students’ meanings for quantified variables. I found that students’ meanings did often change across mathematical contexts that contained different language. In particular, the words “any” and “all” were found to lead some students to use different meanings for quantified variables in calculus statements.

Keywords: quantification, quantifiers, meaning, calculus, mathematical language

Recently, many have called others to focus on students’ logic in elementary calculus courses (Case, 2015; Dawkins & Cook, 2017; Sellers et al., 2021). This is because many calculus statements are *complex mathematical statements* (Sellers, 2018), i.e., involving quantified variables and logical connectives. Yet, when investigating student quantifications of individual quantified variables, some students, in particular calculus students, use different quantifications for individual quantified variables, if they quantify at all (Sellers et al., 2021).

Furthermore, other researchers have called for more investigation into students’ meanings for quantified variables as related to the specific language and grammar given in statements across different mathematical domains (Shipman, 2013; Vroom, 2022). As such, students’ quantifications of the variables in these statements as related to the specific language given in the statements is important to investigate if we want to help them understand calculus ideas.

Others have noted that students’ logic might vary from one mathematical context to the next (Dawkins & Roh, 2020; Dubinksy & Yiparaki, 2000; Epp, 1999; Shipman, 2013). Thus, there is a need to compare students’ meanings for quantified variables across different mathematical contexts which involve different language and grammar.

This study is part of a larger study investigating both students’ interpretations for quantified statements from calculus and their negations of these statements (Sellers, 2020). In this paper, I focus on additional information gleaned regarding students’ meanings for quantified variables as related to the language given across different statements. Specifically, I focus on findings that extend the work of Sellers et al.’s (2021) framework for students’ meanings for quantified variables and continue to address the following research question: *How does language impact student quantifications across different mathematical contexts in calculus?*

Literature Review

Several researchers have noted the complexities of interpreting quantifiers specifically in complex mathematical statements (David et al., 2020; Dubinsky et al., 1988; Selden & Selden, 1995; Sellers et al., 2021). Furthermore, some have posited that interpreting quantified statements may be inherently difficult for students due to the different purposes for quantifier words and logical connectives in mathematics and colloquial English (Epp, 1999; Dawkins &

Cook, 2017; Grice, 1975; Roh, Lee, & Tanner, 2016). For example, if I state the following universally quantified statement, "Every book on the shelf is French," I colloquially infer there is at least one book on the shelf, whereas the statement could be vacuously true in propositional logic (Epp, 1999; Johnson-Laird, et al., 1989). Even more striking, there may be cases where the meaning of quantifier may be completely different in everyday language than in mathematics. Shipman (2013) concluded that students thought "unique" meant "unequaled" instead of "sole," and conjectured that her students' use of the word may have been attributed to the colloquial use of the word. Roh, Lee, and Tanner (2016) found that students assumed the article "a," attached to the existential quantifier "there is," referred to *one* single quantity.

While these previous works do suggest that colloquial language impacts students' reasoning in the mathematics classroom, I do not mean to suggest that instructors should utilize formal semantics or symbolism in the presentation of logical rules exclusively. Stylianides, et al. (2004) found that elementary majors' ability to reason about the truth of statement was higher in verbal cases than symbolic ones. Thus, verbal representations of mathematical ideas are not necessarily to be avoided; rather, an awareness of these colloquialisms may help teachers address these inconsistencies in natural language and mathematics as the need arises in their classrooms.

Theoretical Perspective

The findings from this study use and extend Sellers et al.'s (2021) framework for students' meanings for quantified variables. Similar to Sellers et al. (ibid), I approach this study from a constructivist (Glasersfeld, 1995) perspective. Thus, my focus is on *individual* students' meanings for quantified variables in a variety of calculus statements. A meaning is a scheme, and resides in a student's mind (Piaget, 1977; Thompson, et al., 2014).

Sellers et al.'s framework for student quantifications. In Sellers et al.'s (2021) framework for students' meanings for quantified variables (i.e., quantifications), the authors previously identified five different quantifications. Each of meanings for quantified variables (i.e., quantifications), abbreviated MQ1-MQ4 and NQ, are detailed below. MQ1-MQ4 are *not* intended to be developmental; they are only numbered for convenience of discussion.

MQ1 and MQ2 are indicative of meanings similar to conventional meanings for "there exists and x" and "there exists a unique x," respectively. Students using MQ3 in a specified moment chose a value for x from their chosen domain of discourse and determined whether or not their chosen value for x satisfies the predicate. They then repeated (or imagined repeating) this mental action by checking the predicate for *multiple* values of x until they exhausted *all* the elements in the domain of discourse.

While MQ1-MQ3 are akin to mathematical meanings for the existential, existential unique, and universal quantifiers, MQ4 does not align with mathematical convention. Students using MQ4 chose or looked at a value of x and then checked the predicate only for this selected value. These students sometimes chose another value of x and checked the predicate for this other value, but these values were not strategically selected, but *spontaneously* selected.

Finally, there were other moments where students did not quantify at all, and thus were described as using no quantification (NQ). These students appeared to search for the domain of discourse for a variable, but they did not appear to check the predicate for any values of x. Students that used NQ did not state that they are searching for a specific number of elements of x to satisfy the predicate, but instead interpreted the statement as if it were true. Furthermore, these students simply confirmed what they think the predicate means to them, rather than checking whether or not the values satisfy the predicate.

Methods

In order to further investigate students' meanings for quantified variables in calculus statements, I interviewed four students currently in transition-to-proof courses and four students from advanced calculus or above as part of a larger study.[1] I chose these students because they had *already completed* an entire calculus sequence, and had thus, been exposed to all of the necessary concepts in the statements. These students were selected from a pool of 24 students based on a survey used for theoretical sampling (Patton, 2001). Selected students participated in three exploratory teaching interviews (Castillo-Garsow, 2010; Moore, 2010; Sellers, 2020; Thompson et al., 2014).

Each exploratory teaching interview (ETI) lasted approximately 1-3 hours each, for a total of 5-8 hours, depending upon student responses. During these interviews, students were presented with 6 open statements and graphs of 4 functions and then asked to justify why the statements were true or false for each individual function. The six open statements are presented in Table 1, and the four graphs which were given are shown in Figure 1.

Table 1. Statements given in ETI 1 & ETI 2.

Statements	Statement Type
Statement 1 There exists a real number c in [$^-$1, 8.5] such that for all real numbers r in [$^-$1, 8.5], $f(r) \leq f(c)$.	$\exists x_1 \forall x_2$
Statement 2 For all real numbers w in [$^-$1, 8.5], there exists a real number k in [$^-$1, 8.5] such that $f(w) \leq f(k)$.	$\forall x_1 \exists x_2$
Statement 3 There exists a real number m such that for all real numbers p in [$^-$1, 8.5], $f(p) \leq m$.	$\exists y \forall x$
Statement 4 For all real numbers d in [$^-$1, 8.5], there exists a real number z such that $f(d) \leq z$.	$\forall x \exists y$
Statement 5 There exists a real number t in [$^-$1, 8.5] such that for all real numbers v, $f(t) \leq v$.	$\exists x \forall y$
Statement 6 For all real numbers j, there exists a real number q in [$^-$1, 8.5] such that $f(q) \leq j$.	$\forall y \exists x$

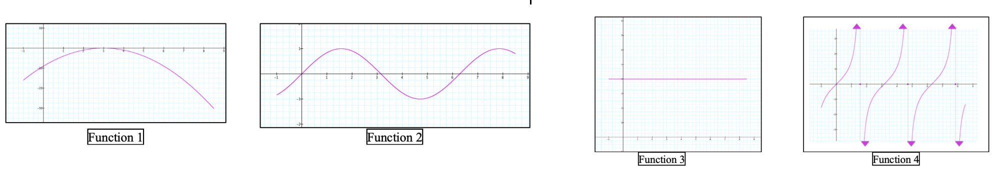

Figure 1. Graphs presented in first two exploratory teaching interviews.

The graphs of functions shown in Figure 1 provided opportunities for me to ask students to explain their thinking about the truth values of the given statements in more detail. Furthermore, these graphs were vetted along with Statements 1-6 in pilot studies and were found to be beneficial tasks for eliciting distinctions in student quantifications. Consider the Extreme Value Theorem (whose conclusion is shown in Statement 1). Since the sinusoidal graph (Function 2) has two values of the input that correspond to the same maximum value, some students in pilot studies stated that Statement 1 is false for Function 2 if they quantified "there exists" as "there exists a unique" (i.e., used MQ2 instead of MQ1).

In the final interview, I presented students with several alternative statements to test how well their quantifications transferred to different mathematical contexts. Additionally, I would

[1] The larger study focused on both students' interpretations and their negations of complex mathematical statements.

often change the quantifier language of these statements and ask interviewees if this language impacted their meanings for the statement. One of these statements is shown below:

Statement A: For all differentiable functions *f* on [*a*, *b*], there exists a *c* in [*a*, *b*] such that $f'(c)=0$. Statement A (Alternative): Suppose *f* is any differentiable function on [*a*, *b*]. Then there exists a *c* in [*a*, *b*] such that $f'(c)=0$.

Data analysis. While interviews were being conducted, I made initial models for students' quantifications and interpretations for each statement using Sellers et al.'s (2021) framework and also recorded students' evaluations for each statement across different moments. After each student's data was collected, I completed both a transcription and content log for each student interview. Initial open coding involved determining how to split my data into *relevant moments* (Sellers et al., 2021) where a student explained their interpretation of a statement or explained why a statement was satisfied. I determined that a new moment began whenever a student was presented with a new question or task, the student changed their evaluation of a statement, or if the student provided a new interpretation of a statement.

Once relevant moments were identified, I conducted iterative coding using Sellers et al.'s (2021) framework, as I could, for each student one at time, moment-by-moment, until I had codes that explained student quantifications across all moments for all students. However, a new code emerged in this process of trying to best explain student quantifications. I then re-observed students' words, gestures, and markings on graphs in order to characterize their mental actions that are associated with their quantifications until all the codes I made had explanatory power across all moments for all students in the study.

Finally, I used the evaluations that I coded along with the raw student data in order to determine why students evaluated statements in particular ways. Codes emerged in this phase for meanings that comprised students' interpretations of complex mathematical statements that also explained students' evaluations. For purposes of this paper, I only focus on one code or theme that emerged that related to students' interpretations of complex mathematical statements: students' meanings for quantifier language.

Results

In this study, three of the eight students in my study exhibited different quantifications *consistently* depending upon the statements at hand. Two of these students were in Transition-to-Proof at the time of the study, while one student was in advanced calculus. For purposes of this paper, I focus my attention on one student, Allison, who was currently in Advanced Calculus at the time of the study. I use Allison as a way in which to highlight some of the implications of quantifier language upon mathematical meanings.

The set-wise collection meaning and its connection to "all." The three students mentioned above each claimed that the word "all" led them to think of some variables as sets, and described how they interpreted and evaluated other statements with different quantifier words. Statements 1-6 all have universally-quantified variables and each of those variables are attached to the word "all." When students described these variables, I noticed that they often used additional words such as "all *at once*" to convey that they imagined grouping the values of the universally-quantified variables. In this subsection, I describe how student words for the values of the universally-quantified variable such as "all at once," "whole interval," and "entire set" helped me identify and describe this quantification.

I utilize the following moment with Allison to highlight how the word "for all" impacted her interpretation of Statement 2 ($\forall w(\exists k\, f(w) \leq f(k))$) along with Graph 4 (the modified tangent graph). Before this moment, Allison had determined that Statement 2 was false for the modified tangent function. During this moment, she was in the process of analyzing her evaluation for graphs against other student arguments. I asked Allison to examine several alternative student responses. I referred to an alternative student, Emma, and her argument for Function 4. Below is the argument I presented to Allison:

Alternate Student Argument: Emma said, "If I put w at 0, then $f(w)=0$, and if I put k at 8, $f(k)$ is approximately 1. In this case, the statement is true because $f(w)$ is less than or equal to $f(k)$. However, if I put w at 1.5, $f(w)$ would be approximately 1, and if I put k at 0, then $f(k)$ would be 0. In this case, the statement is false for this graph because $f(w)$ would be greater than $f(k)$. Therefore, I think that Statement 2 is sometimes true for this graph."

I presented Emma's argument for Function 4 in order to examine Allison's quantifications for each variable and why these quantifications led her to a false evaluation of Statement 2 for this function. I designed Emma's argument to represent the use of MQ4 for the variable w, since Emma checked the predicate for values of w individually, and then concluded that the statement is sometimes true. Allison rejected Emma's argument in the moment below based upon her own quantification for w.

Interviewer: [...] Do you think Emma's argument is the same as your argument?
Allison: She [Emma] was still just considering it one piece at a time, not all cumulatively (gestures as shown).

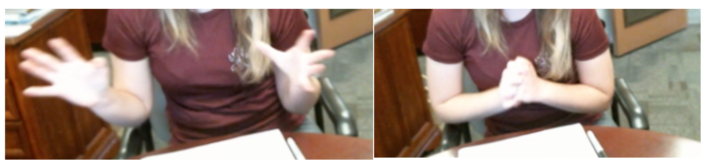

Figure 2. Allison's gestures when discussing w in Statement 2.

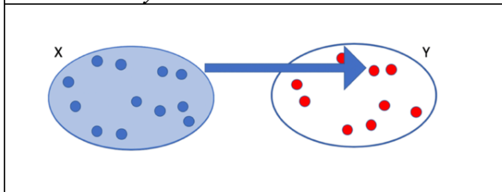
Interviewer: When you say all cumulatively, what are you thinking about in your head [...]?
Allison: I think if [...] you put k at 8, then you can't just check the case that w is 0 and say that that's the case. Because the statement is asking about all $f(w)$'s, I kind of feel like you have to like check them all. […] (still explaining Graph 4 from her perspective) Since this [function] is going to infinity, if I choose one [function output] that's higher up, and I say this [new point] is now w, then that's going to be false because you didn't choose a k for all of these numbers [$f(w)$] [...]
Interviewer: So, do you have to think about all of the values of w and all of their output values together at once?
Allison: Yes.
Interviewer: Okay, can you explain that a little bit more?
Allison: Well, you definitely have to think about all of the w's, because it says "for all." And if we're thinking about all the w's, then we're thinking about all their outputs being less than or equal to this one k and $f(k)$.

In determining Allison's meaning for the variable w, I used her descriptions of the statement, the values of w in relation to Function 4, as well as her gestures. First, I noted that Allison used the words "all cumulatively" which suggests that she was mentally grouping the values of w together. Additionally, when I asked if she was considering the values of w and $f(w)$ "all... at once," she confirmed that this is how she was thinking about the values as well. Beyond her description of her own thinking, she also stated that if she changed the values of w, that this would not be an accurate interpretation of the statement, in her view, because then she could not choose a k for *all* of the values of w, and that thinking about all values made her think that all of the values of w together had to be less than a singular $f(k)$ value. Additionally, Allison's gesture in Figure 2 that accompanied her words "all cumulatively," further indicates that she is collecting all the values of w into one set. I coded Allison's meaning for the variable w in this moment as a "set-wise collection" meaning for a quantified variable. (In light of Sellers et al.'s (2021) framework, I extended the framework and will refer to this meaning as MQ5.)

There are two different ways that a student with a normative meaning for "for all… there exists…" (∀∃) and "there exists… for all…" (∃∀) statements might map elements of one set of values to another set. First, for a statement of the form ∀x∃y, *each x* may be mapped to a different y. Yet, for a statement of the form ∃y∀x, the same y-value is mapped to *each x*. Yet, for the student who uses a set-wise collection meaning views "For all x, $P(x)$" as indicating that he needs to check the predicate for the *entire set*, X, at *once*, and grouping the set of x's into X before the predicate is checked. For a quantified statement of the form ∀x∃y, the student who uses a set-wise collection meaning for x will group the entirety of X at once *before* mapping and searching for the existence of a y-value. As a result, the student needs a *singular y-value* to satisfy the predicate for every x-value. Thus, for both ∀∃ and ∃∀ statements, the student will refer to an individual value of y that must satisfy the predicate. This set of cognitive steps is shown as a mapping in Figure 3.

Set-wise Collection Meaning for x in "For all x… there exists a y…"	Conventional Meaning for "For all x… there exists a y…"
	


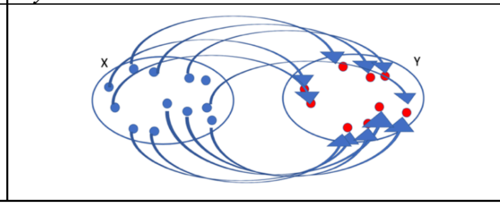


Figure 3. Illustration for student using set-wise collection meaning for universally- quantified variable.

Six out of the eight students (three Transition-to-Proof students and three Advanced Calculus students) I interviewed had some moments where they used MQ5 for quantified variables. MQ5 was used by these students only for universally-quantified variables, and typically when the quantifier word "all" was given in a statement.

How "any" leads to alternative quantifications. There were some cases in this study where ∀∃ statements using the words "all," "any" or "every" led to different cognitive processes than normative interpretations. In the next example, I present a moment with Allison to explain how students' quantifications for the word "any" can also deviate from convention.

On Day 3, I also posed both Statement A and an alternative version of Statement A, using the word "any" instead of "all" (see methods). While Allison did interpret Statement A as an ∀∃ statement, she did not interpret "for any... there exists..." as an ∀∃ statement. Below, I present Allison's description of how this language change impacted her interpretations of the two different statements in the moment below:

> *Interviewer*: So suppose I change this word here "all" [in Statement A] to the word "any." Would that change the meaning of Statement A?
> *Allison*: Seems like it kind of does.
> *Interviewer*: Ok, how so?
> *Allison*: Because, if you say "for any," I feel like that means like you have all of these choices of differentiable functions, and you pick one of them, and you happen to get lucky and you pick one that satisfies that this condition, that it's true.
> *Interviewer*: Okay, alright, so the word "any"-how does that… how is that different than the word "all?"
> *Allison*: So "for all" I feel like you have to […] go through all of them and make sure they all satisfy this condition. Whereas "for any," you have a choice of which one, which differentiable function you pick.
> *Interviewer*: So, then, how would you evaluate that statement if it had the word "any" there instead of "all?"
> *Allison*: I think it would be true, because when I hear the word "any," I just think of like […] any one you want.

Allison was classified by her use of MQ1 (that at least one value of f satisfies the predicate) for the variable f in the alternative version of Statement A that contains the word "any." I classified her meaning as MQ1 because she said that "any" made her think that she could select *one* function out of all of them that would make the statement *true*. Allison interpreted “any” as “any one you want,” and she explained that she wanted one that would make the statement true. This means that for Allison, “any” indicates that you can *choose one* from *an entire set*. As a result, she interpreted the alternative version for Statement A like a “there exists... there exists...” statement, rather than as an ∀∃ statement.

The example with Allison above reveals that the change of the word “all” to the word “any” in an ∀∃ statement should not be considered an automatic fix that will help all students interpret the statement as an ∀∃ statement. Additionally, one should note, changing “all” to “every” is not an automatic fix either, as another student used MQ5 when he was given the word “every.”

Conclusion & Discussion

One of the main findings of this study was a new theoretical addition to Sellers et al.’s (2021) framework for student meanings for quantified variables. I call this meaning MQ5, or the set-wise meaning for quantified variables. In Table 2 below, I show how the framework has been extended to include this new meaning.

Table 2. Characteristics of MQ5, the set-wise collection meaning for quantified variables.

Observable Behaviors	Mental Actions
• Identifies a domain of discourse, X. • Explains or illustrates whether or not X, the collection of all x's, satisfies the predicate. (May use gestures such as marking off boundary or use a grouping gesture.) • Uses words such as “whole,” “the set of,” or “entire” to refer to the collection of values of x in X; Uses words such as “all” or “all at once” to refer to X’s satisfaction of the predicate.	1. Identifies a domain of discourse, X. 2. Determines individual values (x_0) that comprise X. 3. Considers the collection of values of x from X as a singular unit. 4. Checks if the predicate is satisfied by the collective set X at once (i.e., checking $P(X)$, not $P(x)$).

In addition to this new meaning for quantified variables, this study also contributes to our knowledge on how language choice in mathematical statements impacts student quantifications. The word “for any” tends to lend itself to having students use MQ1, because they think “any” implies “any one that makes a statement true,” whereas “for all” might tend to lead students to the use of MQ5, or a set-wise collection meaning for a quantified variable.

Additionally, this study connects how the language of mathematical statements might relate to students’ interpretations of complex mathematical statements holistically. The word “for all” led students to using the set-wise collections meaning for quantification, which then led them to treat ∀∃ statements like ∃∀ statements, similar to Vroom’s (2022) finding. The theoretical construct of MQ5 allowed me to explain how students equate ∃∀ and ∀∃ statements in their minds by using set-theoretic interpretations of these meanings. On the other hand, the word “any” led the same student to treat a different ∀∃ statement as an ∃∃ statement.

This study suggests that in teaching and in curriculum development, certain quantifier language may be more advantageous in certain mathematical contexts than others (e.g., in presenting definition of a function, “each” or “every” might be more productive than using “all”). However, a change from one quantifier word to another is not a “cure all” and may bring other unconventional quantifications to light rather than highlighting the intended meaning of the statement for all students.

An Exploration of Human Factors That Influence the Acceptance of Technology in Calculus Students

Ricela Feliciano-Semidei
Northern Illinois University

Kevin A. Palencia
Northern Illinois University

Alcibíades Bustillo-Zárate
University of Puerto Rico

Studies on the use of technology in calculus courses have focused on the use of different types of technology as learning tools for visualization, representations, and understanding. However, research on students' perspectives about the use of technology in calculus classrooms needs to be expanded. In this article, we interviewed eight calculus students in a US research institution to understand their perspectives about the use of technology. To analyze the data set, we used thematic analysis informed by the technology acceptance model focused on external variables related to human factors. As a result, students identified human factors that may influence their perspectives about using technology in calculus classes such as: their attitude and skills, selection of mathematical problems, feedback, classroom environment, and resources. These findings inform calculus instructors and coordinators about possible considerations before implementing the use of technology in their classrooms.

Keywords: calculus education, students' perspectives, technology to teach

In the last decades, many researchers have explored the use of technology to enhance students' learning experiences in calculus courses (e.g., Ellis Jr et al., 2000; Ferrara et al., 2006; Heid, 1988; Thompson et al., 2013). The use of technology is one of many approaches to target the retention problem of science, technology, engineering, and mathematics (STEM) programs in US institutions, which has been shown to rely on the effective teaching of calculus courses (Rasmussen & Ellis, 2013).

The effective use of technology can promote understanding of calculus concepts by facilitating visualization of structures, representations, and exploration of concepts such as limits, derivatives, and integrals (e.g. Bressoud et al., 2016; Ferrara et al., 2006). Tall (2002) explains that technology facilitates the understanding of fundamental ideas of calculus such as the approximation process and infinitesimals. For example, using numerical and graphical approaches to explore the concept of limits. In addition, the use of technology may build a stronger calculus conceptual understanding by allowing students to explore different ways of reasoning while solving problems (Ferrara et al., 2006).

Many studies have mainly focused on technologies that are used to do mathematics such as graphing or geometric software. While these technologies facilitate the learning of calculus concepts, it is imperative to understand that technology by itself will not ensure an effective learning experience. For example, Takači et al. (2015) found that students' learning about functions and graphs is better when using Geogebra while working in collaborative groups.

In our study, we explore external variables to the technology itself. Specifically we investigate students' perspectives about social aspects that may be controllable by humans when using technology. The research question that guided our study is: *How do students describe the social aspects controlled by humans that may influence their acceptance of the use of technology in calculus classes?* The understanding of these external variables complements research about how specific types of technology can enhance the learning of calculus concepts by providing possible considerations before implementing technology in the calculus classes as a coordinated effort in an R2 institution.

Theoretical Perspective

The Technology Acceptance Model (TAM) provides guidance on how students accept or reject the use of technology in calculus classes (Davis, 1989; Venkatesh and Davis, 2000)

According to this model, understanding a person's acceptance to use technology depends on two key variables: perceived ease of use and perceived usefulness. These determine if a person will accept the use of technology (Davis, 1989). Specifically, if someone thinks a technology is both easy to use and useful, then that person would like to use that technology tool. Conversely, if a person perceives it is not easy or not useful, then will not like to use the technology.

Since 1989, several researchers (e.g., Venkatesh and Davis, 2000) have proposed extensions to these two variables for understanding the complexities of using technology. For example, if a person intends to use the technology and if the person is using the technology, which are commonly known as behavioral intention and actual use. In addition, Venkatesh and Davis (2000) consider external variables that can influence the relationship between the perceived ease of use, perceived usefulness, behavioral intention, and actual use. These variables include social norms, availability of resources, and personal skills.

When considering the teaching and learning of calculus, we consider that these external variables are controllable by either students, instructors, coordinators, or administrators. Thus, they are also considered as human factors. Alomari et. al. (2020) categorize human factors into three main indicators: technological, psychological, and student-instructor interaction characteristics. However, their research identifies positive human factors attributes like attitude, enjoyment, experience, self-efficacy, and promptness that significantly impact user satisfaction and subsequently contribute to the success of learning using technology. Understanding these external variables provide a clearer picture to explore technology acceptance by an individual.

The TAM informs our study as we aim to understand the complexity of students' perspectives toward using technology for calculus classes. Considering the human factors of using technology will facilitate an informed decision-making process for instructors and coordinators to provide students with an effective introduction to new technologies while learning calculus. Specifically, this may help students embrace these technologies as important tools for their calculus learning experience by helping them see these technologies as both useful and easy to use.

Research Methods

To answer the research question, we collected audio-recording interviews from eight calculus students who volunteered to participate in this research study. Previous to the interview each participant completed demographic information.

Participants

Participants were sophomores, juniors, or seniors enrolled in Calculus I, II, or III in a US research university in the Midwest.

The university serves approximately 16,000 students from diverse backgrounds with more than half of the student population being first generation undergraduate students. About 46% of the population is White, 20% Latinx, 17% Black, and 6% Asian.

While reporting on demographic information, one student self-identified as Asian, one as Black, three as Hispanic or Latinx, and three as White. Regarding gender, there were four cis-men and four cis-women. Five participants reported being first generation students and one a non-traditional student. None of the students reported being a veteran or having a documented disability. Seven of them were in a STEM program and one of the students was a non-STEM major pursuing a middle school teaching license in STEM.

Instrument and Data Analysis

We conducted one hour interviews during the summer 2023 to students who were enrolled in a calculus section in the Spring 2023 semester. Questions of the interview were semi structured and focused on relevancy of the course, policies, resources, and technology. In this paper, we analyzed students' responses related to the use of technology in calculus classes.

The interviews were audio-recorded and transcribed for analysis. Data was de-identified by assigning pseudonyms to participants.

The three authors are all junior faculty who self-identify as Hispanic or Latinx. One is a mathematics researcher with focus on analysis, one is a computer science researcher, and the other is a mathematics education researcher.

To analyze data, the three authors conducted thematic analysis (Braun et al., 2019). The three authors initially coded four interviews guided by the TAM framework and met to agree on a codebook. After creating a codebook, two of the authors coded the eight interviews and met until consensus was reached.

Results of the Research

The categories of the code for identifying the human factors are the students' attitudes or skills, the selection of mathematical problems online, the learning feedback, the classroom environment, and the resources.

Table 1. Human factors when using technology for calculus classes identified by participants.

Human Factors	
Factor	Participants
Students attitudes or skills	Audrey, Ben, Diego, Elena, Josephine, Juan, Kate
Selection of online mathematical problems	Josephine, Lin
Learning feedback	Josephine, Kate
Classroom environment	Ben, Josephine
Resources	Audrey, Diego

Students' Attitudes or Skills

Students' attitudes or skills capture the ways students liked or disliked technology. For example, the level of difficulty with using technology to learn calculus, their familiarity, experiences, and perspectives against or in favor of using technology.

Seven students reported some of their attitudes and skills related to the use of technology in calculus classes. The most popular attitude was related to the use of online homework in calculus classes. For example, Kate thinks online homework is beneficial for the learning experience.

Interviewer: Do you think using technology is beneficial for your learning experience?

Kate: I feel like it has been useful just because chances are that's where the world's going is with technology being more useful. So having those lessons with it is helpful. Though I do, I still always end up like even if the assignment is online, I'll write it out on a paper before I do it because it's hard for me to do it all on the computer.

Interviewer: Okay, yeah, and what kind of technology would you like to use in the calculus classes? I don't know. It can be anything. It can be like a web page, an app, or software.

Kate: It can be useful if we use like graphing apps and stuff. So we can plug in like the equation and get an idea of what it's supposed to look like. Because when there's all those different things in it, it's really hard to visualize the graph and like do it and because there's so many different parts to the equation, it's really hard to graph by yourself. But and then I also I like being able to look up similar examples online that are like I don't even know like some sort of like especially with like trig stuff that's always the trouble with me, figuring out how people, if there's like a sine over a cosine or whatever how people treat that in certain problems and different things.

Kate, sees the use of technology as beneficial for the learning experience when perceiving technology as part of keeping up with the uses of technology in the world and as a tool for learning mathematics. It is interesting to see how Kate connects the calculus learning experience with a more global perspective on how people are increasing the use of technology "in the world". However, it is interesting how Kate still sees a need to work on math problems using paper and pencil before sharing the answers in online homework systems. In addition to the online homework, Kate thinks that the use of graphing apps is important to visualize graphs and to see different strategies when solving mathematical problems.

Students also reported on their familiarity with different types of technology. For example, Juan mentioned using several types of technologies in both high school and college.

Interviewer: Okay, so you have experience with scientific calculators. You also have some experience with online homework. Is there something else I'm missing about your experience with technology in math and calculus classes?

Juan: Umm, sometimes in my calc class as a teacher will like pull up a functions calculator or like a plot system to kind of just see things visually. I think those are nice. But for the most part, yeah, that's pretty much accurate. This is my first time ever having online homework for a math class. For my calc 3 class that I'm taking online right now. [...] WebAssign I think it's called Yeah, it's definitely a Cengage Webassign, yes.

Interviewer: You said something about functions and online graphing. Is that also inside WebAssign?

Juan: No, there are some applications in WebAssign where they can use those for certain problems. But I know like the one I'm using right now, because the one prior I can't use it anymore because a lot of my stuff is like in 3D, so I use 3D plot, personally, but that's not like through the instructor. I forget, there's another popular one. That a lot of instructors have used in my calc 1 and calc 2 experience.

Interviewer: So you do use them for your own learning. Is that correct?

Juan: Yes, I do

Interviewer: Okay, is there anything else that you use? Any other technology that you like to use for your own learning outside of class?

Juan: Lecture videos like sometimes if I need extra help on a certain topic. I'll watch a YouTube video. That kind of goes over it again. I use the online homework, which I like. Actually, I never knew if I would like online homework. But, since I've taken a lot of physics classes that have used, even in my high school, that have used WebAssign Cengage, and since I'm really familiar with it, I do like it now. Umm, let me think and then. It's nice to have a calculator. No, I think that's all the technology.

In this interview excerpt, Juan mentions using scientific calculators, mathematical software programs and online homework. He has a positive attitude toward instructors using visual representations in what he describes as function calculators that "are nice". This may be a graphing software that instructors use to visualize functions while teaching calculus classes. While he does not explicitly mention familiarity with these technologies, he may be familiar with using graphing softwares as he likes using other three dimensional graphing software programs outside of the classroom that helps him learn calculus. Regarding online homework, Juan mentions that he likes it because he is familiar with the technology as he used it in a physics high school class.

When asking students about using augmented reality in calculus classes most students mentioned unfamiliarity with how this may be used in a calculus class. They admitted they did not have enough information to have an opinion on how it may or may not be beneficial. For example, when asking Diego if using augmented reality would be beneficial, he said "I would say no [...] but I also don't have any experience with it, so I feel like my opinion just isn't too great just 'cause I don't have that knowledge." Later in the interview Diego explains having an open mind to maybe use it if someone explains how it would be useful with some specific examples.

Selection of mathematical problems online

Another human factor mentioned by some students was the way instructors or coordinators select the mathematical problems online. For example, Josephine finds mathematical problems in ALEKS as tedious.

Josephine: [...] Oh, I thought my Mathlab was horrible, but there is another like program like software, it's called ALEKS. Have you heard of ALEKS?

Interviewer: Yes.

Josephine: I hate it, absolutely hate it. I think I was using that app in appreciation for My Mathlab after using ALEKS because I took a trig summer class. But the difference between My Mathlab and ALEKS is that ALEKS will have you do like 30 different problems on a math subject lower than your math subject before you could even start practicing on your math subject if that makes some sense. So I feel like using the computer is just a little bit too tedious and just you know cause math is complicated, yes, but I feel like the computer makes it even more complicated than it needs to be. That's just my opinion as far as technology and math, I don't think math should have nothing to do with it. Well, math [inaudible] with technology, but as far as I'm learning it, I don't think it's necessary. Technology is not necessary for it though. Yeah.

In her interview, Josephine expresses a dislike of using a specific online homework system, however, the reason is related to the problems selected by the instructor. Specifically, she thought it was tedious to work on problems that were (1) not addressing the concept that was discussed and (2) too many. This presents two factors that can be controlled by an instructor: the alignment with the curriculum and the quantity of problems selected. What Josephine is experiencing with the online homework system may be reflecting the drill and train practice about mathematical procedures.

The lack of alignment when selecting mathematical problems online, was also mentioned by Lin when we asked about ideal technologies for calculus classrooms. Lin said not to use online homework because, in his experience, online homework "wasn't exactly tailored to what they learned for that day. It was more generic for the topic."

Learning Feedback

Students were also concerned about needing more assessment feedback in their calculus classes. Two students mentioned learning feedback as an issue when using technology.

Specifically, Josephine and Kate explained it was difficult for them to know where exactly they had a mistake. For example, when talking about online homework, Kate noted: "[...] it's hard for me to go through and know what I did wrong when it's such a big problem and there's so many little steps that I could have messed up on." While Kate is receiving immediate online feedback on whether a problem is correct or incorrect, she perceives this is not enough feedback. Here, Kate would expect feedback to point out mistakes in her rationale or computations while solving calculus problems.

Classroom Environment

Students reported on the classroom environment while using technology, for example, using a collaborative learning environment, working in small groups, or mimicking other non-math courses' classroom settings.

A student, Ben, noted that he has had a great experience in the college of engineering with collaborative learning when using technology. When asking about recommendations for types of technology we could use in calculus, Ben referred to this experience.

> Suppose potentially having some kind of like a screen that's more of like a table. I don't know what that would be but something that we could all kind of like look down at and kinda talk about like, like I said before, kind of in like that circle, you all kind of look down and kind of have more forward and open discussions versus the way classrooms kind of are, whether you're just kind of staring at the board which is understandably easier but yeah.

Ben perceives that the technological tools available in this engineering class would potentially be beneficial to include in calculus classes. Here, Ben perceives that technology could be used to foster more open discussions in the classroom by using screens and arranging classrooms in circles around those screens. It is worth mentioning that Ben uses the opportunity not only to introduce this as an option to improve mathematical discussions in the calculus classrooms but also to critique that the current classroom setting is traditional and is limiting discussions.

Resources

Participants mentioned that, when using technology, it is essential to consider the institution's available and needed resources. For example, having a computer at home to complete online homework and having access to computer labs in the institution.

For example, Diego agreed to implement technology in calculus classes and referred to resources available at the institution. He mentioned that the institutional access to the internet was pretty good, especially in computer labs. He explained that the institution had computer labs in case "a student did not have those types of resources [personal computer or laptop]."

Significance and Further Research

This study contributes to understanding students' perspectives about the use of technology in calculus classes, including human (students, instructors, coordinators, and administrators) factors. Specifically, students' skills and attitudes, selection of mathematical problems, learning feedback, classroom environment, and resources.

Students' skills and attitudes toward the use of technology would identify the human factor of the student as a learner. Skills and attitudes may result from their experiences or lack of experience with using technology in calculus classes. Understanding these factors may provide information about possible students' issues when mixing technology and mathematics, which could offer calculus instructors and coordinators targeting tools to overcome them. For example, a possible need to train students and help them feel more familiar with the technology before implementing it.

The selection of problems, learning feedback, classroom environment, and resources are primarily human factors related to instructors, coordinators, or institutions. These factors were mostly perceived as contributors to negative experiences from the students when using technology. Specifically, (1) students perceived that the selection of problems had alignment issues and became tedious because of the number of problems, (2) students perceived a need for more feedback than the correct (or incorrect) feedback in online homework, (3) students perceived a need for restructuring classroom environments, and (4) students discussed issues of accessibility when using technology. Some of these have been shown to be important for students' learning of calculus, such as considering the classroom environment when using technology (e.g., Takači et al., 2015) and their attitudes toward the use of online homework (e.g., Lampe and White, 2023).

Instructors may control the selection of problems, learning feedback, and classroom environment. Some of these issues may suggest a need to provide instructors with technology professional development activities before officially implementing online homework as a coordinated effort, as well as effective active learning practices and curriculum alignment. We must see these findings about learning feedback with caution as these vary in different online homework systems and it would not be appropriate to conclude that all online homework systems lack the feedback students perceive they need. For example, there are initiatives to use artificial intelligence to give more meaningful feedback to students when working on online homework. Future research may investigate students' perspectives about using artificial intelligence to provide feedback on assignments.

Administrators may also control some of the classroom environment and resources needed for effectively implementing the use of technology. While instructors have control over classroom settings, some of this effort relies on classroom conditions that facilitate active learning. In addition, when applying technology, it is important to consider if the type of technology would be available to all students.

Instructors, coordinators, and administrators must engage in open discussions to ensure equitable access to technology for all students, fostering an inclusive and technologically enhanced learning environment in calculus courses.

On the Unique Benefits and Challenges of Mathematics
Graduate Student Instructors Providing Teaching Feedback to their Peers

Melinda Lanius	Gary A Olson	Scotty Houston
Auburn University	University of Colorado Denver	University of Memphis

In this paper, we compare the types of teaching feedback that graduate student instructors provide their peers in comparison to more senior faculty at a large research-oriented university. Additionally, we consider the challenges and benefits that graduate student instructors report concerning providing teaching feedback to a peer. Our results reveal that graduate student instructors and faculty contribute distinct perspectives on teacher growth and together can form a strong support system for first-time graduate student instructors. Additionally, while observing a peer does pose real challenges, we found that graduate student instructors develop strategies to overcome these and report more benefits than difficulties.

Keywords: graduate student instructors, feedback, teaching observation, peer mentoring

At many research universities, graduate students in the Mathematical Sciences become instructors of record for one or more undergraduate courses (Eller, 2017; Justice, Zieffler, & Garfield, 2017); we will call these educators graduate student instructors (GSIs). Oftentimes, GSIs have little to no assistance on the front-end in preparing to teach; however, departments across the country have begun to implement training programs for GSIs with the aim of both improving GSIs teaching abilities and improving the learning experience for their undergraduate students (Speer, et al., 2005; Ellis, 2014). One promising training component that can support GSIs in developing student-centered teaching practices is providing them with feedback from a teaching observation conducted by a more experienced educator (Yee et al., 2022). Within a mathematics department, this feedback can come from a faculty member or a more experienced graduate student instructor. In this paper, we explore the following research questions:

Research Questions

1) What types of teaching feedback do peers give to other graduate student instructors and how does it compare to the feedback provided by more senior faculty?

2) What are the challenges or benefits that graduate student instructors report concerning providing teaching feedback to a peer?

Theoretical Perspectives

Concerning feedback. We frame feedback using Kluger and DeNisi's (1996) Feedback Intervention Theory (FIT). This framework has previously been leveraged in the K-12 setting (Khachatryan, 2015) as well as in the setting of graduate student instructor professional development (Yee et al., 2022). We define feedback as action taken by an observer to provide information concerning aspects of the graduate student instructor's teaching performance. We categorize the components of feedback using three levels or scopes: (Whole) comments on the task of teaching as a whole, (Part) focused details within the task of teaching, and (Individual) comments concerning the affect, motivation, or skill of the instructor.

Because we are discussing feedback for novice instructors, who may not have particular knowledge of aspects of teaching, we expand our framework to categorize whole and part scoped components as description, feedback, or feedforward. While feedback focuses on what is effective or not in the present, feedforward focuses on the future by offering particular suggestions. It is important to track the scope of feedback because Yee et al. (2022) found that feedback that includes specific context and focal events (what we call part-type feedback) is more effective at promoting change in graduate student instructor's teaching behaviors than feedback that lacked this contextualization. Additionally, FIT suggests that comments focused on the individual are the least effective in motivating a change in performance (Kluger & DeNisi, 1996). Accordingly, we track individual scoped comments and categorize them as positive (a compliment) or negative (a criticism).

Concerning dimensions of mathematical teaching. To facilitate classification of the content of teaching feedback, we used the topics covered in the Mathematical Association of America's Instructional Practices Guide (Abell et al., 2017). This comprehensive resource operationalizes leading research concerning learning in the undergraduate mathematics classroom.

Methods

Context & Data

All data collection was done in the Department of Mathematics and Statistics at a large land-grant university in the United States. In a typical semester, 30 to 40 faculty members, the majority of which are research-oriented, participate in conducting a teaching observation of each graduate student instructor of record.In addition to this faculty-provided teaching observation, a peer conducts a teaching observation for each first time graduate student instructor. Each graduate student instructor who observed a first-time instructor also completed a reflection about the process. We analyzed 35 of these peer observations and the observer's corresponding reflection, from Fall 2020 — which was a planned remote semester due to the COVID-19 pandemic — ranging to Fall 2022 — which was a standard in-person semester.

For comparison purposes, we will share our analysis of 170 faculty observations of graduate student instructors conducted in the same time range. Please note that our reported analysis of faculty-generated observation data is a subset of an analysis conducted for a larger project focused on how mathematics faculty engage with teaching observation protocols; our analysis of the graduate student instructor-generated observation data and the corresponding reflections is novel and only appears in this report.

Observation protocols. The observation protocol used by graduate student instructors is heavily-adapted and pared-down from Rogers and Yee's (2018) Graduate Student Instructor Observation Protocol (GSIOP). We originally aimed to use the GSIOP, but struggled to effectively implement the required training with our graduate student instructors during the COVID-19 emergency. Our protocol opens with 5 likert-type items concerning student engagement followed by the student-centered techniques chart from the GSIOP. To account for the Zoom setting, we added Small Groups/Breakout Rooms, Polling, Chat feature to engage students with content, and use of Google Docs or Spreadsheets for activities/group work to the chart. Our protocol concludes with essay prompts to summarize the observed class, to discuss strengths, and to suggest areas for improvement. The observation protocol used by faculty begins with twelve Likert prompts asking the observer to rank components of the appropriateness of the mathematics, the quality of the instructor's communication, and the level of perceived student engagement. Next, the observer is provided two essay prompts, one requesting details of the observed session and the second requesting suggestions to help the graduate student instructor improve. The primary difference between the two protocols is that the one used by graduate student instructors has clearly defined notions of student engagement with very specific active learning techniques given. Our faculty, on the other hand, have quite varied notions of effective teaching. Consequently, the observation tool they use is necessarily less concrete.

Pedagogical & mentoring training for graduate student instructors. The graduate student instructors who served as peer mentors received both pedagogical and mentor training prior to conducting observations. The pedagogical training Promoting Success in Undergraduate Mathematics through Graduate Teacher Training (PSUM-GTT) included a teaching seminar during the spring of their first year and fall of their second which focused on modeling active learning strategies and reflecting on journal articles related to teaching and learning. Ongoing professional development was also provided through a critical issues in STEM education seminar facilitated 2-4 times per semester. Mentor training was provided to help clarify the role of a mentor and provide training around communicating effectively, building relationships, setting goals, and conducting classroom observations using an established observation protocol (Manzanares et al., 2023).

Results of First Research Question

Our first question considers what types of teaching feedback do peers give other graduate student instructors and how does this compare to the feedback provided by more senior faculty. We analyzed both the graduate student and faculty observations utilizing *a priori* coding (Saldaña, 2016) with two different code books, one focusing on the types of feedback and the other on the content of the feedback.

Feedback Intervention Theory

Our feedback codes are those types discussed above concerning Feedback Intervention Theory. Table 1 shows the frequency of scopes of feedback in both the graduate student peer observations and the faculty observations. Note that the gray-highlighted rows are the components of the most effective formative feedback, as discussed in theoretical perspectives.

Table 1
Frequency of feedback intervention theory codes in peer vs faculty observations

Scope & Category	Graduate Student Peer Frequency	Faculty Frequency
Whole - Description	0 %	< 1 %
Whole - Feedback	0 %	36 %
Whole - Feedforward	0 %	0 %
Part - Description	100 %	34 %
Part - Feedback	100 %	78 %
Part - Feedforward	100 %	61 %
Individual - Compliment	13 %	38 %
Individual - Criticism	0 %	1 %

Content of Feedback

Table 2 shows the frequency of content codes from the graduate student peer observations and the faculty observations. As briefly mentioned above, our codes concerning dimensions of mathematics teaching were developed from the Instructional Practices Guide.

Classroom community. This code encapsulates students' connections with their GSI, classmates, and university resources. Additionally, it covers classroom norms or atmosphere. For example, one peer observer wrote *"the class was kept at a pace the students can feel comfortable asking questions and I liked the idea of giving thumbs up when something is clear... In general, the class atmosphere was very learner - friendly"*. An example of classroom norms is the feedback:

> *I can tell that you are aware that your classroom is kind of a weird shape. It seems like it makes it hard to make sure everyone can see and participate. Since your room is so big, you could ask your students to all sit closer to the center or pull their tables over towards you. I know that's not the norm for your class since we're so far into the semester, but maybe the next time you teach in a room like that you can anticipate and make them sit closer together.*

Table 2

Frequency of content codes in peer vs faculty observations

Content Code	**Graduate Student Peer Frequency**	**Faculty Frequency**
Classroom Community	63 %	12 %
Student Engagement	69 %	41 %
Student Communication	25 %	2 %
Student Questions	38 %	31 %
Instructor Questions	81 %	28 %
Instructor Communication	44 %	35 %
Collaborative Learning	44 %	6 %
Tasks – Intrinsic Appropriateness	94 %	80 %
Tasks – Extrinsic Appropriateness	6 %	31 %
Technology	38 %	1 %

Student engagement or communication. Engagement refers broadly to the observer's perceptions of students actively participating in their learning. The student communication code captures the various modalities for students to communicate their ideas with one another and their instructor. For example, the quoted comment above concerning the use of the thumbs up button in Zoom is also student communication.

Student or instructor questions. Comments about questions posed by students were coded as student questions; Comments about questions posed by the instructor were coded as instructor questions. Many peer observers discussed wait time, or giving students adequate time to think about a question before expecting an answer. For example, one graduate student reflected *"He has a slight tendency when the answer isn't said almost immediately to give them the answers"* and wrote the following feedback on the observation form: *"waiting after asking questions. Gives students some time to internalize and some are shy."*

Mathematical tasks – intrinsic or extrinsic appropriateness. Intrinsic appropriateness concerns the characteristics intrinsic to a task and whether those characteristics support student learning while extrinsic appropriateness takes into account external factors such as classroom architecture or students' motivation. The discussion above of classroom shape making participation hard is an example of extrinsic appropriateness. The extrinsic appropriateness code only occurred when there was a concern.

Others. Instructor communication skills focused on legibility of handwriting or instructor's speaking volume. Collaborative learning is structured group work managed by the instructor. Technology primarily was comments concerning Zoom during the planned emergency remote semesters, but could be related to any technology in the classroom.

Comparing Peer Feedback to Faculty Feedback

Primarily, if a faculty member discussed an engaged-student learning strategy, it was group work. Our graduate students, on the other hand, leveraged a vast array of techniques coming from the GSIOP, suggesting when and where a strategy could be used; on average, each graduate student peer observer discussed 3.4 strategies. Graduate students 100% of the time employed the components of effective feedback: part description, part feedback, and part feedforward. Many faculty did not provide these components in their observation comments. Additionally, there was a wide difference in the types of topics discussed between graduate student instructors who were observing their peers who were teaching for the first time in the department and the topics covered by faculty observing all graduate student instructors. One might think this is because the first time instructors needed more help, however, we found this to not be the case. Even when a peer observer felt that the instructor they watched was effective, they still described what they noticed and explained why they found it effective. On the other hand, in a similar situation, where the faculty member found the session that they observed to be effective, they were more likely to give whole-type feedback such as "The class went quite well" with no further information about what they noticed.

One area in which faculty greatly outperformed the graduate student observers is their rich and nuanced discussions of mathematical task - intrinsic appropriateness. Our graduate student instructors generally mentioned the mathematical topic of the day and then turned their focus to the other dimensions of classroom instruction. On the other hand, faculty who discussed the mathematical content demonstrated a deep mathematical understanding, for example discussing necessary levels of correctness, alignment of that day's learning outcomes with the course and curriculum more broadly, or presenting the material at an appropriate level for the student population. We believe the differences we observed are primarily due (1) to the graduate student instructors having a tightly formed community of practice while the faculty have no common notions of effective teaching, (2) to graduate student instructors receiving specific training on providing teaching feedback while faculty received none, and (3) to our faculty primarily serving in research-intensive positions with experience teaching a broader range of courses and at an upper level.

Results of Second Research Question

We utilized emergent coding from a grounded perspective (Saldaña, 2016) when working with the 35 reflections. Our aim was to uncover the challenges and benefits that graduate student instructors report after providing teaching feedback to a peer. After individually gaining familiarity with the data, we met as a team to discuss and refine our codes. We met a second time to resolve any discrepancies in our final coding of the data. Importantly, we want to note that in our initial round of coding, we discovered a distinct difference in our perspective as coordinators of teaching professional development versus the perspective of the graduate student instructors. In particular, they found certain aspects of the experience to be a challenge, while we thought of that struggle as a benefit. Because of this tension in perspectives, we will be very purposeful in indicating *who* is perceiving the benefit or challenge.

Awkward or nervous because it is a peer. Four graduate student instructors felt nervous or awkward giving feedback to a peer, but also expressed a strategy to overcome this challenge. One reflected:

> *I thought our follow-up meeting went well, too. Even though I was still (and probably always will be) a little nervous to make suggestions for improvement, it wasn't awkward and I think we are gaining more rapport with one another to talk through those things.*

Another instructor also felt that developing a relationship over time would make this awkwardness not *"much of an issue"*. The source of one GSIs discomfort was their perfecption that their peer actually had more teaching experience than them, writing, "*I feel a little bit of imposter syndrome about giving her suggestions for strengthening/improving.*" The last instructor who felt awkward developed a strategy where *"instead of telling him he was wrong,"* they tried "*asking about certain things and letting him talk through to reach his own conclusion about how effective/ineffective certain things were.*"

Developed a feedback strategy. Eleven graduate student instructors discussed the strategies that they had developed for giving feedback to a peer. Three strategies focused on how to approach the feedback conversation, with one GSI explaining "*I approached it just as a conversation where we point out and maybe debate some aspects of each other's teaching style and approaches*", and the other two explaining that they wanted to come across as "*supportive instead of demanding*" and "*there to help and not out of a place of putting him on trial*", respectively.

One GSI decided to ask their peer if "*there was anything she wanted me to focus on during her observation*", which they felt made the other person "*more open to constructive criticism*". Two GSIs considered how their peer might be more open to suggestions and respectively decided on "*telling him more strengths than weaknesses and always interposing them*" and "*include more positive comments instead of only focusing on where my mentee can improve*". The last GSI also decided to specifically ask their peer what they "*wanted me to keep an eye out for, which allowed her to ask me things she wanted to know about, rather than just what I would say*"

Wrestling with different opinions of "good" teaching. This focusing on another person's perspective and recognizing that there may different ideas of "good" teaching presented a challenge to 3 GSIs. One wrestled with the ways in which different class settings may necessitate different teaching styles, reflecting "*If you have someone teaching finite math and it is active learning versus a calculus class which is lecture based, you do not do things the same way.*" One GSI was concerned that they did not know what the department values, writing:

> *There is not one method or style of teaching that seems to be the "ideal" for the department. It's not clear if the department wants the most effective lecture-style environment, or if they want more active learning, or if they want more in-class assessments, and so on.*

The final GSI wrestled with confronting their own biases and opinions, sharing, "*The thing I find most difficult is the actual assigning of values to her teaching. It is based off my own bias of what I think makes a good teacher and the qualities I identify as important.*" We do want to note that we value the fact that our GSIs are considering and reflecting on this issue to be a benefit of our program, even if the students themselves feel that this is a challenge.

Uncertainty in role. Every graduate student instructor reported feeling prepared to conduct a teaching observation and to provide feedback except for two students who expressed uncertainty in this new role. The first explained, "*I did not feel prepared going into our follow up meeting. I was unsure of what questions I should ask my mentee especially ones that would really make them examine specifics of my teaching style.*" The other expressed uncertainty in the purpose of the observation in the broader context of the department and the GSI training program explaining, "*I wasn't really sure what my mentee would have to do with regards to observation follow up*" This reveals an opportunity for us to provide additional support for GSIs prior to them conducting their teaching observations.

Providing self-reflection. One GSI valued having this dedicated time to discuss teaching with a peer, explaining, "*I was eagerly looking forward to it.*" Six GSIs explained that this process was an effective self-reflection tool, with one even explaining "*I learned more about my teaching*" and *"This was a good process in general because I feel like it encourages both the person being observed and the observer to reflect on their own teaching and seek how to improve.*"

Two reported a boost in confidence after self-reflecting, "*It was really encouraging to realize that my three semesters of experience made me feel completely confident and qualified to offer advice on my mentee's class."* and "*It was an encouraging reminder to me that I have been teaching for a couple of years now, and that experience has taught me a lot!*" The last GSI felt the process provided some accountability for their teaching, reflecting, "*I try to bring up her progress in these areas every time we meet to keep her accountable for working on this. Incorporating more active learning is something I also need to work on, so this keeps me accountable as well.*"

One GSI reported understanding her own teaching in relation to others' teaching practices after discussing feedback with a peer, writing, "*I knew that I had a laid-back attitude in my classroom ... but my mentee pointing out how informal my class was made me realize that that is really not the norm for everyone."* Another GSI also expressed understanding their own teaching better: "*My mentee is very open to getting help and being evaluated, so it made this process easy and eye-opening to things that I could improve on too!"*

Re-conceptualizing teacher growth. Two GSIs thought of growth as a teacher in a new way, with one expressing that this experience made them realize that improving their own teaching will be an ongoing and "*continuous process*" and the other reporting "*I think oftentimes (even in my own teaching) this is something slower to implement. I have tried to emphasize with her that changing teaching style/implementation can and probably should happen slowly. You can't change everything you do overnight.*"

Conclusion

We found that faculty were more effective at giving feedback on mathematical content knowledge while our graduate student instructors were more more effective at giving feedback on pedagogical approaches. This demonstrates that both populations contribute uniquely to teacher growth and together can form a strong support system for first-time graduate student instructors. Although asking graduate student instructors to observe a peer and provide feedback does pose real challenges, such as awkwardness and uncertainty, we found that GSIs develop strategies to overcome these and report many more benefits, such as personal accountability, teaching confidence, and a greater understanding of their own and others' teaching.

Teaching Practices Addressing Multiple Uses of a Word in Mathematics – Case for Derivative

Jungeun Park
University of Delaware

We investigated teaching practices aiming to communicate multiple uses of a common term in mathematics with students focusing on the use of a single word "derivative" for both objects "the derivative at a point" and "the derivative function" using commognitive approach and intellectual needs. Our analysis of a teacher's teaching explicitly attending to this feature revealed several teaching practices with this aim: discussing discursive rules for distinguishing the two uses and using another mathematical object for connecting the uses (e.g., slope); discussing a colloquial object that has a similar feature and is familiar to students, which provided a familiar discourse that students could rely on; and avoiding multiple uses of a common word in one context, Those teaching practices are impacted by multiple uses of a common signifier in communication and mathematical relations among the two objects objectified by a common word, but also impacted how the objects became related.

Keywords: commognition; teaching practice; derivative; words with multiple uses

Multiple uses of same signifiers (words or symbols) have been known to cause potential difficulties in teaching and learning of mathematics (e.g., Biza & Zachariades, 2010; Thompson & Rubenstein, 2000). For example, various calculus terms are used as both process and object or as both function and a specific value (e.g., College Board, 2023; Güçler, 2013). This study focuses on the discourse about the derivative to examine the teaching practices that aim to help students learn about multiple uses of a common term in mathematics. In introductory calculus, derivatives can be separated into the derivative at a point and the derivative function (we use this term for a function obtained by differentiating another function). The observation that the word "derivative" is included in "the derivative at a point" and "the derivative function," the word "derivative" alone is often used for these objects (e.g., College Board, 2023; Stewart, 2016), and students may face challenges distinguishing or relating these objects (Font & Contreras, 2008; Park, 2013), motivated our study investigating potential teaching practices aiming to promote students' learning of the use of this common term with the following research question:

What can be the teaching practices that aim to promote students' learning of multiple uses of a common term for two mathematical objects in formal mathematical discourse?

We adopted the commognitive view of *learning* mathematics as "the process in which students extend their discursive repertoire by individualizing the historically established discourse called mathematics" which we refer to as canonic discourse (Sfard, 2018, p. 222). Such extensions are viewed as meta-level learning when they involve changes in rules of discourse (e.g., learning how to choose one of multiple uses of a new word like the 'derivative'). In contrast, object-level learning only involves changes or expansions of properties of objects that are already introduced in the discourse (Valenta & Enge, 2022). Individualizing a discourse means developing one's ability to communicate with others and oneself according to the rules of the discourse. Given the commognitive view of teaching, "the communicational activity the motive of which is to bring the learners' discourse closer to a canonic discourse" (Tabach & Nachlieli, 2016, p. 303), we assume that there are teaching practices aiming to help students learn about how to apply those rules. Our goal is to reveal such practices in the context of the derivative based on a case study of a teacher explicitly addressing this discursive feature in class.

Theoretical Background

This study builds up on the existing literature about teaching and learning of multiple uses of a signifier in mathematics (Biza et al., 2008; Lamb et al., 2012; Rubenstein & Thompson, 2001; Thompson & Rubenstein, 2000; Zazkis & Kontorovich, 2016). We adopted the commognitive view of teaching and teaching practices (Cooper & Lavie, 2021; Nachlieli & Elbaum-Cohen, 2021; Tabach & Nachlieli, 2016) and intellectual needs (Harel, 2008, 2013) to identify teaching practices aiming to help students learn about multiple uses of 'derivative' and tasks they address.

Teaching and Teaching Practice Promoting Metalevel Learning in Commognition

The commognitive approach is a conceptual and analytic framework that combines cognition and communication and views mathematics as a type of discourse. A discourse is defined as a type of communication characterized by its distinctive use of words and visuals, and what they endorse as narratives. A feature of discourse – routines – are defined as a task paired with a procedure, where a task is "any setting in which a person considers herself bound to act" based on her interpretation of the task and a procedure is the prescription for her actions in the task situation "that fits both the present performance and those on which it was modeled" from her past experience (Lavie et al., 2019, pp. 160–161). Routines are regulated by object-level rules (e.g., rules about addition regulates the routine of adding of fractions) or meta-level rules (e.g., rules that determine the use of "derivative" regulates the endorsement of statements about it).

The commognitive view of learning is changes in one's discourse, and teaching is considered as communicational activities with the motive of bringing students' discourse closer to what is considered canonic discourse (Sfard, 2008). Recent commognition studies considered teaching practice as "the task as seen by the performing teacher together with the procedure she executed to perform that task" (Nachlieli & Elbaum-Cohen, 2021, p. 7). They examined the teaching practices that promoted meta-level learning and called for more studies on this topic. Meta-level learning usually happens when students are engaged in activities regulated by meta-level rules they are unfamiliar with (e.g., proving or defining) (Park et al., 2023; Schüler-Meyer, 2020; Valenta & Enge, 2022) or when they encounter a new mathematical object to which old discursive rules do not apply (e.g., from whole numbers to fractions) (Cooper & Lavie, 2021). Teaching practices aiming to promote meta-level learning often use characteristics of students' old discourses as a starting point towards a new discourse to create discomfort with old discourse (Nachlieli & Elbaum-Cohen, 2021) or to allow students to use old routines in emerging discourse in a way appropriate in the teacher's eyes (Cooper & Lavie, 2021). We contribute to this area by examining teaching practices aiming to promote students' meta-level learning about new mathematical objects involving meta-level rules about multiple uses of a word "derivative".

Intellectual Needs

This study views teaching practice as teachers' actions to address students' intellectual needs, which emerge in a problematic situation that is "incompatible with, or presents a problem that is unsolvable by, his or her current knowledge" and the intellectual need is "the need to reach equilibrium by learning a new piece of knowledge" (Harel, 2013, p. 122). In commognitive terms, 'a problematic situation' can be seen as a task situation where students' existing routines do not work (i.e., do not lead to desirable results) or there is no existing routine they can apply. In this study, we considered task situations broadly in which students need to connect new words with their familiar words/symbols, realizations, narratives, and routines and to learn about how to communicate with the new words. Intellectual needs have been referenced in prior literature about teaching approaches to multiple uses of a mathematical word/symbol (e.g., Zazkis &

Kontorovich, 2016). Similar to those literature, we focused on three intellectual needs:

- Need for Causality: "one's desire to explain to determine a cause of the phenomenon"
- Need for Communication: the need to "externalize…an idea, or a concept, or the logical basis" for other to communicate with them
- Need for Structure: the need to organize "knowledge one has learned into a logical structure" (Harel, 2013, p. 126, p. 137, p. 140, respectively)

Since these needs are inextricably linked (Harel, 2013), we used them collectively to explain teaching practices aiming to address students' needs in their learning of multiple uses of a term.

Multiple Use of a Mathematical Word or Symbol and Teaching Approaches

As multiple uses of a signifier are prevalent in mathematics and cause potential difficulties for students, existing studies have investigated and suggested teaching approaches aiming to help students learn about such uses. Thompson and Rubenstein (2000) provided a list of such words including those that have more than one mathematical meaning (e.g., "square" in algebra and geometry). Rubenstein and Thompson (2001) provided a similar list of symbols with different meanings (e.g., "the raised -1 symbol" for "an inverse function" and a "reciprocal") (p. 268). Thompson & Rubenstein (2000) suggested teaching approaches to help students learn about such words/symbols for example by bringing their attention to different uses (e.g., a writing prompt, "I thought that a function was __. Now I know that a function is __.") and relations among multiple uses (e.g., "Square and cube have geometric meanings and are also used for second and third powers, respectively. How are the geometry and powers related?", p. 517).

Other studies that navigated teaching approaches specific to a word or symbol with multiple uses also focused on differences or relations among them. Lamb et al. (2012) pointed out difficulties that students have with multiple uses of the minus sign as "subtraction", "a symbol for a negative number" and "a unary operation of the opposite of" (p. 5) and suggested asking students to explain different uses of the minus sign in solution processes and providing numerical tasks that can expand to symbolic expressions (e.g., compare – –6 and –6, and then x and $-x$).

Biza et al. (2008) focused on multiple uses of "tangent line" that students encounter from Euclidian Geometry, Analytic Geometry, to Analysis and showed that many Analysis students (108 out of 196) still hold thinking developed in Geometry, "the tangent line is the one that has only one common point with the curve and leaves the curve in the same semi-plane" (p. 64) which do not generally apply to graphs of functions in Analysis. Biza et al. (2009) showed the similar results for teachers. The authors suggested providing students a strong image of "tangent line" from geometry and dominant but incorrect visual claims, and asking to verify algebraically.

Zazkis and Kontorovich (2016) analyzed secondary preservice teachers' (PSTs') responses to a hypothetical student questioning about the two uses of the exponent (-1) as the reciprocal and the inverse function. The PSTs addressed intellectual needs for structures for distinctive uses based on different contexts, terminologies, and locations of the symbol and related uses based on a common word ("inverse") that implies common actions (e.g., "undo") and also address the need for causality for why the same symbol is used in different contexts. They addressed intellectual need for communication using analogies to other symbols with multiple uses.

Two Uses of the Derivative

Our study deals with the two uses of the derivative, for each of the two mathematical objects, the derivative at a point and the derivative function, focusing on how they are different and related in the discourse about the derivative. For example, once the "the derivative at a point" is part of the discourse, it can be used to construct "the derivative function". There are many ways to do this, but one way is called *encapsulating* in Sfard's (2008) terminology. Specifically, once "the derivative at a point" is in the discourse, one can consider, for any number a, the pair $(a, f'(a))$. All the pairs can be collected into a set and encapsulated into a function called "the derivative function". Once the derivative function has been constructed, one can find its value at a specific input by substituting that value into the function. For example, the value of $f'(x)$ at $x = 1$ is $f'(1)$. We call this transition evaluating. Evaluating a function at a point is a process, typically done in calculus by substituting a value into a formula or reading a coordinate from a graph. In calculus, one of the important steps is appreciating the derivative at a point with the result of applying the evaluation process at a point to the derivative function as the same. Previous studies (Font et al., 2007; Park, 2013) have shown that the connection between evaluating the derivative function and the derivative at a point can be challenging for students.

Methods

Data Collection

The participating teacher, William (pseudonym) was educated in the U.S. He has B.S. and M.S. in Mathematics with over 10 years of teaching experience with 7 years of calculus teaching. We observed an Advanced Placement Calculus AB class with 34 students in a U.S. public high school. William used SMART board and generally organized his class starting with explaining key words and solving a few examples on the board, followed by students' individual or small group work on problems, and then whole class discussion about those problems. We video-recorded six 90-minute lessons at the beginning of the derivative unit, before the class began concentrating more on computation, where we could potentially observe the two uses of "derivative", how they were defined and connected to each other, and other realizations and real-life phenomena were discussed. We transcribed the videos including non-verbal communication.

Analysis

In our analysis, we treated the totality of the teacher's talk collected over multiple days as our unit of analysis (Sfard, 2008). However, we separated lessons into several episodes to see how words were used in different contexts. Episodes were defined by William's different teaching activities – e.g., defining a new mathematical term, providing a story involving a real-life object prior to defining a mathematical term, making connections between a newly defined term and previously defined terms, or making connections between a newly defined term and a real-life object – because changes in teaching activities correspond to changes in the context of discourse and, therefore, to potential changes in usage of words whose meaning is context-dependent (Biza & Zachariades, 2010; Thompson & Rubenstein, 2000), like "derivative".

Because we were interested in investigating potential teaching practices that aim to help students learn about multiple uses of the word "derivative" based on how William dealt with the feature, we first identified the mathematical objects that the common signifier signified in William's discourse. In class, William made an explicit distinction between two uses of the single word "derivative," namely as "a number" and as a "function", and we categorized William's use of the word "derivative" alone into two usages, namely as "the derivative at a point" or as "the derivative function," based on whether the surrounding context suggested it was being used as a number or as a function. We also recorded other terms and visual mediators (e.g., slope) used for those objects, and grouped episodes according to whether they included both objects or only one of them. We then recorded connections made between those terms and visual mediators. We operationalized teaching practice as a task–procedure pair (i.e., "the task as seen by the teacher together with the procedure she executed to perform that task") (Nachlieli & Elbaum-Cohen, 2021, p. 110872). Similar to other commognitive literature (e.g., Valenta & Enge, 2022), we first focused on William's actions related to the two uses of the derivative in the data, and wrote general instructional procedures based on these actions. We then identified the tasks William was trying to accomplish through these procedures based on intellectual needs.

Results

Teaching practices aiming to help students learn about the dual use of "derivative" based on our analysis of William's class are organized according to the intellectual needs they addressed.

Teaching Practice Addressing Intellectual Need for Structure and Causality

At the beginning of the derivative unit, William explicitly discussed multiple times how to distinguish the two uses of the signifier "derivative," as shown in the following excerpt observed on Day 2 after he constructed the derivative function graphically:

> This idea of the derivative can be thought of as a number, which represents the slope of the tangent line at a point. But, notice that I can talk about slope of the function at every point along this curve … And the slope is always changing. What we get then, is a function that represents the slope of the tangent line at any point as a function of x. That's called the derivative too. From the context, you understand what I'm talking about. …just remember now we're talking about numbers and we're talking about functions. We have to keep them straight. Then we get into the other half of Calc 1 and talk about integrals. There will be the same thing. There will be some integrals that are numbers, some integrals that are functions…we use the same words because the concepts are related.

Note that after using "derivative" to refer to both the derivative at a point and the derivative function, he provided a rule for distinguishing the two uses: if context shows the object signified by "derivative" is a number, then "derivative" signifies the derivative at a point and if context shows the object signified by "derivative" is a function, then "derivative" signifies the derivative function. This is a metarule because determining which object "derivative" signifies is something that participants in canonic discourse must do repeatedly even if often it is done tacitly. He also mentioned an equivalent metarule regarding how to distinguish the two uses of "integrals," another object with a similar feature that they were to cover soon. This addressed the students' intellectual need for structure for distinguishing the uses when the common word is used.

In the excerpt above, William also addressed intellectual need for connecting the two uses and causality of using one term for both. Specifically, using another object "slope" for both objects, he provided a connection between the two uses of the derivative – the derivative as a number and the derivative as a function – the latter comes into being when the former is expanded to several points over an interval. This connects the two uses via another mathematical object that are used for both objects and also shows how they are connected. He also provided the reason for using one word for two objects by stating "because the concepts are related."

Teaching Practice Addressing Intellectual Needs for Communication

Teaching practices addressing intellectual needs for communication were observed implicitly through the comparison among episodes. We identified the first teaching practice – connecting the dual uses of the derivative to a colloquial object with a similar feature – when William gave a story about a colloquial word with dual use by comparing an episode about "speed" and an episode about “derivative”. Specifically, he used a colloquial story about reading changing numbers on a speedometer to motivate the construction of the derivative function and followed a similar pattern as the colloquial story when constructing the derivative function. He used “the slope of the tangent line” at a point for both speed and the derivative and then considered them on an interval using numbers on a speedometer “changing all the time” similar to the slope “always changing” (see the excerpt in the previous section). Using the same structure and objects to discuss both speed and the derivative and talking about speed as a motivation to define the derivative seemed to address intellectual needs for communication because it allows students to use a new word “derivative” like they use a familiar word “speed” with the similar feature.

Another teaching practice addressed the need for communication. Specifically, the practice of avoiding the common term in one episode after the second object (the derivative function) is defined was observed with a shift in which object the common term “derivative” was used for, between the derivative at a point and the derivative function. In the beginning of the derivative unit, before the derivative function was defined, William used “derivative” dominantly for “the derivative at a point compared to other equivalent terms such as “slope of the tangent line,” or the symbol $f'(a) = \lim_{x\to a}\frac{f(x)-f(a)}{x-a}$. However, after defining “the derivative” as a function, he almost exclusively used the word “derivative” for the derivative function in episodes that involve both objects, except in the two episodes where the other object became included due to students’ questions or participation. Even in those cases, William responded to students using their wording or expressions, and went back to his previous use of the “derivative”.

It should be noted that once this shift in his use of “derivative” was made, he dominantly used “slope of the tangent line” to signify the result of evaluating the derivative function at a point. Specially, on Day 1, William said, “it [the derivative] is a function of any point I give you here, I can tell you what the slope of the tangent line is there”. Then, on Days 3 and 4 he solved five problems about this connection by computing “the slope of the tangent line” at a point given the equation for $f(x)$ by computing $f'(x)$ and evaluated it at a point. In this computation, only the expression $f'(x) = \lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$ was used for the derivative function and only the term “the slope of the tangent line” and a symbol f' with a number (e.g., $f'(3)$) were used for the derivative at a point. In other words, in his class, the derivative function evaluated at a point became equivalent to the phrase “slope of tangent line” and the notation (e.g., “$f'(3)$”), but not to “the derivative at a point” in the way he initially defined it (e.g., “ $\lim_{x\to a}\frac{f(x)-f(a)}{x-a}$”).

Discussion and Conclusion

Our analysis of William’s class suggested several teaching practices aiming to help students learn about multiple uses of a mathematical term that addressed intellectual needs for:

A. Structure – Distinction: Discussing the metarules that distinguish the two uses of “derivative” – a number and a function
B. Structure – Connection: Using another mathematical object (slope) for both objects and showing how one use – the derivative as a function—can be engendered by the other use – the derivative as a number.
C. Causality: Using the connection between the two objects as a reason for using one term
D. Communication: Using the same structure to discuss a word for two mathematical objects and colloquial objects
E. Communication: Avoiding one word derivative in one episode once the second object (the derivative function) is defined

In general, those teaching practices are aligned with the teaching practices identified in the existing literature addressing multiple uses of a mathematical signifier, but also different from those due to the distinctive feature of the two uses of the derivative; the two objects for which "derivative" is used are usually used in the same context and one object is built up on the other object, which we elaborate on with teaching practices A and E only due to the limited space. Similar to the teaching practices addressed in other studies, teaching practice A provided a way to distinguish the two uses of the term "derivative" (e.g., the PSTs in Zazkis & Kontorovich, 2016 suggested what the raised (-1) is next to in order to distinguish between its use between "inverse" or "reciprocal"). However, the teaching practice we identified was making canonic discourse about the "derivative" explicit by stating when it is used as a number, it is "the derivative at a point," and when it is used as a function, it is "the derivative function". Some instructors may not explicitly discuss this metarule about how to distinguish multiple uses or may explicitly use the unabbreviated terms "the derivative at a point" and "the derivative of a function". However, given that students are learning about multiple uses of a common term when they are learning about a new concept, explicitly discussing the metarules of how to distinguish those two uses seems particularly important because one use is built up on the other and they are later related to each other. Being explicit about metarules about a new discourse (about the derivative, in our case) seems aligned with the teaching practices found in the literature for making the boundary between students' old discourse and new discourse explicit with students (e.g., rules about real numbers and rules about complex numbers, Nachlieli & Elbaum-Cohen, 2021). Communicating this could be further aided by providing students opportunity to directly attend to and reflect on the multiple uses of the derivative (e.g., writing prompts, "I thought that the derivative was __. Now I think that the derivative is ___," similar to Thompson & Rubenstein, 2000). The teaching practice E provides a way to communicate when multiple uses of the same term could in the same context. This was observed with a discursive shift in our data, where William initially used the "derivative" as the main signifier for "the derivative at a point", but once he defined the "derivative" as a function, he exclusively used the term for "the derivative function" whenever he talked about the two objects in one context. We note that such a shift could be seen as William's didactic choice, and there is an obvious appeal to avoiding the potential for confusion, ambiguity, and circularity inherent in using one term "derivative" for different objects at the same time. This appeal is magnified by the commognitive observation that student discourse is often initially a (potentially imperfect) imitation of instructor discourse (Sfard, 2014), which suggests that, even if the teacher's discourse carefully avoids such problems, students may not. Notably, given that this shift could be made implicitly by the instructor (as seen in our data), students may not even explicitly notice that the shift occurred in the teacher's discourse. This implicit nature of using "derivative" observed in the shift seems aligned with other literature reporting teachers' implicit shifts between different uses of the same word (Güçler, 2013 for "limit"). These discursive shifts would be interesting to further investigate because the literature has shown that the connection between the derivative at a point and the derivative function can be challenging for students (Font & Contreras, 2008; Park, 2013) and implicit shifts in instructor discourse have been tied to student difficulties (Güçler, 2013). Although derivatives have been intensely studied in the literature, we have not seen shifts like the one we discuss documented before. Note, however, that the instructors studied in (Park, 2015) also dominantly connected "derivative function" to "slope of the of the tangent line" and this leads us to conjecture that this shift may be widespread, but not documented because previous analyses were not looking for such large-scale discursive patterns.

Obligations and Norms: How Instructors Respond to Students' Correct But Non-Traditional Proofs

Andrew Kercher	Anna Marie Bergman	Rina Zazkis
Simon Fraser University	Fort Lewis College	Simon Fraser University

Proof is a central pillar of mathematical practice, and so teaching proof to undergraduate students is a necessary responsibility for undergraduate mathematics instructors. Our study contributes to research on how instructors can achieve this goal by examining their responses to student-generated existence proofs. In particular, the simple logical structure of an existence proof allows for proof-writing norms to be the focus of attention. By analyzing instructors' responses to students' existence proofs in terms of norms, values, and professional obligations, our study attends to the ways in which norms are (or are not) supported by instructors in undergraduate mathematics classrooms.

Keywords: Proofs, Existence Proofs, Professional Obligations, Norms, Values

Among mathematicians, it is not uncommon to agree with Ziegler's (2013) observation that "proofs are the heart and mind of mathematics. They are the pillars upon which the structure of mathematics rests" (p. 130). Among students entering undergraduate mathematics programs, however, the centrality of proof may not be so self-evident; given the scarcity of proving activity featured at the secondary level, this limited perspective is perhaps understandable. It becomes the work of undergraduate mathematics instructors, then, to foster a fuller perspective on proof that more closely aligns with the actual work of mathematics—to illustrate to their students the nature and importance of proof by teaching them what proofs are, how to write them, and what role they serve.

This is not a simple task. Countless studies have explored the difficulties undergraduate students navigate as they come to understand proofs as a concept (e.g., Dawkins & Weber, 2017; Stylianides & Stylianides, 2009; Selden & Selden, 2013). Other researchers have spotlighted particular types of proofs, such as proof by contradiction (e.g., Chamberlain & Vidakovic, 2021), contraposition (e.g., Antonini & Mariotti, 2008) or mathematical induction (e.g., Norton et al., 2022), that are notoriously challenging for students.

By contrast, proving a statement of existence is perceived to be an approachable process for mathematical novices; such proofs are direct, typically constructive, and require only the provision of a single example (Buchbinder & Zaslavsky, 2019). Perhaps for this reason, there is comparatively little research on how undergraduate mathematics students develop an understanding of this type of proof.

But the simplicity of an existence proof is beneficial for researchers interested in how undergraduate students understand the form and function of proofs in mathematics. Because they are not encumbered by logical constructions that are difficult or unfamiliar to them, these students are free to produce existence proofs that adhere most closely to what they perceive a proof "should be like". In this way, existence proofs provide a clearer lens into the norms and values around proof-writing that students have begun to develop.

Simultaneously, the way that undergraduate mathematics instructors read and respond to students' proofs in the classroom—especially those that do not adhere exactly to conventional proof structure—can reveal the mathematical norms and values that inform their teaching. But undergraduate mathematics instructors also have responsibilities towards their institution or their students' learning that might affect how they respond to proofs. Our study examines instructors' reactions to non-traditional student-generated existence proofs to better understand what aspects of proving those instructors value and thus promote in their classrooms. This answers the research question: *What do mathematics instructors consider when evaluating student-written existence proofs and how do their considerations relate to normative conventions for proving?*

Background

To answer our research question, we must first consider what values and norms mathematicians might conventionally hold. Dawkins and Weber (2017) conducted a thorough review of literature in order to present such a list of values, and the associated norms, with respect to proving. The four values they identified were:

1. Mathematical knowledge is justified by a priori arguments.
2. Mathematical knowledge and justifications should be a-contextual and specifically be independent of time and author.
3. Mathematicians desire to increase their understanding of mathematics.
4. Mathematicians desire a set of consistent proof standards.

Each of these values begets a collection of relevant norms, that is, suggested practices for fulfilling the associated value when engaged in proving. For example, the norm "*Irrelevant statements are not presented in the proof"* is a convention used by mathematicians to support the value for increasing understanding; Dawkins and Weber argue that "adding irrelevant statements or assumptions will confuse the reader as she struggles to find out how this is relevant" (p. 131).

Rupnow and Randazzo (2023) extend the work of Dawkins and Weber (2017) by interviewing mathematicians about the values and norms they hold with respect to defining as opposed to proving. They propose an additional value: that mathematicians desire clarity in and for communication when writing definitions.

But when mathematics teachers must respond to student-written proofs or definitions, they are often at odds—they must introduce their students to conventional mathematical values and norms while still attending to the needs of their students, their classroom, and their institution. To understand how mathematics instructors might balance these conflicting needs, we turn to Erickson et al.'s (2021) concept of *professional obligations*. The authors explain: "If norms describe expectations for action held in common by members of a profession, professional obligations help us understand why actions at a particular point and time may deviate from those expectations" (p. 192). Mathematics teachers might experience obligations to the *individual student*, the *social classroom*, the *institution*, or to the *discipline of mathematics*. For example, a teacher might endorse a non-normative proof out of obligation to an individual student if they perceive that doing so would have a positive effect on that student's emotional or intellectual needs. Thus, a mathematics teachers' decisions in the classroom can be seen as aligning with a mathematical norm (and thus, promoting a particular mathematical value), or else as fulfilling a professional obligation to some other entity.

Methodology

Participants and Data Collection

Our data comes from two sources: an online survey and semi-structured interviews, both with mathematics instructors. The survey collected participants' ($n = 86$) reactions to five different student responses; these responses were proofs of the statement, "There exist four different prime numbers the sum of which is prime," and are provided in Table 1. The presented responses were inspired by student work submitted in a course intended to serve as an introduction to proofs.

Table 1. The five student responses assessed by participants in the study.

Participant	Proof
Alpha	True. In order to prove this exists we only have to show one valid example of the statement. *a, b, c, d, e* in "primes" *a + b + c + d = e* Example: 2 + 5 + 7 + 17 = 31 2, 5, 7, 17, and 31 are all primes. Therefore, there does exist a case where four distinct/ different primes sum to equal a prime number.
Beta	True. For example, consider the sum of prime numbers 2 + 3 + 7 + 11 = 23 which proves that there exists four different prime numbers the sum of which is prime. But there also exists four different prime numbers the sum of which is not prime. For example, 2 + 5 + 7 + 11 = 25.
Gamma	True. 2, 3, 5, and 7 are all different positive primes. Their sum, 2 + 3 + 5 + 7 = 17, is also a prime number. This example proves the initial statement that there exists a (at least one) solution. Note that 2 must be one of the primes in the sum: 2 is the only even prime number, so if none of the four primes is 2, then we have odd + odd + odd + odd = (2a + 1) + (2b +1) + (2c + 1) + (2d + 1) = 2(a + b + c + d + 2) = 2k where k is an integer, hence the result is even and cannot be prime (unless k = 2, except all odd primes are greater than 2, so the sum will be greater than 2 making this not possible).
Delta	True, 2 + 3 + 5 + 7 = 17, all primes.
Epsilon	This statement is true. Proving by contradiction, let us assume that this statement is false, then it becomes, "There don't exist four different prime (positive) numbers the sum of which is prime." We can disprove this with a single example, such as 2, 5, 7, and 17, which sum to 31, a prime number. As the inverse statement is false, we can see that the original statement, that there exists at least one group of prime numbers that sum to a prime, is true.

We note that, despite one minor (unintentionally included) error in Gamma's proof (the phrase "unless $k = 2$" should be "unless $k = 1$"), each proof is mathematically correct and logically sufficient to prove the existence of the requisite set of prime numbers. The proofs were chosen for the survey because they did not adhere to the previously observed norm for minimality found in existing research literature (or, in Delta's case, pushed the limits of what a lower bound on minimality might be).

Participants were prompted to "Imagine that you were teaching a math class, and you received the following five homework submissions as an argument or justification for whether the statement is true or false". Under these circumstances, participants were asked to rank the five student responses from "best to worst", under whatever criteria they deemed to be appropriate. More importantly, they were also asked to explain the rationality for their ranking.

The interviewees ($n = 5$) represent primarily a convenience sample, but one that targeted a variety of backgrounds both in learning and teaching mathematics. Interviewees completed the same survey as described above, but in the presence of a member of the research team. Doing so allowed the interviewees to explain in more detail their method for ranking the student responses; it also gave the research team member conducting the interview the opportunity to ask clarifying questions and prompt the interviewee to provide additional insight. Each of the interviews was audio-recorded and transcribed.

Data Analysis

Because the student responses were chosen for their relationship to the norm for minimality in mathematics, participants' explanation of their rankings were first coded by one member of the research team according to whether or not they indicated approval of the amount of content included in each student response. When participants endorsed a student's proof that was not minimal, their rationale was associated with a corresponding professional obligation. In other situations (e.g., when a non-minimal proof was rejected, or when Delta's proof was rejected despite its minimality) techniques from thematic analysis (Braun & Clarke, 2019) were used to identify commonalities between participants' responses. Through constant comparison, these commonalities developed into themes that sometimes aligned with existing norms or values that could be used to add context to the participants' reasoning. Next, a second member of the research team coded the participant explanations following the same procedure and the two researchers met to resolve any differences. An identical process was used to code and recode the interview transcripts.

Findings

In this report, we focus on three of the five responses that provide the most fertile analysis: Gamma, Delta, and Epsilon. We present participants' responses to each of the three existence proofs in separate subsections. Then, we provide a synthesized analysis of these responses.

Gamma

Gamma's response was ranked as the best by a majority of participants ($n = 63$) and by every interviewee. This overwhelming support of Gamma's proof, despite the fact that it is not normatively minimal, can be attributed to several different factors.

First, participants often identified Gamma as having produced the "best mathematical response" by "investigating and extending the problem." In particular, Gamma's observation that one of the prime numbers in the sum must be 2 was more than just an arbitrary mathematical fact appended to the end of the actual proof; participants considered this contribution a "corollary" that unpacks the "underlying structure of the statement rather than just providing an example." Participants stressed that Gamma's extra result was mathematically interesting and alluded to a more general explanation for how a set of primes meeting the requirements of the theorem could be found. This perspective was exemplified in Alan's interview when he said, "I don't particularly like the question. It doesn't do anything. It's nothing. There's no theory behind it. And Gamma, as I said, is the closest to coming up with a theory that makes the question interesting." Alan appears to accept Gamma's breach of the minimality norm because he feels an obligation to the discipline of mathematics, in the sense that it is a disservice to the subject to spend time proving inconsequential results. To Alan, mathematical proof is substantive and worthwhile if it is built on or contributes to existing theory; in his opinion, Gamma's corollary does exactly this.

Other participants ranked Gamma's proof as the best because they ordered the student responses according to the amount of mathematical understanding they revealed. These responses demonstrate an obligation to the student: unnecessarily longer proofs can be allowed when they provide an instructor with insight into their students' ways of thinking. Some participants reported that Gamma's extra work showed "the most conceptual understanding behind the answer"—that is, it revealed the extent of Gamma's mathematical subject matter competency. Other participants noted that Gamma probably "understands that they were done after the first sentence, but they enjoyed proving a little extra." In this sense, Gamma isn't displaying mathematical content knowledge but rather a "meta-theoretical understanding of the role of an example." Gamma's higher-level grasp of the role and methods of proof is evident, somewhat ironically, only because of Gamma's explicit violation of the norm for minimality in proving.

Finally, a number of participants recognized Gamma's proof as the best response because they quantified "best" according to how useful the student's proof would be as a pedagogical tool for promoting mathematical discourse in a classroom discussion. One participant explained that "Gamma […] immediately provided an example in the clearest way possible. The extra work they did actually put them above Delta because it gives me, as an instructor, ways to extend the question in possible follow-up discussion." This sentiment was echoed by Anthony in his interview: "So, in that sense, Delta and Gamma's responses are both good and I think it would be interesting to talk about which one would be preferred […] as a class." Anthony ranked both Delta and Gamma highly out of obligation to the social classroom. That is, he foresaw a chance for his students to collaboratively negotiate a sociomathematical standard for "how much" information should be included in a proof. The length of Gamma's response was acceptable exactly because it was not minimal, and thus could be juxtaposed against Delta's particularly extreme minimalism.

In fact, Gamma's response was never ranked as the worst by any participant and was only identified as the fourth best response a total of eight times. Most often, participants who ranked Gamma especially low took issue with his mathematical mistake (writing "unless $k = 2$" instead of "unless $k = 1$") rather than the length of their response. However, one participant linked the two: "The most concise answers are the best. [Answers like Gamma's], while to be encouraged since they are exploring the problem further, are more likely to lead to responses including incorrect statements."

Delta

Delta's response was ranked as the best by five participants. Their rationale for doing so was consistent: these participants valued Delta's "directness and simplicity," and variously described his response as "concise," "succinct and clear," and "short and to the point". This demonstrates a very clear preference for proofs that adhere as strictly as possible to the norm for minimality. Alan provided another perspective on Delta's work; although he also admitted that he liked it "for its brevity," he explained that brevity was only warranted because "this question is not significant in any way, so I think it's—the response given is on par for the level of the question."

On the other hand, Delta's response was ranked as the worst by half of the total participants ($n = 43$). These participants took a much more negative view of Delta's level of explanation, describing it as "incomplete" or "insufficient". Importantly, this appeared to be a mathematical shortcoming—one participant felt that Delta "provided no warrants at all for how this [example] justifies the claim." Another explained that, although "Delta's example is technically correct," he should "include more structure to make this a more formal argument." These responses indicate that participants were not necessarily concerned with Delta's understanding but instead with the understanding of those who might need to read and interpret his proof. This sentiment was outlined explicitly by Kenneth during his interview:

> For me, proof in mathematics is about communication of ideas. And for me, I—if I didn't have the question in front of me, I didn't know what we were trying to prove, I would have *no* idea what we were trying to do here, right?

This aligns with earlier results from Rupnow and Randazzo (2023) that mathematicians value communication but applied to proofs rather than definitions. However, it can also be interpreted as a type of obligation to the discipline of mathematics. Kenneth appeared to believe that proofs are not just a means of establishing deductive truths, but also a means of sharing those truths with fellow mathematicians. To do this, proofs need to be self-contained; this perspective is, in fact, one of the important mathematical values delineated by Dawkins and Weber (2017). From this perspective, Kenneth's reaction to Delta's proof is an example of competing mathematical norms: A proof must be minimal, but not so minimal that it cannot stand alone as an independent mathematical object.

Other participants who ranked Delta's response last were more concerned with Delta's personal understanding; in the most extreme case, one participant wondered if Delta had even copied their proof from a peer. These participants explained that Delta's work "gave very little insight into their thinking," and thus did not allow them to "assess what they understand." Kenneth's interview added a caveat to this assessment of Delta's understanding. Kenneth recognized that he "might accept this from a graduate student because I would assume that they have a certain baseline level of proof knowledge, but from an intro to proof course, my expectations are a little more, I guess." This illustrates the importance of context for identifying mathematical norms, especially in mathematics classrooms.

Epsilon

Epsilon's response was ranked as the best in eight participants' responses. Interestingly, despite the fact that Epsilon was ranked first in so few responses, there were still two clearly distinct schools of thought as to why it should be placed above its peers.

First, some participants thought that Epsilon's proof was simply the least incorrect. These responses typically took issue with Gamma's mathematical error and Delta's insufficient explanation, leaving Epsilon as the only "valid proof with no errors." Kenneth added some context to this perspective when he explained that

> Epsilon is clearly communicating everything that they're doing. So they—they're clear about what method of proof they're going to use. […] I don't love that they chose proof by contradiction, but they've done it in a nice way and it's clear to me what they're doing.

That is, Epsilon's proof may not be stylistically preferable but is still technically correct. Anthony also summarized this somewhat conflicted appraisal of Epsilon's proof by admitting that "if I was going to write a contradiction proof for this existence theorem, which is bizarre, it would probably look like Epsilon's. I just don't think that's a good idea."

On the other hand, some participants ranked Epsilon's response as the best specifically because of its logical complexity. One participant characterized Epsilon's proof as the "most sophisticated," while another described it as the "most formal." Importantly, this sophistication was seen as evidence of Epsilon's mathematical understanding: not only did he clearly understand how a proof by contradiction should be logically structured, but he was also able to use a proof by contradiction in a surprising and unexpected way. Alan provided a counterpoint to this interpretation of Epsilon's understanding when he observed that "it seems like Epsilon is, like, over formalizing. Maybe because they expect, you know, this is a math class and I'm supposed to be really formal." Then, the use of proof by contradiction could be seen as an explicit lack of understanding. In either case, however, the instructors are acting out of obligation to the student; Epsilon's clearly non-minimal proof is important to allow because it ultimately provides evidence that further conversation should take place with Epsilon.

Epsilon's response was the worst-rated proof in almost as many cases as Delta's ($n = 36$). Almost universal criticism was directed at Epsilon's choice of proof by contradiction, which participants found "labored," "unnecessarily complex," or simply "less clear" than other choices. This was a mathematical consideration; these participants were not concerned with why Epsilon felt that a proof by contradiction was warranted but were simply dissatisfied with the resultant mathematical object. Other participants, however, did identify Epsilon's choice of proof framework as insight into his (lack of) understanding. For example, one participant wondered whether Epsilon might be "uncomfortable with existence proofs". Another inferred that Epsilon was "proving things a bit ritualistically—they seem to be copying a known proof structure without considering whether it is the best way to prove the theorem in question". This was the basis of Gavin's poor appraisal of Epsilon's proof. During his interview, Gavin explained that Epsilon "complicated the solution unnecessarily. I don't think they understand clearly the process of solving—or sorry, proving this question."

Discussion

Our research question asked: *How do mathematics instructors respond to student-written existence proofs and how do their responses relate to normative conventions for proving?* Very commonly, non-minimal existence proofs that included technically extraneous information were accepted by participants. This is best illustrated by the overwhelming approval of Gamma's proof. Participants appreciated that Gamma's additional contribution was mathematically interesting, revealed a deeper understanding, and could serve as a foundation for classroom discussion. The latter two points are unique to the pedagogical context in which Gamma's work is embedded, but the former point is strictly a mathematical consideration. But minimality is also a mathematical consideration, and so in this way, reactions to Gamma's proof illustrate how two mathematical norms for proving can be in conflict even when they are both in service of the same value: that proofs should increase a mathematicians' understanding. A similar observation was made about reactions to Delta's proof, in which minimality was at odds with the need for the proof to make sense as an independent object.

Despite Gamma's positive reception, other non-minimal proofs (i.e., Epsilon's) were largely rejected by the same participants. This is in spite of the fact that, as pointed out by some interviewees, Epsilon's proof does in fact meet the standard for minimality (in terms of a proof by contradiction) and is revealing of Epsilon's understanding. Ostensibly, Epsilon's proof also could be used to stimulate a classroom discussion. We hypothesize that the difference between reactions to Gamma and Epsilon's proofs lies in the fact that Epsilon's proof added logical complexity without any accompanying mathematical insight.

Conclusion

Ultimately, participants in this study illustrated that mathematics instructors are often required to attend to non-mathematical obligations when considering student-written proofs. One limitation of this study was that much of the pedagogical context that might have led to these obligations was not provided in the survey—some participants commented that it was difficult for them to appraise the student responses without more information on the structure and purpose of the class, for example. Future research might include fewer student responses, but within a more elaborate fictional setting to allow instructors the opportunity to make more specific judgements.

What Meaning Should We Attribute to the Colon in Set-builder Notation?

Derek Eckman
Idaho State University

Kyeong Hah Roh
Arizona State University

In this study, we report one group of students' efforts to create a community meaning for set-builder notation collectively. Students' ability to develop and interpret set-builder notation is essential to transition-to-proof courses. Conventionally, a colon is used in set-builder notation to (1) separate the universe of discourse from the set's defining property and (2) indicate an ordering to these components, with the universe to the left and the property to the right of the colon. We describe one normative and non-normative interpretation of this notation and how the students' individual attribution of conventional meanings for the colon to different inscriptions within the notation helped (or inhibited) them from interpreting these expressions. We report how communicative discourse between the students affected their meanings and discussions.

Keywords: Set-builder notation, set-based reasoning, symbolization, transition-to-proof

The mathematical notion of a set is a crucial component of advanced mathematics. In the context of mathematical proof, students' understanding of sets and ability to posit appropriate relationships between sets can positively influence their interpretation of mathematical statements and proofs (Dawkins, 2017; Dawkins et al., 2023; Dawkins & Roh, accepted; Hub & Dawkins, 2018). Instructors often convey information about sets visually (e.g., Euler diagrams) or symbolically (e.g., set-builder notation). Still, many students struggle to reason viably about sets through these representational mediums. For example, Eckman et al. (2023) reported that some students create oval regions in Euler diagrams to (1) *gather* elements of the universe of discourse that fulfill a particular property or (2) *distinguish* between classes of elements when comparing two equal sets. In the symbolic sense, Eckman et al. (2023) reported that students can attribute various meanings to *arbitrary particulars* in set-builder notation (i.e., ΔABC).

This paper aims to investigate students' conceptions of an additional symbolic component of set-builder notation: the colon (:). In the conventional sense, mathematicians utilize the colon (sometimes written as a vertical bar |) in set-builder notation to (1) differentiate between the universe of discourse and the property by which the elements of the universe are partitioned into a set and its complement and (2) denote an ordinality to how students are supposed to create the set (i.e., first define a universe, then sort the elements of the universe). For example, a student considering the set $S = \{x \in \mathbb{Z} : x \text{ is divisible by } 4\}$ would first construe the universe as the set of all integers and then sort these integers into two sets: the integers divisible by 4 (set S) and the integers not divisible by 4 (set S^c, or the complement of S).

We report two instances where three students attempted to interpret set-builder notation to determine the relationship between two sets. Our data stem from the fourth day of a semester-long classroom teaching experiment we conducted to investigate the affordances of set-based reasoning for students' comprehension of transition-to-proof coursework. We provide the following research question to guide our discussion: *What do students' meanings for the expressions in set-builder notation reveal about their meanings for the colon?*

Theoretical Perspective

We adopt the framework proposed by Eckman (2023) to describe students' *symbolizing activity* or the process of mental activities that entails students' creation or interpretation of a perceptible artifact (writing, drawing, gesture, verbalization) to organize, synthesize, or communicate their thinking. We use the term *symbol* to denote a personal artifact to which a student has attributed a meaning (Thompson et al., 2014) that she can re-present to herself through the artifact (c.f., Glasersfeld, 1995). We employ Eckman's (2023) framework, which involves three symbols: *personal*, *communicative*, and *conventional* expressions.

We use the following example to illustrate the difference between the three types of expressions. Suppose an instructor of a transition-to-proof course presents her students with the set $A = \{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$. We consider the set-builder notation $\{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$ to constitute a *conventional* expression because the instructor presents a perceptible artifact to the students as an authorized representative of the mathematical community. In the moment of the presentation, each student attributes a meaning (Thompson et al., 2014) to the conventional notation $\{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$ to organize or synthesize portions of their experience, forming a *personal expression*. As the students interact and negotiate a community-approved meaning, the expression $\{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$ becomes a *communicative expression*. A vital component of a *communicative expression* is that individuals must interpret and reconcile the meanings others attribute to the expression (which may or may not reflect their thinking) with their personal meanings for the symbol.

Eckman (2023) described a *relational meaning* as one that students might attribute to their personal expressions. This paper focuses on relational meaning students may attribute to the colon in set-builder notation, which instructors conventionally use to express a relationship between the universe of discourse and the defining property for a set. There are two components to a relational meaning: *connector* and *comparator*. A *connector-oriented* meaning refers to students' conception of a relationship between two expressions and attributing this relationship to a symbol separating the two expressions. For example, the normative connector-oriented meaning an instructor may attempt to convey through the colon in the expression $\{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$ would be that the set of integers, $\mathbb{Z}$, is the universe of discourse and "multiples of 3" is the property defining the elements in the set. A *comparator-oriented* meaning refers to (1) a comparison action the student attributes to the symbol separating the two related expressions and (2) an ordering in which this comparison must occur. For example, an instructor might portray the colon as denoting an ordered process by which the set is created: (1) define the universe as the set of integers, $\mathbb{Z}$, and (2) use the property "x is a multiple of 3" to separate the elements of the universe into set A and its complement. The instructor would expect her students to use the notation (generally) and the colon (specifically) as *communicative expressions* to convey to others their images of the relationships between the integers and the multiples of three.

Mathematicians often attribute multiple meanings to a mathematical expression (Gray & Tall, 1994). In this sense, we consider a conventional meaning for the relational inscription (:) in set-builder notation to include viable *connector-oriented* and *comparator-oriented* meanings. We further expect that students possessing these meanings can re-present them through their *personal* and *communicative* expressions. In the results section of this paper, we address how the students' various comparator-oriented meanings for the components of set-builder notation facilitated or hindered their construction of *communicative expressions*.

Methodology

The data we present in this paper come from an ongoing project to investigate how set-based reasoning might help students to access transition-to-proof coursework (Dawkins et al., 2023; Eckman et al., 2023; Roh et al., 2023; Ruiz et al., 2023; Tucci et al., 2023). Specifically, we report data from the fourth day of a semester-long constructivist teaching experiment (Steffe & Thompson, 2000) during the Fall 2022 semester at a large public university in the United States. During this session, the students worked in groups to determine relationships between sets defined using set-builder notation. The instructor had presented the conventional meaning of set-builder notation immediately before this activity, and we consider the students' group work to constitute their attempt to co-construct set-builder notation as a communicative expression. We focus on one group of three male students, Enrique, Simón, and Juan. The second author was the instructor for the course, and the first author served as the discussion facilitator.

We collected students' work through audio recordings, photographs of students' notes, and pictures of collective whiteboard work. Our analysis first consisted of identifying moments in the data when the students disagreed about the meaning of an expression and needed to negotiate a collective interpretation. We analyzed these key moments using the principles of grounded theory (Strauss & Corbin, 1998). For example, we initially modeled the coevolution of the students' meanings for the set-builder notation during the critical moments (i.e., open coding). After generating a set of initial codes, we attempted to coordinate our codes into an overarching idea, which we determined to be students' attribution of meaning to the colon inscription (i.e., axial coding). In the results section of this paper, we describe how students' relational meanings they attributed (or did not attribute) to the colon inscription allowed them to interpret set-builder notation appropriately or, in other instances, led to cognitive conflict.

Results

The results section comprises two subsections. First, we provide an example of Enrique, Simón, and Juan's productive reasoning about set-builder notation and the relationship between two sets. Second, we share an example where each group member interpreted an instance of set-builder notation differently. In the discussion section, we describe how the students might have leveraged the non-normative interpretations for components of the notation they exhibited to make the seemingly "correct" interpretations we describe in the first subsection.

Distinct Meanings for Set-builder Notation Producing a Conventional Interpretation

At one point during the class, the students compared sets $A = \{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$ and $F = \{x \in \mathbb{Z} : x^2 - 1 \text{ is not a multiple of } 3\}$. The mathematical relationship between these sets is $A = F$ (i.e., both sets contain, and only contain, the multiples of 3).

During this comparison exercise, Simón and Enrique quickly interpreted the elements of set F and posited a relationship between sets A and F:

Simón Ok, so they're saying $x^2 - 1$ leaves a remainder of either 1 or 2 (*unintelligible*). So either x is a multiple of 3 itself, or, no, I think that's the only option, x has to be like a multiple of 3 because ,like, yeah (…) Ok, so I guess it's the same thing [i.e., set A and set F are identical].

Eckman Juan is looking confused.

Juan I don't understand how you got there.

Simón Because it's like, x, so, like if x were a multiple of 3, then this [$x^2 - 1$] won't be [a multiple of 3], like this $x^2 - 1$.

Enrique Right, because x^2 would also be a multiple of 3, but if you subtract 1, then it's no longer a multiple of 3.

(omitted dialogue)

Simón Or, I guess, it's like you could factor $x^2 - 1$ as $(x - 1)$ and $(x + 1)$.

Enrique Right, since you have a plus 1 and minus 1. Like, the thing about the second number [i.e., the expression "$x^2 - 1$ not a multiple of 3"] is it [i.e., x] has to be a multiple of 3, so it's got to be a multiple of 3 in order for it to [work].

Juan Oh yeah, that makes sense. So they would be the same set.

In this excerpt, Simón's order of reasoning indicates that he considered the multiples of 3 (i.e., set A) to be a subset of all integers x with the property "$x^2 - 1$ is not a multiple of 3" (i.e., set F). In contrast, Enrique's order of reasoning indicates that he considered the integers fulfilling the property "$x^2 - 1$ is not a multiple of 3" (i.e., set F) to be a subset of the multiples of 3 (i.e., set A). Collectively, Simón's reasoning that $A \subseteq F$ and Enrique's reasoning that $F \subseteq A$ satisfy the conditions to show that $A = F$. However, there was no indication from this excerpt that (1) Enrique and Simón recognized the subtle (to them) difference in their thinking or (2) either student attributed both conceptions to their communicative expression $F = \{x \in \mathbb{Z} : x^2 - 1 \text{ is not a multiple of } 3\}$. Juan's final comment indicates the possibility that he considered both qualifications (i.e., $A \subseteq F$ and $F \subseteq A$) when positing the elements of set F.

We purposefully made no direct reference to the colon (:) in this subsection. Instead, we chose to describe the possibility that Enrique, Juan, and Simón agreed on a collective meaning for the elements of the set F while maintaining distinct personal meanings for the set-builder notation denoting these elements. In the following subsection, we describe how these students' differences in *relational* meanings for their communicative expressions might be attributed to their meanings for the colon (:) inscription.

Distinct Meanings Producing a Mathematically Incorrect Interpretation

Immediately prior to comparing sets A and F, the students compared the sets $A = \{x \in \mathbb{Z} : x \text{ is a multiple of } 3\}$ and $E = \{2x \in \mathbb{Z} : x \text{ is a prime number}\}$. The mathematical relationship between these two sets is that $E \subset A$ (i.e., both sets share only the number 6).

The students spent most of their discussion negotiating a meaning for the elements of set E. Similar to the comparison between sets A and F, each student consecutively expressed a different personal meaning for the expression $\{2x \in \mathbb{Z} : x \text{ is a prime number}\}$:

Enrique To answer [the question] is anything in both sets, maybe there's nothing in E. Because you can't have a prime number that's a multiple of 2.

Simón Well, E, to me E was either the set of primes or the set of all the primes times two.

Juan I think [the set E is] all the prime numbers multiplied by two.

In contrast with their comparison between sets A and E, the students recognized the differences in their thinking this time. Enrique first claimed that set E is empty because (to him) no integers exist that are simultaneously even and prime (in actuality, the number 2 satisfies both conditions). Simón countered that the set E constituted one of two options (between which he could not decide): (1) the set of all primes or (2) the set of all primes multiplied by 2. Finally, Juan posited that the set E contains only the doubles of all primes (the normative interpretation). In the following subsections, we describe how each student's responses were influenced by their *comparator-oriented* meanings for the relationship between the expressions $2x \in \mathbb{Z}$ and "x is a prime number," which mathematicians conventionally attribute to the colon (:) inscription.

Enrique: The colon does not matter—the universe is determined by x. Enrique talked the least during the negotiation of meaning for the expression $\{2x \in \mathbb{Z} : x \text{ is a prime number}\}$ and did not explicitly agree to Simón and Juan's final decision for the meaning of this notation. Still, Enrique's comments about his meaning for set E were relatively consistent, as evidenced by the following statements he made at various times during this discussion:

Enrique	Right. But, if you were to like plug in, I don't think this, it can't even exist.
Enrique	No, because then if three equals x, then you'd have six [for $2x$] and six is not a prime number.
Enrique	$2x$ is an element of the integers such that x is a prime number. Could you, does that even exist?
Enrique	To answer [the question] is anything in both sets, maybe there's nothing in E. Because you can't have a prime number that's a multiple of 2.

These excerpts indicate that to Enrique, membership in set E, as defined by the expression $\{2x \in \mathbb{Z} : x \text{ is a prime number}\}$, required an integer first to satisfy the property "x is a prime number" and then satisfy the property $2x \in \mathbb{Z}$ (where $2x$ is also prime). In other words, Enrique first selected the set of prime numbers, P, as the universe of discourse. Then, he attempted to classify primes whose double was also prime as the elements of set E. Conventionally, we might write Enrique's definition for set E as $\{x \in P : x \text{ is a multiple of } 2\}$. When he could find no integers that satisfied his personal meaning for set E, he claimed the set was empty.

Enrique also stated that "the colon [in the set-builder notation] is like a subset." His comment emerged in response to Simón reviewing an example of set-builder notation he had written down in his notes. Enrique's meaning for E and his subset comment about the colon implies that he attributed his personal *comparator-oriented* meaning for the set-builder notation for E to the inscription x. In effect, Enrique considered x in relation to the universe of discourse and the colon as a synonym for "subset," giving no indication that he considered the colon to be more than a dividing symbol between two expressions (e.g., $x \in P, x \text{ is a multiple of } 2$) whose subset-relationship could be utilized to define the elements of a set.

Simón: Does x or the colon relate to the universe? Simón often led group discussions and frequently presented conventional interpretations of sets and relationships. Simón's initial conception of set E was that it contained "the set of primes." After realizing that neither Enrique nor Juan agreed with his personal meaning for the expression $\{2x \in \mathbb{Z} : x \text{ is a prime number}\}$, Simón began to wonder whether the set E contained the set of primes or the set of primes doubled. At this point of the discussion, the group facilitator intervened and asked the students to consider whether individual integers were elements of set E.

Eckman	So I think in this case it might be nice to just pick some numbers and say like, "Oh, [Is] five in E? Is eight in E?" and see if you can figure it out that way.
Simón	Okay, so … like the number 5. So 5 is a prime number, and 10 is an element of the integers?
Enrique	Is that what it's saying that?
Simón	But so then is 5 or 10 the number that is in the set [E]?

Simón's words indicate that to him, membership in E, as defined by the expression $\{2x \in \mathbb{Z} : x \text{ is a prime number}\}$, required an integer to satisfy the properties "x is a prime number" and $2x \in \mathbb{Z}$. Unlike Enrique, who envisioned $E = \{x \in P : x \text{ is a multiple of } 2\}$, Simón considered two distinct sets: $E_1 = \{x \in P : 2x \text{ is an integer}\}$ and $E_2 = \{2x \text{ is an integer} : x \in P\}$. For set E_1, Simón considered the set of primes to be the universe of discourse and claimed E contained all primes whose doubles were integers. This was a different approach than Enrique, who insisted that the double of a prime must also be prime to merit inclusion in set E. For set E_2, Simón considered the universe to constitute the set of even integers, and the elements of set E to comprise those even numbers whose value, when divided by two, is prime.

Although Simón did not explicitly describe his meaning for the colon (:) in the expression for set E, we infer, based on his remarks, that he recognized the order of comparison mattered for the expressions $2x \in \mathbb{Z}$ and "x is a prime number." At the beginning of the discussion, Simón appeared to attribute this ordinality to the inscription x (similar to Enrique). His later cognitive confusion emerged from considering whether to attribute the ordinality to the positions of the expressions (and the colon dividing them) or the variable x. In this case, Simón's *comparator-oriented* meaning for the inscription (:) was in development from a simple connector to an indication of an ordered process and relationship.

Juan: The colon divides the universe (left) from the property (right). Juan actively participated in group discussions when he agreed with the claims of his fellow students and quietly interjected or listened if he did not agree with or understand others' comments. Throughout the discussion about sets A and E, Juan insisted (quietly at first, then more rigorously later) that the set E contained the set of all primes doubled (the normative interpretation of set E). After Simón attempted to discern whether 5 or 10 was an element of E, Juan took command of the discussion:

Juan	Is the variable x the number that's in the set [E]? I don't think it is.
(*omitted dialogue*)	
Juan	Yeah, so what I'm reading here in my notes for set-builder notation is that where the $2x$ is in the general form [of set-builder notation], there's an $f(x)$ that represents a format by which every element of the set can be represented.
Enrique	Oh, that's useful.
Juan	So, every element of the set [E] is 2 times a prime number.

In this excerpt, Juan pinpointed what he considered the central point of conflict in the discussion: whether the integers represented by x were given inclusion in set E or the integers represented by $2x$ were given inclusion in the set. After referring to his notes on the general form of set-builder notation that he had taken during direct instruction, Juan stated that the expression $2x \in \mathbb{Z}$ was the arbitrary "format" (i.e., universe) by which to define the set and concluded that "2 times a prime number" was the way to denote the elements in set E.

Although Juan used his written notes to justify his claim about membership in set E, he repeatedly commented throughout the discussion that the elements of set E were the set of primes multiplied by 2. His consistent comments imply his *comparator-oriented* meaning for the colon (:) included a distinct and consistent ordering. This ordering included a notion that the expression that comes to the left of the colon constitutes the universe, and the expression following the colon constitutes the defining property for determining membership in a set. Juan's description of set-builder notation in arbitrary form (e.g., the first expression is $f(x)$) could also indicate that he was beginning to construct a general form of set-builder notation, which has been called a *personal expression template* (Eckman, 2023) or a *symbolic form* (e.g., Jones, 2013).

Discussion

The purpose of this paper was to provide insight into the question: *What do students' meanings for the expressions in set-builder notation reveal about their meanings for the colon?* In this discussion, we address three distinct ideas: (1) the three types of comparator-oriented meanings revealed by our data, (2) how Simón and Enrique might have leveraged their meanings for set E to make their mathematically correct interpretation of set F, and (3) the relevance of this paper in the context of research literature and student instruction.

We have described three relational *comparator-oriented* meanings that Juan, Simón, and Enrique attributed to the expressions $\{2x \in \mathbb{Z} : x \text{ is a prime number}\}$ and $\{x \in \mathbb{Z} : x^2 - 1 \text{ is not a multiple of } 3\}$. All three students appeared to attribute viable *connector-oriented* meanings to both expressions, perceiving that the expression on one side of the colon referred to the universe of discourse and that the other expression referred to the property by which elements of the set are identified.

However, the portion of the expression to which each student wished to attribute a *comparator-oriented* meaning differed. For instance, Enrique (and, at times, Simón) attributed a *comparator-oriented* meaning to the inscription x, which they considered to relate to the universe of discourse. Consequently, in these moments, the students merely attributed a *connector-oriented* meaning to the colon to divide two connected (to them) ideas. As the discussion progressed, Simón's *comparator-oriented* meaning developed so that he discerned two distinct ways to describe the elements of set E. In this moment, Simón began attributing a *comparator-oriented* meaning to the colon. Still, his meaning was tenuous and only achieved equal status with his prior meaning for x. Finally, Juan's intervention and description of his *comparator-oriented* meaning resulted in the group attributing exactly one order to the notation, indicating the relationship between a universe of discourse and a set defined within that universe.

Simón agreed, and Enrique did not disagree, with the Juan-proposed meaning for the communicative expression $E = \{2x \in \mathbb{Z} : x \text{ is a prime number}\}$. Still, it is possible that Simón and Enrique continued to leverage their personal meanings for x as an indicator of the universe to relate the two expressions for the set $F = \{x \in \mathbb{Z} : x^2 - 1 \text{ is not a multiple of } 3\}$. For instance, these students might have (1) identified the expression containing x ($x \in \mathbb{Z}$) to define the universe of discourse and (2) selected elements in the domain of discourse that satisfied the other expression (i.e., $x^2 - 1$ is not a multiple of 3) to define the elements of F.

This study furthers previously reported research on students' understanding of sets, set-builder notation, and symbolization. For example, our report provides additional insight into how students might interpret set-builder notation previously reported by (Eckman et al., 2023). Additionally, our explanation of *comparator-oriented* meanings including an ordered component adds to the examples and constructs proposed by (Eckman, 2023). This study also supports (to some extent) that conventional meanings for mathematical topics and symbols are not merely transmitted to individuals. Instead, the individuals must construct their personal meanings and attribute them to a conventional symbol to achieve a normative meaning for a mathematical topic. The students' active participation in the group discussion seemed to serve as a catalyst to bridge their personal meaning and conventional meaning by engaging in community efforts to build a collective meaning for the notation as a communicative expression.

This study also informs efforts to improve the instruction of sets and set-based reasoning in the context of transition-to-proof courses. For example, our results provide further insight into how students come to interpret set-builder notation, which can further inform teaching-oriented research projects related to set-based reasoning (Dawkins & Roh, accepted; Hub & Dawkins, 2018; Roh et al., 2023). Specifically, we describe a potential idiosyncratic student interpretation of set-builder notation, students' attribution (or misattribution) of *comparator-oriented* meanings in the context of set-builder notations. We encourage transition-to-proof instructors to explicitly address the comparison order between expressions in set-builder notation and the inscription (i.e., the colon :) to which this meaning should be attributed.

University of Nebraska Omaha

Serving diverse student populations equitably is a focal concern for mathematics educators (Association of Mathematics Teacher Educators, 2017), particularly given recent teacher shortages in high needs schools. Teacher preparation programs are tasked with preparing new teachers to thrive in these settings. In this paper, we examine what preservice, secondary mathematics teachers found valuable engaging in structured mentoring and guided reflective opportunities that integrate theory into practice. Participants engaged in authentic experiences including learning assistantships along with traditional practicum experiences. Participants completed guided written reflections throughout the semester, in addition to meeting regularly with a faculty mentor. We utilized Wenger-Trayner and Wenger-Trayner's (2014) value framework to examine the data and share findings that suggest most participants developed an awareness of mathematical content knowledge, pedagogical content knowledge, and knowledge of students (Ball et al., 2008) at an earlier phase of their training than may be expected in traditional teacher preparation programs.

Keywords: preservice teacher development, reflection, mathematics teacher development

The recruitment of highly qualified mathematics teachers is a pervasive issue in K-12 education (Darling-Hammond et al., 2016; Ingersoll & Perda, 2010). Prior to the COVID-19 pandemic, nearly every state reported shortages of highly qualified mathematics teachers (United States Department of Education Office of Postsecondary Education, 2017), with attrition rates for math and science teachers nearly 70% greater than this average, particularly in high poverty, urban settings (Carver-Thomas & Darling-Hammond, 2019; Sutcher et al., 2019). A recent study (Institute of Educational Sciences, 2022) found 45% of public schools had one or more vacancies nationwide, with major disparities for schools serving students living in poverty. These figures, in conjunction with declining enrollment rates in teacher preparation programs (Partelow, 2019), highlight a critical need to recruit, train, and retain highly qualified mathematics teachers.

Serving students in urban, high needs settings requires educators keep students' background knowledge and cultures at the forefront of their planning and teaching. However, beginning teachers' concern often rests in their own inadequacies, situational responses, supervisor feedback, and classroom management (Fuller, 1969; Fuller & Brown, 1975). Further, mathematics teachers require high levels of pedagogical content knowledge (PCK) and mathematical content knowledge (MKT) (Ball et al., 2008; Schulman, 1986). In response to this need, our university developed a layered model of authentic teaching and learning experiences, where preservice teachers (PSTs) engaged in both learning assistantships in college math courses as well as in traditional K-12 classroom practicums. We paired these experiences with structured reflective opportunities, seeking to answer the question: *What do PSTs value about field experiences and learning assistantships when paired with targeted mentoring and reflection as part of their teacher development?*

Literature Review

Shulman (1986) developed the idea of pedagogical content knowledge (PCK) to differentiate among content knowledge, curricular knowledge, and effective teaching strategies and representations for students. In the field of mathematics education, PCK is defined in three parts: knowledge of content and the curriculum, knowledge of content and teaching, and knowledge of content and students (Ball et al., 2008; Hill et al. 2008). Master teachers with strong PCK can interweave students' prior knowledge with mathematical concepts and create a clear infrastructure for students to decipher and build their comprehension, which van Es et al. (2017) and Lebak (2022) describe as “ambitious pedagogy.”

Fuller (1969), and later Fuller and Brown (1975), identified three phases of concern for novice teachers: (a) self-survival (awareness of self), (b) teaching situation (awareness of task), and (c) pupil (awareness of student-impact). Over time, teachers gradually move away from solely focusing on their own actions and toward how students grapple with content. Specific to mathematics teaching, the goal is for PSTs to shift away from examining non-mathematical classroom matters, such as engagement or classroom management, and toward mathematical teaching and learning (Mewborn, 1999; Roller, 2016). These shifts often take time for novice teachers to make but can be supported through structures such as targeted mentoring and reflection (Feiman-Nemser, 2001; Mewborn, 1999). Powell (2014; 2016), for example, found that PSTs increased their take up of these stages of concern in undergraduate methods courses, particularly the task-oriented stage, however he found little change between or among stages across the span of a semester-long course. More research is needed about the contextual factors that influence PSTs’ stages of concern and impact their development over time.

Research on teacher preparation consistently points to the need for PSTs to have authentic teaching and learning experiences in classrooms to support retention in the profession (Darling-Hammond, 2005) and to help them develop effective teaching practices (McDonnough & Matkins, 2010), including culturally responsive pedagogies (Ladson-Billings, 2021). Traditionally, field experiences (practicums) are incorporated into teacher preparation programs as opportunities for PSTs to apply what they are learning in methods courses (Darling-Hammond et al., 2002; Ellerbrock et al., 2018; Garza et al., 2013). Learning assistantships offer an alternative model for engaging in teaching and learning experiences, whereby undergraduate students act as learning assistants (LAs), supporting undergraduate peers and faculty instructors in college courses versus K-12 classrooms (Ellerbrock et al., 2018). LA programs can reduce student-teacher ratios, support faculty in incorporating active learning practices, and offer increased supports for student-centered learning (Otero et al., 2006), and increase the content knowledge of LAs as they engage with near peers (Gomez Johnson et al., 2021; Closer et al., 2016; Talbot et al., 2015). Research also indicates that LAs later recruited to K-12 teaching positions exhibit more reform-based practices than their peers (Gray et al., 2016). Authentic teaching experiences, including both field experiences and learning assistantships, create avenues for PSTs to actively partake in community-based classrooms with experienced mentor teachers. When collaborating and reflecting with these mentors, PSTs can discover the realities of educating students in real time (Ellerbrock et al., 2018; Garza et al., 2013).

Opportunities to reflect *in* practice and *on* practice (Schon, 1987) can be facilitated through both formal and informal means. Effective reflective opportunities can help PSTs hone their skills in determining what is worth taking note of related to teaching and understanding students and making connections between pedagogical theory and practice (van Es et al., 2017; Kersting, 2008). One of the goals of reflective activities in PST programs is to develop their professional noticing to progress more quickly through Fuller and Brown's (1975) stages of concern in anticipation of working with students in diverse settings. Therefore, it is important for researchers and teacher educators to identify effective elements of such reflective opportunities to create robust opportunities for PST growth.

Theoretical Framework

Collaborative experiences support meaningful learning (Lave & Wenger, 1991), thus understanding how opportunities for PSTs to engage in authentic teaching experiences (field experiences and learning assistantships) supported through collegial structures is important to understand. In this paper, we investigate PSTs' reported value participating in such experiences and examine how engaging in structured reflections after the fact influenced their capacity to shift from focus on self to students during instruction (Fuller & Brown, 1975).

Situated learning theory (Lave & Wenger, 1991; Wenger, 1998) proposes learning is an intrinsic factor of collaborative participation between agents in an organization. Value can be viewed as connected and flexible such that researchers can examine participant experiences in their social and academic contexts (Wenger, 1998; Wenger et al., 2011). Wenger et al. (2011) and Wenger-Trayner & Wenger-Trayner (2014) identified five value cycles: immediate (in the moment), potential (for the future), applied (tested implementation), realized (actualized implementation), and transformative (broader dissemination to others) value. Naming specific aspects of learning experiences that PSTs find valuable, and interrogating how those are linked to their development along the stages of concern can help teacher preparation programs maximize opportunities for PSTs to evolve and develop their MCK and PCK. This study is part of a larger study at a mid-sized, urban, midwestern university investigating undergraduate PSTs participating in a STEM education scholarship program. In this paper, we analyze the guided reflective opportunities that augmented PSTs' early authentic teaching and learning experiences to support their mathematics teacher development.

Research Methodology

The NebraskaMath Noyce project, a National Science Foundation (NSF) Robert Noyce Teacher Scholarship project (Grant No. 1852908), seeks to recruit, train, and retain high-quality mathematics teachers. The authors of this study are members of the project leadership team. This study is part of a larger investigation into the value that PSTs experienced during program activities (e.g., professional development, community of practice, mentorship). Qualitative research methodology was utilized to allow us to uncover participant conceptions of value and developmental stages of concern (Charmaz, 2008) by exploring "how people interpret their experiences, how they construct their worlds, and what meaning they attribute to their experiences" (Merriam, 2009, p.5) through the collection of rich, descriptive data (Yin, 2018). We used qualitative methods to examine the research question: *What do PSTs value about field experiences and learning assistantships when paired with targeted mentoring and reflection as part of their teacher development?*

Context and Participants

In Fall 2020, the Noyce scholarship program began integrating learning assistantships in undergraduate mathematics courses as part of the experiential component of the program. By Fall 2021, the project leadership team began to proactively consider PST and faculty pairings so that each undergraduate student was placed in active learning mathematics courses where they would engage with students and observe evidence-based practices each day.

Participants included nine undergraduate students who served as Learning Assistants (LAs) in Fall 2021. Five participants had completed at least one formal field experience at the time of the study (however, these early experiences were limited by the COVID-19 pandemic). Two participants had completed one field experience, while the remaining four participants had not engaged in a field experience at the time of the study. Participants were placed as LAs in one to two mathematics courses where their roles primarily involved encouraging and supporting students through one-on-one or small group engagement. The participants were paired with eight mathematics faculty members who taught using active learning techniques in their undergraduate mathematics courses (e.g., college algebra, quantitative reasoning, precalculus). These faculty members also met with the LAs outside of class to mentor them in areas such as lesson planning, personal and academic life check ins, and reflection on events from the week.

Data Collection and Analysis

We collected 10 reflection journal entries from each participant (totaling 90 reflections). A member of the research team also conducted a focus group with participants at the end of the semester. We aggregated and de-identified all data from the journals and focus group transcript to ensure the anonymity of study participants and, where appropriate, pseudonyms are used in this report. Reflective journals were a program requirement not only as a data source, but also to support the literature on PST development (e.g., Collins, 2006; Shulman, 1987; van Es & Sherin, 2008). Reflections can frame PSTs' thinking around their teaching practice and can offer a unique opportunity for them to highlight both seemingly large and small occurrences during teaching moments across the semester. Participants were prompted to write their reflections around one of the eight following categories:

1. Learning Assistantship Reflections- based on…participation & engagement in campus math courses.
2. Professional Development (PD)- based on…Noyce Math or campus-offered PD workshops, book study, colloquium, etc.
3. Community of Learners- based on…interaction with other Noyce Math participants or study groups.
4. Outreach- based on…community or campus activity where you were able to work with youth or on a project.
5. Mentoring- based on…interactions with a faculty mentor, whether formally assigned or informal partnership (can also include practicum mentor).
6. Learning Mathematics- based on… experiences as a student of mathematics.
7. Leadership- based on…personal leadership experiences where you took initiative to organize your peers or create a new process/project/event.
8. Lesson Plans- based on…creation of a lesson for your learning assistantship experience, a practicum lesson reflection, or other tutoring planning.

We used a combination of directed content analysis (Hsieh & Shannon, 2005) and thematic analysis (Clarke et al., 2015), mapped onto our theoretical framing of the Wenger et al. (2011) value framework (Jakopovic & Gomez Johnson, 2021; Gomez Johnson et al., 2021), to derive meaning from participants' written reflections and the focus group interview. Via directed content analysis, we leveraged prior research related to key concepts (e.g., teacher preparation, PCK, MCK) as our initial *a priori* codes, using the five value types (immediate, potential, applied, realized, and transformative) to develop common working definitions and examples of each code (Hsieh & Shannon, 2005). We first deductively coded value to find areas of saturation (LeCompte & Schensul, 2013). We then reanalyzed the data using a thematic lens. Thematic analysis is an appropriate approach for answering research questions about people's lived experiences and perspectives on particular topics (Clarke et al., 2015). In the second cycle of coding, we examined data for themes that emerged, which we unpack in the following section.

Findings

Participants had access to both K-12 classrooms (practicum) and undergraduate math courses (learning assistantships) where they participated in authentic learning and teaching activities. While participants were intentionally placed in "active learning classrooms" with master teachers as LAs, their field experiences varied greatly in the level of mentorship and quality of instructional practices they observed and enacted. In our analysis, we found participants most often valued what they learned about their developing understanding of learners' needs. Participants reported immediate value (i.e., experienced in-the-moment awareness) in the following four areas as they participated in authentic experiences and guided reflection: the importance of building relationships, student motivation and confidence, the importance of students' mathematical background knowledge, and the role of differentiated instruction. PSTs discussed these topics, considering their impact in the classroom along with their level of satisfaction teaching and learning.

Building Relationships

Participants noticed the ways in which building relationships with students impacted the overall experience of working with students and helping them learn. For example, James reported that his "first goal was to learn every name," and while it was often a challenge, he continued "redoubl[ing] my efforts because during my third week there, I got the evil eye from a student when I asked for his name yet again." After learning names, he remarked on the impact that act had on students' reactions to his instruction. Along with learning names, participants also described how building relationships meant getting to know learners as "whole people," which involved creating a safe space for students to take risks and show that instructors can be caring adults who care about their success (Stipek, 2010). As Monica noted, "One thing that I am confident in is that my students will know... that I accept each of them just as they are... I am not just there to teach them Math." Monica, along with other participants, shared their increased awareness of students' perceptions of PSTs' investments in them as individuals and the positive impact this had on the classroom environment overall.

The Role of Student Confidence and Motivation

Additionally, participants identified in-the-moment situations where students lacked confidence or motivation, resulting in various student behaviors. Several participants recognized student engagement as a concern and made conjectures about why students might elect to not participate during instruction, as well as ponder their role in addressing classroom engagement. As Anthony wondered, "As a teacher, how can I approach a student who is having difficulties in a class to the point that they give up?" In our data other participants, like Nicole, indicated that specific strategies might be necessary to support and engage learners, whether it be offering one-on-one support, continuing to foster positive relationships, or noticing other aspects of a student's reality that might be influencing their willingness to participate in math class.

Participants indicated that at times this may be more about culture, context, and experiences (Ladson-Billings, 2021; Safir & Dugan, 2021), and less about a student's intrinsic interest in mathematics. Helen reported observing differences in the learning environments between upper-level mathematics classes and on-or below-level mathematics classes,

> The honors students seem eager to learn and the "general ed" classes... seem to lack motivation. It makes me wonder how much of that is due to school culture/teacher expectation and how much of it is the student themselves.

In her reflection, Helen pondered how the classroom environment and student backgrounds might influence both behavioral and educational experiences. Several participants noticed that larger, system level factors may lead to inequities in classrooms (Ladson-Billings, 2021).

Students' Mathematical Background Knowledge

Participants also valued opportunities that highlighted the role student background knowledge plays in their classroom interactions. For example, Leslie explained her struggle to identify the appropriate level of difficulty as a new teacher, "It is such a scary thing when you show something to them that's too advanced for them, they just shut down...but then if you give them something that's way too easy, they might get mad at you." She noticed that, without an accurate prior assessment of a student's mathematics level, significant consequences can occur without knowledge of where a student is situated on a learning trajectory. While PSTs learn about theory such as Vygotsky's zone of proximal development (1978), seeing the application when students have a broad range of prior knowledge raises a new level of consideration for PSTs. This can. be rare for new teachers, who typically are not yet at the stage of concern where they notice how students interact with content (Fuller, 1969; Mewborn, 1999).

Differentiation in Action

A final theme for several participants was the recognition that students often do not have the expected level of background knowledge, along with the fact that within any given class this understanding likely exists along a continuum. Some realized their role as a teacher was to respond with different strategies or approaches than they may have experienced in their own learning (Ball et al., 2008; Hill et al., 2008). Monica shared a moment where she wrongly assumed what an adult learner was struggling on a particular concept. "That was way more advanced than he was ready for, and I was like, oh okay, we have to take another step back and I looked at that." Monica noted that as a teacher she needed to reframe her thinking.

For many early career mathematics teachers, identifying moments where differentiation is needed can be challenging. Participants in the study identified the need to tailor content and identify specific, effective teaching strategies. Eddie shared that, "You have to have multiple different tools to be able to teach students. Some students just don't understand something that 15 people will, and you have to work a little harder...for that one student." James reflected on his observation of his mentor teachers' approaches to this, and talked about how their decisions impacted learners. James mused, "The students that got the easy one are worried they aren't properly prepared for the hard one...[and]...the group with the hard one felt rushed by everyone else." James' noticing of students' reactions to the differentiated problems allowed him to consider how he might approach differentiation in ways that were similar or different to this experience. This example helps to illustrate the depth at which James, among other participants, noticed and analyzed the impact of differentiation on learners.

Implications

Preparing the next generation of mathematics teachers requires both the art and science of teaching. For many PSTs, the realities of the myriad roles they play, along with the knowledge, skills, and dispositions they need to develop can be overwhelming. Early opportunities for PSTs to interact with students in a variety of environments and to reflect on these experiences can illuminate key areas of concern for teaching. In terms of immediate value, the most prevalent takeaways for our participants revolved around the students themselves. As they grew to understand how to teach content, they noticed key elements of understanding learners necessary for successful teaching. Pinpointing areas such as background knowledge, motivation and confidence, and engagement, can provide PSTs with a drawing board of essential components for their future planning. Furthermore, these features of understanding students can facilitate their development as effective teachers qualified to teach in diverse settings.

Student Agency and Identity in Reading Didactical Mathematics Texts

Aaron Weinberg
Ithaca College

Emilie Wiesner
Ithaca College

Ellie Fitts Fulmer
Ithaca College

Reading didactical texts, such as textbooks, requires particular sets of literacy practices. Researchers have proposed that these practices are related to aspects of identity and agency, and have described aspects of these constructs separately. In this study, we examine the interactions between students' agency and their macro- and micro-identities. We present data from two undergraduate students reading a section of a calculus textbook and explore the ways the interactions between the students' identity and agency shape their reading activity.

Keywords: Agency, Identity, Literacy, Textbooks

Didactical texts—that is, media such as textbooks and instructional videos—play an important role in college mathematics instruction. Many students are asked to read mathematics textbooks or watch instructional videos (e.g., Butler, 2019; Shepherd & van de Sande, 2014; Weinberg et al., 2022), and these texts constitute an important resource for student learning outside of in-person instruction.

Disciplinary texts have long been viewed as requiring particular sets of skills and literacy practices to read productively (e.g., Moje, 2007; Shanahan & Shanahan, 2008). Fang and Schleppegrell (2010) described their grammatical resources, Lee and Spratley (2010) described discipline-specific reading actions, and others (e.g., Morgan, 1998; Rezat & Rezat, 2017) have contrasted aspects of genres in mathematics texts with those of other disciplines. In addition, Shanahan et al., (2011) demonstrated that mathematicians, chemists, and historians enact distinct literacy practices when reading texts from their own disciplines.

Some studies of mathematics disciplinary literacy have focused on the identities of the readers (e.g., Wiesner et al., 2020) and the relationships between these identities, the text, and the discipline itself (e.g., Fulmer et al., 2022; Weinberg et al., 2022), while others have explicitly incorporated functions of agency into this exploration (e.g., Fang & Schleppegrell, 2010). Both identity and agency have been widely studied in mathematics education research. A close examination of theoretical descriptions of these concepts suggests that they are intertwined—for example, Boaler and Greeno (2000) suggested that "positional identity" is related to the enactions of these positions; Barton and Tan (2010) alluded to the "intersecting roles" of agency and identity; Cobb et al. (2009) suggested that identity is related to "the ways that students are able to exercise agency" (p. 44); and Hitlin and Elder (2007) stated that agency is grounded in ideas of "the self." Although some studies (e.g., Fulmer et al., 2022; Louie, 2020) have explicitly discussed the entanglement of agency and identity, few have explored their interaction in depth.

Our current research has two goals. First, we want to understand students' mathematical identities, agency, and potential interactions between these aspects. Second, we are curious about the extent to which students' agency and identity manifest themselves in the ways they read and attempt to learn from mathematics texts.

Theoretical Framework

Agency

Agency is generally described as an ability make independent choices and act on those choices (e.g., Anderssen & Norén, 2011), although Gresalfi et al. (2009) point out that agency exists in moments of action rather than being a permanent characteristic of a person. Some researchers (e.g., Barton & Tan, 2010; Emirbayer & Mische, 1998) regard these actions as existing in a structure-agency dialectic (Bourdieu, 1977), so that the structures promote and constrain particular types of action and the actions, in turn, influence the structure.

Many mathematics education researchers cite Pickering's (1995) notion of a "dance of agency" (e.g., Boaler & Greeno, 2000; Brown, 2018; Cobb et al., 2009; Grootenboer & Jorgensen, 2010; Sengupta-Irving, 2016; Wagner, 2007) involving human agency—individuals' acts of creating ideas and making choices—and the agency of the discipline, which refers to established mathematical practices. In this notion of a dance, disciplinary norms are the product of collective human activity and that activity is, in turn, constrained by the norms; thus, this dance mirrors the more general agency-structure dialectic.

Barton and Tan (2010) point out that disciplinary norms aren't immediately affected by individual acts of agency and, thus, Pickering's perspective doesn't allow researchers to account for more localized entailments of position and power. They called for a formulation of agency that attends to its "socially transformative" nature (p. 191) and integrates context, position, knowledge, and identity. Similarly, Fulmer et al. (2022) worked to bridge Pickering's formulation of agency with a more "emancipatory theory of constructing knowledge" that attends to the "interplay of autonomy, identity, power, and knowledge" (p. 632).

We draw on Barton and Tan's (2010) formulation of agency in which "Agency is at once the possibility of imagining and asserting a new self in a figured world at the same time as it is about using one's identity to imagine a new and different world" (p. 193). Agency is grounded in the individual's perception and enaction of control and choice. Thus, moments of agency can be identified by either affective or enactive dimensions. In the former, the participant expresses a perception of their ability to make a choice or feels in control of a situation; in the latter, the participant takes an action (or describes acting) in a way that clearly demonstrates a choice they have made. These feelings and actions exist within a set of locally negotiated and constructed interactional roles and structures that entail a status quo, so actions that run counter to the status quo are evidence of agentive moments.

Identity

Identity has been theorized in many ways within the discipline of mathematics education. Darragh (2016) distinguished between two broad perspectives in which identity has been framed. In the first perspective, identity is presented as a stable construct that you acquire over time. For example, Aguirre et al. (2013) describe mathematics identity in terms of "dispositions and deeply held beliefs" about participating in mathematical contexts. This perspective aligns with the structure-agency dialectic in which identities are described in relation to a socially established notion of "what it means to know and do mathematics" (Cobb et al., 2009, p. 44). Wood (2013) describes these long-term stable constructions as *macro-identities* and points out that their scale makes them difficult to use to examine relationships with moments of learning or to describe the multiple, dynamic identities a student might simultaneously inhabit.

The second perspective frames identity in terms of activity. For example, Boaler and Greeno (2000), citing Holland et al. (1998) described positional identity as "the way in which people comprehend and enact their positions in the worlds in which they live" (p. 173). This perspective focuses on interactions in which people "convey positions or identities for themselves and all others involved in the interaction" (Wood, 2013 p. 778) in a way that draws on the socially constructed context. Wood (2013) refers to the narratives that individuals construct to make sense of these interactions as micro-identities. This focus on positioning enables researchers to describe relationships between enactments of identity and moments of learning, and to consider students' sense of self as potentially multiple and divided.

In our research, we examine both students' macro- and micro-identities. The former enables us to consider the students' perceptions of themselves in relation to long-term narratives (e.g., "I feel like I'm good at calculus"), whereas the latter lets us resolve apparently conflicting identity-related narratives (e.g., "I'm not good at derivatives of trig functions") and to relate aspects of identity with the meanings they construct as they attempt to learn from a didactical mathematics text. Thus, statements in which students describe their self-perception provide evidence of identity, and the interactions—or described interactions—between students and other participants in their socially-constructed worlds also can be evidence of their identity.

Methods

Materials

Examining literacy practices for didactic mathematics texts required using text materials for which the participants would have the necessary background knowledge, yet could engage in the reading process for the purpose of learning a new concept. We selected Newton's method for finding roots as the target concept since it only requires knowledge of derivatives and tangent lines and is not always taught in first- or second-semester calculus. Our materials consisted of four pages from a standard calculus textbook (Stewart, 2016) that introduced Newton's method, provided examples of using Newton's method, and included exercises at the end of the section.

Participants

We sent invitations to participate in the study to two groups of students at our institution: (1) all students who had declared either a major or minor in mathematics and hadn't yet completed a course in numerical analysis; and (2) all students who had been enrolled in first-semester calculus the previous semester and earned at least a C-. All participants who replied and were available during the times the researchers were able to conduct the interviews were included in the study. This resulted in five math majors/minors and five non-math majors/minors. For the current study, the restricted length of the conference paper format led us to randomly select two student participants for analysis: one math major and one non-math major/minor. We expected that such a pairing would allow us to identify similarities and differences in their identities and the ways they reported interacting with pedagogical situations and didactical texts.

Data Collection

Each student participated in a 75-minute interview, conducted by the first author, who is a professor in the mathematics department. They were asked about their positionality with respect to calculus, college, learning, and textbook-use (e.g., "how would you describe your relationship with calculus?"). Then they described their knowledge of calculus and worked on a problem using linear approximation to estimate the value of a function at a point.

Next, the participants sat at a computer that displayed an electronic version of the textbook excerpt; participants were able to use the arrow keys to "turn" the pages. The participants were asked to read the textbook section for the purpose of learning about the concept of Newton's method. As they read, an eye-tracker recorded their gaze pattern. After reading the excerpt, the participants watched a recording of their eye movements, with a red dot on the screen indicating the area of the text they had been looking at each moment. As the recording played, the participants were asked to describe what they were looking at and what they were thinking about; both the participant and interviewer were able to pause and resume the playback.

In the final stage of the interview, the text was segmented into conceptual chunks consisting of (1) an example to motivate Newton's method; (2) the derivation of Newton's method; (3) a description of instances when Newton's method would fail; (4) an example of using Newton's method to approximate the roots of a polynomial; (5) a description of the idea of precision in Newton's method; (6) an example using Newton's method to approximate the root of a number; (7) an example using Newton's method to approximate the intersection of two functions; (8) a description of the impact of choosing a first approximation; and (9) a collection of exercises; each chunk was further sub-divided into a graph (if present), an equation in a blue box (if present), and the rest of the text. The interviewer first asked the participant to describe the main ideas of the text, and then to describe what was being shown or described within each of the indicated conceptual chunks, figures, and boxed equations.

Analytical Methods

We divided the text into areas of interest that matched the conceptual chunks, graphs, and equations described above. Then we used the eye-tracking data to record which of these parts of the text the participants were looking at and how long they looked at each part. We used these data to construct a holistic description of each participant's reading activity.

We used thematic analysis (Braun & Clarke, 2006) to describe the participants' identities and agentive moves. After segmenting each interview transcript into talking turns, we identified turns where the participants demonstrated agency by (1) indicating that they felt they were making a choice and expressed a feeling of control, (2) describing a previous situation in which they felt they were making a choice, or (3) took action that appeared to run counter to the status quo; this identification process took into account the positionality of the participant within the relevant social structures—specifically, the context of mathematics classrooms, independently learning mathematics for a class, and the interview itself.

We then identified turns where the student described or enacted aspects of their identity by (1) describing a stable narrative about their self (i.e., a macro-identity), (2) describing their feelings about their self in the moment, and (3) enacting or describing behavior that reflected particular forms of interactional relationships within the relevant contexts. After identifying turns that reflected aspects of agency or identity, we generated themes inductively by looking for similarities and patterns among the turns. Throughout the identification process, we worked collectively to identify, discuss, and resolve differences in our interpretations.

Results

Non-Math Major [NMM]

Activity. NMM spent approximately 63% of his reading time looking at the three examples, with nearly half of that time on the first example. He spent approximately 31% of his time reading the expository text; nearly 1/3 of this time was spent looking at the equation in the blue box and the surrounding text. He spent only 2% of his time looking at the graphs. He generally read the text in order, but there were 12 instances of him either glancing forwards/backwards or skipping to a different conceptual chunk.

Identity. NMM described being a person who enjoyed both school (e.g., "I've always kind of liked school") and calculus ("it is interesting, but hard, and parts of it are easy and cool"). However, he simultaneously contrasted himself with "people who are quicker with math," suggesting a multi-faceted macro-identity. NMM's interaction with the textbook suggested a micro-identity as somebody who could make sense of mathematical concepts (e.g., "I was kind of just trying to see like, all right, like what's the point of this? Like where is this going?"). He had a strong image of himself as a mathematics student, describing himself as "a numbers person" and "not a graph person," distinguishing himself from other "people who like to look at the graphs rather than the numbers." Entailments of this macro-identity included "lik[ing] equations" and "seeing people do something" that he could repeat. At several points in the interview, he described his activity in a classroom, saying that he would (e.g.) "want to be prepared for [problems on an exam]"; this implicit interaction between himself and an instructor suggested his position in the classroom as a student.

Agency. NMM described a lack of agency for reading mathematics texts, describing how he "steered away from" them and "found other textbooks easier to read." More locally, during the interview, he skipped some parts because he didn't "really understand the context." Although it is possible to view these decisions to avoid reading parts of the textbook, in the context of a mathematics classroom we interpret these as reflecting his feeling of a lack of agency.

Despite this feeling of a general lack of agency, NMM regularly offered critiques and evaluations of pedagogical aspects of the textbook (e.g., describing a figure as "a nice thing to include" and a paragraph as "important to add"), suggesting some feeling of agency. NMM regularly made choices about which parts of the textbook excerpt to read and when to read them (e.g., "I spent a second or two on these side graphs, but I wasn't really drawn to them"); if the status quo is to read all parts of the textbook in the order they are presented, then these actions reflect choice and control, and, thus, are agentic moves. Similarly, he made choices about what to write in his notes based on personal goals (e.g., "I kind of just wanted to give myself an example of how I would go about solving the problem like that"), reflecting feelings of agency.

NMM also demonstrated agency in relationship to the mathematical concepts described in the textbook excerpt. He felt capable of "figur[ing] out what [the equation] actually means" and looked for connections with other concepts he had learned (e.g., "it's kind of like with asymptotes…"). These agentic moves were underscored while he was working on the pre-reading problem, when he transformed symbols (e.g., "I converted [decimal numbers] to fractions because I feel like it's easier") and created his own examples (e.g., "I'm operating under the assumption that the equation f of x is equal to two x") to help him solve the problem; this "tinkering" demonstrates moments of agency.

Intersection of Agency and Identity. We noticed several aspects of NMM's identity and agency that built on each other to significantly influence his reading activity and learning. First, his identity as an "equations person" and as a person who can understand mathematical concepts prompted him to focus on the equations that were presented in the excerpt and enabled an agentive relationship to (agentively) "figure out" what things mean. For example, he described his sense-making activity: "I like equations and stuff like that. I was immediately drawn to the f of x equation up there. I kind of just figured, like, well, that's an equation. How can I figure out what it actually means?" His identity as an "equations person" was related to his identity as not a "graph person," which, coupled with his agency to choose which parts of the excerpt to read and which to skip. For example, he described his choice to skim part of the excerpt: "I'm sure for other people who are more like graph-based learners, it [text describing one of the graphs] would be helpful. just for me as a learner, like I'm not going to look at that graph."

NMM's identity as a student and as an "equations person" was, similarly, coupled with his choices about which parts of the excerpt to focus on, and guided his notetaking. For example, he described his rationale for taking detailed notes on the equations in one of the examples: "I kind of just wanted examples to look back on, like as if they were my notes for an actual test."

Math Major [MM]

Activity. MM spent approximately 62% of her reading time reading the expository text, with roughly half of this time reading the paragraph that described the derivation of Newton's method. She spent approximately 19% of her time reading the examples, with this time split roughly evenly between the three examples. She spent roughly 5% of her time looking at the equation in the blue box and only 2% looking at the figures. She generally read the text in order, but there were 7 instances of her either glancing forwards/backwards or skipping to a different conceptual chunk; when she was reading the paragraph describing instances where Newton's method failed, she looked back and forth between the text and the figure 4 times.

Identity. MM described herself as a person who enjoyed math (e.g., "I was taking math courses for fun") and, in particular, calculus, describing it as "my favorite form of like mathematics because I like solving the derivatives and the integrals and all that." She described herself as "an audio-visual learner," but didn't elaborate. MM described her interactions and position in a math classroom in terms of her status as a student. In particular, she described not being able to fully understand concepts until "the professor goes over it" the next day and wanting to know "what they'd be asking" to guide her reading and learning from the textbook.

Agency. MM "felt confident for the most part" about reading and using textbooks and reported developing her own strategy for reading the textbook by "skimming it for important aspects" and then "go[ing] back to find the answer" to problems. MM regularly made choices about which parts of the textbook excerpt to read and when to read them. She regularly described "skimming" various parts of the excerpt, looking "more at the equations" than the diagrams, and "looking back" at previous equations and explanations when she felt confused.

MM also demonstrated agency in relationship to the mathematical concepts. She felt capable of solving calculus problems in general (e.g., "I like solving the derivatives and the integrals and all that") and that she can do so "on [her] own." She worked to resolve uncertainty by revisiting confusing sections of the text and constructing her own interpretations. For example, when she felt confused about instances where Newton's method fails, she reported "just trying to make sense of that because the wording tripped me up" and went back to the first page "to try and double check." As part of this process, she looked for connections with other concepts she had learned (e.g., "it's kind of like Reiman sums, how it's like the more, the smaller and smaller you make the rectangles the more accurate you're going to get").

Intersection of Identity and Agency. MM's identity as a person who enjoyed calculus appeared to be closely connected to her sense of agency at solving calculus problems, noting that calculus is her "favorite form of mathematics because I like solving the derivatives and the integrals and all that." Similarly, her identity as a confident textbook reader appeared to be connected to her having chosen a textbook-reading strategy.

MM's identity as a student, coupled with her choices about which parts of the excerpt to to focus on appeared to be connected. For example, she described her choices as guided by the obligations she would face as a student: "I like looking at the exercises just to like, get a sense of like what the problems are like or like what they'd be asking and how similarly they are structured to one another."

There were several instances where MM moved on from a section of the text without understanding concepts. For example, she described her feeling when after reading the paragraph that described instances where Newton's method would fail: "I think I understood it enough, but at the same time, I think I was still confused that I was like—I'm just going to move on. Probably that would have been something if I were in class, like I would ask about the next day." In this moment, MM appeared to have been weighing her options for action based on her assessment of her understanding. Her identity as a student allowed her to position herself with respect to the textbook, the mathematical concepts, and the (imagined) professor, and this position facilitated her choice for a course of action.

Discussion

Both NMM and MM shared aspects of their macro- and micro-identities, as well as their feelings and enaction of agency. Both students enjoyed calculus, and they both felt and demonstrated agency for figuring out mathematical concepts. They made connections between the text and their prior learning and made decisions about which parts of the text to read and when. In terms of their reading activity, both students chose the order in which to read the text components and neither student spent much time looking at the graphs.

The two students also exhibited some differences in their identities, agency, and reading activity. While MM felt confident about reading textbooks, NMM expressed a lack of confidence. In their reading, NMM spent most of his time examining the examples, while MM focused on the expository text, examined the exercises, and did look back and forth between one of the figures and the corresponding text.

For each student, their identity, agency, and activity intersected in different ways. NMM's identity as a student prompted him to seek out formulas he could use to solve problems on a test and to consider the examples as helping him build a library of problem types he could use as templates for later solving problems; his identity as an "equations person" and his sense of agency with mathematical concepts appeared to enable him to try to make sense of the equations. At the same time, being not a "graph person" led him to avoid examining the graphs, which potentially contributed to his occasional feelings of confusion, which, in turn, led him to skip particular parts of the text.

MM's identity as a student connected with her sense of agency differently than NMM. At first, her identity as a student appeared to guide her read the text to help her solve problems on a test. However, MM also worked to understand the expository text; this could be connected to both her identity as an effective textbook-user and her sense of agency for mathematical concepts. MM's student identity also appeared to be connected to her perceived choices when she encountered confusing parts of the text: rather than exhibiting a lack of agency, she formulated a course of action that involved utilizing the expertise of her (imagined) professor, and choosing a course of action that she felt would help her resolve that confusion.

Taken together, these data show students making agentic moves based on their stated and enacted identities and their relationship to both mathematics (as a subject) and the text. This demonstrates the flow between identity and agency, and vice versa. What we find particularly interesting is that the students in this study are bringing their humanity to the experience of reading the textbook—that they *do* have identities relative to the experience, and that there are many moments of agency that they experience. Thus, it is relevant that their identity and agency affect their reading activity, but the central take-away is not that there is a causal relationship between these two concepts, but rather these two aspects work together to shape the students' activity.

Understanding mathematics identity development has yielded insights for undergraduate mathematics education. In this work, we build on existing conceptualizations of mathematics identity to explore this construct in the context of mathematics graduate students with academic career aspirations through analyses of “Dear Math…” letters. We identify and detail four dimensions of graduate students’ mathematics identity: Doer of mathematics, Sharer of mathematics, Feeler of mathematics, and Believer of mathematics. We conclude by discussing implications of these dimensions, as well as the unique opportunities of “Dear Math…” letters to provide valuable insight into graduate students’ mathematics identities.

Keywords: Graduate Students, Mathematics Identity, Methodology

Introduction

Mathematics identity development has emerged as a critical area of research, providing insight into students’ achievement (e.g., Gonzalez et al., 2020), persistence (e.g., Joseph et al., 2017), and career choices (e.g., Cribbs et al., 2021), and informing curriculum, pedagogy, and instruction that can better support students’ identity development (e.g., Clark et al., 2013, Fernández et al., 2022). Despite our increased understanding of mathematics identity in K-16 education, little is known about the mathematics identities of graduate students. Graduate education has historically served to socialize and develop graduate students’ professional identities as professors (Van Lankveld et al., 2017). However, within the mathematics discipline, this process may be more complex and nuanced. Scholars have explored graduate students’ professional identity formation as teachers (e.g., Beisiegel & Simmt, 2012) and as researchers (e.g., Hancock & Walsh, 2014). Still, we have yet to critically examine their sense of selves as mathematicians or attempt to understand how they make sense of and identify with the discipline in ways that do not conflate with their professional identities as mathematics professors. Mathematics graduate students have succeeded and persisted through years of rigorous mathematics studies, thus focusing on their identities allows us to both incorporate and extend beyond notions of competence, performance, and traditional markers of success to dive deeper into dimensions of mathematics identities that may not be as prevalent in K-16 students.

In this work, we also introduce the use of “Dear Math…” letters (e.g., Webb, 2020), or letters that students write to the mathematics discipline, and illustrate how this type of qualitative data provides new perspectives into graduate students’ mathematics identities. This can inform us about the formative and disruptive experiences in their mathematical journeys and we contend that a better understanding of graduate students' mathematics identities can position departments and institutions to better support their transition to academic positions. The research question that guided this study was: How did mathematics graduate students reflect on their mathematics identities through writing letters to the discipline?

Conceptual Framing

Scholars generally describe mathematics identity as the ways students relate to mathematics and position themselves within or around mathematics. This identity is dynamic and transformative, changing depending on the context and the accumulation of mathematical experiences (Gardee & Brodie, 2021). However, the exactitudes within different definitions vary. Cribbs et al. (2015) divide the concept into three sub-categories: ways in which students perceive their competence in mathematics, their interest in mathematics, and their recognition as mathematically capable by themselves and others (e.g., instructors, peers). Crossley et al. (2018) present a similar three-part definition, including students' math self-concept about their ability, their interest in mathematics, and the value of mathematics in terms of its utility in their lives. These two conceptualizations describe mainly individual perceptions and traits. In contrast, Voigt (2020) posits a conceptualization that explicitly draws on social and contextual aspects of mathematics education. He describes mathematics identity as encompassing students' perceptions of their ability to effectively perform and participate in mathematical environments, the ways they position themselves within or outside mathematical communities, and how they negotiate their identity within institutional, individual, and societal contexts. These are just three examples of the numerous avenues scholars conceptualize mathematics identity. However, the majority of contemporary research focuses on the undergraduate level, with very limited work on graduate students' mathematics identity. Given the many ways undergraduate and graduate school differ, in this study we leverage the wide scope of research on mathematics identity and the multiple definitions presented to examine graduate students' mathematics identity.

Method

Context and Participants

This study was conducted at a Minority-Serving Institution in California with a mathematics department that offers graduate programs in mathematics at the masters and doctoral levels. We used convenience sampling (Miles et al., 2020) to recruit graduate students in the mathematics department. Sixteen doctoral students completed a survey that elicited self-identified/self-selected demographic information and requested their participation in a 90-minute qualitative interview. Six students participated in the interview and are identified in this study by their pseudonyms and pronouns: Connor and Landon (he/him); Kayla, Kendall, and Morgan (she/her); and Martin (they/them). All participants reported actively pursuing mathematics faculty positions.

Data Collection and Analysis

We utilized Zoom to conduct the 90-minute interviews. In the first hour, we used a semi-structured interview protocol (Rubin & Rubin, 2011) focused on students' experiences in graduate school, including the supports and barriers they encountered, their perceptions of the mathematics professoriate, and their understanding of mathematics teaching. Within the last 30 minutes, participants wrote the "Dear Math…" letter in which they personified the mathematics discipline and wrote correspondence to it. They were prompted to reflect on their experiences with mathematics, their career choices, and how mathematics has impacted their sense-of-selves and then tell the discipline how they really feel. Although the first author was present in the Zoom call, participants wrote the letters without any interaction or interference. For this study, we utilized these "Dear Math…" letters as the primary data source.

We consider self-reflective, narrative activities as mechanisms of identity development. Prior scholars have emphasized that narrative activities (e.g., writing self-reflections, telling stories, etc.) are identity constructing activities and can be methodological tools for researchers to examine identities (e.g., Beijaard et al., 2004). We posit that writing letters to the discipline is one avenue for students to share stories that illuminate dimensions of their mathematics identities. The use of letters is a facet of correspondence and arts-based methodology (Leavy, 2020), and is different from asking participants to narrate their experiences in an interview. Most notably, writing letters provides participants with an avenue to privately share experiences and emotions they might not comfortably share in an interview (Harris, 2002; Stamper, 2020). Webb (2020) found that letter-writing methodology allowed students to critically self-examine their experiences with mathematics past and present.

To analyze the data, the research team first individually read through the letters and wrote memos about what we noticed in how graduate students described themselves, others, and mathematics. Then, as a group, we open-coded (Miles et al., 2020) the letters and found three initial themes: (1) *Doers* of mathematics, (2) *Feelers* of mathematics, and (3) *Sharers* of mathematics. The research team verified the relevance of the codes by re-coding the letters and in this round, another theme emerged: *Believer* of mathematics. In our final round of coding, we re-coded all the letters using the four themes listed above, which we conceptualize as dimensions of graduate students' mathematics identity.

Findings

We now highlight how our analysis of graduate students' letters to the mathematics discipline revealed four key dimensions of their mathematics identities: *Doers*, *Sharers*, *Feelers*, and *Believers* of mathematics.

Doer of Mathematics

The first dimension that emerged from our analysis was students positioning themselves as *Doers* of mathematics. In these instances, our participants described how they make use of mathematics or see its function in the world (i.e., its utility). For two of our participants, the utility of math was mostly a form of play, whereas one of our participants saw it as a means to gain valuable life skills. Morgan and Kendall referred to doing mathematics as fun and playful. For example, Morgan described how she "loved playing with numbers and coming up with my own problems that I could subsequently solve." Similarly, Kendall stated how "you are extremely fun to explore and play with." These two students viewed themselves as *Doers* of mathematics for the purpose of playing, exploring, and having fun.

Landon described a more practical application of what it means to do mathematics. For example, he wrote that "most importantly, I love how you have taught me how to think. Doing math has clearly changed the way my internal world model interprets and analyzes sensory data …equivalent to upgrading from an old computer to a new one." We see that Landon viewed himself as a *Doer* of mathematics for the purpose of developing cognitive skills like logical thinking and sensemaking. Further, he placed value on skills that he has acquired through doing mathematics. Interestingly, he explicitly specified that the act of doing mathematics was not as a requirement to fulfill in school or necessary to enter a mathematical career, but rather "these things all feel secondary to doing math as a way to learn how to think clearly about things and apply this clear thinking to every aspect of my life." Again, whereas Morgan and Kendall viewed themselves as *Doers* of mathematics for enjoyment, Landon viewed himself as a *Doer* of mathematics for the purpose of developing valuable and widely applicable skills for life.

Sharer of Mathematics

The second dimension that emerged pertained to how students positioned themselves as *Sharers* of mathematics. In their letters, the participants discussed mathematics both in terms of their role in sharing mathematics with others and their sense of mathematics as a community. This dimension frequently appeared as students assuming the responsibility to share the positive side of mathematics with others. An awareness of common negative perceptions associated with mathematics prompted many students to write about how they see themselves as advocates for the discipline. Kendall noted in her letter that she hopes she "can help more people see you [mathematics] as a friend." Many participants, like Kendall, identified teaching as a way they could take on this advocate role. Martin wrote, "I see [my students] grapple with your theorems and symbols, but I want to show them who you truly are – what you can really do." Similarly, Connor wrote, "I'm thankful for…the moments of teaching I remember when I finally showed someone something very cool about you." These participants saw teaching as a prime opportunity to share their love and admiration for the discipline with others.

Affiliation with a mathematics community and awareness of how mathematics is shared within that community also revealed how participants identified as *Sharers* of mathematics. For instance, Connor wrote how "you've led to the creation of some of my most treasured communities, you've led me to some of my best friends". Kendall wrote of a similar experience, writing "I appreciate how much I have learned from you and the people you've brought into my life. You really have the best friends." For these two participants, mathematics fostered community and friendships. For Landon, mathematics could be used to bring people together through a universal language, writing "I can communicate perfectly with someone that doesn't speak a word of english." For some, the notion of a mathematics community did not always come with positive experiences or connotations. Morgan wrote explicitly about how she felt excluded as a result of being a woman in a male-dominated field, writing "I learned, through thousands of little words and actions, that I wasn't welcome in the boys' club that is the world of math." She later wrote about persevering and finding her place within the community, but acknowledged how exclusionary it can be. Overall, we saw both positive and negative experiences in how graduate students described being *Sharers* of mathematics.

Feeler of Mathematics

We also found that participants described themselves as *Feelers* of mathematics. This dimension of their mathematics identities refers to affective factors relating to their experiences with mathematics, relationships with members of the mathematics community, and overall feelings toward the discipline. Participants described experiencing a range of positive and negative feelings towards mathematics over the course of their educational experiences. These feelings were not static and were often influenced by their graduate education experience. Some students revealed that early experiences with mathematics fostered curiosity, excitement, and interest, and this often came from being positioned as successful by their teachers and peers. However, positive early experiences were not always shared by the participants. For example, Martin wrote, "When we first met, we didn't get along – at least, I didn't understand you and wanted you to go. Multiplication was hard, and those timed worksheets made me anxious…Honestly, you scared me, or so I thought." Here, Martin expressed how their early feelings surrounding mathematics were marked by anxiety and fear, illustrating that graduate students can have widely different early emotions with mathematics that shape their identities.

Additionally, students detailed how graduate school marked a period of time when they contested with negative feelings about themselves and the discipline. This detrimentally impacted their mathematics identities and made them question their place within the discipline. A frequently cited area of dissent was when graduate students compared themselves to their peers and were made to feel like their mathematical abilities were not adequate for this space. For example, Kayla noted that entering graduate school involved confronting the idea that "there were other people that were just as good at you as I was," which made her feel "threatened" and "jealous." Kayla was faced with reconciling her mathematics identity, mainly related to her competence, in comparison to how she perceived her peers. Similarly, Morgan described feelings of exclusion due to gendered mathematics spaces, leading to feeling that "every success was handed to me for the sake of diversity, or so I was told, until I believed it." These feelings of exclusion constitute an affective component of Morgan's positioning within mathematics.

The most common sentiment across the letters was gratitude. The participants reflected on the experiences that mathematics afforded – including the connections and community that they developed. Kayla expressed gratitude to mathematics for "bringing [her] joy all through [her] school years" and for "your friendship." Similarly, Morgan wrote, "I wanted to take a moment to…express gratitude for the profound impact you made on my life." Despite the varying feelings expressed about themselves and mathematics, the participants described being drawn to mathematics and feeling motivated to continue their studies and pursue faculty positions.

Believer of Mathematics

The final dimension of mathematics identity which emerged was the *Believer* of mathematics. This theme echoes the work of scholars who investigate the notion of mathematical study and religion as conjuring parallel experiences, both in their embodiment and in their rejection (Jonker, 2012; Krajewski, 2021; Kurniawan & Hidayati, 2020). Kurniawan and Hidayati (2020) define religion in part as a way one "seeks the meaning of life, the value of truth, and the meaning of the world." Many of our participants described ways that mathematics provides universal meaning and truth. In the same way that understanding one's religious identity yields insight into their worldview, we view understanding the ways in which an individual "believes" in mathematics and its power as something which yields insight into a student's mathematics identity.

One way in which this theme appeared was through the participants' frequent assignment of powerful qualities to mathematics. In her letter, Kayla contrasted her initial negative feelings towards mathematics with her present feelings of "appreciating your beauty and mystery." Similarly, Morgan noted her passion for "studying the beauty of your theory", and Martin noted the "utility and richness of your subjects." Landon described mathematics as "foundational to understanding the world", and cited this as a reason he was drawn to the field. In some instances, participants expanded on these qualities in ways that went beyond ascribing a quality and characterized mathematics in a more holistic way. Connor made two such potent characterizations: that "the spirit of discovery resides in you", and that "we will unlock the secrets of the universe with your help." Both of these characterizations are not out of line with a religious profession of exalt; Connor is expressing his exaltation of mathematics through the ascription of spiritual characterizations to the subject.

The participants also described mathematics in ways that reflect omnipresent and omniscient properties often ascribed to religious deities. Connor explained how mathematics "is the hope I have for a brighter future…, because humanity has hope through you and the insights you hold." Regarding mathematics' far-reaching power, Martin further wrote that "you are everything, everywhere, all at once, and I think nothing else can explain the universe in a better way." Landon and Martin also positioned mathematics as a determinant of universal truth. For example, Martin noted that mathematics "offer[s] exactness in a time and place where everything is changing, and… keep[s] me grounded to this existence." In these ways, the participants' descriptions reflect a higher "belief" in the power and truth of mathematics.

Discussion and Implications

The participants' letters revealed four main themes that suggest important dimensions in mathematics graduate students' expressions of their mathematics identities. These themes both connect and diverge from literature focused on undergraduate students' mathematics identity.

The *Doer* dimension reflects mathematics identity conceptualizations that include utility, or the "degree to which a student thinks that math is or will be useful to their life" (Crossley et al., 2018, p. 13). Landon's letter, for example, reflects this, discussing how mathematics supported the development of critical thinking skills useful in numerous aspects of his life. The *Feeler* dimension relates to affective components within students' mathematics identity but expands on the usual limitation to students' level of mathematical interest. Cribbs et al. (2015) define mathematical interest as "a student's desire or curiosity to think about and learn mathematics" (p. 1052). The participants described feelings of curiosity, such as when Kayla wrote how "ever since I was of a young age, I always knew that I wanted to learn more about you." However, they also expressed numerous other emotions including excitement, inspiration, enjoyment, and appreciation around mathematics, as well as anxiety, fear, and annoyance. For example, Connor described how he is "annoyed with you so very often." Thus, while interest and curiosity appeared in some of the letters, participants described additional feelings that relate to their mathematics identity such as perceptions of ability and mathematical self-efficacy.

The *Feeler* dimension also demonstrates connections to perceptions of ability. Martin described not "getting along with" mathematics initially, implying that a lack of perceived ability hindered their relationship with mathematics. Kayla also describes changes in her perceived ability, reflecting back on grade school when "you made me stand out as a very smart and exceptional student," whereby in graduate school, "there were other people that were just as good at you as I was, and I became threatened and jealous." As a result of her lower self-efficacy, she questioned that mathematics "maybe… [was] never my friend to begin with." Thus, perceptions of ability still appear in graduate students' construction of their mathematics identity, whether as a consequence of earlier experiences or within graduate school itself.

The *Sharer* dimension exhibits similarities and differences with existing literature on undergraduate students' mathematics identity. Echoing existing literature, the participants frequently referenced their positioning within or outside of a mathematical community. Connor and Kendall described the friends they have gained through mathematics. However, Morgan cited gender-based exclusion within the "boys' club" of mathematics and Connor noted his dislike toward competition within mathematical spaces. These notions of community reflect conceptualizations of mathematics identity focused on belonging and recognition (Cribbs et al., 2015; Voigt, 2020). However, the *Sharer* dimension also included a unique component of graduate students' mathematics identity, namely their role in sharing mathematics as a teacher. Multiple participants described teaching as a way to change negative perceptions around mathematics and communicate their love for the discipline. For these participants, the co-construction of professional and mathematics identity was an important component of their graduate school experience. Beisiegel and Simmt (2012) note that "it is through the formative experiences of graduate school that mathematics graduate students' identities are shaped as mathematicians, researchers, teachers, or more generally as professors of math" (p. 35). The dimensions of *Doer* and *Sharer* are particularly relevant to Beisiegel and Simmt's assertion;

understanding how graduate students see themselves as doing and sharing mathematics in relation to their mathematics identity can illuminate their professional identity development.

The identity dimension that most diverges from existing literature on undergraduate students' mathematics identity is the *Believer* of mathematics. This appears to be a unique facet of mathematics graduate students' mathematics identity. The salience of this theme across all of the participants' letters suggests that a belief in the power of mathematics is a significant factor in their mathematics identity. The participants expressed this dimension in various ways, from admiration of mathematics' beauty and spirit to its bringing hope to humanity and grounding one to this existence. These statements do not align well with previously established mathematics identity components such as perceptions of ability, interest, utility, sense of belonging, participation, etc. Given the novelty of this theme, further investigation is needed to determine how fundamental or universal this dimension is among graduate students, whether undergraduate students who resonate with this aspect of mathematics identity are more likely to pursue graduate education, and if and how instructors could instill this within their undergraduate students.

The letters also reinforced how mathematics identity is a fluid construct, subject to change across time and experience. We see past mathematics identities present in Kayla's narrative, as she reflected on mathematics as bringing her her "greatest joys" and "lowest places" in a temporal way. She associated a shift with the beginning of graduate school, in which she began feeling "threatened and jealous" – something she identified as a "false narrative" that resulted in "ill feelings." In addition to considering previously held mathematics identities through descriptions of feelings and experiences, there was one instance of consideration of a future mathematics identity present in Kendall's letter in which she writes she "[has] no doubt we will be lifelong friends." These elements of both a past and a projected future mathematics identity are integral to how students position themselves with respect to mathematics as a discipline, and thus serve as informants of their mathematics identity. We see this as a possible area of application for Markus and Nurius's (1986) *possible selves* in which identities are given temporal dimensions, and past or possible considerations of identity are conceptualized as irrevocably intertwined with the current self. In the same way that possible selves have been leveraged to provide insight into professional development in other realms on education (e.g., Blaney et al., 2022; Park & Shallert, 2020; Quaisley et al., under review), so too could they provide insight in the developing mathematics identities of graduate students.

Conclusion

Overall, our work suggests that graduate students' mathematics identity development reflects and extends beyond traditional notions of identity. We recognize the salience of social identities (e.g., gender, race, etc.) in the shaping of mathematical experiences (e.g., Leyva et al., 2020; Voigt, 2020); future work is needed to more carefully examine the connections between these identities and the mathematics identity development of graduate students. We view examining letters as a novel and insightful approach to making sense of mathematics identities as they afforded students opportunities to articulate self-perceptions, stories, feelings, etc. that may have been difficult to convey through other data collection efforts. We posit that writing "Dear Math…" letters is one avenue that professional development efforts can take up to gain insight into the experiences that graduate students consider supportive or hindering in their progression through graduate school and their pursuit of academic positions. A continued examination of graduate students' mathematics identities can inform mathematics departments and higher education institutions on how to better support their transition to the mathematics professoriate.

An Exploration of Undergraduate Mathematics Education Measures and Their Validity Evidence

Christine K. Austin
Texas State University

Kate Melhuish
Texas State University

Jim Gleason
The University of Alabama

Yvonne Lai
University of Nebraska-Lincoln

This report discusses the validity evidence reported in undergraduate mathematics education measures. Through a comprehensive literature review of articles published from 2000-2019, we identified 166 measures that provided validity claims and evidence to varying degrees. Findings overall suggest that validity evidence can be more robust within measures of RUME constructs, although there are examples of rigorous validity arguments. Of the validity evidence, the major sources of validity were reliability, test content, and internal structure. We report on the number of sources of validity, by construct, and the types of evidence to support the validity claims.

Keywords: validity evidence, undergraduate, measures, reliability

Measures play a key role in research in undergraduate mathematics education. Measures provides a means to quantify elements of teaching and learning to investigate quantitative hypotheses. Types of measures might include cognitive measures (e.g., Precalculus Concept Assessment; Carlson et al., 2010), affective measures (e.g., Motivated Strategies for Learning Questionnaire; Pintrich & de Groot, 1990), or learning environment measure (e.g., Inquiry-Oriented Instructional Measure; Kuster et al., 2019) As researchers, we have observed the use of many different measures in our field, but it is less clear the degree to which they have sufficient validity evidence to assure that scores and interpretations of them are meaningful. Previous literature has shown a lack of sufficient validity and reliability evidence in mathematics education assessments, broadly (Bostic et al., 2019; Krupa et al., 2019). Thus, we aim to explore whether this claim holds true in undergraduate mathematics education research. This report addresses:

RQ1: What measures are currently in use by RUME researchers?

RQ2: What types of validity evidence support the validity of their usage?

Background

Measurement theory is the process of investigating varying forms of evidence to form the basis of a valid and reliable instrument (Crocker, 2012). For claims of an instrument to be meaningful the instrument needs to be assessed to ensure it is measuring what it was intended to. In doing so, researchers assess the reliability and the validity of the instrument. Reliability is the degree in which the results/scores of an instrument are replicable, consistent, and accurate (Brennan, 2006; Crocker & Algina, 2006). Some examples for evidence of reliability include test-retest, alternate test forms, item response theory, Cronbach alpha, and inter-rater reliability. Validation, on the other hand, has been described by Cronbach (1971) as the collection of evidence to support the claims drawn from the results of the instrument by the assessment creator or the user of the instrument. In education, validity is defined in the *Standards for Educational and Psychological Testing* as “the degree to which evidence and theory support the interpretations of test scores for proposed uses of tests” (American Educational Research Association [AERA] et al., 2014, p. 11). In the *Standards*, five forms of validity are noted: test content, response process, internal structure, relation to other variables, and consequence of testing (AERA et al., 2014). Primary sources of evidence for the five types of validity are provided in the *Standards* (AERA at al., 2014) and *Validation in Mathematics Education* (Krupa et al., 2019).

Five Sources of Validity

Test content validity is explained as "the relationship between the content of a test and the construct it is intended to measure" (AERA et al., 2014, p. 14). Evidence for test content stems from the judgments of experts, observation, and logical or empirical analyses (AERA et al., 2014, p. 14). In practice, such validity evidence includes, but not limited to, data from experts (i.e., experts in the field), field work, literature reviews, alignment of a learning trajectory, and participant generated content (i.e., the participant creating the data for the researcher) (Krupa et al., 2019). *Response process* validity is concerned with "the fit between the construct and the detailed nature of the performance or response actually engaged in by test takers" (AERA et al., p. 15). In other words, this form of validity ensures that the test takers engage in the appropriate thinking, processes, and analyses in which the construct was designed to be measured for proper claims to be made (Lavery et al., 2019). A non-exhaustive list of Validity evidence for response processes includes, cognitive interviews, focus groups, eye-tracking, predicted response patterns based on learning trajectories, and think alouds (AERA et al., 2014, Krupa et al., 2019; Lavery et al., 2019).

Validity from *internal structure* addresses "the degree to which the relationships among test items and test components conform to the construct" (AERA et al., 2014, p. 16). This validity type is focused on confirming that the construct adheres to the theories in which it was built upon (Lavery et al., 2019; Krupa et al, 2019). Further, validity evidence of internal structure confirms that the construct is unidimensional. A unidimensional construct assesses a single dimension or attribute (e.g., a student's level of multiplicative reasoning) (Bond & Fox, 2015). Validity evidence of internal structure includes, but is not limited to, factor analysis, Item Response Theory, Rasch modeling, and multidimensional scaling (AERA et al., 2014, Krupa et al., 2019; Lavery et al., 2019). *Relation to other variables* validity is defined as "the degree to which the relationships among test items and test components conform to the construct" (AERA et al., 2014, p. 16). Many instruments are developed with the expectations that the construct will relate to other constructs or variables in predictable ways or patterns (Lavery et al., 2019) thus, this source of validity evidence connects results to other constructs (Krupa et al., 2019). Such types of validity evidence include correlations analysis, regression analysis, structural equation modeling, hierarchical linear modeling, and alignment with expert opinion of user (e.g., teacher). Lastly, validity of *consequences of testing* is the process of "gathering evidence to evaluate the soundness of [the] proposed interpretations for their intended use" (AERA et al., 2014, p. 19). *Standards for Educational and Psychological Testing* discuss three main types of consequences of testing: unintended consequences (e.g., differences in test score based on race/ethnicity), claims made that are not based on test score interpretations (i.e., the need for new more information to address the results of the testing), and the interpretations and uses of the test scores intended by the instrument creators (AERA et al., 2014). Evidence for consequence of testing validity include explicit intended use/interpretations, motivational consequences, differential item functioning, and appropriate cut scores (AERA et al., 2014; Krupa et al., 2019).

Methods

This project began in 2020 as part of an NSF-funded collaboration (BLINDED) to catalog mathematics education measures that have been in use for the last twenty years. The authors of this paper have led the work on the undergraduate sub-team. To identify measures in use, we conducted a literature search spanning 2000-2019. We searched the mathematics education research journals identified by Williams and Leatham (2017) along with *International Journal of Research in Undergraduate Mathematics Education* as its newness means it was not contained in Williams and Leatham's list. We used the following Boolean string to identify articles: (tertiary OR post-secondary OR undergraduate OR college OR university OR "graduate student") AND (test* OR assess* OR instrument* OR measur* OR survey* OR inventor*). From this initial search, we identified 2,603 articles. At this point, we developed an inclusion and exclusion system with for criteria: (0) Must focus on undergraduate or graduate mathematics students and/or instructors (exclusive of primarily statistics or pre-service teachers as they fall under other subteams (1) Must be an empirical study (2) Used an instrument that is uniform across the population, that should be useable by other researchers with at most minimal modification, potentially in a different setting (3) That is associated with a named or described construct. After training with a set of 30 articles within the full set, the remaining articles within the 2,603 articles were coded according to these criteria by two members of the research independently, then coming to agreement about whether to include to the next stage. Here, 432 articles met these criteria. At this point, we switched to identifying measures. To be considered a measure, we required a composite score of some type. That is, an instrument that only reports data at an individual item level was not included. We identified 241 unique measures.

The final stage of this process was then to identify validity evidence. For each measure, we went into the article where it was found, then determined if that article contained its validity evidence. If not, we searched for another source of evidence (such as a reference validation study.) For any measure with validity evidence, we documented: focal construct (cognitive, affective, learning environment), usage information, and any validity evidence or claims provided categorized within the five types of validity evidence in the prior section. We aligned our classifications with the larger project teams' set of evidence types. In the next section, we present an overview of the types of instruments and most common types of validity evidence.

Results

Of the 241 unique measures identified to fit our criteria, only 166 measures were reported to have validity evidence for the constructs. Ultimately, 75 measures were eliminated due to having no apparent reported validity evidence within the manuscript. Our final list of 166 undergraduate mathematics articles contained three prominent construct types that were broken up into their focal construct: affective domain, cognitive domain, and learning environment (see Table 1). Our findings show that there is a skew in the type of constructs being implemented in undergraduate research. These results indicate that the majority of the instruments measure the affective (47%) and cognitive domain (45%) and only about a tenth (11%) are designed to measure an undergraduate student learning environment.

On average, two (M = 1.92, SD = 1.06) forms of validity evidence (including reliability) were reported for each measure. Only one measure provided all sources of validity and reliability evidence. Given that most of the articles only contained two sources of validity, on average, the most prevalent source of validity was computed. Table 1 illustrates the validity evidence broken down by construct type. The most reported form of validation was test content (n = 113) followed by reliability (n = 87). Very few undergraduate mathematics measures reported validity evidence for consequences of testing (n = 4) or response process (n =15).

Table 1. Source of Validity by Construct Type

	Construct Type [Total # of Articles]							
Source of Validity	AD [72]	AD / CD [2]	CD [72]	CD / LE [1]	LE [13]	LE / AD [4]	Other [2]	Total [166]
Reliability	46	1	25	0	9	4	2	87
Test Content	43	1	56	1	8	0	1	110
Response Process	3	0	9	0	3	0	0	15
Internal Structure	36	1	16	0	9	1	1	64
Relation to Other Variables	18	0	15	0	4	0	1	38
Consequence of Testing	0	0	4	0	0	0	0	4

Note: AD = Affective Domain, CD = Cognitive Domain, and LE = Learning Environments

Table 2 reports the types of validity evidence that were documented for the 166 measures. Our findings indicate that of our 87 measures that made claims for reliability, 72 (83 %) reported a Cronbach Alpha Coefficient as the source of evidence. Further, the 38 measures that provide evidence for relation to other variables predominantly used correlation analysis (n = 27) as their source of evidence (71%). As shown in Table 2, other than evidence type for test content, there is little variation to the evidence type documented undergraduate mathematics education research.

While in general, the validity evidence for measures was scarce, there were some notable exceptions in the set. Of the affective focused measures, *Mini-IPIP Scales* (Alcock et al., 2014) and *Attitudes to Technology in Mathematics Leaning Questionnaire* (Forgarty et al., 2001) had 7 and 6, respectively, forms of validity evidence (see Table 2 for validity evidence types). The cognitive focused measures with 6 or more types of validity evidence consisted of the *Group Theory Concept Assessment* (Melhuish, 2019), *Calculus Readiness Assessment* (Pyzdrowski et al., 2013), *Function Concept Inventory* (O'Shea et al., 2016), *College Readiness Assessment* (Bernbaum et al., 2011), *Calculus Concept Inventory* (Bison et al., 2016), and *Proof Comprehension Tests* (Mejía-Ramos et al., 2017). Lastly, of learning environment focused measures, *Survey of Calculator Usage Extensiveness and Subordinality* (Mao et al., 2017), *Concept Test* (Kaw & Yalcin, 2012), and *Inquiry-Oriented Instructional Measure* (Kuster et al., 2019). While we highlight these measures, we note that it is not the number of validity evidence types that matters so much as the integration of validity evidence into a validity argument. Nonetheless, when validity evidence is presented primarily as reliability, it is difficult to marshal this evidence into a robust argument that an instrument measures a particular construct as intended.

Table 2. Validity Evidence

Source	Evidence Type	
Reliability	Alternate Test Forms	1
	Inter-Rater Reliability (Kappa & Percent Agreement)	7
	Cronbach Alpha	72
	Item Response Theory and/or Rasch Modeling	2
	Item Remainder Correlations	2
	Kuder-Richardson Formula 20	4
	Sensitivity Analysis	1
	Split-Half Reliability	2
	Test-Retest	10
Test Content	Alignment with Framework/Theory/Learning	24
	Data from Experts	38
	Fairness of Content	2
	Field Work	4
	Literature Review	36
	Participant Generated Content	16
	Revision Process	15
	Standard Setting	1
Response Process	Cognitive Interviews	4
	Rater Agreement/Reliability	3
	Rater Training and Collaboration	2
	Student Written Work	5
	Think Aloud	2
Internal Structure	Factor Analysis*	58
	Item Difficulty	4
	Item Scale Correlations	8
	Item Response Theory (IRT)	6
	Rasch Modeling	5
Relation to Other Variables	Alignment with Expert Opinion	1
	Convergent or Divergent Association	4
	Correlation Analysis	27
	Discriminant Validity	1
	Hierarchical Linear Modeling (HLM)	1
	Statistical Testing (e.g., regression, t-test, chi-square)	5
	Triangulation	1
Consequence of Testing	Appropriate Cut Score	2
	Cost-Benefit Analysis	1
	Item Function (e.g., DIF)	1

*Includes Bifactor, Exploratory/Confirmatory Factor Analysis, Parallel Analysis, Principal Axis Factoring, and Principal Component Analysis

Discussion

Our analysis of measures used in the undergraduate mathematics education literature points to several findings. First, we found that Bostic et al.'s (2019) and Krupa et al.'s (2019) reflection on the state of measures in math education was largely true in the undergraduate context. While many instruments are in use many provided limited or no validity evidence at all. This is particularly problematic when scores from such measures are used in service of testing particular hypothesis or have impacts on students or instructors in practice. That is, the trustworthiness of an instrument is determined by the degree we can be assured it is valid.

If we consider our results more broadly, we can see that certain types of validity evidence are more frequently reported. For example, Cronbach's alpha is by far the most common type of validity evidence in our data set. This is not surprising as it is a relatively easy type of statistic to calculate with associated indices of what is acceptable for different measure purposes. We also documented other common psychometric and quantitative approaches to validity with the prevalence of factor analysis and correlation with variables. These common approaches still accounted for less than half of the measures reporting any validity evidence.

We note the measures were more frequently reported with quantitative evidence and less qualitative validity evidence. We suggest a robust validity argument (e.g., Kane, 1992) is made with mixed methods. For example, response process evidence was quite infrequent. This type of evidence stems from making sure that participant response to items actually reflects their thinking. This can be done through cognitive interviews, collecting written work, and other approaches. Without such evidence, we may be left wondering the degree to which an instruments' scores truly reflect participants.

We acknowledge some limitations of the current work. First, our exclusion and inclusion process mean that we may have overlooked instruments that have not been discussed in primary mathematics education journals. Additionally, it is possible that we overlooked a source of validity evidence that might be found in harder to access internal reports. There is also likely some variation in how our coders interpreted different types of evidence and therefore, we suggest caution when generalizing from frequencies that are similar.

Finally, we note directions for future research. In our own data set, we have made some initial notices that within our construct categories we can find some interesting patterns. For example, a full 28 of the affective instruments were focused on mathematics attitudes and belief scales. This means that there are many instruments in use targeting the same construct. We also note that within the cognitive construct measures, instruments that aligned themselves with concept inventory procedures (e.g., Group Theory Concept Assessment, Function Concept Instrument, Calculus Concept Inventory) often had more robust amounts of validity evidence likely due to commonalities in development approach. The next research direction will involve better understanding the nature of the instruments within each category and their relation to the types of validity evidence shared.

We conclude by suggesting that the field consider a variety of validity evidence types when creating measures. It may be a truism that the validation process is never complete. Each new sample and use require recalibration. The stronger the evidence is for our measures, the more we can trust the results of our quantitative studies.

What Makes a Proof a Proof?: It's Your *Job* to Decide

Andre Rouhani
Arizona State University

Dov Zazkis
Arizona State University

This study investigates students' conceptions of what makes a particular written mathematical communication a proof. To that end, we implemented one-on-one task-based interviews involving mathematical communications. These communications were presented as trios, and we called each communication a job. We intentionally designed some of these jobs to sit in the vague space between proof and calculation. Our study investigated the reasons why participants believed certain jobs were proofs, allowing us to develop a model of students' conceptions of proofiness. This model revealed differences among students in terms of which attributes they thought contributed to or detracted from proofiness, as well as those they thought were and were not relevant to whether a job is a proof. These differences and how they relate to normative conceptions of proofiness point to aspects of proof that may require further attention in these students' introduction to proof courses.

Keywords: Proof, Introduction to proof students, Remote data collection.

What follows is the novice portion of a larger planned expert novice study (e.g., Inglis & Alcock, 2012). The overall project addresses the question "What makes a proof a proof?" We use the term *mathematical communication* to broadly capture any written work that establishes a mathematical fact or property. For example, a calculation that finds the roots of a polynomial might be considered a mathematical communication that establishes what the roots of the polynomial are. Similarly, a written proof is a mathematical communication that establishes the truth of some theorem.

This portion of the research addresses the research question: "What are undergraduate mathematics students' conceptions of what makes a mathematical communication a proof?" To facilitate our discussion, we borrow a construct name from Seife (2010), *proofiness*. In his work "Proofiness: the dark art of mathematical deception," Seife defines proofiness to be manipulations of mathematical norms that, "make falsehoods look like numerical fact" (Seife, 2010, p. 18). Instead, we use *proofiness* to refer to a person's personal conceptions of the attributes that make a written communication a (correct mathematical) proof; in other words, *proofiness* refers to the qualities of a text that distinguish proofs from non-proofs. Those are the attributes that keep a purported proof from being an instance of proofiness in Seife's sense of the word. So, from our perspective, our use of this construct name is more precise than Seife's usage and more consistent with the mathematical concept of proof (Weber, 2014).

To simplify the conveyance of ideas, we refer to mathematical communications as *jobs*. We used our *jobs*-based tasks, and data from clinical interviews with undergraduate mathematics students, to develop a *proofiness* framework. This framework can be implemented to classify the attributes of a mathematical communication which a person thinks are relevant to certify or discount it as a proof. In the future, this might allow us to implement more informed learning trajectories for guiding students toward normative conceptions of proof. As alluded to earlier, determining mathematicians' conceptions of *proofiness* is part of a planned followup to the current study. Thus, the utility of this framework will be demonstrated in a second order followup study. The students' conceptions of *proofiness* will inform the design of a learning trajectory (Simon, 2020; Simon & Tzur, 2012) that is intended to advance students' understanding of proof toward observed mathematicians' conceptions.

Literature Review

Proof is, out of necessity, not well defined (Inglis & Aberdein, 2016, Weber & Czocher, 2019). This means that, even among expert mathematicians, there is often no consensus on whether a particular mathematical communication is a proof (Weber & Czocher, 2019). Czocher and Weber (2020) addressed this fuzziness by describing proof as a cluster concept (Lakoff, 1987), which is when "a number of cognitive models combine to form a complex cluster that is psychologically more basic than the models taken individually" (p. 74). The cluster concept nature of proof means that novice provers' conceptions of proof are, inherently, a fuzzy picture of an already fuzzy picture. However, whether a mathematical communication is a proof is also context dependent (Stylianides, Stylianides, & Weber, 2017) and students, especially those in introduction to proof (ITP) courses (David & Zazkis, 2020), have only experienced proofs in the single context of their course. This means that asking an ITP student the question "is this a proof?" implicitly asks, "is this considered a proof within the context of your ITP course?" The existing research on conceptions of what a proof is and what counts as a proof is primarily focused on expert mathematicians (e.g., Inglis, & Aberdein, 2016, Weber & Czocher, 2019). Here, we shift toward studying students, since a good grasp of student conceptions of proof is needed to use this knowledge as part of well-informed learning trajectories for proof.

We argue here that, especially given both how much variety there is in approaches to ITP course work (David and Zazkis, 2020) and the importance of proof in mathematics, there is value in exploring ITP students' impressions of what makes a proof a proof. However, the nebulous nature of proof necessitates a shift away from traditional tasks and interview questions (Zazkis & Hazzan, 1998).

<u>Context</u>: For $f: R \to R$ defined by $f(x) = x^{"} + x - 6$,

Job (1): Justify that f has two roots.

<u>Claim</u>: f has roots -3 and 2.

<u>Justification</u>: Note that $f(x) = x^2 + x - 6 = (x + 3)(x - 2)$. If $(x + 3)(x - 2) = 0$, then $x = -3$ or $x = 2$. Thus, f has roots -3 and 2.

Job (2): Justify f is not one-to-one.

<u>Claim</u>: f is not one-to-one.

<u>Justification</u>: Suppose to the contrary that f is one-to-one. This means that if $f(x_1) = f(x_2)$, then $x_1 = x_2$. Note that $(-3, 0)$ and $(2, 0)$ are ordered pairs that satisfy f. In this case, we have $f(-3) = 0 = f(2)$, but $-3 \neq 2$. And this is a contradiction, since f is one-to-one. Thus, our supposition that f is one-to-one must be false. Therefore, f is not one-to-one.

Figure 1. An example task which presents two jobs for the subject to compare.

Method

Participants were undergraduate students, each of whom completed a zoom-based think-aloud one-on-one task-based clinical interview (Clement, 2000). Remote data collection was needed because of the COVID-19 pandemic. The ten participants were students in the same section of an ITP course offered at an Anonymous State University (ASU) in the Southwestern United States. Six of the ten were pursuing a degree in mathematics, and the rest were engineering or science majors.

Students were presented trios (or sometimes pairs) of *jobs* that spanned the range from proof to calculation (from our perspective). Throughout the interview, students were asked which of the *jobs* in front of them were proofs, and then asked to justify their assertions by referring to the *jobs* and their attributes. A pair of example *jobs* are shown above in Figure 1. As a reminder, most of the *jobs* in our study occurred in trios, but we include this pair due to space limitations.

Working in the spirit of grounded theory (Strauss and Corbin, 1997) allowed us to generate a framework of the components of *proofiness* that participants attended to. We refer to our organization and categorization of these components as the Personal Conceptions of *Proofiness* framework (PCP). Documenting which students attended to which segments of the PCP allowed us to create a personalized *proofiness* profile (PPP) for each participant.

Results

First, we present the components and definitions of our Personal Conceptions of *Proofiness* (PCP) framework. Then, we utilize the PCP to create personalized *proofiness* profiles (PPP) for each of our participants. We then narrow our focus to the parts of students' PPP that differ from student to student. These highlight differences in our participants' conceptions of what makes a *job* a proof. The differences in students' PPP are particularly relevant, since all participants were recruited from the same ITP section at the same institution, and thus had ostensibly comparable experiences with proof.

The PCP is divided into two *domains of proofiness*: *norms of communication* (how a mathematical communication is written and presented) and *purposes of communication* (why a mathematical communication is written, and how and whether it meets its mathematical aims). Figure 2 presents the *domains, subdomains, and dimensions of proofiness* that make up the PCP. Figure 2(a) displays the *norms of communication domain*. The *subdomains* in the left table of Figure 2(a) refer to mathematics-specific conceptions, while the *subdomains* on the right describe conceptions that pertain to argumentative writing in general. The primary difference between the left and right tables in Figure 2(a) is that the conceptions on the right are broadly applicable in written argumentation that is not mathematical (e.g., legal argumentation), while those on the left are more closely related to mathematical argumentation. Figure 2(b) details the *purposes of communication domain* of the PCP. Since the PCP was generated from student remarks in aggregate, the relative size of Figure 2(b) compared to Figure 2(a) is an important finding: it highlights that participants spoke relatively little about *purposes of communication*; most students focused their attention on *norms of communication.*

We used the PCP to classify each student's PPP. A subset of each student's PPP can be seen in Figure 3. The table is written so that + means the student believes that dimension *of proofiness* is necessary (though not sufficient) for a *job* to be a proof. We use ++ to indicate when the student was emphatic in their statement of a *dimension*'s importance that enthusiasm is not part of the analysis in this paper, we maintain the convention to be consistent with future work. We use - to indicate the student believes the *dimension* detracts from a *job's proofiness*. We use the symbol / to indicate that the student explicitly indicated that the *dimension* has no effect on whether a *job* is a proof. Finally, the symbol ~ means the student was inconsistent in their assessment of the *dimension*.

Domain	Sub-domain	Dimension	Description of Dimension
Norms of Communication	Sufficient Detail	Explicit Reference to Definitions	Stating "By definition of…" and especially followed by a verbatim statement.
		Assumptions Stated	Explicit statement of assumptions. As opposed to taking them as shared between author of claim and writer of Job. Even if assumptions are listed one line before, ensuring that assumptions are stated as a necessary first line.
		Fastidiousness	Thouroughness. Writing things out for the sake of being thorough, with attention to the detail in reproducing text they have read or written before, especially with definitions.
		Explicit Statement of Warrant / Backing	Stating why a certain inference was made, though no participant used that language. Explicit statement of warrant / backing (no participant used that language either). Participants talked about explaining why a step was taken (though not necesssarily why the outcome is true). If a function was factored, stating something like "By factoring, …". If the associate property was used, stating that it was. Ensuring that steps do not "come out of nowhere".
	Adherence to Norms of Mathematical Communication	Generality	Addressing more than a single case, preferably many or all cases.
		Arbitrariness	Acknowledgement of arbitrary choice.
		Variables	Letters as stand ins for either one or multiple numbers.
		Unidentified variables	Letters that are used but not intoruduced with words, described, or named.
		Specific Numbers	Using known, non-arbitary numbers with no variable label. Like "5".
		Symbols	Set notation. Elementhood / inclusion symbol. Blackboard R, N, and Z.
		Use of Examples	As stated by the participant, the presence of and use of an example. There were times when students called things examples that normatively were not.
	Mathematical Content and Context	Familiar Context	Contexts that participants have seen in their transition to proof course, including functions (but only special kinds like 1-1, and not polynomials), sets, divisibility, relations, number theory, etc.
		Unfamiliar Context	Contexts that participants have not seen in their transition to proof course that, importantly, remind them of their previous mathematics experiences. Especially calculus. No instances of mathematics contexts that the participants had never seen before. For instance, a Job whose mathematical context was in topology or graph coloring.
		Algebra	Presence of one or multiple lines of algebraic work like manipulation of equations, factoring, expansion of polynomials, etc.
		Higher Sophistication of Math Context	Lower sophistication: quadratic functions and calculus. Higher sophistication: number theory (divisibility) and classifying functions as 1-1. Mathematical concepts that were treated in their transition to proof courses felt more sophisticated to some participants.

Domain	Sub-domain	Dimension	Description of Dimension
Norms of Communication	Structure	Givens, Work, Goal	A structural concern. Starting with a statement of some assumptions and then taking steps (doing work) to somehow arrive at a goal.
		Proof Framework / Outline	The Job makes use of a recognizable proof framework or outline.
		Transition Words to Link Steps	Words like "hence", "thus", "therefore", "yields", "which means", "and then".
	Visual Cues	Paragraphs	As opposed to one block of text, the Job is written in paragraphs.
		Typesetting	Underlining of words like "Claim:","Justification:" and "Proof:", followed by indented text that contains the body of the Job.
		Centered Equations	As opposed to in-line equations.
		Pictures	The presence of pictures, especially graphs.
	Adherence to Norms of Written Argumentation	Conventionally Proofy Language	Words like "let", "assume", "suppose", "thus", and "therefore".
		Complete Sentences	The text of the Job is written in complete sentences.
		Long Length	More words. More lines. The Job takes up more physical space.
		Efficiency / Concision	The Job is lean. Does not take more steps than necessary. Brevity.
		The Word "If"	Presence of the word "if" in the Job.
		Voice	A composite dimension that is composed of various written English dimensions of *proofiness* . An understanding that proofs have or are written in
	Tone	Helps Reader	Effort is made by the Job to help or guide the reader, or otherwise advance the understanding of the reader.
		Convincing	The Job works to convince the reader of the truth of the claim or persuade the reader of something.

Figure 2(a): Norms of communication domain of PCP.

Domain	Sub-domain	Dimension	Description of Dimension
Purpose of Communication	Normative Mathematical Value of Proof	Inevitability	The claim is the logical conclusion that follows from the work done in the Job.
		Coherence	The conclusion of the Job matches the claim.
		Unpacking and Repacking	Definitions are used to make statements about some fact. Manipulation of those statements yields something of a sub-conclusion. This sub-conclusion is presented according to a definition, and this is the conclusion. Unpacking definition: writing a fact in a more useful form. Repacking definition: using that more useful form to make a conclusion, which is achieved by refrencing the language of a definition. Note that participants that explored this dimension of *proofiness* did not necessarily explicitly reference logical inference.
		Worthwile	The Job proves something that is nontrivial or proves something that requires a proof.
		Circular Logic	Assuming the conclusion. Or using rules that depend on other rules.
	Types of Claims	If / Then	The Job is an attempt ot justify a conditional statement.
		Answer-Getting	The Job is an attempt to solve a calculational problem. The Job amounts to a calculation.

Figure 2(b): Purposes of communication domain of PCP.

Participant	Major	Explicit Reference to Definitions	Inevitability	Coherence	Unpacking & Repacking	Worthwhile	Circular Logic	If / Then	Answer-Getting
Redmond	Mech E	++							
Megan	Math	++							-
Gem	Math			+					
Javon	Math	+	+		++	+	-		
Aidan	Math	++							
Eric	EE & Math			+			-	+	-
Claudette	Comm & Math	+							
Estrella	EE	/	++						
Han	Chemistry								-
Sabrina	*Professional*	~							

Figure 3: A subset of the participants PPP. Note the thick border, separating domains.

To illustrate these distinctions, consider the following two quotations from Han and Estrella, both of which are relevant to the Generality *dimension of proofiness* in the PCP framework:

Han: "Broader case feels *proofier* than talking about one specific case."

Estrella: "Not all proofs have to be arbitrary. You can still prove something for like a specific situation."

Han indicates he holds the conception that Generality is a dimension of *proofiness* that increases *proofiness*, while Estrella states that she does not believe that Generality affects *proofiness*. This indicates differences in their personal conceptions of proof. Since the mathematically normative conception of Generality is that a proof can be general or specific, depending on the claim, we see that not all students agree with that normative conception: two of them stated explicitly that to be more general was to be more *proofy*.

We further explore the PCP by comparing Claudette and Redmond's remarks associated with the Long Length dimension of *proofiness*, which relates to a *job* having more words, more lines, and taking up more space on the page. Claudette said she thinks proofs should have "lots of words", even referring positively to its "sheer amount of words" when claiming one *job* was *proofier* than another. Redmond, on the other hand, stated he did not like one of the *jobs* because, in his words, "It's too long." Therefore, Claudette has a + in the relevant space, while Redmond has a -.

The table in Figure 4 allows us to glean patterns and differences in the students' *personal proof profiles* (PPP). For example, we can notice that seven of the ten participants mentioned that they hold the belief that the inclusion of Conventionally *Proofy* Language contributes to *proofiness*. The three participants that did not verbalize this view on language did not bring up language at all, indicating de facto consensus. This stands in contrast to the group's conception of Algebra (the presence of one or multiple lines of algebraic work like manipulation of equations, factoring, expansion of polynomials, etc.)—some students believe that Algebra decreases a mathematical communication's (*job's*) proofiness, and others believe that Algebra is irrelevant to the *proofiness* of a mathematical communication. This indicates disagreement regarding whether the presence of algebra contributes to *proofiness*. More broadly, we found that, taken as a whole, there was consensus among our participants with respect to Assumptions Stated, Explicit Statement of Warrant / Backing, 'Givens, Work, Goal', Proof Framework / Outline, and Conventionally *Proofy* Language as positive contributors to *proofiness*. Moreover, we saw strong support for the detrimental effect to *proofiness* that Unidentified Variables, Unfamiliar Context, and Answer-Getting yielded (see Figure 2 for descriptions of these *dimensions of proofiness*). Further, students broadly disagreed about the *proofiness* of Long Length, Algebra, and Generality. Lastly, the Explicit Reference to Definitions *dimension of proofiness* is noteworthy: most participants agreed enthusiastically that this *dimension* contributed positively to *proofiness*, with only one stating it did not matter, and another being inconsistent. This is intriguing, if not worrisome, since many mathematicians believe that, across contexts, full statements of definitions should not be included in proofs (Lew and Mejia-Ramos, 2020). This discrepancy about whether to include definitions is related to lack of clarity (Ibid.) on what student-produced proofs should look like, according to mathematicians.

Dimension of Proofiness	Redmond	Megan	Gem	Javon	Aidan	Eric	Claudette	Estrella	Han	Sabrina
Explicit Reference to Definitions	++	++		+	++		+	/		~
Assumptions Stated	+		+		++		+			+

Answer-Getting		-				-			-	

Figure 4: PCP framework (applied to students). Note the thick border, separating domains.

One final observation merits consideration: Figure 4 illustrates sparse attention among the pool of participants to *purposes of communication.* In fact, only four participants had a + listed in any *dimension of proofiness* within this *domain*. Put another way, six out of the ten participants did not attend at all to the *purposes of communication domain.* This is understandable given that the participants are at the ITP stage in their mathematics education. However, we hope that future study can inform ways to support students like these to do more than "show their work" nicely, and in doing so they may consider more deeply exactly what the "work" of proof is.

Discussion and Conclusions

We used *job*-based tasks to study individual students' conceptions of *proofiness*. This allowed us to develop a framework for which attributes emerged in discussion of what makes something a proof. Compiling all these conceptions into one organized list of *dimensions of proofiness* is what we call the Personal Conceptions of *Proofiness* framework. Applying this to each of our participants creates a personalized *proofiness* profile, which allows us at a glance to notice patterns and trends in our data related to student beliefs about *proofiness*. For example, we were able to notice differences in our student participants regarding conceptions of generality in proof, and that there was consensus regarding students' belief that the use of a proof framework / outline was relevant to determining whether something is a proof–that is, it increased the *proofiness* of a *job*. Given that all participants were enrolled in the same introduction to proof (ITP) section, this information provides a kind of profile of conceptions of proof that emerged from that class as a whole.

In this connection, we could also envision using these same tools (our *jobs*-based tasks and the PCP) to compare the class profiles of two separate sections of the ITP course taught by different instructors with different instructional approaches. Documenting this could lead to richer understandings of what kinds of instructional approaches lead to conceptions of proof that are more/less aligned with normative mathematical perceptions of *proofiness*.

Finally, we plan on using and further developing both our *jobs*-based tasks and the PCP and getting a better sense of the range of mathematicians' PCP. This followup work should aid us in creating curricula aimed at, among other things, developing students' PCP and simultaneously tying this research to currently available research on mathematicians' conceptions of *proofiness*.

Inquiry-Based Calculus I: What is the impact on student performance?

Kayla Heacock
Ohio University

Allyson Hallman-Thrasher
Ohio University

Kelly Bubp
Frostburg State University

While active learning has been found to support student success, it has not yet emerged as the dominant instructional approach in undergraduate mathematics (Stains et al., 2018). This study focuses on student performance in undergraduate Calculus I where we compared the performance of students in inquiry-based (IBL) Calculus I with students in non-IBL Calculus I courses. Additionally, we examined the performance of first-year and upper-year students as well as students who were or were not pursuing a math-intensive major. Students in IBL Calculus performed on the final exam an average of nine percentage points higher than those enrolled in non-IBL Calculus. Differences in performance between first-year students and upper-year students and between students majoring in math-intensive fields and those in non-math-intensive narrowed in the IBL classes. This study aims to add to the ever-growing body of research showcasing the benefits of IBL in improving student course performance.

Keywords: inquiry-based learning, calculus, student performance

In 2016, the Conference Board of Mathematical Sciences (CBMS), a coalition of nineteen professional undergraduate mathematics organizations, issued a compelling statement urging "…institutions of higher education, mathematics departments, and the mathematics faculty, public policy-makers, and funding agencies, to invest time and resources to ensure that effective active learning is incorporated into post-secondary mathematics classrooms" (CBMS, 2016, p. 1). Research has consistently demonstrated the positive impact of active learning and student-centered approaches on improved student course performance (e.g., Abdi, 2014; Bruder & Prescott, 2013; Dunnigan & Harlow, 2021; Freeman et al., 2014), a deeper appreciation of challenging content (Cilli-Turner, 2017), and increased persistence and confidence in doing mathematics (Laursen et al., 2011).

Additionally, the attrition of students from STEM fields is a pressing concern, particularly when high-achieving students who are often successful in other subject areas are leaving STEM (Olson & Riordan, 2012). Troublingly, almost 90% of students cite poor instruction as a factor in leaving STEM (Kung & Speer, 2020). Moreover, Calculus has been noted as one of the largest gatekeepers and barriers for STEM majors, ultimately excluding students who would otherwise be successful (Bressoud et al., 2013; Rasmussen & Ellis, 2013). However, there are signs of improvement as active learning pedagogies have helped increase student performance (Freeman et al., 2014) and even significantly decreased achievement gaps for underrepresented students in STEM (Theobald et al., 2020).

Although mathematics departments have the support of organizations like the CBMS and MAA (Abell et al., 2018; CBMS, 2016), and there are many positive findings regarding the benefits of active learning in undergraduate STEM courses, active learning pedagogies are still not the dominant instructional method in undergraduate STEM (Stains et al., 2018). Because of active learning's overwhelmingly favorable results in supporting STEM students (e.g., Bruder & Prescot, 2013; Laursen et al., 2011), we studied the effects of inquiry-based learning (IBL), a specific type of active learning, on student course performance in an undergraduate Calculus I course. We contribute to the growing body of research on the effectiveness of IBL in improving student course performance. Additionally, this study explores the benefits of IBL on course performance for various groups of students who often struggle in STEM, such as upper-level students (Gregg-Jolly et al., 2016) and students majoring in fields that are not math-intensive such as the life sciences (Kokkelenberg & Sinha, 2010; Rasmussen & Ellis, 2013). In particular, we use final exam scores to measure differences in student performance between first-year students and upper-year students as well as between students in math-intensive majors and non-math-intensive majors. By shedding light on these aspects, we seek to contribute to the existing body of research on IBL implementation and, in turn, encourage other instructors to embrace active learning pedagogies. Specifically, this study seeks to answer the following research questions:

1. How does the final exam performance compare between students enrolled in inquiry-based (IBL) Calculus I and those in non-inquiry-based (non-IBL) Calculus I?
2. Do IBL and non-IBL final exam scores differ for first-year and upper-year students?
3. Do IBL and non-IBL final exam scores differ for students enrolled in math-intensive majors and students enrolled in non-math-intensive majors?

Inquiry-Based Learning

Inquiry approaches to undergraduate education have been gaining momentum (Laursen & Rasmussen, 2019) since the CBMS released their statement supporting active learning (CBMS, 2016). One such approach is IBL, where students work through a “carefully scaffolded sequence of mathematical tasks” (Ernst et al., 2017, p. 570) to construct their mathematical knowledge under the guidance of an instructor. In IBL, students actively communicate with their peers, posing questions and testing conjectures, fostering a collaborative and interactive learning environment. IBL differs from other active learning methods in three distinct ways. First, strategically sequencing tasks allows topics to build on each other throughout the semester instead of using a task unrelated to others. Second, IBL encourages students to actively reinvent mathematics they knew before or create mathematical ideas that are new to them. Third, IBL fosters critical reflection among students and instructors on their perceptions of mathematics and what it means to know, teach, and do math (Laursen & Rasmussen, 2019).

Table 1. The four pillars of inquiry.

	Mathematical Space	**Social Space**
Student Behavior	Engage deeply with meaningful tasks	Collaborate with classmates in processing ideas
Instructor Behavior	Inquire into student thinking and reasoning	Foster equity, respect, and responsibility

Adopted from Foley (n.d.).

The key tenets of IBL are built on the four pillars of inquiry (see Table 1), which consider the behaviors and actions of students and instructors mathematically and socially (Laursen & Rasmussen, 2019). In the mathematical space, students deeply engage with meaningful tasks and work collaboratively to process intricate mathematical concepts. Concurrently, the instructor tries to draw out and understand students’ thinking and reasoning, aiming to acknowledge each individual’s unique perspective. In the social space, students collaborate with their peers, exchanging mathematical ideas and collectively constructing their understanding of concepts, leading to deeper mathematics learning. The instructor’s social role is to cultivate an inclusive learning environment where every student's voice is respected, and students take responsibility for their learning.

Methods

Context

In this study, we analyzed three consecutive semesters of implementation of IBL and non-IBL Calculus I courses at a large, public, midwestern university. Instructors of the IBL and non-IBL sections varied each semester, and instructors had the freedom to choose which type of section they wanted to teach. Importantly, no explicit indication in the course offerings differentiated the IBL and non-IBL sections. Therefore, students enrolling in these sections were unaware of the pedagogical style beforehand. All sections shared the same learning objectives, met for the same amount of time per week, had approximately the same number of enrolled students, and used the same final exam, making them suitable for comparing the pedagogical differences between IBL and non-IBL Calculus and their impact on student performance.

The non-IBL sections had a single instructor in class, while the IBL sections incorporated graduate and undergraduate students as learning assistants (LAs) to support group work (see Webb et al. 2014), aiming for an instructor-to-student ratio of 15:1. In the IBL sections, students took an active role in their learning and spent most of their time working collaboratively in small groups, engaging with *Active Calculus* tasks (Boelkins et al., 2018). Instructors and LAs provided support by addressing difficulties, asking questions, checking comprehension, encouraging discussion, and fostering independent problem-solving skills rather than providing direct answers to student questions. On the other hand, the non-IBL sections primarily relied on lecture-based instruction from the instructor. While some non-IBL sections included elements of IBL Calculus, such as small group work, they did not emphasize students' responsibility for developing strategies, procedures, or conceptual understanding. Instead, instructors primarily directly presented these procedures, strategies, and key concepts to students.

Data Collection & Analysis

The participants in this study were students enrolled in either non-IBL (n = 381) or IBL Calculus I (n = 310). In both IBL and non-IBL Calculus sections, all students completed the same standards-based final exam each semester, designed to align with specific course objectives and assess conceptual and procedural understanding. While the exams varied slightly across semesters, they were created by the same calculus coordinator, who adhered to the same exam guidelines, making it suitable to compare final exam performance across semesters. We used Welch's t-test (α = .05), a robust test, to account for the unequal variances between the populations to compare exam scores for groups of students in both IBL and non-IBL sections. We also used Cohen's d (Cohen, 1988) effect sizes to help determine the practical significance of the differences observed by certain groups. For these analyses, we followed Cohen's recommended benchmarks for small (d = .20), medium (d = .50), and large (d = .80) effects. Finally, we ran these same tests on subgroups of students including first-year and upper-year students, in addition to students pursuing math-intensive (MI) majors, those that required a mathematics course beyond Calculus II, or non-math-intensive (NMI), majors where Calculus I or Calculus II was the terminal mathematics course required at our institution.

Results

Here, we present our findings organized by research question. First, we compare IBL and non-IBL participants' performance on a standards-based final exam. Then, we discuss how participants' scores differed based on whether they were first-year versus upper-year students or students majoring in a math-intensive field versus a non-math-intensive field.

IBL vs. Non-IBL Final Exam Performance

Overall, IBL students outperformed non-IBL students. As can be seen in Table 2, IBL participants' average final exam score was nearly a full letter grade higher than non-IBL participants' average final exam score. IBL participants' final exam scores ($M = 68.37$, $SD = 16.82$) were significantly higher, ($t(687.21) = 6.59$, $p < .001$), than the scores of non-IBL participants ($M = 59.24$, $SD = 19.65$). The effect size (Cohen's d = 0.50) indicated a moderate difference in the final exam performance of IBL vs. non-IBL participants. Thus, students in IBL scored significantly and noticeably better, on average, than their peers in non-IBL, averaging over 9 percentage points higher on the final exam.

Table 2. IBL vs. Non-IBL Participants' Exam Performance.

	n	*M*	*SD*	*t*	*p*	Cohen's d
IBL	310	68.37	16.82	6.59	<.001	0.50
Non-IBL	381	59.24	19.65			

First-Year vs. Upper-Year Final Exam Performance

The average final exam score of first-year students ($M = 67.64$, $SD = 17.45$) across both IBL and non-IBL sections was significantly higher ($t(679.373) = 5.80$, $p < .001$) than the average final exam score of students in their upper years of school ($M = 59.49$, $SD = 19.29$). The effect size (Cohen's d = 0.44) indicated a moderate difference in the final exam performance of first-year and upper-year participants. As seen in Table 3, first-year participants' final exam score average was nearly eight percentage points higher than upper-year participants' final exam average.

Table 3. First-Year and Upper-Year Participants' Exam Performance in IBL and Non-IBL

	First-Years	Upper-Years
IBL	71.58 (n=132)	65.42 (n=173)
Non-IBL	64.76 (n=181)	54.34 (n=199)
Total	67.64 (n=313)	59.49 (n=372)

We further examined the differences in exam scores of first-year and upper-year students between the IBL and non-IBL sections. We found that upper-year IBL students' average final exam score ($M = 65.42$, $SD = 16.99$) was significantly higher ($t(300.572) = 3.54$, $p < .001$) than upper-year non-IBL students' average final exam score. The effect size (Cohen's d = 0.60) showed a strong difference between the scores of upper-year students in IBL and non-IBL, indicating IBL may have better served upper-year students than did non-IBL. Additionally, first-year IBL students' average final exam score (*M* = 71.58, *SD* = 15.83) was significantly higher ($t(300.572) = 3.54$, $p < .001$) than first-year non-IBL students' average final exam score (*M* = 64.76, *SD* = 18.06). The effect size of (Cohen's d = .40) indicated a moderate difference in exam scores among first-year students, with those in IBL scoring about 7 percentage points higher on the final exam than the first years in non-IBL.

Furthermore, we compared final exam scores between first-year and upper-year students enrolled in the same type of section. The average final exam score for first-year non-IBL students (*M* = 64.76, *SD* = 18.05) was significantly higher ($t(377.983) = 5.38$, $p < .001$) than the average final exam score for upper-year non-IBL students (*M* = 54.34, *SD* = 19.72). The effect size (Cohen's d = 0.55) indicated a moderate difference in the final exam performance of first-year and upper-year students in non-IBL. In the IBL sections, the average final exam score for first-year students (*M* = 71.58, *SD* = 15.83) was significantly higher ($t(291.193) = 3.26$, $p < .001$) than the average final exam score for upper-year students (*M* = 65.42, *SD* = 16.99). Thus, in both IBL and non-IBL, first-year students were performing better than upper-year students. However, the effect size (Cohen's d = 0.37) was not as strong for IBL as it was for non-IBL (Cohen's d = 0.55), indicating a larger difference between first-year and upper-year students in non-IBL. This is evident in the percentage point gap of nearly 6 percent between first-year and upper-year students in IBL compared to over 10 percent between first-year and upper-year students in non-IBL. Therefore, it seems that IBL may have helped lessen the gap between first-year and upper-year students' final exam performance.

Math-Intensive vs. Non-Math-Intensive Final Exam Performance

Regardless of being in an IBL or non-IBL section, the average final exam score for MI majors (*M* = 63.34, *SD* = 19.55) was not significantly higher ($t(477.703) = 0.39$ $p = .697$) than the average final exam score for students in NMI majors (*M* = 62.74, *SD* = 18.50) (see Table 4). The effect size (Cohen's d = 0.03) indicated very little difference in the final exam performance based on whether students were required to take a course beyond Calculus II for their major. Thus, average exam scores did not differ based on the intensity of mathematics courses required for a major.

Table 4. Math-Intensive and Non-Math-Intensive Participants' Exam Performance in IBL and Non-IBL

	Math-Intensive	Non-Math-Intensive
IBL	67.18 (*n* = 104)	68.55 (*n* = 201)
Non-IBL	60.46 (*n* = 139)	57.77 (*n* = 235)
Total	63.34 (*n* = 243)	62.74 (*n* = 436)

We next examined the differences between MI and NMI majors' exam scores for students enrolled in IBL or non-IBL sections. Math-intensive IBL students' average final exam score was

(M = 67.18, SD = 18.54) significantly higher (t(299.453) = 2.72, p = .007) than the average final exam score for MI non-IBL students (M = 60.46, SD = 19.85). The effect size (Cohen's d = 0.35) indicated a small to moderate difference between MI majors in IBL and non-IBL, with a difference of about 7 percentage points on the final exam. Thus, the averages of MI majors in IBL were noticeably higher than MI majors in non-IBL. Similarly, NMI IBL students' average final exam score (M = 68.55, SD = 15.78) was significantly higher (t(433.295) = 6.428, p < .001) than the average final exam score for NMI non-IBL students (M = 57.77, SD = 19.22). The effect size (Cohen's d = 0.61) indicated a moderate and stronger effect than those students in MI fields. NMI majors in IBL scored an average of about 11 points higher on the final exam than NMI majors in non-IBL. These results indicate that IBL benefited both MI and NMI majors and it was not the case that MI majors outperformed NMI majors or masked poor performance from NMI majors.

Finally, we compared the exam scores of MI and NMI majors enrolled in courses with the same pedagogical approach. Within a type of instruction, typically MI majors and NMI majors performed about the same. The average final exam score for MI non-IBL students (M = 60.46, SD = 19.85) was not significantly higher (t(282.356) = 1.28, p = .201) than the average final exam score for NMI non-IBL students (M = 57.77, SD = 19.22). The effect size (Cohen's d = 0.14) indicated a small difference in the final exam performance of non-IBL MI and NMI participants. For IBL participants, the average final exam score for MI majors (M = 67.18, SD = 18.54) was not significantly lower (t(181.566) = – 0.64, p = .523) than the average final exam score NMI IBL students (M = 67.18, SD = 18.54). The effect size (Cohen's d = –0.08) indicated little difference in the final exam performance between the majors. The NMI majors scored over one percentage point higher than MI majors in IBL. In contrast, in non-IBL, NMI majors scored nearly three percentage points lower on average than MI students.

Discussion

This study provided insights into the effects of IBL on student performance in undergraduate Calculus I. We aimed to compare student performance on a common final exam between the following populations of interest: 1) students in IBL Calculus and those in non-IBL Calculus, 2) first-year and upper-year students, and 3) students in math-intensive majors and students in non-math intensive majors. We specifically choose to examine comparisons between year and major because both our own experience and research has shown that upper-years (Gregg-Jolly et al., 2016) and those not in math-intensive fields (Kokkelenberg & Sinha, 2010; Rasmussen & Ellis, 2013) struggle in calculus.

Overall, IBL participants outperformed non-IBL participants on the final exam, with a difference of nine percentage points (see Table 2). Although this study used a smaller sample than some prior studies (Freeman et al., 2014), the fact that the final exam was relatively consistent across semesters, made by the same course coordinator, using the same guidelines, and was administered to all Calculus I students in courses with similar student populations helped us draw strong conclusions about student performance. The significant difference and moderate effect size (Cohen's d = 0.50) reinforces the idea that IBL can improve student performance in Calculus I; students enrolled in IBL sections scored nearly a letter grade higher than students enrolled in non-IBL on the same final exam.

Unsurprisingly, overall, first-year students performed significantly better than upper-year students. However, the largest gap in final exam performance was between upper-year students in IBL and upper-year students in non-IBL. Thus, IBL significantly benefited both first-year and upper-year students' course performance. Moreover, we see these differences in performance between first-year and upper-year students narrow in IBL. The IBL structure provided a learning environment that focused on (1) deliberate practice, where students worked on scaffolded tasks and received immediate feedback from course instructors, and (2) a culture of inclusion that fostered respect among students and demonstrated confidence and interest in each student's individual success in calculus (Theobald et al., 2020). We claim this structure supported these upper-year students who often struggle in STEM courses as they feel the pressure of making academic and life decisions about their chosen career path (Gregg-Jolly et al., 2016) which helped lessen differences in performance between first-year and upper-year students.

In terms of the intensity of mathematics required for students' majors, we did not find a significant performance difference between whether or not a student's major required a mathematics course beyond Calculus II. However, both students who required a math course beyond Calculus II and students whose terminal math course was either Calculus I or Calculus II benefited significantly from the IBL pedagogical approach. Effect sizes indicated the largest difference to be between NMI majors in IBL and NMI majors in non-IBL with students in IBL scoring nearly 11 percentage points higher on the final exam, which is critical as NMI majors are those students who most frequently leave calculus (Rasmussen & Ellis, 2013). By incorporating IBL, students enrolling in these majors succeeded at a greater rate, and hopefully, in turn, persisted with their majors.

Conclusion and Limitations

Overall, our results indicate the potential for benefits of instruction informed by an IBL approach. Two groups of students in particular benefited: upper-year students and students in non-math-intensive majors, who are traditionally less successful in STEM (Gregg-Jolly et al., 2016; Kokkelenberg & Sinha, 2010; Rasmussen & Ellis, 2013). In some ways, we anticipated better performance of IBL students than non-IBL peers, as suggested by prior research (Freeman et al., 2014; Laursen et al., 2011). However, further data analysis revealed subtle differences in how those benefits played out. Notably, differences in performance between upper-year and first-year students was significantly smaller in the IBL classes than non-IBL. Similarly, there were no significant differences in performance for NMI majors and MI majors in IBL classes, debunking the notion that an IBL approach is only for mathematically strong students. Thus, not only was stronger course performance associated with the IBL approach, but an IBL approach may have also better supported students who traditionally leave STEM fields (Gregg-Jolly et al., 2016; Kokkelenberg & Sinha, 2010; Rasmussen & Ellis, 2013). By incorporating IBL, college math instructors can create a learning environment that supports overall student success in Calculus I and specific populations who traditionally struggle in STEM. Although we did not have adequate sample sizes for analyses in this study, future research could examine the effects of IBL on differences in performance of other traditionally underrepresented groups in STEM: women, black and Latinx students, first-generation students, and students of low socioeconomic status (Theobald et al., 2020).

Groupwork as a Site for Servingness among Undergraduate Latin* Mathematics Students

Luis A. Leyva Vanderbilt University	Martha H. Byrne Sonoma State University	Megumi Asada Rutgers University
Nicollette D. Mitchell Vanderbilt University	Rocío Posada-Castañeda Vanderbilt University	Ronimar López-Bazán Sonoma State University

Undergraduate mathematics classrooms are racialized spaces for Latin students, even at Hispanic-Serving Institutions (HSIs) with educational missions of cultural affirmation. Instruction plays an important role in reinforcing and disrupting racial oppression in mathematics, which has significant implications for gateway courses (e.g., calculus) that impact STEM persistence. Groupwork is a widely-adopted practice in gateway mathematics courses with intentions to promote equitable access to content and participation; however, research has shown that groupwork can perpetuate inequitable experiences for historically marginalized groups in STEM, including Latin* students attending HSIs. The present study addresses these concerns of racial equity in undergraduate mathematics by exploring Latin* students' groupwork experiences in gateway courses at a HSI. Our findings capture how groupwork facilitated or removed access to a sense of racially-affirming community, which was central in Latin* students' visions of equitable support as mathematics learners at a HSI.*

Keywords: groupwork, Hispanic-Serving Institutions, Latin* students, race, servingness

Purpose of the Study

Latin*[1] students experience undergraduate mathematics as a racialized space due to instances of isolation and underestimation of ability (Leyva, 2016; Oppland-Cordell, 2014). Such realities in gateway courses (e.g., calculus, introduction to proofs) can limit racial equity in educational opportunities, including negative effects on Latin* students' mathematics identities as well as access to course content and STEM majors (Brown, 2018; Convertino et al., 2022). Instructional practices in gateway courses, such as groupwork, that are adopted to build equitable access to content and participation hold potential to disrupt racial oppression for Latin* learners (Laursen et al., 2014; Leyva et al., 2021; Fullilove & Treisman, 1990; Villa et al., 2023). However, research has shown that groupwork can perpetuate inequitable experiences for Latin* students and other minoritized groups (Johnson et al., 2020; MacArthur & Dobie, 2023; Oppland-Cordell, 2014). Researchers have called for work that centers minoritized student populations' groupwork experiences to better understand equitable practices (Ernest et al., 2019; Reinholz, 2018).

Even at U.S. colleges and universities with the federal designation of being Hispanic-Serving Institutions (HSIs), mathematics education remains a racialized environment for Latin* students (Leyva et al., 2022; McGee, 2016). This reality reflects a broader structural concern at HSIs – namely, their lack of institutional visions for serving Latin* students to promote racially-equitable outcomes and culturally-affirming experiences (Garcia, 2020). Research at HSIs that uncovers features of practices and policies for racial equity is a critical need (Vega et al., 2022). To guide such work, Garcia and colleagues (2019) conceptualized *servingness* as a framework that addresses various dimensions of culturally-enhancing opportunities for better serving Latin* students at HSIs, including outcomes, experiences, organizational structures, and external forces.

[1] *The term Latin* is inclusive of gender-nonconforming identities in the Latin American diaspora.*

Research on servingness in STEM has focused on student outcomes related to institutional structures, such as departmental policies (Burn et al., 2019) and support programs (Rodríguez Amaya et al., 2018). However, limited work has examined Latin* students' experiences of STEM instructional practices. Such work is important in gateway mathematics courses that impact STEM retention (Bhattacharya et al., 2020; Byrne et al., 2023; Convertino et al., 2022).

The present study addresses the two areas of needed research in undergraduate mathematics identified above specific to equity issues in groupwork and servingness through instruction. We explored Latin* students' groupwork experiences in gateway mathematics courses at a HSI to uncover features of peer collaboration that constrained and promoted identity-affirming learning opportunities. The study addresses two research questions: (i) How does groupwork in gateway courses reinforce and disrupt mathematics as a racialized experience for Latin* students? ; and (ii) In what ways does groupwork advance and limit opportunities for actualizing Latin* students' conceptions of servingness as mathematics learners at a HSI?

Methods

Our study is from a larger project exploring influences of faculty professional development about culturally-responsive pedagogy in promoting equity for Latin* mathematics students at Sonoma State University – a medium-sized, public university recently designated as a HSI. The university's undergraduate demographics are about 45% white, 35% Latin*, and 20% some other race. The larger project explores instructors' and Latin* students' perspectives on servingness in instruction across gateway courses for STEM majors, including calculus, statistics, introduction to proof, and developmental mathematics sequences. Our team has completed two years of recruitment and data collection since fall 2021. A total of 24 Latin* students were recruited in Year 1 to complete individual interviews via Zoom and journaling about instructional experiences. Fifteen students completed in-person group interviews at Sonoma State during Year 2. Only one student participated in both years. The present report focuses on group interviews.

We invited Latin* students in gateway courses to express interest as participants via email and class visits. We purposefully sampled from students who expressed interest to have multiple voices from different gateway courses as well as to ensure variation in ethnicity and gender. In fall 2022, a total of 31 Latin* students were invited to complete a 2-hour, semi-structured group interview that was audiotaped and transcribed. Fifteen students completed interviews, resulting in six conducted interviews (two for statistics, two for calculus, and two for other courses). The majority of our sample identifies as Mexican or Mexican-American, which is reflective of Sonoma State enrollment. Eleven of the 15 interviewed students are cisgender women. Students with nonbinary gender identities were invited to participate, but were unable to attend the interviews. To the best of our ability, we paired each participant with at least one student of the same gender to mitigate feeling tokenized and make space for variation in race-gender identities. One faculty and two Ph.D. student researchers from outside of Sonoma State conducted the interviews, each with 2-4 participants. To the extent possible, we matched interviewers and participants by race and gender as an effort to build comfort with discussing racism and other forms of oppression. A Latin* researcher was present for all interviews.

Interviews consisted of three parts: (i) students' views on servingness, (ii) responses to three prompts of instructional scenarios corresponding to themes of servingness from Year 1 data analysis (see Leyva et al, 2022 and McNeill et al., 2023), and (iii) responses to an excerpt from Sonoma State's HSI Task Force Report. One scenario featuring instructional practices addressed groupwork:

> My professor asks us to work in groups when solving a mathematics problem, either in class or as homework, followed by presenting our group solution to the class. I often feel concerned about collaborating with classmates in groups because I am unsure if I will have something meaningful to contribute and if my ideas will be welcomed or taken seriously. Groupwork can also be an isolating experience for me as a Latinx student in the mathematics classroom because students may choose to work with classmates of the same racial and gender identities.

For the prompts and report excerpt, we asked about the extent to which Latin* students related as mathematics learners, instructional aspects (dis)affirming of their identities, and ways to improve support. Our analysis focused on the first and third interview parts and the groupwork scenario.

A pair of researchers (one from Sonoma State and one from an outside university, at least one of whom was Latin*) coded each transcript. Sonoma State researchers coded de-identified versions to protect participant confidentiality. We independently and inductively coded to flag instructional and departmental features that students viewed as fostering or limiting servingness, including attention to Latin* students' intersectional identities and cultural backgrounds. A coder from each pair synthesized codes for each transcript to identify themes discussed as a team.

Our team approached the analysis with critical self-reflexivity. We have robust diversity among faculty and students across intersections of race (Asian/Filipinx, Black, Latin*, white) and gender (nonbinary, cisgender woman, cisgender man). Half of our team involved in the present analysis identifies as Latin*, and several members are first-generation college students. As individuals, we brought awareness of how our respective areas of privilege and oppression impact our study of servingness in mathematics at HSIs. We resisted deficit engagement with Latin* students' perspectives and constantly recognized how undergraduate mathematics is situated in broader systems of social power. We bracketed our lived experiences when interviewing and coding to avoid distorting students' perspectives, all while interrogating structures that limit servingness in groupwork and other mathematical contexts at Sonoma State. Our findings avoid essentializing portrayals of Latin* experiences by looking across three cases of groupwork for first-generation females from low-income, Mexican families enrolled in different gateway courses[2].

Findings

Our analysis uncovered how groupwork in gateway mathematics courses can be an opportunity to advance servingness, particularly in terms of Latin* students building a racially-affirming community. Participants shared different reasons for why they valued groupwork, such as accountability to complete assignments, decreased vulnerability of asking questions in class, and meeting new people. Appreciation for groupwork aligned with values of community that were central across participants' views of servingness at Sonoma State. Several students reported feeling served through Sonoma State's student support services (e.g., Educational Opportunity Program office), where they built communities that nurtured their mathematical success. Latin* students, however, also described a lack of race-conscious support in mathematics, including groupwork as an oppressive experience that limited access to content and participation as well as negatively impacted their mathematics identities. Despite an overall lack of servingness in mathematics, participants addressed possibilities through instruction that can disrupt groupwork as an oppressive context and promote a sense of community affirming of their Latin* identities.

[2] The findings do not specify the gateway mathematics course for each participant to protect confidentiality.

We now present findings from analyzing perspectives from three participants (Kayla, Indrid, and Oliva), which offer illustrative cases of how access to community in groupwork can impact servingness. Kayla is a third-year Mexican-American female[3] studying humanities. Indrid is in her first year and Oliva in her second year. Both identify as Mexican females in STEM majors.

The first two sections of the findings address our first research question by detailing racial (in)equity in Lain* students' groupwork experiences. First, we present how social forces, such as stereotypes and structural inequalities, shaped groupwork as a racialized experience. Next, we show how groupwork afforded or disrupted Latin* students' access to a racially-affirming peer community. The final section of the findings addresses how groupwork fell short or advanced each Latin* participant's perception of servingness, answering the second research question.

"If You're Latina… They Don't Take You Seriously If You're in a Group Project"

All three participants addressed how stereotypes of mathematical ability and structural inequities of access contributed to experiences of isolation, with groups often segregated by race and gender. Kayla felt white peers were assumed to be smarter and chosen more often as partners, "When students get to choose our own groups, sometimes for Latinx students, we would feel left out… It's hard to find a group because everybody pairs off with the smart people… because they're white." With strong representation of white students in Kayla's class, she often had white groupmates who seemed to undermine her ability and limit her contributions.

> A lot of Caucasian people, I try to put my inputs, try my best, but when I give the answers, they always look at me like it's wrong. Essentially, they do all the work and I just put my name on it. I still feel I'm not learning anything because then if I ask, 'Oh, how do you do this?' They're like, 'Well, it's simple. Just look at the notes.' I could look at the notes all I want. It's gibberish. Essentially, it's making me feel, again, like I don't know it.

Racialized assumptions of who is mathematically able made groupwork exclusionary for Kayla, restricting her access to learning opportunities and a positive sense of mathematical competence.

Oliva saw herself contributing to racialized segregation during groupwork because she was concerned that collaborating with classmates who did not share her Latinx or Mexican identity could limit her mathematical contributions, "I understand the self-isolation because I still self-isolate… If it were [a] choose-your-own kind of group, I would one hundred percent choose people that look like me, so I can feel related to and I can put forth what I feel like I need to put forth." Her intentional selection of Latinx or Mexican groupmates allowed her to connect with peers who understood her and to protect herself from racialized judgment. Indrid similarly shared how being stereotyped as a Mexican female shaped groupwork as a racialized-gendered space. When asked if being in a mathematics class impacted how students select collaborators, she said, "You unconsciously go towards people that look like you… Yeah, because… stereotypes. If you're Latina… 'Girls are not good at math. Latina, Hispanic girls are just raised to end up being housewives… [or] pregnant'... They don't take you seriously… in a group project." Groupwork was a racialized-gendered space where stereotypes disallowed productive peer collaboration. Indrid recalled an instance of racial stigma when a white female groupmate proposed working on textbook problems independently followed by assuming that she could afford to buy the book and not trusting her to borrow it. Being low-income also stigmatized Indrid during groupwork.

[3] We used language consistent with how students described their identities, including their interchangeable use of terms for their race (e.g., Latinx, Hispanic, Mexican) and gender (e.g., female, girl, woman) during the interview.

“Have a Community That Understands the Math and… Without Feeling Ashamed”

Participants viewed racialized dynamics in groupwork limiting opportunities to find and build community that supported their Latin* identities. We now show how exclusion in groupwork was reinforced or disrupted for Kayla and Oliva, impacting access to community.

As a white-passing Mexican-American female, Kayla grappled with tensions of concealing her Latin* pride (e.g., not speaking Spanish) to contribute more in groupwork, “[A white person] hears me speaking Spanish, they’re like, ‘Oh, you’re not white?’… I also grew up knowing what I can and cannot do [as a Latin* person], and sometimes the white-passing helps with the things I’m able to do… They treat you differently once they find out [you’re Hispanic].” In addition to such linguistic racism in groupwork, she saw white peers’ backgrounds with “parents having higher education” as reinforcing inequities of available support. As a first-generation college student, Kayla saw her family limited in offering support for her in mathematics because her parents did not attend college, “I can’t ask him [Kayla’s father] for help. He never finished high school… They [Kayla’s parents] don’t know the level of math that I’m trying to learn.” Racial inequities in terms of families’ educational backgrounds and access to peer support were left unchallenged in Kayla’s mathematics classroom where she lacked a community of support, “It would be nice to have a community that understands the math and I can go to them without feeling ashamed.” Even with groupwork, she was on her own to succeed mathematically.

In contrast to Kayla being denied community in groupwork, Oliva shared a recent classroom moment allowing her to overcome fears of racialized judgment that isolated her and to collaborate with a racially-diverse group who became close friends. Her instructors opened the course with a discussion about recognizing social diversity and prioritizing mutual respect.

> First day of instruction… they’re [instructors] like, ‘We’re going to have a conversation… We respect everybody.’ That changed the aspect of the class completely… We were able to sit down, have a conversation, and be like, ‘Okay, I am this, but I am also this. Intersectionality is a real thing.’… That’s probably why I feel really strongly about that class. I was able to talk to people in other races and genders…and still be able to collaborate.

Oliva perceived this practice of encouraging students to be identity-conscious and respect each other as establishing a “sense of community,” which facilitated positive groupwork experiences with classmates across social differences and thus disrupted racialized segregation in groupwork.

“There Was Just Much More Communication… That Opened Up A Lot of Doors For Me”

Latin* students’ groupwork experiences that lacked a racially-affirming sense of community constrained opportunities to experience servingness as mathematics learners. Kayla viewed having a community that understood her struggles and motivated her pursuits of academic success as central to being served as a first-generation Hispanic female at Sonoma State. She saw being in a multicultural sorority providing a racially-affirming community missing in mathematics. “The sorority that I am rushing, a lot of them [are] first-gens, low-income… which makes me feel more [of a sense of] belonging… I’ll have somebody that have gone through the same struggles as I have.” The racialized space of groupwork, where Kayla navigated white peers’ judgment for her questions and marginalization as a contributor, left her without a community where she felt seen and supported like in the sorority space. Kayla saw hiring Hispanic mathematics tutors fluent in Spanish as one way to increase Latin* students’ access to such a peer community, “A lot of the tutors… are students and not many of them are Hispanic, especially in math… I tend to use Spanish to get my points across and sometimes we can’t really do that with someone that doesn't speak Spanish." Mathematics groupwork free of racialized judgment and an openness to speaking in Spanish would promote Kayla's vision of servingness.

Indrid's oppressive experience in groupwork restricted access to a community where she felt seen for her financial struggles, which played a major role in her view of being served as a low-income Mexican college student, "Honestly, it's [servingness is] just more financial help… Luckily for me, I got FAFSA. That helped with my tuition… groceries, just basic needs. And then housing is a struggle sometimes." Racialized tensions with white groupmates, such as the female peer who denied loaning her a textbook, reinforced structural inequities that limited Indrid's access to learning opportunities and therefore servingness in mathematics. When asked the extent to which Sonoma State serves Latin* students in mathematics, she critiqued the lack of faculty diversity, which she saw impacting comfort in seeking support unavailable in groupwork.

> In the group, I was always the social one, so I had to email the teacher… We should have a more diverse faculty… If we had a Latino or Latina math teacher… that would be good too because Hispanic, Latino students will most likely be more comfortable talking to them and reach[ing] out for help than a white teacher that they are most likely intimidated by.

Indrid viewed having Latin* professors for mathematics increasing access to support for overcoming struggles in groupwork. Presence of Latin* mathematics faculty would enhance servingness for Indrid by expanding her community of racially-affirming support at Sonoma State, which can mitigate oppression due to stereotypes and structural inequities in groupwork.

Unlike Kayla's and Indrid's groupwork experiences that departed from their conceptions of servingness, classroom norms of mutual respect and social awareness that guided groupwork in Oliva's classroom aligned with her views of being served as a Mexican female at Sonoma State. She perceived open dialogue in her mathematics classroom as resonating with her Mexican family's value for communication, which she described as important to her success, "There was just much more communication [in the class], which I personally need, especially… coming from the family that's mostly just speaking to each other on how to get points across. I feel like, at least in that class, I thrived." With the classroom experience of "having that conversation" about mutual respect being likened to communication practices in her family, this instructional practice advanced servingness for her because it established a collaborative space attuned with her values in her family and culture as a Hispanic mathematics learner. Oliva perceived Sonoma State serving her as a Mexican female by providing transformative educational opportunities that go beyond those that her family can offer and will inspire future generations.

> I have the opportunity to continue in education… That's something I don't come from. My family, definitely not… It's what I've been told, 'This is what you can do to better yourself and everyone that comes before and after you.' So, just the fact that I'm given the opportunity to be able to do that… I'm truly grateful... When you say [Sonoma State] serves me… that's what it is… A home away from home, but with more opportunities… It changes you as a person… I'm also first-gen, low-income, have younger siblings and other people at home I gotta impress, pave the way, [and] get there so they can get there with a little more support. But it just makes you a stronger person at the end of the day.

Personal transformation through education in Oliva's perspective on servingness is evident in the long-term positive impact of open dialogue in her mathematics classroom. She shared, "That [the value of communication in class] opened up a lot of doors for me… That class has led me to where I'm at right now. I can talk to the professor, not having to be [about] math… That little seed right there has really been pushing me." Such open communication, which established classroom norms of respect, nurtured Oliva's personal growth as a Mexican female. She overcame fears of racialized judgment in peer collaboration and actively sought faculty support, both academic and personal, that motivated her persistence. Thus, the disruption of racial exclusion in groupwork contributed to transformative learning opportunities that Oliva sought in being served at Sonoma State and provided her with a community of support in mathematics.

Discussion

The scholarly significance of our findings is threefold. First, our findings add knowledge to address the lack of clarity about groupwork approaches for equity (Hwang et al., 2022; Reinholz, 2018). Our analysis contributes to research on racially-equitable collaborative learning in mathematics (e.g., Bhattacharya et al., 2020; MacArthur & Dobie, 2023) by elucidating how groupwork expanded and constrained identity-affirming support for Latin* students. Second, the study deepens understandings of equity-oriented instruction in gateway mathematics courses through its focus on a single racially-minoritized group (Latin* students) and a single type of classroom practice (groupwork). By centering three Latin* first-generation college women in the findings, we also shed light on intersectional complexities on how gender overlapped with race, language, and social class to impact equity in groupwork. Third, our study addresses limited inquiry on instructional experiences for servingness in STEM. The findings provide a novel view of how HSI structures that foster community can inform equitable groupwork in mathematics.

Our analysis raises implications for research. Future studies can examine perspectives from mathematics faculty at HSIs on designing groupwork opportunities that promote equity for Latin* students. Exploring how these views converge and diverge from students' conceptions of servingness can orient faculty learning in translating HSI missions of culturally-affirming support into instructional practices. Additional research on student experiences of groupwork and other classroom practices across various HSI contexts with different Latin* populations can inform more robust understandings of servingness in undergraduate mathematics education.

In terms of implications for practice, Latin* students' isolation in racially-segregated groups as well as limited access to faculty and peer support underscore how faculty play a key role in structuring groupwork to mitigate oppression (e.g., Oliva's instructors setting norms for socially-conscious collaboration). Faculty can make informed decisions about grouping arrangements by learning about students' backgrounds and collaboration histories using a short survey at the beginning of the semester. In addition, faculty can structure groupwork tasks with rotating roles and frequent check-ins to ensure Latin* students are collaborating well with peers, engaging deeply with the mathematical content, and receiving adequate support. Latin* participants' references to campus support structures at Sonoma State where they experienced servingness (e.g., Educational Opportunity Program office, multicultural sorority) raise implications for mathematics departments about building partnerships with such offices and units. Mathematics faculty and student support leaders can share their respective struggles and successes in providing Latin* students with a racially-affirming community. Such exchanges can guide faculty to structure instruction, including groupwork, that enhances servingness in mathematics.

Opposing Dimensions in Mathematicians' Counter Narratives Written for Undergraduate Students

In mathematics, counter narratives can be used to fight the dominant narrative of who is good at mathematics and who can succeed in mathematics. Eight mathematicians were recruited to co-author a larger NSF project (RAMP). In part, they were asked to create author stories for an undergraduate audience. In this article, we use narrative analysis to present five polarities identified in the author stories. We present various quotations from the mathematicians' author stories to highlight their experiences with home and school life, view of what mathematics is, experiences in growth in mathematics, with collaboration, and their feelings of community in mathematics. The telling of these experiences contributes towards rehumanizing mathematics and rewriting the narrative of who is good at and who can succeed in mathematics.

Keywords: Counter narratives, narrative analysis, mathematicians

Stories provide a particularly powerful way to make sense of our lives and provide structure to society. Stories may be personal narratives, the narratives we tell ourselves about our lived experiences, as well as dominant (master) narratives that are culturally shared. In the United States, there are prevalent deficit narratives in relation to students of color (e.g., Adiredja, 2019; Berry III et al., 2011) and women (e.g., Leyva, 2017) and their ability to do mathematics. As elaborated by Berry III et al.,

> Master narratives embody and dictate expectations about how things work and how stories are framed. Often, master narratives present contrasts between groups of people by advantaging dominant groups and disadvantaging members of marginal groups such as women and people of color (p. 11).

An important means of challenging dominant (or master) narratives are *counter stories* or *counter narratives* (e.g., Solórzano, D. G. & Yosso, 2002) which run counter to status quo and dominant narratives. Many scholars have presented such narratives as a way to disrupt prominent stories of who is good at math and who can succeed at math (e.g., Berry III et al., 2011; Harris et al. 2011; Langer-Osuna et al., 2016; Leyva, 2016; McGee, 2009). These narratives are often crafted by researchers or those marginalized and brought into spaces to perturb and make change.

Narratives themselves are constructed with a certain audience in mind. Kaasila (2007b) explains, "when we are telling a narrative (or narratives), we often take our audience into consideration and adapt what we say and how we say it accordingly" (p. 206). In this project, we examine a set of narratives that were crafted explicitly for students to read in undergraduate proof courses. Eight mathematicians whose stories challenge the dominant narratives of who can succeed in mathematics, provided two-page biographies for students.

In this proposal, we share an analysis of these narratives, identifying rhetoric and plots these mathematicians shared. For the scope of this paper, we present findings from the portion of our analysis focused on "key rhetoric" (Kaasila, 2007a) indicating opposing polarities internal to the author's stories. This analysis is led by the following research question:

What opposing dimensions are salient in mathematicians' career counter narratives as told for a student audience?

Narrative and Mathematical Identity

A narrative approach to identity emphasizes that identity is created by the stories we tell about our lives. Narratives are stories that include events that are "attach[ed] to a character" (Kaasila, 2007b, p. 206) and are organized into plots. Identity is then a "subjective, constructed, and evolving story of how one came to be the person one currently is" (McLean & Syed, p. 320). Furthermore, the author of a narrative imparts coherence to the story. Kaasila (2007a) identifies, "[k]ey rhetoric [a]s a coherence system through which different life events are connected and their relation is explained by dividing the narrated world into different dimensions of reality" (p. 377). Kaasila (2007b) further asserts that key rhetoric often points to expectations, whether met or subverted, adapting Tennen's (1979) notion that expectations determine how narratives are shared. That is, the author of a narrative may be framing their story as adhering to or subverting their own or societal expectations.

Relatedly, many scholars argue for distinctions between master (or dominant) narratives and alternative (or counter) narratives. McLean and Syed (2016) elaborated that, "Master narratives are culturally shared stories that tell us about a given culture and provide guidance for how to be a 'good' member of a culture; they are a part of the structure of society." These narratives may be unproblematic if one's life easily fits into the dominant narratives. However, one's personal narrative may involve adopting an alternative narrative that differs or resists the dominant narrative. We take on McLean and Syed's stance implying there is *negotiation* between self and society and *internalization* of dominant narratives. We would anticipate that subversion of expectations may be reflected in personal narratives when alternative narratives are provided of who is good at math and what it means to do mathematics.

Mathematics identity becomes salient when one tells stories of their mathematics experiences including "stories about one's relationship to mathematics, its learning and teaching. This means that a person's mathematical identity is also context bound and always under construction" (Kaasila, 2007b, p. 206). Martin (2007) suggests that mathematics identity is the "dispositions and deeply held beliefs that individuals develop about their ability to participate and perform effectively in mathematical contexts and to use mathematics to change the conditions of their lives" (p. 15). From a narrative perspective, this means considering how one's stories and experiences with mathematics are constructed within their institutions, communities, and in relationship to sociohistorical dominant narratives (Larnell, 2016). That is, mathematics identity is reflected in the stories told of how one arrived at their current dispositions and beliefs, and how expectations were subverted or maintained in this process.

Methods

Eight mathematicians joined the larger RAMP project team to develop curriculum materials for introduction to proof. The mathematicians were selected based on their reputation in the field and via snowball sampling (Parker et al., 2019). That is, mathematicians recommended colleagues and friends who are active in the field and dedicated to supporting a more diverse and inclusive mathematics community. Amongst the group of eight mathematicians, two identify as Black/African American men, one identifies a Black woman, one a Black and Chinese woman, one as a Latinx woman, one a Latino man, and one a woman and Native Pacific Islander.

The eight participating mathematicians were asked to exhibit mathematical results (without restriction on the origin of statements) through proof writing based on their own intended goodwill and mathematical expertise. The authors refined their work through team-led proof sculpting--a process to reduce the noise of mathematical exclusivity in favor of amplifying reception by vetting choices of transmission based on a form of accessible reasoning. This type of collective engagement recasts expertise. The resulting pieces run counter to the style prevalent in research mathematics: Concluding the veracity of a mathematical statement does not have to cost the reader (nor the author) their humanity as an act to pay homage to mathematical elitism. These costs and refutations were mentioned amongst other themes in author stories that were requested to accompany the proofs. A set of guiding (but not required) questions were provided to help shape the author stories which had an overarching aim of sharing how the mathematicians arrived at their current career. These included prompts about their life before becoming a mathematician, finding meaning and joy in math, struggles and overcoming struggles, and what it means to do mathematics. Each narrative was roughly two pages and designed to be part of the curriculum provided for students.

We took an “analysis of narratives” approach (Polkinghorne, 1995) analyzing the narratives for themes that hold across them. We focused on mathematical identity markers, mathematical socialization markers, key rhetoric reflecting polarities, and plot features. The plot features and key rhetoric were adapted from Kaasila (2007a) where plots were considered in terms of *outcomes*, *key events*, and *important people*, and key rhetoric to identify how incoherent or differing dimensions of life stories are connected. All instances of contrasting language such as “but”, “however”, or explicit language such as “contradiction” or “surprise” were identified in order to identify and analyze the “polarities” described in the mathematician stories. To focus on mathematical identity, we adapted Larnell’s (2016) coding scheme marking instances that reflected, “importance of mathematics”, “motivation”, “strategies”, “opportunities”, “constraints”, and “capacity to perform.” For socialization, we used Larnell’s categories: “institutional”, “sociohistorical”, “community-home.” We note that it is in the sociohistorical category we are most likely to observe dominant narratives endorsed or contradicted in the mathematician stories. Each story was read and analyzed independently by two members of the team. In the next section, we report on some of the polarities that were salient in relation to mathematical identity and socialization as indicated by key rhetoric in the narratives.

Results

For the scope of these results, we share a series of polarities identified and some quotes that illustrate the ways they were discussed in the narrative collection.

Polarity: Home and School Life

An early polarity observed through the narratives was a divide between home and school. This polarity difference was not always experienced the same, but the contrast between the two environments was salient. One mathematician shared that mathematics was an escape, elaborating, “In a whirlwind of instability, I could always rely on math to be a subject where I could solve problems and feel good about the world.”

However, more commonly, school was described as constraining with one mathematician explaining:

> As a child and teenager, I was diligent and shy at school, while being loud, goofy, and creative at home. Most of my weekends were spent gathering with our large extended family, celebrating our Indian heritage. I remember these times fondly. I felt, and still feel, at home with my cousins, in sharp contrast to how out of place I felt at school.

Similarly, another mathematician contrasted school as causing an “academic conflict” that became problematic as the rigidity of the “high school schedule” contracted with their earlier experiences both with the philosophy of Montessori and also the “freedom of viewing/connecting dots outside of the classroom.” That is, the school setting was presented as a constraint (in various ways) in their mathematics story.

Finally, we note another contrast that emerged in some of the stories: the math opportunities outside of school versus inside whether those be competitions, or camps, or in the case of one mathematician’s games,

> Whether it was finding the logic to solve a puzzle or simply counting dominoes to record the score of a game, I really enjoyed it all. In school, the story was a little different. I always performed well in math classes but found them repetitive and not very interesting.

It seemed frequently outside experiences of math were salient to supporting interest.

Polarity: Mathematics as Creativity and Computation/Speed

A related polarity can be found in mathematicians’ descriptions of what mathematics is. As seen in that last quote, school mathematics was often linked to its “repetitive” and closed nature. It was common for stories to contrast earlier understandings of what mathematics is, such as one mathematician noting, “I thought all the interesting questions had been answered and that being a professor meant knowing all the answers.” To follow up this statement with “Spoiler alert: none of that previous sentence is true.” There were often key events that led to this shift such as research opportunities.

Another relevant storyline is the way that the dominant narrative around mathematics, that what it means to be good at mathematics, is somehow tied to having absolute knowledge or speed. For example, one mathematician shared an experience learning a new topic that interested one of their students:

> I would imagine a few years back, I would be nervous about understanding a topic with which I was unfamiliar. I realized this was tied to my ego. I didn’t want to look like I didn’t know something about mathematics. This is a contradiction, it seems. If the mathematics I love is about ideas, then why is my ego involved? Why should I care about who did the problem fastest?

This quote describes two contrasts: the contrast between where the mathematician is now versus “a few years back” and the contrast between “speed” and “ego” versus “love” of mathematics.

Finally, we note one other way this polarity came out. One mathematician explained, “I try to convey that everyone (not only white men) can do math, that math is more than computation and arithmetic, and that math can be fun.” Here the contrast is explained in the context of making efforts to change a dominant narrative. It would be remiss not to note that nearly every author story did not conclude with them doing their mathematics work, but ways that they have integrated changing narratives for others into their lives.

Polarity: Mathematical Breakthroughs and Struggles.

Another polarity is part of what Larnell (2016) calls the strategies of mathematics. Related to ideas that math should be fast, with answers known immediately and quickly recited, is the inherent tension of breakthroughs and struggles. Across the stories, the mathematicians contrasted these elements with statements like: "To me, mathematics is messy and that is the beauty of it, because it allows me to be messy without judgment," "I became more comfortable with the fact that mathematics is very hard and that challenges are ok," and,

> The most glorious moments are always the breakthroughs of a new idea, or an epiphany. It's an indescribable moment that I hope we all get a chance to feel. One moment, the struggle is real, frustrating and long. I can feel like I am getting nowhere. There are times where it feels like I have wasted time. But when the moment of clarity arrives, it's worth it.

If we consider key rhetoric as bringing coherence to stories, we can see the ways that messiness, challenge, and struggle are all coherent parts of the beauty and joy of doing mathematics. While the polarities are in contrast, they are not in tension in the work of the mathematicians in their reflections on the present day.

Polarity: Isolation and Collaboration/People

Another dominant narrative frequently subverted in the stories was the idea that mathematics is not a human endeavor and that mathematical activity is meant to be done in isolation. This isolation was often highlighted as a part of their mathematical journey that contrasted with the joy they later felt. For example, mathematicians explained the challenges of feeling alone in school or the challenges related to research in their careers with one mathematician noting, "I found it very difficult to keep my research going since, at the time, I did not have collaborators."

Many of the mathematicians contrasted this isolation with feelings of joy in connecting with others through mathematics. For example, the mathematician above described a key event where they had given a talk and invited collaboration which led to:

> In the years that followed, we got together and had the best time cranking out some super neat results on posets and order dimension. It still brings tears of joy to my eyes when I think about those days in the basement of the math department at [blinded] with these phenomenal women because it was the first time I truly felt like an honest-to-goodness mathematician, working on some very cool math with some very cool people.

Others described the joy in collaboration or made similar comments about the integration of people and mathematics. One mathematician noted, "I came to realize that I find the most meaning in mathematics through human connection and interaction" or another reflected, "So what brought me back to this world of academic and research mathematics? People."

We note that the role of people went further than just people to do mathematics with, but also included the many role models, family members, and community in the lives of the authors. As one mathematician noted, "Who are the people who support us unconditionally? Surrounding yourself with these people can create a life more expansive and fulfilling than you can possibly imagine."

Polarity: Outlier and Belonging

Finally, we note one last polarity related to the human element: belonging or being an outlier. This polarity is intimately tied to representation and the people around you. The mathematics discipline is notoriously white and male. When taking classes, mathematicians mentioned ideas like, "this love for combinatorics did not remedy how alone and isolated I often felt not knowing other people like me in mathematics," "I am often the odd one out racially and/or culturally wherever I go," and,

> On the other hand, I often felt out of place in many of my classes at [blinded university] as a woman of color. I remember constant signaling from my peers and other professors that I didn't belong in math. I found refuge from these experiences through my hobbies and social life, and especially through my participation in a competitive collegiate dance.

One mathematician reflected that they still feel a degree of imposter syndrome despite their CV:

> You might never guess that is how I feel when you look at my CV and all of the math I have done and learned along my mathematical journey. Yet, that feeling lingers. Now that I am older, I understand that some of that feeling is often triggered because I did not see myself reflected in those who I considered mathematicians: my teachers and professors. The fact remains that being Latinx and a woman means I am often one of the few in a room who is not part of the dominant group in mathematics: male and white.

This feeling of "not seeing" oneself amongst others in mathematics was quite salient. Key events in the authors' stories would allude to seeing themselves represented or collaborating with others that are not part of the dominant group.

For example, one mathematician noted the impact of seeing a Black, male professor explaining a critical moment,

> A tall large Black man entered the room. He took his suit jacket off and said: "I am [name blinded]. This is analysis." He began to detail the course and what it was about. It was at this moment where I whispered to myself: "That is who I want to be."

Across the stories, mathematicians talked of building community and not just in the sense of collaboration above but building community amongst others like themselves. With one mathematician explaining,

> I worked to find a community of mathematicians where I do feel like I belong. The mathematicians I am closest to are not only my colleagues, but also my friends. We connect on shared values and views and work together to promote equity and justice in the mathematical community.

Further, as discussed above, this work was also done to open doors for others coming up, students, young scholars, and as one mathematician noted about the stereotype of who does math, "By dispelling this stereotype, we create a more inclusive culture for mathematics.

Discussion

An overarching goal of stories and narratives is to center the humanity of both the individuals and their communities. Humanizing mathematics has been a part of the endeavor to improve education of mathematics in service of justice and inclusion (e.g., Berry III, 2021; Tan et al., 2022; Yeh & Otis, 2019). If we want students to see themselves as doers of mathematics, it is necessary that we problematize popular narratives of mathematics in terms of both who is capable of doing mathematics and what mathematics is. Some of this work has been championed taking a humanistic approach to mathematics. In summarizing Hersch's contributions, Pais (2018) explained, "the purpose is not (only) to study mathematics in itself, but as an activity, developed by humans in a variety of different settings" (pp. 235-236). This approach stands in stark contrast to the materials often provided in proof-based classes. Davis and Hersh (1981) elaborate that proofs often obfuscate the humans involved with an "ideal" mathematician writing to "conceal any sign the author or the reader is a human being. It gives the impression that, from the stated definitions, the desired results follow infallibly by the purely mechanical procedure" (p. 36).

If we consider the narratives provided, we can identify many ways that mathematics, as engaged in by mathematicians, is a fully human experience. People and communities shaped the stories told. These narratives eschew not only dominant narratives that only certain types of people should and can succeed at mathematics, but also what mathematical success entails. The stories elaborated on how school mathematics geared towards speed and computation is not necessarily the mathematics of joy and discovery that supported and inspired the authors' journeys. The mathematicians were agents in the stories, and the proofs they produce are not authorless. As we consider ways to humanize mathematics for students, author stories can provide a powerful means to challenge the status quo. While it is unlikely that the norms of how proofs are written will shift any time soon, we can certainly take strides in pulling back the curtain and sharing not just the final product, but the process and the people involved.

Active learning in STEM classrooms has been shown to increase student outcomes in multiple ways. We present here a discussion of data analysis supporting these types of conclusions using data from a large-scale randomized study of the implementation of an active learning-based curriculum for Calculus I that collected 1019 observations of student outcomes over three semesters. We compare fixed-effects models including cluster levels of student learning outcomes to mixed-effects models with random cluster level effects. We discuss the differences between the models and the resulting effect sizes suggested by the different factors included in the models.

Keywords: calculus, regression model, fixed effects, mixed effects

Introduction

Evidence of the effectiveness of active learning (AL) classrooms in STEM includes increases in student achievement, attitudes, and persistence in college (Duran et al., 2022; Ellis et al., 2016; Freeman et al., 2014; Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023). Most of these studies have measured this effectiveness by conducting non-randomized experiments and focused on evidence gathered from observational studies or performed meta-analyses of studies with varying implementations in order to interpret the outcomes across a collection of studies with different sets of participants or contexts. In (Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023), the authors present a large-scale study of the implementation of an active learning-based curriculum for Calculus I that collected 1019 observations of student outcomes over three semesters with a variety of instructors teaching at multiple times. On the one hand, this study presents compelling evidence that student learning in an active curriculum has the potential to be far more effective than in traditional lecture-based paradigms. The random allocation of students to the treatment and control conditions allows the comparison of student outcomes across populations while controlling for multiple demographic factors including incoming mathematics background, race and/or ethnicity, gender, and student enrollment status. At the same time, students are grouped into sections at the same time of day/day of week and instructors will be present in different sections, introducing random effects on student outcomes (Hedges, 2009).

In this work, we present a fixed effects model (FEM) of student learning outcomes dependent on multiple demographic factors and show that the differences between the treatment and control group outcomes are statistically significant. We then compare that FEM to the mixed-effects model (MEM) in (Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023) and discuss the ways in which the random effects in that model compare to the FEM properties. We also discuss changes to the MEM and show that the MEM presented in (Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023) and using the data set from that project here (Kramer, Fuller, Watson, Castillo, Duran

Oliva, et al., 2023) possesses the same structure as both the FEM as well as these other models. Finally, we provide a comparison of the effect sizes and confidence intervals for different models.

Methods

In (Castillo et al., 2022; Duran et al., 2022; Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023) the authors collected data from a trial of an active learning based curriculum where students were randomly allocated and presented a number of outcomes analyses. In this study, 1019 students were randomly allocated to either the treatment condition which utilized the Modeling Practices in Calculus (MPC) approach to student learning or the control setting based on existing instructional practices that were primarily lectured based. Student data was collected from institutional records that provided potential fixed demographic effects on student outcomes including mathematics background from standardized tests/high school GPA (*MBS*), gender (*Gender*), race and/or ethnicity (*RE*). Along with these data, the section of the course (*Section*) and the instructor of record (*TIDw*) were recorded as random effects that depended on student choices made during enrollment. In addition, student outcomes were recorded both as grade outcomes in the course as well as a measure of student learning, *LearningMeasure*, collected from embedded final exam questions implemented within the common final administered across all sections of the courses and assessed in a blinded form by multiple evaluators (Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023).

Using these data, a fixed effects model with interacting terms can be constructed to determine the dependence of the measure of student learning from the study, *LearningMeasure*, on these factors including the cluster levels *SecPair* to represent the grouping of participants by their time of day and day of week classroom groups. Note that these sixteen pairs then split into 32 based on random assignment, and this is also a representation of the instructor level clustering. The linear model used here is then

$$\begin{aligned} LearningMeasure_i \sim & \beta_0 + \beta_{i1} Treatment_i + \beta_{i2} MBS_i + \beta_{i3} Gender_i + \beta_{i4} RE_i + \\ & \beta_{i5} SecPair + \\ & \beta_{jkl} Treatment_{ij} MBS_{ik} Gender_{il} + \epsilon_i \end{aligned}$$

where *LearningMeasure* is the vector of students' scores, *Treatment* is the predictor (a dummy variable, 0:Non-MPC sections; 1: MPC sections), β is the regression coefficient for the covariates measured, and ϵ is the vector of residuals, assumed to be distributed N(0,2I). Other variations involving either *Section* or *TIDw* for cluster levels as fixed effects were not considered, as they introduced collinearity with *Treatment*. Similarly, a variation of the mixed effects model presented in (Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023) can be constructed using the fixed effects above but instead applying *SecPair* along with *Section* and *TIDw* as random effects. Models were implemented in R (R Core Team, n.d.) using the glm and lme4 (Kuznetsova et al., 2017) packages.

Results

Coefficients for the FEM with both interacting and non-interacting terms along with a model with Treatment as the only fixed effect were computed and found to have the values shown in Table 1. The model shown using the sixteen cluster levels of *SecPair* also has the interaction terms of the first model.

Computing effect sizes within a MEM is more complicated and in general must be approximated (Hedges, 2009). The effect sizes for each section pair were computed and shown in Table 4, and the precision weighted effect size (DerSimonian & Laird, 1986) for the Treatment effect computed from those using the standard error for each.

Table 4. Effect Sizes for Each Section Level Pair of Treatment and Control groups

Section Pair	Hedges *g*	95% Confidence Interval lower	upper
1	1.097	0.483	1.748
2	-0.501	-1.094	0.076
3	1.003	0.400	1.639
4	2.221	1.412	3.127
5	-0.259	-0.903	0.375
6	0.569	-0.001	1.158
7	0.200	-0.591	1.004
8	1.662	0.655	2.800
9	0.673	0.104	1.262
10	0.993	0.453	1.560
11	0.932	0.362	1.530
12	0.899	0.309	1.518
13	1.226	0.699	1.782
14	1.021	0.375	1.706
15	0.740	-0.185	1.727
16	0.808	-0.142	1.828

In some cases, the variance of the outcome data due to the number of data points in some pairs increases the error and uncertainty in the outcomes for that cluster. This pattern is reflected in a forest plot of the effect sizes (Hedges' *g*) computed within the section pair clusters as shown in Figure 1.

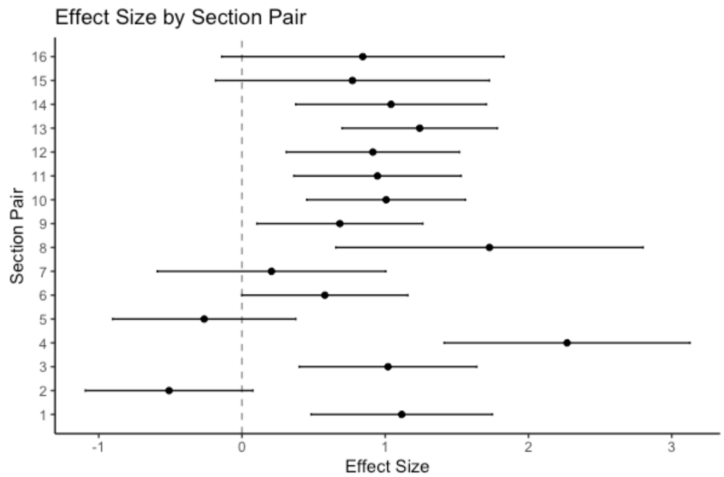

Figure 1. Forest Plot of Section Pair Effect Sizes

Of the 16 pairs, twelve have statistically significant increases in outcome for the Treatment section, and four do not. Two of the four with indeterminate outcomes are positive effects, and two are negative. The precision weighted effect size in this case is d_{pw}= 0.8008 (CI [0.4589, 1.1427], t=4.99 p=0.0002).

Discussion

The fixed effects model indicates that the treatment condition is statistically significant even in the presence of the other fixed effects. Specifically, the models show that the treatment is statistically significant and positive even in the model with interactions (β = 30.48, 95% CI [7.30, 53.65], t(660) = 2.58, p = 0.010) when controlling for mathematics background, race/ethnicity, and gender. The FEM interaction terms are found to be insignificant (the null hypothesis of zero-valued coefficients cannot be rejected). In addition, the model without interactions is found to have a better fit (AIC = 5787.4) than the model with interactions (AIC = 5792.7), but the model with interactions and the SecPair cluster levels is best (AIC = 5767.6) with a coefficient of β =28.91 which is almost equivalent to the non-interacting estimate. This model compares well to the mixed effects model that includes random effects from the *SecPair*, *Section* and *TIDw* clusters. In that model, fixed effects were found to explain 39.4% (with marginal R^2=0.303) of the outcome while the FEM was found to explain 38.4% (R^2 = 0.384) of the outcome with interactions and SecPair cluster levels. The MEM is perhaps preferred since it incorporates the impact of student choice of section and the presence of the instructor, but this analysis shows that these factors explain approximately ~10% (conditional R^2=0.1) of the outcome in this data. In determining the treatment effect on outcomes, the FEM gives a similar model for interpretation even though the MEM is a slightly better fit. One benefit of the MEM approach, however, is that it also characterizes the intraclass correlation (ICC = 0.13) for these underlying clusters and provides some insight into the degree to which those correlations might impact the outcomes. In (Kramer, Fuller, Watson, Castillo, Oliva, et al., 2023), the fixed effect Cohen's d = 0.774 (CI [0.618,0.930]), and cluster adjusted effect size from the random effects of the MEM d_T =0.771, CI [0.468,1.073] are consistent with the metanalytic approach here using only the section pair data.

The coefficient similarities between the linear FEM and the MEM with random effects in some sense reflect the fact that the data form distinctly linear structures when modeled on the strongest effect, *MBS*. As shown in Figure 2, a LOESS curve approximation of the data plotted within a scatterplot of *LearningMeasure* against *MBS*, we see that the majority of the curve is linear in nature with low levels of uncertainty, and that only in the outlier regions where few data points exist do the curves show high levels of non-linearity and uncertainty.

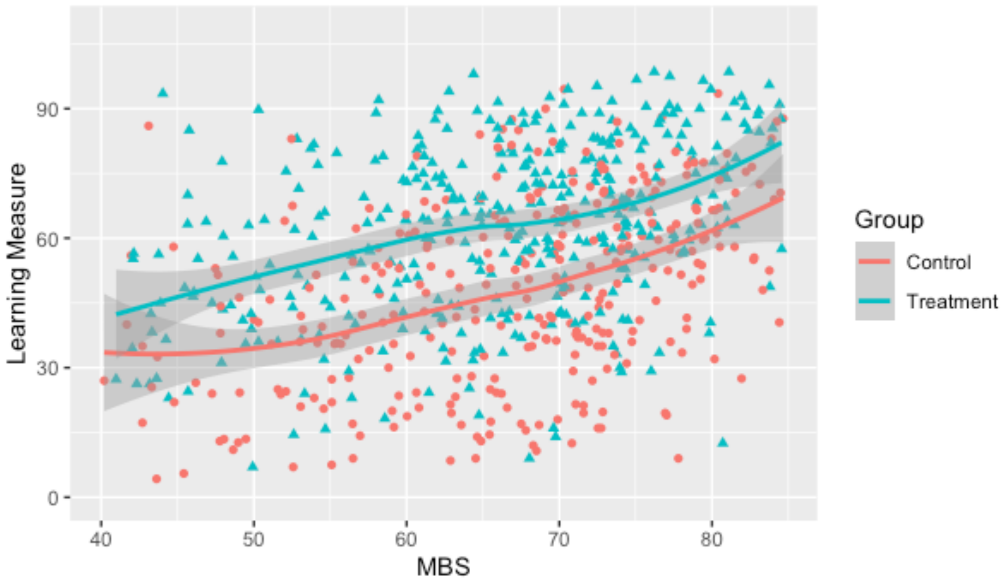

Figure 2. Scatterplot of LearningOutcome Against MBS (Math Background Score) for Treatment and Control Groups with LOESS Curve Approximations. Dark Grey Areas Indicate the 95% CI Surrounding the Approximating Curve

Conclusions

In the data analyzed in this article, the underlying cluster structure has a relationship to the outcome variable variance but this explanatory power is small when compared to the other fixed and random effects. The impact of the time of day/day of week of the courses was on the order of 50% of the effect found for *Treatment* and *MBS* in the FEM. The estimates for the coefficients of *Treatment* in all the models are similar and the computed effect sizes are consistent using either model. The MEM approach has the advantage of estimating the relative variance due to cluster levels in a way that represents their underlying random nature, while incorporating *SecPair* into the FEM approach yields similar results. Both analyses support the conclusion that the treatment condition led to medium to large increases in student learning outcomes.

Dynamical Systems and Mathematical Practices for Future Secondary Teachers

Gerardo Cruz

Chris Rasmussen
San Diego State University

The relevance of upper division mathematics courses for future secondary teachers is a longstanding thorny issue. Suggested improvements include capstone courses and revised upper division content courses to explicitly address future teachers' relevant secondary mathematics content knowledge, beliefs about teaching and learning, and experience with learning mathematics while engaging in authentic mathematical practices. In this report, we investigate prospective teachers' reflections on their opportunities in an upper division Inquiry-Oriented Dynamical Systems course to engage in the eight Common Core State Standards for Mathematical Practice. Analysis of students' self-reported engagement in the eight Practices revealed five practices that strongly resonated with them and the various ways that their experiences in an inquiry-oriented classroom supported meaningful and powerful engagement in these Mathematical Practices. We conclude with implications for practice.

Keywords: mathematical practices, inquiry, prospective teachers, dynamical systems

The relevance and usefulness of upper division mathematics courses for prospective secondary school mathematics teachers has long been of concern (Begle, 1972; Klein, 1932; 2016; Wasserman et al., 2019). A number of studies document that teachers find their advanced mathematics courses have little relevance to their teaching (e.g., Cofer, 2015; Wasserman, 2017, Zazkis & Leikin, 2010). While these challenges are longstanding and pervasive, professional organizations have outlined possibilities for improving the connection between university and secondary mathematics for prospective teachers (Association of Mathematics Teacher Educators [AMTE], 2017; Conference Board of the Mathematical Sciences [CBMS], 2001; 2012). Creating capstone courses is one approach. Another recommendation, and the one taken in our work, is to redesign upper division math content courses so intentionally strong connections to high school mathematics content and teaching are made.

In recent years progress has been made on the university-secondary mathematics connection. For example, a recent issue of *ZDM Mathematics Education* focuses on how the intersectional nature of mathematical and mathematics educational content might be addressed in a wide range of university courses in order to prepare better secondary mathematics teachers (Wasserman et al., 2023). We contribute to this uptick in progress by investigating the opportunities for prospective teachers in an Inquiry-Oriented Dynamical Systems and Modeling (IODSM) course to engage in the eight Common Core State Standards for Mathematical Practice (MP) (Common Core State Standards Initiative [CCSSI], 2010). The eight Standards are: 1) Make sense of problems and persevere in solving them, 2) Reason abstractly and quantitatively, 3) Construct viable arguments and critique the reasoning of others, 4) Model with mathematics, 5) Use appropriate tools strategically, 6) Attend to precision, 7) Look for and make use of structure, and 8) Look for and express regularity in repeated reasoning. In particular, we address the following research question: *How frequently do prospective teachers in an IODSM course report engaging in the eight Standards for MP and how do they describe their engagement in these Standards?*

In related prior work, Apkarian et al. (2023) investigated the impact of an IODSM course on prospective teachers' knowledge of rate of change, their shifting beliefs about learning and teaching, and their self-reported ways in which their emerging beliefs and knowledge would influence their future practice. The work reported here adds a new dimension to this prior work by examining IODSM student-reported connections to the eight Standards for MP.

Theoretical Background

The "inquiry" part of the IODSM course is heavily influenced by the following four pillars of inquiry described by Laursen & Rasmussen (2019): 1) Students engage deeply with coherent and meaningful mathematical tasks, 2) Students collaboratively process mathematical ideas, 3) Instructors inquire into student thinking, and 4) Instructors foster equity in their design and facilitation choices. In the IODSM course, students collaboratively reinvent mathematics by engaging in the kind of work that potentially reflects how mathematicians go about their work and which are embodied in several of the Standards for MP. Our use of reinvention is informed by the instructional design theory of Realistic Mathematics Education (RME), which views mathematical concepts, structures, and ideas as inventions that humans create to organize the phenomena of the physical, social, and mental world (Freudenthal, 1973).

Our work is also informed by the emergent perspective (Cobb & Yackel, 1996), which views learning as both an individual and social process. Of particular relevance for this report are the emergent perspective's constructs of social and sociomathematical norms. Social norms refer to regularities in discourse, such as students routinely explaining their own thinking, listening to and attempting to make sense of others' thinking, asking questions if something is unclear, and indicating their agreement or disagreement with reasons. We conjecture that social norms have considerable overlap with the first and third MPs (Make sense of problems and persevere in solving them and Construct viable arguments and critique the reasoning of others). Also related to these Standards is the sociomathematical norm that justifications be based on underlying concepts as opposed to appeals to procedures or external authorities such as the text or instructor. This particular norm may, for example, relate to the third and sixth Standards for MPs.

In this report we do not examine actual classroom interactions and hence the full power and full set of constructs of the emergent perspective cannot be leveraged. Instead, we use the constructs of social and sociomathematical norms to reflect on the extent to which students' report how often they engage in the various Standards and the nature of that engagement.

Methods

The participants were 30 students enrolled in an upper division IODSM course at a large, Hispanic-serving institution in the southwestern United States. This course fulfills an upper division math elective requirement and it was designed specifically for prospective secondary teachers by infusing content related to high school mathematics. We collected qualitative data from a survey taken at the beginning of the semester, a detailed homework assignment where students explored the Standards for MP (CCSSI, 2010) and their connection to their experiences in the IODSM course, and an hour-long interview with a subset of students. In this report, we only discuss findings from their written homework assignment.

On this homework assignment, students reflected on how their IODSM classroom experiences relate to the Standards for MP. Students were asked to read the eight practices and categorize each practice into one of three bins based on how often they experienced the MP in class, and to explain why they placed each practice into the Bin that they did. Bin 1 was the most opportunities, Bin 2 was some opportunities, and Bin 3 was the least opportunities. Students also provided an example from classwork to support their justification. The assignment provided insight into students' understanding and engagement with the Standards for MP. It allowed for an in-depth exploration of students' perceptions and experiences, contributing valuable qualitative data to the field. By linking their experiences to specific Standards, the students provided a rich and detailed view of their interaction with the mathematical concepts laid out in the Standards, helping us gain a nuanced understanding of their learning experiences. We note that the Standards for MP were never discussed in class. Therefore, the responses from students reflect their own interpretation of the MPs.

To analyze the data, we used a thematic analysis approach, as described by Braun and Clarke (2006), to identify, analyze, and interpret patterns within the data. Students' responses were separated by MP into a spreadsheet that included their bin classification, justification, and the example. Note, if students mentioned uncertainty in placing an MP between two bins, we coded them as the less often bin. This happened only two times and both were deciding between Bin 1 and 2; and thus, they were placed in Bin 2. After data were organized, two researchers read students' responses and took notes according to their interpretation of the students' explanation to identify interesting aspects and patterns. Then all researchers met to discuss meaningful ways to organize and code the data. We discussed interesting trends students demonstrated as a response to their classification of bins and possible explanations for them. Initial codes were created for each MP and highlighted specific aspects of the MP description. Common themes helped to identify what parts of the MP students considered to experience the most in the class and why they placed each practice in the corresponding bin. After collapsing overlapping themes, re-working and refining codes, all authors agreed on the coding of all of the MPs. Lastly, we found the frequency of common themes. We also calculated the standard deviation for each practice. This allowed us to see which practices students agreed on more about engaging in and those that they did not. In this report, we focus only on practices where there was more agreement (low standard deviation) or modest agreement (medium standard deviation).

Results

The average number of the bin placement for each mathematical practice ranged from 1.032 to 2.000 (i.e., for some practices nearly all students selected Bin 1 [the most often bin] while for some practices the average selection was Bin 2 [the second most often bin]). Standard deviations were between 0.1796 and 0.7878. Three natural groupings of the practices emerged by standard deviation (SD), with three practices having SD less than 0.5 (most agreement), two practices with SD between 0.5 and 0.75 (modest agreement) and three practices with SD between 0.75 and 1 (least agreement). As mentioned, we only report on the practices with the most or modest agreement. We hypothesize that practices that received a higher SD can be partly attributed to the ambiguity of wording of the practices and/or students' personal interpretations. Table 1 lists the mathematical practices by SD group, as well as the themes identified across student responses and the frequency of occurrence for each theme. Only themes that were identified in the responses of at least one third of the class are listed in Table 1.

Practices with Most Agreement (Low Standard Deviation)

MP 1. The first theme for MP 1 was *highlighting the emphasis on making sense of problems* which was when students mentioned the importance of taking a step back to read and understand the problem to make sense of things. The second theme was *the importance of working hard and* *not giving up* which was when students reflected on attempting problems and their perseverance towards the correct outcome. This student response exemplifies making sense of problems:

> ... for a lot of problems in the class, you just cannot look at the given information and just solve for one variable, and that's it. There has to be more meaning to it, what exactly is the solution we are looking for, how do we work for the problem in question, what can we do and then we can attempt a method and change up our attempt if needed.

The students addressed the importance of making sense of a problem by stating that when working on a problem their solution approach cannot be deciphered by just looking at "one variable" or applying a single technique and solving for it, instead they dive further into finding meaning and value in the text, and only then, continue working towards a solution. That is, students in the class described that solving problems requires more than purely manipulating variables, they said that the solution has to make logical sense and they need to question themselves continually to check if their solution approach is right.

Students' responses coded as *importance of working hard and not giving up* referred to the importance of being perseverant when solving a problem and if they committed a mistake that they could step back and try a different approach. For example,

> Some of the problems that I encounter in class can be particularly challenging and require a great deal of patience and perseverance to solve. It is important to remain focused and persistent in working through these problems, breaking them down into smaller parts and utilizing any available resources or strategies to find a solution.

Students also described that due to the nature of the course more challenging problems were constantly being encountered which forced them to persevere in working out solutions. Also, students recognize that mathematics is not about getting the correct answer at the first try, but that it is important to persevere and change methods as necessary.

Table 1. *Student themes from Mathematical Practices.*

SD	**Mathematical Practice**	**Themes Identified**	**Freq.**
Low	(MP1) Make sense of problems and persevere in solving them	*Highlights the emphasis on making sense of problems*	30
		Importance of working hard and not giving up	11
	(MP2) Reason abstractly and quantitatively	*Contextualization or decontextualization*	20
		Doing mathematics with meaning	16
	(MP4) Model with mathematics	*Mathematics applications*	16
		Mathematical techniques	10
Medium	(MP3) Construct viable arguments and critique the reasoning of others	*Critiquing and revision of ideas*	22
		Group work and collaborative learning	22
		Constructing Arguments and Justifying Answers	13
	(MP6) Attend to precision	*Precision in communication ideas*	28
		Group work and collaborative learning	13

MP 2. Themes identified for MP 2 included *contextualization or decontextualization* and *doing mathematics with meaning.* An example student response for the first theme is "A lot of times we are given problems with context, then we create mathematical models of the scenarios, solve the problem using math, then relate our solutions back to the context/scenario" which highlights the transition between abstract mathematics and contextual understanding of the problem and vice versa. Additionally, some students talked about giving meaning to the variables when working with equations and functions in class and such responses were coded under the second theme of *doing mathematics with meaning*. For example, a student reported,

> This standard most directly applies to our use of putting differential equations into words. We explored each piece of a differential equation individually, and then we worked on putting a differential equation into a sentence. We spoke of a differential equation with meaning, rather than speaking out the signs, numbers, and letters as they are. We have used these statements of meaning in most of our work in this class thus far.

In the excerpt above the student mentioned that it is important to be aware of the symbolic representations of models in regard to the context, emphasizing the need to provide meaning to them. The student expressed the necessity to read equations with intention and comprehension. In addition, students described their experience in the class with differential equations as translating them into meaningful sentences rather than mere symbol recitation, which exemplifies the practice's aim to ensure students can contextualize symbols and equations in real-world problems.

MP 4. The fourth practice revealed that students were seeing differential equations as a powerful tool to model real world phenomena and the two main themes identified were *mathematics applications* and *mathematics techniques.* The first theme was when students mentioned real-world scenarios in which mathematical concepts were applied. For example,

> …there have been many times in the class where our problem is a model of a real-world situation, with examples of the salty tank problem, the helicopter problem, and the list problem just to name a few. I also think that we have been given the opportunity to think about whether the model fits the situation as for example when we were asked if the model of the fish population matched the mathematical model…

Student responses highlighted the application of differential equations to model real-world systems, which aligns with the practice's focus on using mathematical knowledge to address real-life situations. The second theme in MP4 was the use of *mathematical techniques* in facilitating problem solving. Responses which discussed the use of Euler's Method (or as we called it, the Tip-to-Tail method), graphs, slope fields, phase lines, and other math techniques were coded in this theme.

Practices with Modest Agreement (Medium Standard Deviation)

MP 3. Three main themes were identified for the third practice. These included *critiquing and revision of ideas, group work and collaborative learning and constructing arguments and justifying answers.* For the first theme students acknowledged the importance of peer review and critiquing of ideas when developing their understanding of mathematics and underscored the value of the collaborative nature of the learning experience. For example,

> ... We are asked to come up with our own explanations for certain answers or approaches. We have to share them with the rest of the class and also take critiques if others don't agree until everyone has a satisfactory answer and explanation. Many examples where groups would have to come up with a graph tend to cause some disagreement thus leading to more discussion and ultimately to a well-backed understanding.

The student described the active engagement in constructing explanations, presenting them to peers, and refining them through critique until a shared understanding is achieved. This not only embodies MP 3's focus on constructing arguments and critiquing reasoning but also echoes the collaborative nature of mathematical exploration emphasized in MP 3. Other students' described the collaborative nature of the course. The next most common theme for MP 3 was *group work and collaborative learning* which was attributed to responses mentioning the value of discussing problems with classmates, sharing ideas, and collectively analyzing and working on problems. The following excerpt by students mentions the use of group work daily in class which leads to discussions and support from teammates:

> Since this class consists of almost entirely group work, constructing clear and viable arguments is crucial as we are always explaining our thought process to everyone else in our group, and sometimes the rest of the class. In order to do this successfully we must fully understand what we are doing and be able to explain why each step was made … This class is a team sport, and that quality of respect is crucial as we are all in a learning environment where mistakes are welcomed as long as we work through them together and help each other out along the way…

The student above describes daily group work and emphasizes the process of understanding and exploring mathematical problems and the "team sport" reference signifies the collaborative nature of learning in class. Finally, the third theme was attributed to students who emphasized reasoning and justifying their approach to problems. For example, "although critiquing the reasoning of others is very much one of the more common things that happens during class, the construction of arguments is done in a way more informal which is the reason it is in bin 2". Other student responses expressed this sentiment, or the feeling that there was not always enough time available in class to construct careful arguments.

MP 6. Two main themes emerged for the sixth practice including *precision in communicating ideas and group work and collaborative learning*. Note the second theme around group work also emerged for MP 3. The first theme was attributed to responses which emphasized the clarity and exactness in mathematical communication, including a need to refine mathematical language and avoiding vague terms. For example,

> ....I feel that I have had the most opportunity in this class to engage in this mathematical practice because communicating in a precise manner underpins all the work that we do in this class. Whenever I ask a question, present a result, or draw a graph, I strive to be accurate with my spoken words and written statements….

The students who brought up this theme addressed the importance of communicating mathematical ideas and concepts to others with precise language which relates to the second theme identified for *group work and collaborative learning*. For example,

> Communication is a huge part of this class. Group work and class discussion is what makes this class impactful. If we were to do things on our own all the time, there is a low chance that if we were to get something wrong, we'd understand why and how to find the right answer. Communication with others keeps each individual on track when it comes to using the correct definitions and meanings, symbols, math processes.

Students who mentioned group work and collaborative learning in relation to MP 6 mainly pointed out communication with others and being precise in their language in doing so to get their ideas across. Additionally, students mentioned the importance of working with others as time to get constructive criticism on delivering their ideas.

Conclusion

The AMTE (2017) Standards state that effective mathematics teacher preparation programs should provide opportunities for prospective teachers to learn mathematics that enable them to engage in mathematical practices, and that mathematics content should be taught using teaching methods that serve as models of effective teaching (AMTE, 2017). Consistent with this call, we investigated prospective teachers' reflections on their opportunities in an upper division inquiry-oriented mathematics course to engage in the eight Common Core State Standards for Mathematical Practice. We found that students' self-reported engagement centered five practices (MP 1, 2, 3, 4, 6) as strongly resonating with them. There were three practices (MP 5, 7, 8) that had higher standard deviations in terms of which bins students placed them in. This meant there was not as much agreement on how these practices were reflected, from the students' points of view, in class. We posit high SD may have been because these practices appeared in the latter half of the assignment (so perhaps not read as carefully) and/or that students may not have understood aspects of the educational terms in these practices. Recall that the Standards were never discussed in class.

Collaboratively processing ideas showed up in more than practice (MP3 and 6). This relates to social norms (Cobb & Yackel, 1996) in that central to students engagement in class was the time to collaborative process ideas. Students discussed how sometimes mathematical concepts did not make sense to them until another student explained something or provided more information. Relatedly was the concept of being precise with language. A sociomathematical norm in the class was speaking with meaning (e.g., avoid saying "it"). Being precise in language is not only critical as an MP but also important for future teachers to be precise in their language when engaging with their future students. Lastly, the idea of critiquing was often discussed. Importantly, some students took a negative connotation to critiquing in that they argued that they did not *critique* but they went back and forth discussing mathematics until concepts were agreed upon. Whereas some students fully embraced what it means to critique in their IODSM class. To them, it was important to critique because it meant that ideas were only getting better when the class critiqued reasoning to improve upon said reasoning.

Our next steps are to analyze the interviews already conducted which investigated student perceptions of the MPs in deeper detail, their beliefs about learning and teaching mathematics, and the connections they made between the upper division college mathematics content and secondary school mathematics. We also intend to conduct additional iterations of this course, at the same and different universities, expanding our focus to approximations of practice.

Networking Theories to Investigate Status and (In)equities in Small Group Proof Contexts

Carlos Acevedo
Texas State University

Jenna Ashby
Texas State University

Efforts have been made to study (in)equity in undergraduate mathematics education research. Across various fields, there is a foundation of work on how status impacts students' learning and participation in small groups as well as how differing patterns of interaction contribute to inequitable outcomes. This report contributes a networked theory for analyzing relationships between status and (in)equity in general. We argue that applying this methodology to proof-specific contexts has the potential to uncover how status hierarchies form in proof classrooms using group work components. We hope to promote conversations within the RUME community around taking actionable steps towards delegitimizing status hierarchies in proof classrooms.

Keywords: Status, Inequity, Small Group, Proof

Generally, increasing student-student interactions in classrooms changes the quality of interactions, creating more opportunities for societal narratives about who can do what kind of mathematics to influence who participates and how (Battey & McMichael, 2021). A dominant societal narrative is that 'doing mathematics' reflects 'doing masculinity' (Jaremus et al., 2020; Leyva et al., 2017; Mendick, 2006) and simultaneously privileges whiteness (Battey & Leyva, 2016; Martin, 2019) and Eurocentric perspectives (Rowlands & Carson, 2002). Scholars have argued that students who identify with the dominant culture of mathematics inherit this privileged status, particularly in advanced proof-oriented classrooms (Weber & Melhuish, 2022). The power that these narratives have can be corroborated by the fact that advanced courses are predominantly taught by (mostly white) men and the majority of students who take them are men (Blair et al. 2013). If a goal is to increase student-student interactions in these spaces (Saxe & Braddy 2015; the MAA Instructional Practices Guide, 2018), then it stands to reason that issues of inequities related to status and power must be considered.

Scholars have recently attended to status and power in proof-based contexts (e.g., Brown, 2018; Ellis & Alzaga Elizondo, 2023; Hicks et al. 2021). Adapting an authority framework, Hicks et al. (2021) explored how four students' mathematical authority was distributed while working on an abstract algebra task. They found discrepancies in authority relations and offered reasons why these discrepancies might have occurred, such as only some students authoring ideas in public spaces, students self-selecting to not participate, and assessing ideas to give or take away authority. Drawing on Shah and Lewis's (2019) work, Ellis and Alzaga Elizondo (2023) investigated how status attenuated/amplified (in)equities during small group work in an intro-to-proof course. Using relational and participatory equity as an analytic lens, they claimed that a 'less mathematically collaborative' episode exhibited a more balanced status relationship while a 'more collaborative' episode exhibited strained power relations. While intriguing, these claims could have been strengthened by a clearer theoretical connection between status, power, and inequity, which guided the empirical analysis of their data.

This report contributes a possible theoretical approach to empirically identify how status hierarchies form in small group interactions. That is, we claim that networking positioning theory (Harré & van Langenhove, 1999) with systemic functional linguistics (SFL; Halliday, 1978) may provide empirical evidence of discursive processes by which students attribute academic status to themselves and others. This approach may yield stronger claims regarding how inequities are attenuated/amplified in small groups (Shah & Lewis, 2019).

Background

In classrooms where students interact with each other regularly, issues related to status and positioning are more likely to occur (Cohen & Lotan, 2014; Esmonde, 2009b; Shah & Lewis, 2019). In general, 'status' refers to the idea that it is desirable to be in a higher position relative to another (Cohen et al., 1999; Ridgeway, 2018). For example, narratives around socioeconomic status allude to the idea that it is better to have more monetary capital than less, and people generally agree that is advantageous to be in a higher status position than a lower status position. In classroom contexts, academic and peer status greatly influence perceptions of where individuals fall along a status continuum (Cohen & Lotan, 2014). The former relates to perceptions of who is 'smart' or doing well in the class. The latter relates to perceptions of social standing (i.e., popularity, attractiveness). Then, 'diffuse status characteristics' refer to identity markers that are perceptible upon initial encounters with others, such as race (via skin color) or language use (via intonations or accents), gender expression, and certain forms of ability status. For our purposes, when we say "status" we mean academic status while acknowledging that peer and diffuse status characteristics influence attributions of academic ability or competency in proof classrooms.

Researchers studying student-student interactions during collaborative small group activities have made theoretical connections between status and positioning (Langer-Osuna, 2016; Esmonde, 2009a; Shah & Lewis, 2019). For example, Lange-Osuna (2016) argued that "students interactionally position themselves and one another with academic and social power that can affect collaborative mathematical work" (p. 108). To examine authority relations, they asserted that students who are positioned with more intellectual authority – that is, students positioned as valid sources of information directly related to the current task – accumulated more influence, and thus, academic status. In their coding scheme, influence was attributed to a student whenever their idea was "positioned as having become part of (or rejected from) the solution path" (p. 112). This aligns with our notion of influence as the combined result of being given opportunities to contribute that are subsequently evaluated positively by others.

An indirect link can be made between status and research on students' participation in groups since identity markers, such as gender, have been shown to influence participation (Ernest et al. 2019; Langer-Osuna, 2011; Reinholz et al., 2022). For instance, Ernest et al. (2019) found that men and women participated at relatively similar rates in private group talk, yet men dominated the public space in class discussions. Likewise, investigating gender roles in small groups using mixed methods, Langer-Osuna (2011) showed how Brianna's project-related conversation declined overtime and self-perception went from "good leadership" to "being bossy" while Kofi's project-related conversation increased, and he perceived himself as the "smart" student in the group.

At the undergraduate level, quantitative studies have pointed to gendered disparities in performance on proof-based tasks. Johnson et al. (2020) reported findings that indicated men fairing significantly better in inquiry-oriented proof classes compared to men in traditional classes, while there were no significant differences in performance for women. Reinholz et al.

(2022) built on this analysis by studying participation patterns, finding that performance disparities could be attributed to women's participation rates. We argue that there is a need to provide qualitative explanations for such results, and one possible direction is to explore how status hierarchies are de/legitimated (Adams-Wiggins et al., 2020) in proof contexts where small group work occurs, such as in inquiry-oriented classrooms.

Networking Theories to Evidence Status Relations

This report contributes a possible theory to analyze student-student interactions mediated by discourse – conceptualized as language-in-action used to communicate meaning, including written, verbal, gestural, and other forms of communication. We contend that networking positioning theory with SFL may provide useful analytic tools to document how status hierarchies form in small group interactions. With such evidence as a guide, we argue that situations in which status hierarchies are legitimated likely amplify inequities, while situations where status hierarchies are delegitimated likely attenuate inequities, with *in*equities defined as situations that prevent access to resources needed for learning (Shah & Lewis, 2019). It is worth noting that because human interactions and power relations fluctuate based on available positions, no situation will ever be 'status-free' or fully 'equitable'.

Positioning Theory

Positioning theory explains the processes underlying how participants in an interaction attribute rights and obligations to themselves and others (Harré & van Langenhove, 1999; Harré, 2012). Relationships between communication acts (i.e., the meaning embedded in speech and other forms of communication) and storylines (i.e., accepted sociocultural repertoires for how to interact in a situation) are what give rise to available positions or 'rights and duties' (Herbel-Eisenmann et al., 2015). In an educational setting, for example, a traditionally accepted teacher-student storyline is one where teachers are the authority and students are obligated to do what the teacher says. Such a storyline may be evidenced in the communication acts between participants; perhaps the teacher issues a command to students (e.g., "Please get out your notebooks and a pencil") and students accept the obligation by getting out their notebooks and a pencil. In positioning theory, when communication acts and storylines work together to make rights and duties available to participants, there is always a choice to accept, negotiate, or reject the positioning. For example, in the teacher-student scenario, perhaps a student does not get out a notebook or pencil. This could be interpreted in multiple ways; maybe they do not have the materials with them or perhaps they are rejecting the command intentionally.

Broad narratives about mathematics and who is perceived to belong to mathematics culture can operate as storylines associated with mathematics classrooms that students are likely aware of. For instance, mathematics culture is widely perceived as Eurocentric, white, and dominated by men (Battey & Leyva, 2016; Jaremus et al., 2020; Leyva et al., 2017; Martin, 2019; Mendick, 2006; Rowlands & Carson, 2002), which positions students who identify with this culture with higher status in mathematical spaces relative to others. A problematic exception is that students are well aware of the societal narrative that Asians are "good at math," which perpetuates the "model minority myth" (Poon et al., 2015; Shah, 2017). This is problematic since it positions students in a place of higher status (i.e., gifted academically) while also excluding them from communities of other minority students along with associated supports for those communities (Ng et al., 2007; Suzuki, 2002).

In sum, positioning theory provides conceptual grounding for why (and how) status hierarchies form in small group interactions. A limitation is the conceptual vagueness around interpreting the meaning embedded in participants' communication acts and the possible storylines at play (Herbel-Eisenmann et al., 2015). Therefore, we bring in analytic tools from systemic functional linguistics to evidence how positions are created and maintained through participants' discourse.

Systemic Functional Linguistics (SFL)

Broadly, SFL offers a learning theory centered on language use, with language operating as a complex, dynamic, and context-based system (Halliday, 1978). Three metafunctions of language comprise SFL: *interpersonal*, *ideational*, and *textual*. The textual metafunction "manages the flow of information to make extended discourse coherent and cohesive" and the ideational metafunction "constructs ideas and experiences" (Gebhard & Accurso, 2020, p. 1029). The interpersonal metafunction represents socially constructed positions and power structures. In our methodology for studying how status operates to organize interactions in classrooms, we are centrally concerned with the interpersonal metafunction which is mediated by "tenor" choices – resources including (but not limited to) the use of mood systems.

Within the mood system, statements made evoke a declarative mood, questions asked evoke an interrogative mood, and commands issued evoke an imperative mood (Gebhard & Accurso, 2020). Gebhard and Accurso (2020) assert that within the interpersonal metafunction and mood system, textual analysis can evidence how statements, questions, and commands influence social structures and power dynamics, particularly in classroom interactions. For example, such an analysis can capture who has the right to speak versus who remains silent, "who uses statements to construct authoritative 'facts'; who asks questions and engages in negotiating meaning; who gives commands and how commands are taken up or resisted" (p. 1032). For our purposes, the textual artifacts analyzed are transcripts of students interacting during group work.

We argue that the interpersonal metafunction of SFL, including tenor resources such as the mood system, provides concrete evidence of power relations emerging and shifting during group interactions through discourse patterns. We conjecture that documenting these processes can evidence how status hierarchies form in interactions because *who* issues commands, uses statements to convey authoritative 'facts' and maintains the right to speak will likely be perceived as having higher status relative to others in the interaction.

Interaction Process Related to Status Formation

Through the interaction process of creating opportunities to contribute and evaluating contributions, certain students are positioned as having more influence (e.g., Langer-Osuna, 2016). Those who acquire more influence during the interaction will have higher relative status compared to others, ultimately legitimating or increasing status hierarchies within the group. In what follows, we describe this process in the context of proof.

Opportunities to contribute. When assessing *opportunities to contribute* among members of a small group, we examine instances in which the group encounters a problematic situation and consider group members' attempts to offer a resolution, the timing of these offerings, how these offerings are solicited by other group members, and the time and attention members have when responding. For example, a group may need to interpret an assumption when working together to develop a proof. A group member may ask, "Does anyone know what [term] means?" followed by wait time. Such a generic solicitation often confers an opportunity to contribute upon the highest-status members of a group, who tend to experience the least psychological risk when offering a suggestion and will often be the first to respond. Alternatively, a member (or instructor) may ask a specific groupmate, "I remember you said something helpful about [term] before. Can you remind me what you said?" Depending on the relative status between the participants, this may elevate the academic status of the groupmate granted the opportunity to contribute, potentially countering the hierarchical effects of peer status and diffuse status characteristics.

Evaluations of contributions. Any contribution by a group member, unless interrupted by the end of a small-group activity, is implicitly or explicitly evaluated by the group. When analyzing *evaluations of contributions* from group members, we consider both explicit evaluations (immediate verbal and nonverbal responses to the contribution) by other members and implicit markers such as an attempt to reinforce or reconcile the contribution with other prior contributions, a follow-up question or suggestion building on the contribution, or a group moving on without appearing to give serious consideration to the idea suggested.

Students' evaluations may have status implications when they appear to agree or disagree with a peer's contribution. For example, when asked to provide a proof of a proposition about equivalence of two expressions involving set operations, a student in a group might suggest drawing a Venn diagram illustrating each sequence of set operations. Another group member, skeptical of the viability of this approach, might simply say, "[Instructor] said that a Venn diagram isn't a proof," implicitly dismissing the possibility that a diagram might support the group's thinking. Alternatively, they might say, "Can you show how you would use a diagram for this problem?", inviting the student to elaborate on their initial contribution. A third possibility is that a peer might ignore the Venn diagram suggestion entirely and say "We need to assume that x belongs to A and B but not C." We posit that each of these interactions has different implications for the status of the group member who suggested the diagram, both as evidence of their academic status within the group and as potential incremental effect on the student's status within the group and in the class.

Influence. When considering each group member's *influence* in a proof-oriented context, we examine instances in which a group must make a decision about a strategy, validity of a claim or contribution, or about the group's collective focus (such as a decision to move on to a different problem or task). In each such instance, we review group members' verbal and nonverbal communication to determine: (1) whether group members seem to defer to a specific member or subset of the group when making the decision; (2) whether a member's input into the decision is taken up by the group; and (3) whether a member suggests criteria or heuristics for decision-making that ultimately inform the group's actions. As an example of the latter, consider an episode in which a group must prove that a sequence converges to a limit, and a student starts by writing the inequality $|a_n - L| < \varepsilon$. At this point a peer might interject and say that this inequality is what the group must prove, and a proof is not allowed to begin with the statement to be proven. If this persuades the group to move away from this strategy, this would point to the peer's influence over the group's decision making. If on the other hand the student continues manipulating this inequality (perhaps as a strategy to discover a value of N corresponding to ε) and is able to enlist the group into helping, notwithstanding the peer's objection, this might point to the first student's influence. It is important to consider that the direction the group takes in this scenario is not purely a function of how well each group member argues in favor of their strategy; it depends on the group's implicit judgment about each member's propensity to identify and validate potential strategies for developing the proof.

Example of Theory in Action

In this section, we demonstrate the analytic potential of the proposed networked theory. Ellis and Alzaga Elizondo (2023) previously analyzed the role of status in two small-group episodes using the constructs *opportunities to contribute*, *evaluations of contributions*, and *influence over group decisions.* The participants were students in an introduction-to-proofs course taught remotely over Zoom with the second author attending class each day (see Alzaga Elizondo, 2022). Alison, a white woman, became a focal participant since interactions in one episode with Lee (East Asian man) evidenced differing participation patterns compared to an episode with Justin (white man). Based on daily observations of class interactions (including virtual breakout rooms), Lee was perceived to have higher academic status relative to Alison. Both Lee and Justin also benefited from belonging to demographic groups that granted them higher academic status in mathematical spaces.

Questions Support Leveling Academic Status Positions

In the following exchange, Lee and Alison used a balanced combination of statements and questions as they worked on a shared Google doc to prove that group isomorphisms preserve inverses.

Lee: From here can I just jump to like, therefore e_2- therefore phi(e_1) is the identity by definition or is that skipping some steps? (pause) [Question]
Alison: Hold on I'm thinking (pause) [Statement]
Alison: yeah I think that's good. [Statement]
Alison: (reads) "By definition of identity." So phi(e_1) must be the identity in-
Lee: Oh wait, but we're not saying for all H, we have to prove that that's all H. [Statement]
Alison: the identity- What do you mean all h? [Question]
Alison: Oh for the identity for all h? [Question]
Alison: But we've already proved that there is only one identity. [Statement]
Alison: Isn't that in the definition of identity? [Question]
Lee: Yeah, but like this is showing the identity for all these, some elements of H until we show- [Statement]
Lee: I guess we can use onto right? [Question]
Alison: Yeah. (nods affirmatively) Yeah, we probably have to use onto. [Statement]

Overall, the discursive move of asking questions to elicit evaluations of intellectual contributions functioned to level the perceived academic status between the pair. For instance, Lee, a relatively higher status student compared to Alison, started off the exchange with a question inviting Alison to evaluate his suggestion to "jump" to the desired conclusion. This attributed academic status to Alison as someone who had the right to validate mathematical ideas. Alison accepted this position by using a declarative statement that positively evaluated Lee's idea ("yeah I think that's good"). Further along, Lee began a talk turn with a statement declaring what he knew about a particular line in their proof, saying "this is showing the identity for all these." He then used a question to ask Alison how they should approach a refinement, saying "I guess we can use onto right?" Again, this attributed academic status to Alison by positioning her as a knowledgeable peer.

Declarative Statements Uphold Unbalanced Academic Status Positions

In the subsequent exchange, Alison and Justin engaged in a back-and-forth about how to move forward with their proof that elements of a Cayley table are unique (see Ellis & Alzaga Elizondo, 2023).

Alison: Yeah it's different actions but I think for the sake of our proof we need to somehow say we're limited to you know (pause) [Statement]

Alison: just four, well in this case we don't have- however many symmetries there are. (pause) [Statement]

Alison: I might be articulating that wrong. (pause) [Statement]

Justin: I think the original route we're going down is right, where we have this, I think this is definitely the right way. [Statement]

Justin: I'm just trying to make sure that we have the proper way saying that proper, like-

Alison: Yeah, I agree, we have to find the way to set it up before we can just say. (pause) [Statement]

Justin: Well, (cross talk with Abigail) I just want to make sure there's no holes, I guess- [Statement]

Abigail: (cross talking) Q is identical to W then [Statement]

Alison: (responding to Justin) I understand that. [Statement]

Using declarative statements as discursive moves seemed to assert each speaker's own knowledge and authority over the work. For instance, Justin made a declarative statement evaluating Alison's prior contribution ("I think the original route we're going down is right"), positioning himself with the right to validate the group's work. Alison responded with a declarative statement "Yeah, I agree, we have to find the way to set it up…" which functioned as a positive evaluation of Justin's contribution. Rather than offer or invite a suggestion for how to accomplish what they agreed they needed to do to move the proof forward, Justin used another declarative statement, "I just want to make sure there's no holes" maintaining his right to validate their mathematical work. Instead of using questions to elicit intellectual contributions, as in the exchange between Alison and Lee, this interaction pattern functioned to uphold Justin's higher relative status he entered the interaction with.

Discussion

This report contributes a potential theory to empirically identify how status hierarchies form in small group interactions. We have argued that exploring processes by which status hierarchies form is necessary in proof contexts because such qualitatively-driven empirical analyses can potentially explain prior inequitable quantitative results, particularly regarding gender. While this theoretical approach seems fruitful, it has limitations. Additional data about students' experiences in group work is needed to obtain a more complete picture of how de/legitimating status hierarchies attenuates/amplifies inequities in small group interactions (see Adams-Wiggins et al., 2020). Specifically, sociometric data about social relations in the classroom environment and interviews to allow students the opportunities to elaborate on their experiences would serve as appropriate data sources to confirm or disconfirm our interpretations from the status analysis. We hope this work sparks conversations around how status functions in small groups for the purpose of discussing and implementing possible instructional approaches that delegitimate status hierarchies in proof spaces.

Students' Productive Techniques for Approaching Well-Definedness and Everywhere-Definedness

Rosaura Uscanga
Mercy University

Kathleen Melhuish
Texas State University

John Paul Cook
Oklahoma State University

Functions are critical in mathematics but have received limited attention at the advanced level. Research in advanced contexts has primarily focused on students' reasoning about specific types of functions (e.g., isomorphisms) but not on the function concept itself. In this paper, we explore students' productive techniques involving the definitive properties of function: well-defined and everywhere-defined. We found that the techniques students productively employed extended far beyond canonical procedures (like the vertical line test) and largely drew upon function meanings involving coordination of the domain, codomain, and rule, which previous research has highlighted the importance of but stopped short of directly investigating. Two contributions of this work include our focus on productive, successful techniques (rather than challenges and difficulties), and explicit focus on everywhere-defined (which has not received direct attention).

Keywords: function, well-defined, everywhere-defined, advanced mathematics

Functions are an essential concept in advanced mathematics underscoring ideas like binary operation, continuity, and homeomorphisms. We treat functions as having two defining properties (Even and Tirosh, 1995): "(1) they should be defined on every element in the domain, and (2) for each element in the domain there should be only one element (image) in the range; this condition is also known as univalence" (p. 4). We refer to the first property as everywhere-defined and the second as well-defined. These properties can serve to support or constrain student reasoning about abstract types of functions in later mathematics (Melhuish et al., 2020). For example, many students determine that functions like $f(x) = 1/x$ are not continuous because of their asymptotes (e.g., Takači et al., 2006). Students may not be considering that a function must be everywhere-defined on its domain. Similarly, in abstract algebra, well-definedness plays a crucial role as students work with functions on structures such as quotient groups whose elements are equivalence classes. In fact, Rupnow (2021) has documented that instructors may spend an entire lesson on these properties (along with onto and one-to-one).

The larger body of literature about student understanding of function primarily illustrates students' incomplete or non-generalizable meanings and techniques (e.g., Dorko, 2017; Even & Bruckheimer, 1998; Martínez-Planell & Trigueros Gaisman, 2012). Even and Tirosh (1995) proposed that the concept of well-definedness is often viewed in a rote and procedural way which is found to be superficial upon probing. Indeed, the most common manifestation—procedural or otherwise—of well-definedness at the K-12 level is the vertical line test or checking listed set of elements. The vertical line test can be a useful technique when accompanied with meanings of well-defined (e.g., Clement, 2001; Melhuish et al., 2020; Thomas, 2003); however, researchers have also noted that students over rely on the vertical line test and such techniques remain salient at the advanced level (e.g., Zandieh et al., 2017).

Beyond the vertical line test, researchers have also documented that students may not attend to function properties at all (e.g., Melhuish et al., 2020; Vinner, 1983). Thompson (1994) argued that the "predominant image evoked in students by the word 'function' is of two written expressions separated by an equal sign" (p. 5). Furthermore, introductory examples of function tend to draw on metaphors like the "function machine" (Tall & Bakar, 1992) which appeal to diagrams and tables where properties are readily identifiable by observation. Thus, even when students draw attention to the defining properties, it is not always in a way that is operable in terms of techniques for other contexts (e.g., Vinner 1983). We also note, despite the important role of everywhere-definedness (such as the continuity example above or in support of understanding homomorphism), few researchers have addressed this property explicitly, and we were not able to find any documented techniques. In this paper, we explore: What types of techniques do advanced mathematics students use to productively engage with well-defined and everywhere-defined properties when determining if a given relation is a function?

Theoretical Framing

We broadly take an approach aligned with Paoletti and colleagues' (2018) distinction between techniques and meaning. We share similar constructivist assumptions that students have developed their meanings for a particular concept based on an array of prior experiences. That is, the meanings students have for functions and the properties of well-defined and everywhere-defined reflect not an in-the-moment cognitive state, but rather more overarching understandings. In contrast, techniques refer to "student's words and observable activity as she addressed a single task" (p. 95). Students draw on their knowledge when engaging in problem-solving tasks, and techniques describe what they know-to (Mason & Spence, 1999) do in-the-moment. In our study, we were particularly interested in documenting the techniques used as students drew on their meanings for functions related to well-definedness and everywhere-definedness.

As noted in the introduction, it is essential that students move beyond a common meaning for functions as only a rule or formula. We suggest that function meaning requires coordination between the domain set, the codomain set, and rule that incorporates the two defining properties. If, when explaining why a proposed correspondence is or is not a function, students make explicit reference (in their language, gestures, or inscriptions) to (1) an element in the domain, (2) an element in the codomain, and (3) the rule, it would suggest that they are drawing on a meaning that has some coordination between these key components.

Methods

We conducted task-based clinical interviews (Clement, 2000; Goldin, 2000) with five students who (1) had already completed an advanced mathematics course (e.g., abstract algebra, cryptography, number theory) and (2) successfully approached basic "is this a function?" tasks. To identify such students, we reached out to several advanced mathematics courses at a large research university in the United States to ask for participants.

Data Collection and Task Design

We conducted two to three interviews with each student individually for an hour to an hour and a half each. Each interview was conducted and video-recorded over Zoom. The tasks were created with each category of non-examples from Uscanga and Cook (2022) being represented (sometimes in the modified form of an example). These categories are: *well-definedness – domain choice* (where an element in the domain can be represented in different equivalent ways and the symbolic rule maps these representations to distinct outputs), *well-definedness – codomain choice* (where the rule requires a choice of the outputs in the codomain, even though it does not invoke different equivalent representations), *everywhere-definedness – domain restriction* (where the symbolic rule maps an element in the domain to an output that is not contained in the proposed codomain), and *everywhere-definedness – domain expansion* (where the symbolic rule assigns to an element in the domain an output that is not contained in the proposed codomain but is contained in an easily accessible superset). The interviews were centered around four core tasks which asked students to identify if a proposed correspondence was an example or a non-example of a function. Additional tasks were designed for subsequent interviews to test and refine the hypotheses we established for each student, so they were adequately supported or refuted based on our observations.

Data Analysis

We engaged in both ongoing and retrospective analysis. Ongoing analysis occurred during and between sessions. This involved generating tasks and questions to test specific hypotheses about the students' reasoning. After data collection, we independently analyzed students' responses to five tasks. We identified excerpts from the transcripts that illustrated the techniques used by students to explore each task and coded these for definitional properties (well-defined or everywhere-defined), focus on domain, codomain, or rule, and the tool or approach utilized to solve the task. Codes were revised until agreement was reached and summaries of each student's approaches were created. This allowed us to compare techniques across students as well as across tasks. A second round of analysis involved grouping the data by type of property explored in order to identify the different techniques students used to productively engage with well-definedness and everywhere-definedness. Finally, we categorized these individual techniques into broader categories that described the general approaches students employed.

Results

Well-definedness

The well-defined property has been the subject of many empirical studies (e.g., Clement, 2001; Dorko, 2017; Even & Bruckheimer, 1998; Even & Tirosh, 1995). In this section, we highlight two overarching themes in students' activity: sameness and divergence. We begin by illustrating students drawing on prototypical examples in their open explorations, then consider the more sophisticated techniques used by students in more abstract settings.

Table 1. Students' techniques for engaging with well-definedness.

Technique	Focus	Method
Diagram or Table	Canonical Technique	Identify diverging outputs or repeats
Vertical Line Test	Canonical Technique	Identify multiple points along a same vertical line
Rule Ambiguity	Symbolic Rule	Identify if symbolic form assigns multiple outputs
Rule Equivalence	Symbolic Rule	Manipulate symbolic rule into known equivalent form
Attending to Function Notation Elements	Rule Focus, Domain Secondary	Determine if symbolic form of how an element is represented in input notation impacts output
Attending to Equivalence in the Domain	Domain Focus, Rule Secondary	Identify equivalence classes in the domain and explore their corresponding outputs
Attending to Equivalence in the Domain and Codomain	Domain, Rule, Codomain Focus	Identify equivalence classes in the domain and examine outputs via equivalence classes in the codomain

Canonical techniques. We suggest that the literature-based techniques (multiple outputs for one input identified via listing elements or vertical line test) might be deemed early canonical. Our advanced mathematics students drew on such examples when prompted to create functions and non-functions (see Figure 1). For example, Student B explained, "one of the guys from the domain goes to like, four different outputs, so that violates our condition." Student C stated, for instance, "if we drew like a vertical line, we know there's a lot of points where, you know, our one input value has two different output values." From the point-of-view of sameness and divergence, these techniques do not require identification of sameness, but rather rely on identifying divergence of outputs. They simplify the relationship between the domain, rule, and codomain to draw attention to inputs and outputs without substantial exploration of the surrounding sets.

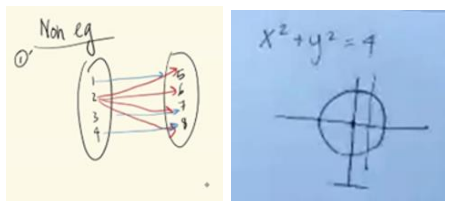

Figure 1. Left. Student B's function diagram of an example and a non-example of a function. Right. Student C's depiction of the vertical line test to establish a circle is not a function.

Attending to divergence. We begin by elaborating a technique that involves forefronting the symbolic rule which involves recognition of the potential for a rule to lead to divergence. Many of the students discussed this issue in relation to the correspondence $f: \mathbb{R} \to \mathbb{C}$ given by $f(x) = \sqrt{x}$. For example, Student A explained, "we have made a convention that if you just see a square root sign, you automatically decide that it's the positive square root sign." These students went on to provide a counterfactual that without this convention, it would not be a function, because, as noted by Student B, "our four could map to plus two or minus two. And then we don't know which one we're choosing, so that's an ambiguity." We note that the students are attending primarily to the symbolic rule but coordinating the role the rule plays diverging a single input to two outputs—drawing on the well-defined meaning. The students' language also reflects sophistication in their meanings with attention to the role of convention and ambiguity.

Attending to equivalent functions. When exploring the rule $f: \mathbb{Q} \to \mathbb{Q}$ taking $\frac{a}{b}$ to $\frac{a+b}{b}$, several students worked with this unfamiliar rule with a lens of sameness: finding a familiar well-defined function. After some algebraic manipulation, Student B explained, "my assignment can be abbreviated as x going to $x + 1$, which is, which is a function." We note that this approach is not explicating the coordination between sets and rule nor the definition of well-defined. However, we infer that the student using this technique likely had an awareness of that, as Student E stated, this function "is simply your input plus one" which is quite obviously well-defined. Thus, we suggest that manipulating the rule can be a productive technique if there is an obvious equivalent function.

Attending to function notation elements. Techniques that attend primarily to the rule are not sufficient in approaching a common area of concern for well-definedness: equivalence classes in the domain set. We identified two different ways that domain sameness was coordinated with rule divergence. The first attends primarily to the rule in terms of not just the outputs produced from an input, but also the notation of the input in function notation. For example, regarding the function $g: (0, \infty) \to \mathbb{R}$ given by $g(x) = \frac{1}{x}$, Student B explained that "given an x, it could be in the form a divided by b … But the formula, the assignment does not need that information." This student is attending to elements of the domain (recognizing the set involved and potential representations), but then acknowledging that the function, as written, would not use that information. In contrast, for $\phi: \mathbb{Q} \to \mathbb{Z}$ given by $\phi\left(\frac{a}{b}\right) = a + b$, Student B explained, "the formula in this case, actually depends on the representation. Like, depends on how we have written the fraction." They go on to provide an example, $\frac{1}{2}$ and $\frac{2}{4}$ are the same, but do not give the same output (divergence). This student is drawing on meaning and coordination between the domain set ($\mathbb{Q}$) and the rule in order to determine if elements from the domain can have distinct representations and whether the rule, attending to function notation input, will act on those representations differently.

Attending to equivalence in the domain. Other techniques centered the domain to determine if an "equivalence" relation existed. This technique involved identifying equivalent elements (sameness) and then testing if the rule produced two outputs (divergence). Consider Student A's response to a modular arithmetic task ($f: \mathbb{Z}_3 \to \mathbb{Z}$ given by $[a]_3 \mapsto a$):

> Look, zero-three [writing $[0]_3$], I could write it a different way, right? … I could write this as six-three [writing $[6]_3$]. Those are the same element in $\mathbb{Z}_3$. … If I was gonna do six-three, your rule tells me that I have to map it to six. … the element zero-three maps to zero, six, three, nine … There's a lot of, a lot of outputs, and I'm only allowed to have one output.

This sort of exploration and attention to specific elements was found not just in the modular arithmetic tasks, but also the rational number tasks.

Everywhere-Definedness

We now transition to the everywhere-defined property which has received less attention in the literature. The results in this section are organized around three main themes that arose from students' activity: containment, existence, and set operation. We begin with a students' prototypical example from their open exploration and then explore more sophisticated techniques used by the different students throughout the interviews.

Table 2. Students' techniques for engaging with well-definedness.

Technique	Focus	Method
Diagram	Canonical Technique	Identify inputs that do not have corresponding outputs
Attending to Output Containment	Codomain and Rule Focus	Determine if outputs assigned by the symbolic rule are contained in the proposed codomain
Attending to Output Existence	Domain and Codomain Focus, Rule Secondary	Determine if symbolic rule assigns an output to every input
Manipulating Sets via Extending	Domain and Codomain Focus, Rule Secondary	Operate on domain or codomain by extending the set and focusing on a superset
Manipulating Sets via Subsetting	Domain and Codomain Focus, Rule Secondary	Operate on domain or codomain by subsetting the set and focusing on a subset
Manipulating Sets via Partitioning	Domain and Rule Focus, Codomain Secondary	Subdivide domain into sets where the symbolic rule causes known problem areas

Canonical technique. The students rarely evoked everywhere-defined while generating examples and non-examples. Only one student attended to it when asked to provide an example of a non-function. We deemed their approach canonical as it is the type of example students might be used to from K-12 settings. As seen below (Figure 2), the student drew a function diagram where one element in the domain had no corresponding output in the codomain. They explained:

> I was like "oh, well, could I have no outputs? … Would that be, a part, would that break it being a function?" Well, that wouldn't even count because a relation requires that each input has at least one output … So, I could make it not a relation by sticking this F in here, and it has no arrow. Well, then it's not a function because it's not a relation.

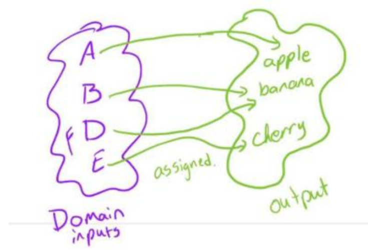

Figure 2. Student A's function diagram which fails the everywhere-defined property.

Attending to output containment. Several students attended to whether the outputs assigned by the rule were contained in the proposed codomain. They viewed the rule as assigning an output to each input and focused on whether the resulting outputs were contained in the codomain specified. For instance, when dealing with the non-example $h: \mathbb{Z} \to \mathbb{N}$ given by $h(x) = x^3$, Student A explained, "this relation has its own meaning, and its meaning, says, something about, this $\mathbb{N}$ right here, having, to include the answer that the rule would go to." In more detail, they noted:

> What happens when I plug in negative two? Right? Well then the rule, says that, I have to go to negative two cubed … that has to be negative eight, and negative eight does not live in $\mathbb{N}$ … So I can't say if it's a function because it's a nonsensical thing … Negative two lives here, look it's right there, and it's telling me to go to negative eight, but negative eight, I can't, I can't go. It won't let me. This, this won't let me go there."

This reflects a two-stage process, attending to the rule and then coordinating with the codomain.

Attending to output existence. A slightly different technique focused on the correspondence not assigning outputs to certain inputs. For example, Student B used this technique to explain why $h: \mathbb{Z} \to \mathbb{N}$ given by $h(x) = x^3$ was not an example of a function:

> So the first thing that we need to have is, we have to have a relation between stuff in the range, the stuff in the domain and the stuff in the range. But, so if I tried to write down an ordered pair here, I will not have anything to write for minus one. So, that, we can't even get an ordered pair. So we can't even get a relation for minus one.

This student argued that there is no output assigned to -1. The attention is on the domain and codomain and the rule either relates the two sets or does not.

Manipulating sets via extending and subsetting. Two other techniques that arose involve operating on the domain or codomain by extending the set or subsetting it. For instance, Student E subsetted the codomain when working with the square root function and explained how they restricted their focus on a subset, "So if it was negative, it would result in a complex number, but when you're considering the function is mapping from reals to reals, then you have to restrict the domain. But it's still a function." They continued, "It's just your domain, the y values don't exist for this particular field that we're considering. But you defined the mapping as from reals to the complex numbers, which means that your domain is unrestricted here."

We also observed students extending the domain, as Student E did when discussing the function $g: (0, \infty) \to \mathbb{R}$ given by $g(x) = \frac{1}{x}$, "since you restricted your domain, this is a function … if you would have said that you were just mapping from reals … x cannot equal to zero … you do not have a valid y value for that." The student extended the domain to explore the issues that arise with the correspondence and notes that the domain is not extended in this case so there are no issues. In this technique, the students' focus is on a superset of the specified domain or codomain, whereas in the first technique the student focuses on a subset of the proposed domain or codomain.

Manipulating sets via partitioning. The other related technique involved subdividing the domain as a result of a known problem area related to the symbolic form of the rule. Students then further made arguments about containment of the outputs. For example, Student C noted about the x^3 non-example:

> So our two sets here is the integers and the natural numbers. And so this, function that we wrote here, the x cubed, you know, there are some things that "okay, yeah we can put some numbers in for x and we can get some natural numbers, that's fine." But there's also some numbers, you know, our negative numbers, if we put negative numbers in here, we're not getting output values in the natural numbers.

Here, the student is subdividing the domain into the positive and the negative integers since negative integers could have issues with this rule. By exploring the places where possible issues might arise with the symbolic rule, students were able to determine whether the provided correspondences were or were not functions.

Discussion

In this paper, we described different types of techniques that advanced mathematics students used to productively engage with the properties of well-defined and everywhere-defined when determining if a given correspondence is a function. We found that the students in the study used techniques that extended far beyond the canonical techniques that rely primarily on observing irregularities (multiple outputs or lack of outputs). For well-defined, students used ideas of convention and ambiguity to attend to issues with symbolic rules and naming conventions, and sameness and divergences to consider equivalence classes and representations in the codomain and domain sets. For everywhere-defined, students used ideas of containment and existence to consider implications of certain rules and operated on sets to consider extensions and subsets that may complicate the relationship with the rule. This is a key contribution because while researchers had previously examined various facets of reasoning productively with functions in mathematics in general (e.g., Oehrtman et al., 2008; Tall & Vinner, 1981) and in advanced mathematics in particular (e.g., Melhuish et al., 2020; Zandieh, et al., 2017), investigation into well-definedness and everywhere-definedness has been rather limited.

These results can provide a foundation for additional research that could attend to ways students might develop these techniques. Future research can elaborate how techniques like the ones identified here might influence students' reasoning about more advanced concepts within the context of abstract mathematics where these properties have crucial roles in formal proofs.

Two Students' Meanings for Partial and Directional Derivatives when Constructing Linear Approximations: The Cases of Alonzo and John

Zachary S. Bettersworth
Western Kentucky University

In this paper, I describe two vignettes of two students' meanings for partial and directional derivatives. The data was collected in the Spring 2023 academic semester from two STEM students who had completed multivariable calculus at least two semesters prior to participating in the study. The interviews were conducted using task-based, exploratory teaching interviews with the goal of creating explanatory models of student thinking to highlight the nuance in their meanings for differential multivariable calculus ideas. The two students, Alonzo and John, each exhibited novel meanings for partial derivatives that were constructed over several semesters of mathematics and physics instruction. These results add to the field's understanding of students' thinking about a relatively underdeveloped area of the research literature, specifically multivariable calculus education.

Keywords: Students' meanings, partial derivatives, directional derivatives, multivariable calculus education

Introduction and Literature Review

Investigations of students thinking about multivariable and vector calculus ideas have been of increasing interest to undergraduate mathematics education researchers over the past several years (Jones, 2020, 2022; Mhkatshwa, 2021; Moreno-Arotzena et al., 2021). Despite a relative lack of mathematics education research literature investigating students' conceptions of multivariable calculus topics (Rasmussen & Wawro, 2017), Multivariable and Vector Calculus (MVC) is positioned at an important point in the sequencing of the undergraduate mathematics curriculum. Specifically, MVC is typically offered as the third semester of university-level Calculus and is sometimes required as a prerequisite course for upper-division mathematics courses such as Linear Algebra or Differential Equations. Further, the differential calculus ideas normally discussed in a MVC course are often necessary to make sense of certain concepts and systems of equations encountered in upper-division physics and engineering courses (Bajracharya et al., 2019; Dray & Manogue, 2006; Roundy et al., 2015). To better understand how undergraduate STEM majors think about partial and directional derivatives, I conducted a set of exploratory interviews in the Spring 2023 semester. In this paper, I share two vignettes from this study that highlight nuance across two students' meanings for partial and directional derivatives.

Theoretical Perspective

Discussions about students' meanings for mathematical ideas necessarily elicit recursive discussions about what we, as mathematics education researchers, "mean" by meaning.

The Meaning of "Meaning."

Thompson (2013), described the recursive nature of meaning, and the development of meaning, in the context of mathematics education in the United States. Thompson provided an in-depth analysis of what several philosophers meant by "meaning." As a genetic epistemologist, Piaget appeared to understand "constructing a meaning" as "constructing an understanding," and appeared highly related in Piaget's Genetic Epistemology (Glasersfeld, 1995; Montangero & Maurice-Naville, 1997; Piaget, 2001). In the context of Piaget's theory, *assimilation* is a biological notion in which an individual grafts new sensorimotor experiences, or mental activity, onto previously constructed mental structures, or *schemes*. For Piaget, assimilation was the source of all schemes, and *accommodation* was the driving mechanism behind the creation of new schemes and differentiations in existing schemes to create new schemes through the process of Reflective Abstraction (Glasersfeld, 1991; Piaget, 2001). In the context of the learning theory that emerges from adopting Radical Constructivism as a background theory or an epistemological stance (Simon, 1995), learning is conceptualized as the process of iterative cycles of assimilation and accommodation driving individuals, conceptualized by Radical Constructivists as individual cognizers, towards a temporary state of *cognitive equilibrium* (Cobb & Steffe, 1983; Glasersfeld, 1991, 1995). If having an understanding is therefore the result of assimilating to a scheme, then the corresponding understanding accompanied by an inference, or a set of inferences in the moment, would be someone's meaning that resulted from the assimilation to their scheme(s) (Thompson, 2013; Thompson et al., 2014).

Students' Classroom Experiences and the Negotiation of "Shared Meaning."

However, the construction of meaning is incomplete without consideration of the conveyance of one's personal meanings to another individual, which will always impact the nature of the interaction between two or more people (Blumer, 1986; Thompson, 2013). For instance, in classroom contexts, one aspect of a teacher's role is to act as a brokering agent between the local classroom context and the larger community of mathematicians and mathematics students (Zandieh et al., 2017). It makes sense that a teacher's meanings will necessarily impact the meanings that students construct, and the negotiation of meaning is often a subtle and difficult-to-grasp process in settings as dynamic as classrooms (Thompson & Thompson, 1994). As such, I decided to first analyze the meanings that students *had* constructed as a start to building second-order models of students thinking about partial and directional derivatives (Cobb & Steffe, 1983; Steffe & Thompson, 2000).

Further, while first-order models of student thinking can inform the initial set of tasks or instructional materials, engaging with students' genuine mathematical realities will result in more viable models of student thinking. Therefore, a researcher who adopts Radical Constructivism as a background theory takes seriously the notion that knowledge resides in the mind of the individual and rejects the notion that the researcher has "direct" access to the student's internal cognitive process, or *students' mathematics*. Thus, adopting Radical Constructivism implies an acceptance of the building models of student thinking is the best we can do as qualitative researchers to build theories about student thinking (Cobb & Steffe, 1983; Steffe & Thompson, 2000). Since I chose to adopt Constructivism as a background theory, I decided to follow the recommendations of Steffe and Thompson (2000) to engage in exploratory teaching with students to get in touch with their mathematical realities, or *the mathematics of students*.

A Quantitative Meaning for Partial Derivative as a Directional Rate of Change Function

In the context of MVC instruction, Mhkatshwa (2021) highlighted students' struggles with conceptualizing partial derivatives in non-kinematics contexts using covariational reasoning. Mhkatshwa's results corroborated other research results that students will conceptualize derivatives differently depending on the problem context (Jones, 2017; Zandieh, 2000; Zandieh & Knapp, 2006). For example, conceptualizing a partial derivative as a directional rate of change function would entail (i) a meaning for constant rate of change as a constant of proportionality which multiplicatively compares an amount of variation in the value of a single independent quantity and the corresponding amount of variation in the value of the dependent quantity, while mentally holding the value of the other independent quantity fixed, and (ii) a meaning for rate of change function as a record of the relationship between the value of the independent quantity and how quickly the value of the dependent quantity changes due to infinitesimal amounts of variation in the value of the independent quantity. Such a meaning would lead to the anticipation that the symbolization $f_x(x, y) = x^2y$ where $z = f(x, y)$ would imply that $f_x(2,1)$ represents the rate of change of the z value for any change in x away from $x = 2$ where the y value is fixed at $y = 1$. The rate of change would represent an equivalence class of ratios leading to the inference that the corresponding change in z is $f_x(2,1)$ times as large as the corresponding change in the x value away from $x = 2$, e.g., $\Delta z \approx f_x(2,1)\Delta x$.

Conceptions of partial and directional derivatives align well with recent instructional recommendations of research groups investigating student thinking about partial and directional derivatives by explicitly lecturing on 3D slopes (Martínez-Planell et al., 2017; Martínez-Planell & Trigueros Gaisman, 2021; McGee & Moore-Russo, 2015; Moore-Russo et al., 2011) and tactile manipulatives from the *Raising Calculus to the Surface* workshops (Wangberg, & Dray, 2022). The issue is that students' conceptions of rates of change as slope, e.g., as a graphical measure of the slantiness of a line or plane, cannot be assumed to automatically "transfer" to non-graphical contexts (Lobato & Siebert, 2002). As such, further research is required to investigate students' quantitative conceptions of partial and directional derivatives as rate of change functions whose dependent quantities have an equivalent measure to the 3D slopes of tangent planes as described by previously mentioned research groups.

Methods

The data presented here emerged from a study designed to highlight the nuance in STEM intending students' meanings for partial and directional derivatives across a set of symbolic, graphical, and dynamic geometry tasks (Bettersworth, 2023). The tasks were designed using a combination of literature on students' meanings for partial and directional derivatives (Jones, 2022; Martínez-Planell et al., 2017; Mhkatshwa, 2021) and my conceptual analysis for the two dynamic geometry tasks (Bettersworth, Year), to support students in engaging in the goal directed activity of using derivatives to create linear approximations for particular functions in graphical and symbolic settings.

Each student completed a 30-minute screening interview, which included questions about interpreting the limit definition for derivatives and partial derivatives in graphical and symbolic settings. Alonzo (he/him) and John (he/him) were invited to participate in up to five task-based, think-aloud style, exploratory teaching interviews with the goal of producing explanatory models of student thinking (Cobb & Steffe, 1983; Goldin, 1997; Steffe & Thompson, 2000). While the initial goal was to engage in *intuitive and responsive interaction* with each student, the interviewer would transition to making teacher moves if either student expressed discomfort or unfamiliarity with a particular subset of the ideas presented in my tasks or interview protocol. The teacher moves made by the teacher-interviewer were based on my a priori conceptual analysis for the previously mentioned geometry tasks (Bettersworth, 2021; Thompson, 2008).

I engaged in retrospective analysis of each interview recording by reviewing each video between interviews to determine any areas which required further clarification, or to inform the design of future tasks and teaching interventions. After the conclusion of the data collection, I engaged in ongoing analysis of the data through iterative rounds of open coding (Strauss & Corbin, 1998). Once an initial set of codes was established, the interview data was reanalyzed using quantitative reasoning (Thompson, 2022) as a lens for investigating the degree to which each student conceptualized variables (Carlson et al., 2002; Thompson & Carlson, 2017), function notation (Oehrtman et al., 2008; Thompson & Carlson, 2017), graphs (David Parr et al., 2018; Moore & Thompson, 2015), and rates of change (Thompson, 1994) as a record of their conception of the relevant quantities within each task.

Context of Student Data

Alonzo (he/him) and John (he/him) were selected from a group of five students who participated in a set of screening interviews in February 2023. Alonzo is a physics major at a large research university in the southwest United States. Alonzo completed the undergraduate calculus sequence at a local community college before transferring to the university. John is a double major in mathematics and physics at the same university. John completed the undergraduate mathematics sequence during high school and commented frequently about his positive STEM instructional experiences in high school. Both students were very vocal with their thinking and agreed to participate in the exploratory interviews after the completion of their individual screening interviews and after signing the approved study participation forms.

Results

Alonzo and John demonstrated varied and nuanced meanings for partial and directional derivatives that include interrelated conceptions of other MVC ideas (e.g., dot product, cross product, basis vectors, and projection) while constructing linear approximations. However, due to space limitation, I will share two vignettes related to Alonzo and John's meanings for partial and directional derivatives.

Vignette 1: Students' Meanings for Partial Derivatives

In the first vignette, I highlight Alonzo and John's meanings for partial derivatives which included: (i) curves on the surface in the x and y direction, (ii) tangent lines to each trace in the x and y direction, and (iii) slopes of the lines tangent to the curves on the surface in the x and y direction, or contained in a plane parallel to the xz or yz plane.

Meaning 1: Partial derivatives are the curves on the surface. Throughout the second and third day of Alonzo's interviews, it appeared that his meaning for partial derivative was evoked differently based on whether he anticipated mentally evaluating the partial derivative function for a particular set of values for both independent quantities. For instance, as demonstrated in the following transcript, when finding the partial derivatives of the function $f(x, y) = xy^2 - xy$ in task 2.1.2 (day 2, task 1, question 2), Alonzo interpreted $f_x(x, y)$ and $f_y(x, y)$ differently than he interpreted $f_x(2,1.5)$ and $f_y(2,1.5)$ in task 2.1.3. The task statements are pictured in Figure 1(b).

Alonzo: Okay, find the partial derivative of x of the function of f and the partial derivative of y with a function of f. What do these partial derivatives represent? So, find partial. I'll start with that, with partial of x. So, that would be f of x is equal to $y^2 - y$, f of y is equal to $2xy - x$.

Interviewer: Nice, and then how did you come up with those again?

Alonzo: So here [*points to* f_x], I held everything but the x variable is constant, so these y's are just constant in this case, and here [*points to* f_y] I held everything but the x variables everything with the y variable is constant. So, the x variables were constant.

Interviewer: Nice.

Alonzo: Okay, and then what do these represent? These represent I'd say curves on the 3D surface.

After I asked him to clarify his response, Alonzo sketched the diagram pictured in Figure 1(a). Alonzo explained that $\frac{\partial f}{\partial x}$ and $\frac{\partial f}{\partial y}$ represented the curves on the surface in the x and y direction respectively. This meaning appeared highly associated with his attention to mentally fixing the value of one of the independent quantities by treating the variable as a constant when differentiating. Relatedly, when interpreting $f_x(2, 1.5)$ and $f_y(2, 1.5)$ in task 1.3.3, Alonzo explained that once he evaluated the partial derivative function, for example f_x, at $x = 2$ and $y = 1.5$, $\partial f/\partial x$ and $f_x(2, 1.5)$ represented the slope of the tangent line to the curve at the given point (as shown in Figure 1(b)) while mentally fixing the value of $y = 1.5$. This example of Alonzo's meaning for partial derivatives is interesting because it highlights how Alonzo evokes different aspects of his apparent scheme for partial derivative based on his current goal (either differentiating, evaluating the function at a point, or attending to graphical interpretations).

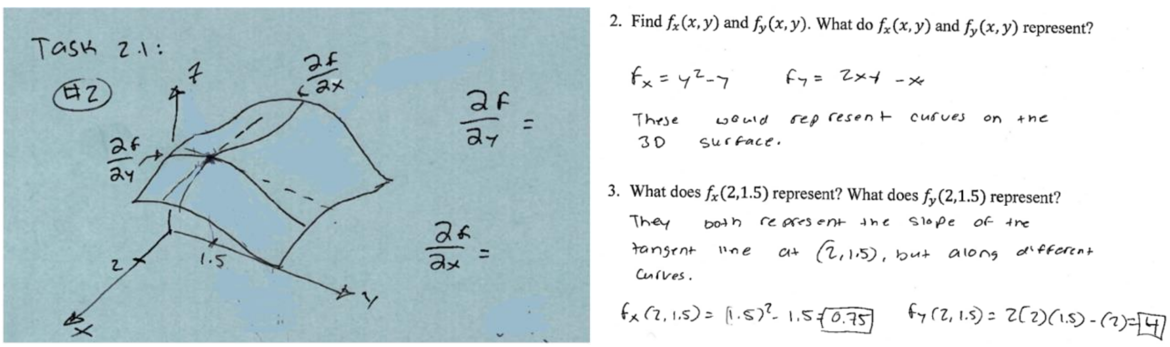

Figure 1: (a) Alonzo's sketch in task 2.1 accompanying his explanation for task 2.1.2 and 2.1.3. (b) Alonzo's response to task 2.1.2 and 2.1.3 demonstrating his dual meanings for partial derivative notation.

Meaning 2: Partial derivatives are the slopes of the tangent lines to each curve. John's meaning for partial derivative, on the other hand, consistently included a conception of partial derivatives as the slope of the tangent line contained within a plane parallel to either the xz or yz plane respectively. When responding to task 2.1.2, John's meaning for $f_x(x, y)$ and $f_y(x, y)$ included a graphical representation of the surface and slopes, as demonstrated by his gestures moving along an imagined surface graph. For John, mentally fixing the value of one of the independent quantities corresponded to isolating his attention on the graph of the function to a particular cross-section represented by intersecting the surface graph with a plane, as demonstrated in the following transcript.

John: Okay, so what do these represent? Well, if I had a sheet [*moves hands along an imagined bump which smooths out as he moves hands away from one another*] right? Then I can take a plane in the x direction [*chops hand down pointing to his left*] and if I fix the x value [*gestures with same hand to the right*] then I should be able to find the instantaneous slope [*moves pinched fingers up and to his right*] in the y direction. If I were to just look at that, that graph right there [*brings hands together flattened together at the fingertips*], then I would be able to figure out what the derivative would be with this, what the slope would be [*moves right hand along holding left hand fixed flat*].

While Alonzo's meaning for $f_x(x, y)$ and $f_x(2, 1.5)$ foregrounded different aspects of his more general meaning for partial derivatives, John's meaning for $f_x(x, y)$ and $f_x(2, 1.5)$ remained relatively consistent across all day 2 tasks.

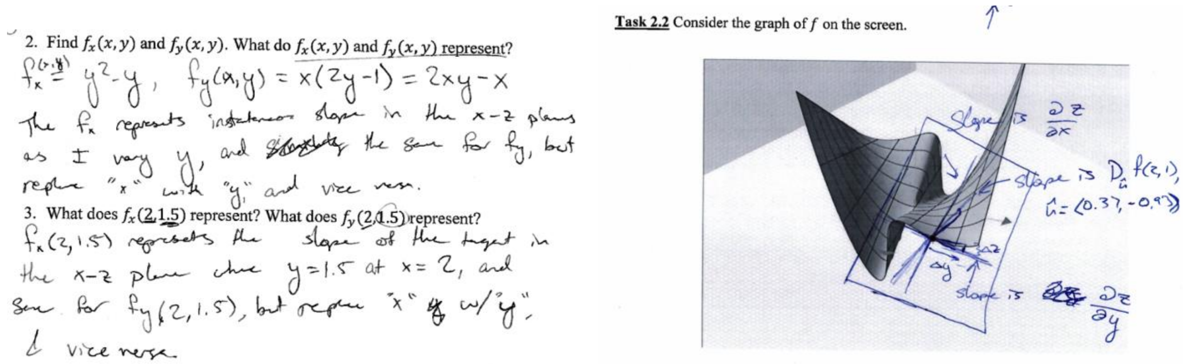

Figure 2: (a) John's response to tasks 2.1.2 and 2.1.3 demonstrating his consistent meaning for partial derivatives. (b) John's annotation of the surface graph in task 2.2 slope of the tangent line meaning.

Vignette 2: Student's Meanings for Directional Derivatives

Alonzo was not comfortable with the idea of directional derivatives, so we spent most of the remainder of his day 2 interview making teacher moves aligning with the meanings for directional derivative as outlined in my conceptual analysis. John, however, due to his recent Differential Geometry course, had revisited these ideas and exhibited numerous meanings for directional derivatives which included: (i) the rate of change of z in the $\hat{u}$ direction, (ii) the slope of the tangent line resulting from intersecting the graph of the surface with a new "shifted" uz plane, and (iii) as the amount of variation in z due to change in the $\hat{u}$ direction.

Meaning 1: The directional derivative is the slope of the tangent line to the curve in the new, shifted uz plane. As shown in Figure 2(b), John's meaning for directional derivative included a conception of slope in the $\hat{u}$ direction. While it may look like John conceived of partial and directional derivatives as the slopes of the tangent planes in task 2.2, this was not explicitly the case. In task 2.2, John was tasked with sketching the best local, linear approximation for the given function at a specific coordinate triple. He then discussed his meaning for $D_{\hat{u}} f(2, 1)$ using the relative size measurement of the horizontal and vertical segments he sketched in Figure 2(b). However, John's meaning for directional derivative is better demonstrated in the following excerpt from his work on task 2.1, where he describes his construction of the new "shifted" uz plane, which is also demonstrated in his response to task 2.1.5 in Figure 3(a).

John: Okay, this right here is a directional derivative. And so, if I were to want to find, turn my plane now [*rotates hands together*]. I'm going to turn my plane so that the u vector is pointing [*points thumb in a particular direction*] in the direction of my plane, in the xy plane, right? [***omitted***] And so, this u vector lies in here and so beforehand we were talking about this plane [*sketches xz plane*] we were talking about this plane right here [*sketches yz plane*] and now I want to talk about varying this plane right here [*sketches plane parallel to the z axis containing the u vector*].

Interviewer: Great.

John: And so, if I take that plane and I move it around however I need to [*moves vertically-held hands around in front of him*] and find the directional derivative that's the derivative in that direction [*points with pen*]. So, it represents the rate of change in the direction of u-hat. Yeah, I guess that's probably the easiest way to say that.

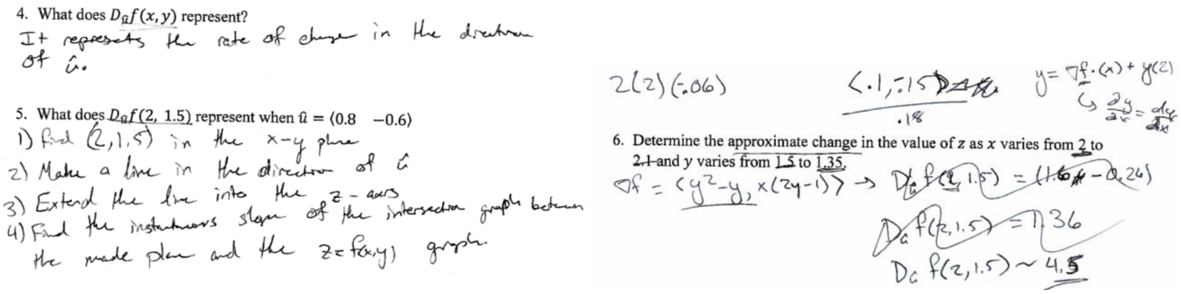

Figure 3: (a) John's response to task 2.1.4 and 2.1.5 demonstrating his slope in the uz plane meaning. (b) John's response to task 2.1.6 demonstrating his meaning for directional derivative as the amount of variation in z.

Meaning 2: The directional derivative is the amount of variation in z. While John appeared to have a robust meaning of linearization which was highly interrelated to his meaning for derivative, it appeared that, at times, John conceptualized rates of change as amounts of variation in the value of the dependent quantity, as shown in Figure 3(b). For instance, in task 2.1.5, John described the directional derivative as "the best approximation you can make if you're assuming that it's from here starting at this point [*underlines x=2 and y=1.5*] and goes to these points [*underlines x=2.1 and y=1.35*]." While it is not uncommon that students conceptualize rates of change as amounts of variation in the value of the dependent quantity of the function, it does highlight the importance of supporting students in differentiating between the concepts of rate of change and variation earlier in their mathematics instruction, as the complexity of attending to the values of more than two quantities as they change together, vectors and vector notation, and the calculus of MV functions is enough of a cognitive load for students without worrying about conflating rates of change with amounts of variation.

Discussion and Conclusion

In this paper, I shared two vignettes of two student's nuanced meanings for partial and directional derivatives. These vignettes highlight the importance of ensuring that students construct a strong foundational understanding of derivatives as rate of change functions in single variable calculus, to support the generalization of their meanings to MVC settings (Harel, 2021; Martínez-Planell & Trigueros Gaisman, 2021; Thompson, 2019). Second, these results highlight a need to support students in differentiating between amounts of variation and rates of change as distinct quantities (Thompson, 2022). This is an important, but difficult, conceptual distinction that students struggle to make in single variable calculus settings. Since students' meanings for derivatives of functions appear to influence the meanings they construct in MVC settings (Bettersworth, 2023), more research is required to support students in making this distinction.

Limitations

The mathematics of students presented here represent second-order models of student thinking emerging from the analysis of two students' responses within the context of exploratory teaching interviews. As such it is impossible to claim that these are representative of every possible meaning a student might possess or construct. Future studies could attempt to replicate or generalize the results presented here with a larger collection of students from a different or more varied cross-section of students majoring in STEM.

Online Mathematics Tutoring: Where Did We Come From; Where Did We Go?

Keith Gallagher, University of Nebraska Omaha
Nicole Engelke Infante, University of Nebraska Omaha
Deborah Moore-Russo, University of Oklahoma

Online mathematics tutoring has become a fixture of the educational landscape in higher education. Using Lepper and Woolverton's (2002) INSPIRE model for effective in-person mathematics tutoring as a basis, we developed a codebook to analyze online tutoring, modifying existing codes to reflect how they manifest in the online environment and augmenting our codebook with behaviors that were not present in the in-person environment. We give a description of the current state of online mathematics tutoring and identify methods used by online tutors to actively engage students in the learning process. In addition to our results, we include a brief description of some challenges we faced as researchers when engaging with research on online tutoring and the solutions we reached.

Keywords: online tutoring, student engagement, affect, equity

Background

Access to high-quality online tutoring is an issue of equity. Student utilization of mathematics tutoring services has been correlated with an increase in final course grades (Byerley et al., 2018; Rickard & Mills, 2018; Xu et al., 2001) and with improvements in persistence, retention, and degree completion (Astin, 1993; Pascarella & Terenzini, 1991, 2005; Rheinheimer et al., 2010; Rheinheimer & Mann, 2000; Rouche & Snow, 1977). This is critical for academically fragile students as individual or small group tutoring allows instruction to be tailored to student needs (Anghileri, 2006) while helping students develop mathematical identities (Bjorkman & Nickerson, 2019). Peer tutoring centers can also provide a space for at-risk students to find support and build community, as first-generation college students have reported needing to work harder than their peers to attain the same level of achievement, and underrepresented minority students have reported that lacking a sense of belonging presented a significant challenge to persistence in college (Richardson & Skinner, 1992). Anecdotally, the authors have witnessed an increase in the need for high-quality mathematics tutoring among undergraduate students at their institutions since the widespread school closures in 2020, an effect that was predicted by Chetty et al. (2020) and Kuhfeld et al. (2020).

Despite its importance, online mathematics tutoring has not been extensively studied. Directors of online tutoring centers face myriad decisions related to drop-in vs. appointment-based tutoring, hours of operation, types of technology to use, tutor training and evaluation, and advertisement of services, among others. As funding continues to become a more pressing concern for many college tutoring programs (Johns & Mills, 2021), it is essential that tutoring center directors are able to make informed decisions about the types and quantity of services to offer. The body of literature on online tutoring provides insight into these topics (Johns & Mills, 2021; Turrentine & MacDonald, 2006), but there has been no comprehensive systematic implementation and evaluation of online tutoring practices for undergraduates. For that reason, we present a description of online tutoring in college mathematics describing ways that tutors engage students in online tutoring and outlining challenges particular to this type of research.

Research Questions

During the advent of the modern era of online tutoring via video conferencing in Spring 2020, the authors observed that online tutoring had become something like a "drive-thru" homework service without the benefits tutoring often offers when in-person, where tutors provide emotional and metacognitive support to students, provide community, and act as a repository of institutional knowledge (Blackwell et al., 2007; Boaler, 2013; Cohen & Sherman, 2014; Dweck, 2007; Dweck et al., 2014; Moser et al., 2011). Even during purely mathematical tutoring sessions, skilled tutors often place much of the problem solving in the hands of their students by asking thought-provoking questions and guiding students to exhibit more mathematical habits (Lepper & Woolverton, 2002).

Our main goal with this research was to find ways to restore these more "meta-mathematical" practices in our online tutors and to place more focus on the needs of their students. We began with simple observations of online tutoring sessions to gain a deeper understanding of what was already taking place in these sessions to determine how best to improve them. This led to the first research question we attend to below: *What does online mathematics tutoring look like?*

With a general sense of how online tutoring sessions typically operate, we returned to our original goal of improving the student experience in online tutoring. Our second research question focuses on just one aspect of the online tutoring experience: *How are tutors engaging students in the online tutoring process?*

Theoretical Framing

We viewed our data through the lens of Lepper and Woolverton's (2002) INSPIRE model for effective tutoring. This model identifies cognitive, metacognitive, and affective strategies and considerations employed by expert tutors. These strategies focus on academic content, but also emphasize the importance of study skills and student mindsets. The INSPIRE model, outlined in Table 1, categorizes the practices and dispositions of expert tutors into seven categories.

Table 1. INSPIRE Model category descriptions.

Category	Description
Intelligent	Knowledge of subject matter and pedagogical strategies
Nurturant	Developing a personal rapport with the tutee
Socratic	Asking questions to foster dialogue rather than telling
Progressive	Purposeful selection of problems, systematic feedback, predictable routines
Indirect	Providing appropriate types and amounts of feedback
Reflective	Asking the tutee to explain reasoning and generalize
Encouraging	Promoting confidence, challenge, curiosity, control of the learning

Although the INSPIRE model is a comprehensive summary of the practices of effective tutors, the model was developed from observations of tutors operating in the in-person tutoring environment. Using the INSPIRE model as an established baseline for "good tutoring," our work expands on these results by describing effective practices in the setting of online tutoring.

Methods

Data were collected from Spring 2021 through Spring 2023 at two universities, U1 and U2, and consisted of recorded online tutoring sessions. Both universities offered tutoring in two modalities: in-person during the day and online via Zoom in the evening. Each semester there were five tutors at each university providing online tutoring and participating in the research project. All tutors received tutor training, and those who were tutoring online received training specific to the online environment. Additionally, online tutors were provided with a tablet and stylus to facilitate writing capabilities in online sessions. All students, regardless of whether they were enrolled in in-person or online classes, could attend either in-person or online tutoring.

U1 Context

U1 is a research-focused institution in the mid-Atlantic region of the U.S. with a total enrollment of about 21,000 undergraduate students. It is approximately 50% residential, with mostly freshmen living on campus. U1 has two campuses, A and B, about 2 miles apart. The mathematics tutoring center is located on Campus A in the same building as the mathematics department and offers drop-in, in-person tutoring. Although most math courses are offered on Campus A, only about 9% attend their mathematics class in the same building as the tutoring center, and 25% of students enrolled in a math class attend their class on Campus B.

U2 Context

U2 is a research-focused institution in the southwest region of the U.S. with a total enrollment of about 23,000 undergraduates. It is 29% residential, with most freshmen residing on campus. U2's mathematics tutoring center offers drop-in, in-person tutoring. U2's tutoring center is located on the main floor of the building where about 75% of its math classes are offered and where all mathematics instructors' offices are located.

Codebook Development

Four researchers developed and participated in the development of our codebook and the analysis of our data. Data analysis began by applying codes that were adapted from Lepper and Wolverton's (2002) INSPIRE model presented above. As their study was focused on in-person tutoring sessions, the codes needed to be adapted for the online tutoring environment. The codebook underwent several revisions across 11 coding-specific meetings as we began adapting the codes to what was present in the data. Table 2 below describes our final broad category codes including their relation to the INSPIRE Model categories.

Table 2. Descriptions of coding categories used for study.

Code	Description
Technology	Technology and digital resources used during tutoring captured with subcodes to indicate tutor or student sharing screen, who writes, etc.
Multiple Students	Tutor work involving multiple students during a session
Modes of Interaction	Tutor's interaction modes: artifacts, gesture, inscriptions, and speech
Tutoring Content Knowledge	How the tutor approaches the student making meaning of the mathematics; how the tutor's understanding of the content drives the tutoring episode; how the tutor facilitates learning including how his explanations/questions drive the session, degree to which tutor tries to facilitate student understanding; related to the Intelligent and Progressive categories
Tutor Affective Interactions	How the tutor facilitates or drives the tone of the interaction; related to Nurturant and Encouraging categories
Tutor Communicative Interactions	How the tutor facilitates the student being an active participant engaging in communication; related to the Socratic, Indirect, and Reflective categories
Student Pursuit of Understanding	How the student enters the tutoring space; how student expectations drive the session; degree to which student seeks understanding

Units of Analysis

When data analysis began, we set the unit of analysis to be the interaction between tutor and student on a single problem. Although this fairly granular level of analysis allowed certain interactions to be captured, it missed others, especially affective interactions. There was also significant repetition in coding since interactions across problems in a setting were extremely similar. Hence, we zoomed out and tried using a single student-tutor interaction; using the problems they completed together in a single "sitting." Again, we found that some key interactions were overlooked such as how a tutor handles multiple students in the session and transitions between students. Thus, we settled on each individual recording that corresponded to the tutor's shift for the day, usually 1 to 2.5 hours, as our unit of analysis.

Results

The nature of the tutoring we observed among the tutors in our study has changed dramatically since data collection began in Spring 2021. At the inception of our study, online mathematics tutoring looked like a "drive-thru" homework service. *Student pursuit of understanding* was often minimal in that students arrived in the online tutoring space with questions like "I don't know how to do number 10 in my homework. How do you do it?" In response, *tutor communicative interactions* were lacking; as the tutors typically solved the problem for students, rarely involving the students in the process, and then students would leave the tutoring space. There were few *affective interactions,* and tutors and students were scrambling to figure out ways to share their thinking and writing (*modes of interaction*). This is not entirely surprising since tutors were not trained to operate in the online environment, and the technology to which tutors had access varied widely. After tutors were given tablets and training specific to tutoring mathematics online, the nature of tutoring sessions began to change. In this section, we will first discuss what online mathematics tutoring looks like when tutors have appropriate technology and training, and then we will identify specific strategies employed by tutors to engage students in the tutoring process in the online environment.

What Online Mathematics Tutoring Looks Like Now

Tutoring sessions begin differently now than they used to; tutors are more intentional about welcoming students into the tutoring space. It is very easy for students to feel like they are being ignored when they enter a video conferencing session, and a tutor is already deep in conversation with another student. Unless the tutor explicitly acknowledges that students have entered the tutoring space, the students may not know if anyone has noticed their presence. Moreover, tutors keeping their cameras on is particularly important, as students may not even know if a tutor is present when they enter the virtual tutoring space without this visual information.

Some in-person tutoring practices related to *tutor affective interactions* have translated well to the online environment. For example, when a new student enters the tutoring space while a tutor is already working with a student, tutors often ask what class the new student is in as well as more details on why they are coming to tutoring. It was common to hear, "What do you need help with today?" When the new student's needs overlap with the topic of the conversation in-progress, the tutor will invite the new student to work along with them so both students can be helped simultaneously. If the new student's needs differ significantly from what the tutor is working on with the first student, the tutor will then bounce between students, giving one student a task to work on while discussing progress that has been made by the other student. In this manner the *tutor communicative interactions* are attempting to help more than one student actively engage in learning mathematics during the tutoring session.

In some cases, we have observed a set of new practices develop that are better suited to the online setting than in-person – on the parts of both tutors and students. Students have expressed being able to learn by listening to conversations between tutors and students in which they were not actively taking part. In person, it is often difficult to listen in on other conversations in the tutoring space because of physical distance between students, background noise from other conversations, and other factors. Video conferencing software makes it especially easy for students to eavesdrop on other conversations. So, for some students, the *student pursuit of understanding* has shifted from attending online tutoring to get help with certain homework problems to attending to learn through listening to the conversations of others and piping in with questions about another's tasks.

Regarding *tutor communicative interactions* involving multiple students, there is one in-person tutoring practice that has not been noted in online tutoring. In person, tutors often encourage students to sit in pairs or small groups in the tutoring center to work on similar problems so they can collaborate while the tutor helps other students. Our data set does not contain any instances of students working together while the tutor works with another student. To do this online without disrupting others, the tutor would have to place students in a breakout room and then move between breakout rooms to check on different students. It is possible that our tutors either do not know how or are not comfortable doing this. It is also possible that, in the moment, they have decided that the costs in terms of time and efficiency outweigh the benefits.

Looking at the *modes of interaction*, gesture usage in the online environment is particularly interesting. Deictic (pointing), iconic, and metaphoric gestures (Alibali et al., 2014) are nearly absent from online tutoring. Tutors seem to realize that many gestures are hard to see and that others cannot identify the referents of their pointing gestures, rendering them ineffective. However, we observed a large number of what Alibali et al. (2014) call writing gestures: "writing or drawing actions that were integrated with speech in the way that hand gestures are typically integrated with speech but that were produced while holding a writing instrument (usually chalk or marker) and that involved writing to indicate or illustrate the content of the accompanying speech (e.g., underlining an equation on the board while saying 'this equation')" (p. 76). Tutors became adept at writing or drawing with different colors for the purpose of emphasizing or differentiating between different kinds of information, such as text written as part of a problem's solution and text written as an annotation of that solution for their student's edification. As with deictic gestures, tutors seemed to understand that students could not see where their stylus was when they were tracing over a figure, as when tracing over the graph of a parabola to emphasize its shape, or when repeatedly tracing over a tangent line to emphasize its slope. Tutors used color in these instances to call students' attention to the importance of certain features or to add new information to previously drawn figures.

How Tutors Engage Students in Online Tutoring

Tutors' engagement of students in the tutoring process has improved substantially since the inception of the modern age of online tutoring in Spring 2020, both in terms of *tutor affective interactions* and *tutor communicative interactions*. Tutors have improved in their abilities to create an inviting space for students to engage with them and with mathematics. Tutors have also become much more adept at using technology to facilitate interactions that allow students to become active participants in the conversation.

Tutors have adopted a subtle strategy whose power is often understated in the in-person tutoring environment: casual and welcoming conversation. The tutors in our sample began each session by intentionally greeting and welcoming students into the online tutoring space and engaging them in casual conversation by asking how they were doing or what their plans were for the weekend, commiserating about the challenges of being a student, or discussing events taking place around campus. More than just creating a comfortable space, this act seemed to prime students for social interaction and set a tone for the tutoring session in which both tutor and student were active participants.

Tutors now engage in much more questioning behavior than in the early days of online tutoring. After the tutors welcomed students into the session, the next tutor move was typically to ask students what they need help with and to describe the progress made so far, and in some cases reenact their thought process up to the point where they encountered difficulty. This allowed the tutors to identify what students already understood and to diagnose any misconceptions or gaps in understanding. Tutors continued to ask questions throughout their sessions, encouraging students to think instead of passively receiving information from tutors. When working on procedural tasks such as solving equations, tutors often asked students for procedural information with justification (i.e., next algebraic step and why that operation is the correct choice) or more conceptual questions related to task at hand.

Tutors' increased facility with technology has improved their ability to engage students. One thing we noticed after providing tutors with tablets was that, rather than replacing their original device with the tablet, they used the tablet in concert with the original device. The purpose of the original device shifted to become solely for face-to-face interaction with their students, while the tablet was used for writing and drawing. This experience mirrors the in-person tutoring environment by allowing tutors the ability to look at the students and their work simultaneously, as if they were working side-by-side with a sheet of paper or a whiteboard between them.

Tablets facilitated our tutors' ability to act as scribes during sessions in which their students were not able to write on their own devices. In the early days of synchronous online tutoring, in many cases, neither tutors nor students had a device that would allow them to work together in a visible collaborative space. Our tutors' access to tablets gives them the ability to ask students questions and keep a record of their work, allowing students to drive conversations about solving algebraic equations and computing derivatives and integrals while tutors simply keep track of their work for them.

Discussion

We have learned quite a bit about how to make the online mathematics tutoring experience better for students. Most importantly, we have learned that, with access to training and tools, tutoring practices improve. Since Spring 2020, the tutors in our sample have transitioned from simply serving as a quick homework solution service to providing highly interactive learning experiences for students. The practices our tutors now demonstrate are well aligned with established best practices for in-person tutoring – though more in-depth study is necessary to determine a set of best practices for online tutoring. Our work takes a necessary first step toward establishing these best practices in the research literature.

In person, nonverbal communication conveys a substantial amount of information. Through communication via video conferencing software, much of this nonverbal information is lost (particularly if a person's camera is turned off) or must be communicated in different ways. As we observed in our data, gestures, especially deictic gestures and beat gestures (which are often used for emphasis and to direct attention), do not seem to be used as frequently as they are during in-person communication. However, among the tutors in our sample, writing gestures seem to have supplanted many forms of gesture, and these writing gestures are often supplemented with strategic use of color to draw students' attention.

Challenges of Online Mathematics Tutoring Research

When working on such a multifaceted topic, we, as researchers, experienced more challenges than initially anticipated. Issues related to data collection, codebook development, selection of an appropriate unit of analysis, and other things arose as our project progressed. We conclude by discussing a selection of these problems and our solutions to them. This list is not exhaustive, but we present it for the benefit of others who may consider engaging in similar research.

As noted earlier, we revisited the process of selecting an appropriate unit of analysis several times. As we operationalized this decision, we quickly realized that tutoring sessions varied greatly in terms of length, with some lasting only 10-15 minutes and others lasting upwards of 2 hours, and tutor behaviors in the first 10 minutes of a session often look very different than they do after an hour. Eventually, we accepted that there was likely no choice that would allow us to uniformly capture all the information we wanted, and we settled on our current unit of analysis in the interest of advancing the project. Subsequent analyses may call for a different unit.

Development of an appropriate codebook was also challenging. Using the INSPIRE model as an initial guide, we set out to investigate the prevalence of a subset of these practices: the Nurturant, Socratic, and Encouraging aspects of the framework. As we coded, we realized that the difference in environment (online vs. in-person) introduced behaviors not accounted for by the original model (e.g., issues and behaviors related to technology), forcing us to expand the codebook. Furthermore, within each of the behaviors coded, we recognized that many were present to varying degrees: for some tutors, drawing several pictures per session was commonplace, while others might only draw one picture per session; though two tutors might both ask questions, one tutor may ask significantly more questions. This caused us to augment our codebook in places to include subcodes related to degree – strong, weak, or mixed.

Conclusions and Future Work

We have made great strides toward improving the online tutoring experience for students. The online tutoring environment has become much more like the in-person environment, and students are able to be much more interactive participants in the learning process instead of passive recipients of information. Despite our best efforts to make the online environment feel like the in-person environment, we must acknowledge that the online environment is not, and will not be, the in-person environment, and therefore some differences may persist. With access to training and appropriate technology, tutors can adapt the online environment to work just as effectively for students as the in-person environment.

Research into mathematics tutoring is a complicated process (see Johns et al., 2021), and this is doubly true for online tutoring. The online environment now seems to be a permanent fixture of the educational landscape; we must understand its similarities and differences with in-person environments to provide our students with the best learning experience possible.

Undergraduate Gender Differences in Knowledge of the GRE and Perception of the GRE as a Barrier to Applying to Graduate Mathematics Programs

Graduate Record Examination (GRE) scores are commonly required in applications to graduate school in mathematics. We examine undergraduate mathematics majors' knowledge of the GRE and their perceptions of the GRE as a barrier to applying to these programs as part of a larger project studying student knowledge of the graduate school application process and how it contributes to lack of diversity in graduate mathematics programs. We found that there was an association by gender, and that women were less likely to report that they had heard of the GRE General and Subject Tests. Similarly, women were more likely to report that the GRE tests were a potential barrier to their decision to apply to graduate mathematics programs.

Keywords: Graduate Record Examination, Graduate School Applications, Gender, Social Cognitive Career Theory

The field of mathematics lacks diversity; this becomes more pronounced at higher levels of education. While 50.8% of the U.S. population identify as women and 31.9% as Hispanic/Latinx or African American (U.S. Census, 2020), in recent years only 39% of mathematics bachelor's degrees were earned by women (Golbeck et al., 2019) and 15.9% of mathematics and statistics (mathematics-only data unavailable) bachelor's degrees were earned by minoritized[1] students (National Center for Science and Engineering Statistics, 2019). At the highest levels of formal education, only 24.1% of new mathematics doctoral recipients were women and 7.4% were minoritized (Golbeck et al., 2020).

Many graduate programs in the U.S. require students to take the Graduate Record Examination (GRE) General Test, and some programs also require the discipline specific test as well (e.g. mathematics, physics). Graduate programs often use the GRE to gauge applicants' preparedness for graduate school. Despite recommendations against this practice from the ETS (Miller et al., 2019; Posselt, 2016), some programs advertised cut off scores for the Subject and General Test in order to apply (Miller et al., 2019; Petersen et al., 2018). Other programs weigh GRE performance heavily to speed up the review process (Petersen et al., 2018; Posselt, 2016). The frequent use of cut off scores and heavy weighting of the GRE led to investigation into whether these practices disadvantage certain groups. Studies found that minoritized students and women score lower on the GRE than their counterparts (Bleske-Rechek & Browne, 2014; Cochran et al., 2018; Miller et al., 2019; Petersen et al., 2018). In fact, women and minoritized students were less likely than their peers to score above a program's stated Subject Test threshold, which reduces their chances of being accepted to a given program (Miller et al., 2019; Posselt et al., 2019; Verostek et al., 2021; Young & Caballero, 2021). Several other studies found

[1] Minoritized is an alternative way of referring to people who are often labeled as "Underrepresented Minorities" in STEM. This alternative phrasing makes it clear that it is power imbalances and systematic oppression that cause these groups to be less represented in STEM (Wingrove-Haugland & McLeod, 2021).

similar results for the General Test (Petersen et al., 2018; Posselt et al., 2019). Building on these results, researchers have investigated whether the GRE predicts PhD completion, finding that GRE performance does not predict PhD completion or success in a PhD program (Miller et al., 2019; Petersen et al., 2018; Roberts et al., 2021; Wilson et al., 2018). So, while the usefulness of the GRE in predicting success is uncertain it still often serves as a barrier for women and minoritized students pursuing graduate education. In this paper we examine data related to what undergraduate mathematics majors know about the GRE as they prepare to apply to graduate school.

This study is part of the Undergraduate Knowledge of the Mathematics Graduate School Application Process (Knowledge-GAP) project which was created to explore undergraduate mathematics majors' knowledge about the graduate school application process and differences in perceived barriers to applying to graduate school across different demographic groups. This paper focuses on the results related to the GRE. Specifically, we examined differences in knowledge and perceptions of the GRE between graduate school applicants.

1. *What do undergraduate mathematics majors know about the GRE?*
2. *Do knowledge and perception of the GRE differ by gender identity of the students?*

Theoretical Background

Social Cognitive Career Theory (SCCT) incorporates Tinto's non-cognitive and contextual factors known to be important in retaining minoritized students and women and expands them for use in STEM career choice for these groups (Lent et al., 1994, 2000; Tinto, 1975, 1993, 2007). Tinto's sense of academic belonging is particularly important for student groups marginalized in STEM; SCCT refines this aspect and identifies several additional significant barriers affecting degree interest and completion for minoritized students and women, each of which are exacerbated by institutionalized environmental barriers at every level of education (Alexander & Hermann, 2016; Cutright et al., 2015; Estrada et al., 2016). The SCCT model incorporates gender as an individual characteristic and situates it within a person's context specific characteristics. Kanny et al., (2014) discussed SSCT studies focusing on individual characteristics (e.g. race, ethnicity), structural barriers (e.g., institutional and classroom climates), psychological factors (self-efficacy or sense of belonging), and family influences (including gender role socialization and self-concept), and perceptions of STEM careers. Within the SCCT framework, each of these contextual factors impacts career trajectory by acting as either a facilitator or a barrier and they may even be the key factors influencing lower participation of women and minoritized people in STEM careers. For example, racist and sexist systemic barriers may affect both the entrance and persistence of marginalized groups in STEM careers by negatively influencing their STEM self-efficacy and their STEM career outcome expectations.

Within this framework, we view the GRE as representative of a structural barrier for some groups of students wishing to enroll in graduate programs in mathematics. A recent study of mathematics graduate programs at three large research universities reported that only 18%, 15%, and 12% of applicants were women, respectively (Gevertz & Wares, 2020). Given the widespread use of the GRE as an application requirement, gender differences in knowledge of and perception of the GRE as a barrier to applying has the potential to impact the demographics of mathematics graduate education.

Methods

Instrument Development

The research team created a survey based, in part, on a survey used to determine undergraduate physics majors' interest in graduate school and how important they believed different aspects of the application process were (Chari & Potvin, 2019). Nineteen survey items were adapted from that instrument, though a notable difference in our survey was that we provided an opportunity for participants to express their lack of knowledge about different parts of the application process. The final survey had 57 items separated into four categories: (a) knowledge about different aspects of the application process, (b) barriers to applying, (c) interest in graduate school and what students look for in programs they apply to, and (d) demographic questions. Most questions were Likert scale or multiple choice, though four were open-ended and some of the multiple-choice items allowed participants to type in a text response. The full survey is available at this link: https://researchrepository.wvu.edu/faculty_publications/3291/

Data Collection

To ensure broad participation, the research team sent the survey to department chairs and undergraduate program directors at all undergraduate mathematics programs at colleges and universities in the U.S. with at least 1000 students total ($N = 985$). We asked programs to send the survey to all undergraduate mathematics majors. Initial emails were sent Fall 2022 through Spring 2023, via Qualtrics, and follow-up emails were sent to encourage a greater response rate. In addition to direct emails, the research team also posted the survey on social media, listservs, and in newsletters for several professional organizations in mathematics.

Data Analysis

We received 1090 responses from students at 181 colleges and universities, with 519 complete responses. Note that students could miss part of a question and still have their response marked as complete. Thus, the *N*s for different items are not always the same. Statistical tests were run in IBM SPSS.

To address our research questions, we analyzed responses to five survey items. Three were binary response items asking participants about the following aspects of both the GRE General Test and Mathematics Subject Test: if they had previously heard of, or taken, the tests; if they knew about the different sections on the test, testing modality options, testing frequency and locations, costs associated with taking exams and having scores sent to institutions, and availability of fee waiver codes. The final two were the Likert scale items: *To what extent are the following factors a potential barrier to your pursuit of graduate school?* and *How important are the following factors in choosing which schools you apply to?* Both items were adapted for our study from Chari and Potvin (2019). The first item had 17 sub-item topics, rated on a scale of 1 (not at all a barrier) to 5 (very significant barrier). The second item had 15 sub-item topics, rated on a scale of 1 (not at all important) to 5 (very important). For this paper we only analyze responses to the seven sub-item topics related to the GRE.

Results

Participant Demographics

Table 1 shows demographics of participants with complete responses. Participants were able to select more than one option for gender, so the total adds up to more than 100%.

Table 1. Self-identified Gender.

What is your gender?		
Gender	*N*	Percentage
Man	251	48.4%
Woman	226	43.5%
Genderqueer or Non-Binary	41	7.9%
Agender	12	2.3%
Transgender	21	4.0%
A gender not listed	2	0.4%
Prefer not to say	8	1.5%
Total	519	

Knowledge of the GRE

Overall participant knowledge of the GRE was incomplete at best. While a majority of the participants (379/518, or 73.2%) had heard of the test before, only half (270/518, or 52.1%) had heard of the GRE Mathematics Subject Test. More worryingly, when asking participants who had heard of the GRE what specifically they knew about the exam, there were large gaps in specific knowledge about the exam. Of the 346 participants who said they had heard of the GRE General Test before, only about half (50.7%) knew that the test had three sections: Verbal Reasoning, Quantitative Reasoning, and Analytical Writing. Only about half of those participants (168/346, or 48.6%) knew that the test is offered with regular frequency, and that it is possible to take it from home. For questions pertaining to the cost of the exam, only a third of participants (115/346, or 33.2%) knew the cost of the test ($220). Just over a fifth of participants (74/345, or 21.4%) knew that it costs $30 to send GRE scores to a graduate program after taking the test and just over a fifth (79/345, or 22.9%) knew that fee waivers were available for the GRE.

For the GRE Mathematics Subject Test, of the 267 participants who said they had heard of the test before, only about a third (96/267, or 36.0%) knew that the test is only available three times a year. About 40% (107/267) knew that at the time the survey was administered, the test was not available to take from home and you had to travel to a testing center to take it. Finally, only 30.5% (81/266) knew the cost of the test ($150).

It is necessary to mention that these results are for a subset of the larger sample. For example, 36% of participants who had heard of the Mathematics Subject Test knew how often the tests are available, but only 52% of participants overall had heard of the Mathematics Subject Test. Therefore, the percentage of participants overall who knew how often the Mathematics Subject GRE is offered was only 96/518 = 18.5%. In addition, only a small number of participants had taken either of the two GRE tests before taking the survey: 50/518, or 9.7%, for the General Test and 25/518, or 4.8%, for the GRE Mathematics Subject Test.

Based on the established literature on gender and GRE performance we tested if there was a difference in knowledge or perception of the GRE as a barrier by participant gender. One issue we encountered in our data analysis was that our participants were not limited to a gender binary like most previous studies of the GRE. To get results comparable to previous studies participants were separated into two groups based on their answer to the survey item asking for their gender. Participants who said they were women, regardless of whether they selected any additional gender identities were labeled as “Women” for our analysis. This includes women who are also cisgender, agender, transgender, and/or non-binary. Similarly, participants who did not select the women option were labeled as “non-women”. We use this categorization to have results comparable to studies that had a binary definition of gender, while also being inclusive of our participants’ other identities. We found that there was an association by gender, women were less likely to say they had heard of the GRE General Test before taking the survey $\chi 2(1, N = 518,) = 13.47, p = <.001$ ($V = .16$). Similarly, there was an association by gender, and women were less likely to say they had heard of the GRE Mathematics Subject Test before taking the survey $\chi 2(1, N = 518) = 14.95, p = < .001$ ($V = .17$). Both results had a small effect size. There were no associations by gender for the other survey items about knowledge of the GRE (All p’s > .05).

Perception of the GRE

We report here on the GRE-related sub-item topics for the two Likert scale items, five for the first item and two for the second item. A one-way analysis of variance (ANOVA) was not employed because for 3 of the 7 sub-item topics the Homogeneity of Variance assumption was violated. Thus, for ease of comparison and consistency, Mann-Whitney U tests were performed using the women/non-women variables for all sub-item topics. Table 2 contains Mann-Whitney U test results for the women/non-women groups for the 519 participants who responded to the selected sub-item topics from the first item. The output of a Mann-Whitney U test is a Z value on a normal distribution. The Z values in Table 2 indicate that the women group has greater means than the non-women group. These results show there is a statistically significant difference (all p’s < .05) between the women/non-women groups in the responses for all five sub-item topics. In all cases, women were more likely to view each sub-item topic as a potential barrier to their pursuit of graduate school than their peers. All these results had a small effect size (all r’s between 0.1 and 0.3).

Table 2. Mann-Whitney U test results for selected items for the question “To what extent are the following factors a potential barrier to your pursuit of graduate school?” using the women/non-women variable.

Item	Group	*N*	Mean	Mean Rank	*U*	*Z*	*p*	*r*
The need to do well on the GRE General Test	Women Non-Women	226 291	3.08 2.57	295.28 230.82	24684	-5.01	<.001	0.22
The need to do well on the GRE Mathematics Subject Test	Women Non-Women	226 291	3.37 2.75	301.06 226.33	23376.5	-5.80	<.001	0.26
Paying for the General GRE Test ($220)	Women Non-Women	225 290	3.10 2.57	289.42 233.62	25556	-4.32		0.19
Paying for the GRE Mathematics Subject Test ($150)	Women Non-Women	225 292	3.05 2.51	291.35 234.07	25571	-4.42	<.001	0.19
Sending GRE scores to programs ($30 per program)	Women Non-Women	224 292	2.84 2.43	283.58 239.26	27086.5	-3.44	<.001	0.15

							<.001	

For the second survey item, “How important are the following factors in choosing which schools you apply to?”, it should be noted that not all participants saw this item. Prior to this, survey participants were asked to state their interest in graduate school in mathematics. Only participants who responded with anything other than “Not interested in graduate school in mathematics” saw this item. Table 3 contains Mann-Whitney U test results for the women/non-women groups for the 438 participants who responded to the selected sub-item topics from the second survey item. The Z values in Table 3 indicate that the women group have greater means than the non-women group. Results show a statistically significant difference (all p’s $< .05$) between the women/non-women groups in the responses for all five sub-item topics. The women were more likely to view each sub-item topic as an important factor in choosing which school to apply to than their peers. All results had a small effect size (all r’s between 0.1 and 0.3). These Mann-Whitney U test results show that women are more concerned about all aspects of the GRE compared to their peers.

Table 3. This table provides Mann-Whitney U test results for selected items for the question “How important are the following factors in choosing which schools you apply to?” using the women/non-women variable.

Item	Group	N	Mean	Mean Rank	U	Z	p	r
No GRE General Test requirement or no minimum score requirement	Women Non-women	184 253	2.83 2.46	240.37 203.46	19344.5	-3.10	.002	0.15
No GRE Mathematics Subject Test requirement or no minimum score requirement	Women Non-Women	184 254	2.99 2.47	248.55 198.45	18022.5	-4.19	<.001	0.20

Discussion

Overall, we found that while students may have heard of the GRE, they rarely had detailed knowledge of the exam, including where and when it is offered, and its associated costs. Those last two points are especially problematic; if students miss the deadline or do not have the finances to afford the exam, they cannot apply to any program that requires GRE scores. The financial barrier is particularly a problem, since minoritized students often come from lower income families than their peers, and thus are more likely to have the cost of the GRE serve as a barrier to applying to graduate school (McEldowney et al., 2024). Since this survey was conducted, the Educational Testing Service recently changed many aspects of how they offer both the GRE General and Subject Tests, including offering them remotely (Educational Testing Service, 2023a, 2023b). This did not impact our results since these changes occurred after data collection was completed.

We contribute to the literature on gender differences in GRE test scores by finding gender differences in knowledge and perception of the GRE. Women were less likely to have heard of either GRE test, but for those who had heard of the exam their knowledge of the exams was not statistically different from other participants. More research is needed to determine the cause of this observed difference. As for perception of the GRE, women were more likely to state that the GRE, both the General Test and Mathematics Subject Test, were barriers to applying to graduate school. Women were also more likely to favor applying to programs with less rigorous GRE requirements. Given the established literature showing that womens' average scores are lower than their peers on the GRE, which disadvantages them in the application process, (Bleske-Rechek & Browne, 2014; Miller et al., 2019; Petersen et al., 2018) it is not surprising that women would view these exams negatively. Our results demonstrate that the GRE acts as an institutionalized environmental barrier, as proposed by SCCT, that affects degree interest and interest in applying to programs is perceived differently depending on the gender of the participant.

A recurring part of the conversation surrounding the GRE is whether it should be part of the graduate admissions process. During the height of the pandemic many programs dropped the GRE due to unavailability. Even now many programs have decided to continue not requiring the GRE (Google, n.d.). Many disciplines have dropped the subject GRE requirement altogether to the point where the ETS now only offers three subject tests: Mathematics, Physics and Psychology. There are very few studies of the Mathematics Subject GRE, though there is research on the reliability and impact of the Physics Subject Test (Miller et al., 2019, Young & Caballero, 2021). We challenge the research community to study the Mathematics Subject GRE to this level of rigor.

An important consideration we had for this paper was how to utilize the provided demographic information of our participants. Most existing research on the GRE assumes a gender binary while our results give a more honest and interesting reflection of gender among American college students. To tie our work back to the established literature we decided to use the women/non-women categories. While this categorization is imperfect, it was the most ethical solution we found to run statistically meaningful tests. That said, we call on future researchers to use gender beyond the binary in their quantitative research. New formulations and solutions will be needed to do this well, but we owe that to our participants.

Representations of the Derivative Valued by Post-Secondary Teachers

Michael Gundlach
Laramie County School District #1

Introductory calculus classes often serve as prerequisite classes for science and engineering majors. However, some researchers have questioned whether calculus courses, as currently taught, are filtering students appropriately (Black & Hernandez-Martinez, 2016; Williams, 2012; Williams & Choudry, 2016). Central to introductory calculus classes is the derivative (Kidron, 2019). Scholars have discussed the ways in which representations of the derivative differ between disciplines (Dray et al., 2019), but there has been no formal research investigating the representations of the derivative valued by teachers of calculus and teachers of subsequent non-mathematics classes. This study, through a new survey instrument, determined there are significant differences between the representations of the derivative valued by various post-secondary teachers in majors requiring calculus. By analyzing these differences, recommendations can be made to improve calculus as a preparatory course for non-mathematics majors.

Keywords: calculus, STEM education, derivatives, gateway courses

In a popular comedy sketch, a mad scientist reveals his latest depraved invention: junior high school (Studio C, 2014). As part of his invention, the mad scientist forces a student to take algebra and geometry. When asked by his assistant if a student will at least use what he learns later in life, the mad scientist replies, "Yes…if he ever teaches geometry or algebra" (Studio C, 2014, 1:33). In horror, his assistant asks, "You mean they exist only for themselves?" (Studio C, 2014, 1:42). Based on the laughter from the live studio audience in the video, these comments resonated with the audience's experiences.

Research has repeatedly found that students share the belief that mathematics is not valuable to them in their future personal or professional lives (Black & Hernandez-Martinez, 2016; Brown et al., 2008; Di Martino, 2019; Hernandez-Martinez & Vos, 2018; Rellensmann & Schukajlow, 2017; van der Wal et al., 2017; Vos, 2018). This feeling is encapsulated by a study that found a group of graduates from engineering programs "perceived their mathematics courses as islands, with no relation to the rest of their education" (van der Wal et al., 2017, p. S98). Mathematics classes existing only for themselves is concerning because mathematics classes, especially calculus, serve as filters for many science and engineering majors (Bressoud et al., 2013; 2015). As noted by Bressoud et al. (2015),

> At least one term of calculus is required for almost all STEM majors. For too many students, this requirement is either an insurmountable obstacle or—more subtly—a great discourager from the pursuit of fields that build upon the insights of mathematics. (p. v)

There have been calls for calculus to serve as a pump for science and engineering majors, rather than a filter (Bressoud et al., 2015). However, as noted by Bressoud et al., there seems to be little evidence of this change taking place despite multiple efforts to reform calculus classes.

Purpose of the Study

The purpose of this study was to gather quantitative data to determine the representations of the derivative favored by teachers of calculus classes as well as the representations favored by teachers of classes in majors requiring calculus. The goal of this comparison is to make recommendations for improving the current content taught in calculus I. As noted by Dray et al. (2019), students have struggled with representations of the derivative used in upper-level physics classes that are not emphasized in calculus I classes. Since Dray et al.'s report was developed using anecdotal data from the teaching experiences of the researchers, this study aims to generate more general data that can be analyzed to determine which representations need to be emphasized more in general calculus I classes. Additionally, the focus of Dray et al. was on physics students. However, it is estimated that only about 4% of calculus I students are pursuing physical science degrees, which includes both physics and chemistry degrees (Bressoud et al., 2015). This study cast a wider net and surveyed teachers from faculty in multiple disciplines to better determine which representations should be emphasized to better serve the students taking mainstream calculus I.

Research Question

This study sought to answer the following research question: Is there a difference in the value post-secondary teachers of calculus and teachers of non-mathematics classes requiring calculus ascribe to different representations of the derivative?

This survey was distributed to post-secondary faculty at colleges in the state of Wyoming. Since Wyoming has only one public university and seven community colleges, surveying faculty at all institutions was a feasible project. Additionally, Wyoming law empowers the state community college commission to establish common course numbering across undergraduate courses throughout the state (Common College Transcripts, 2018). This made surveying teachers of common classes across the state of Wyoming easy and efficient, as the course numbering and most prerequisites are the same across the state.

Significance of this Study

Based on the work of Dray et al. (2019), I suspected that numerical and experimental representations of the derivative would be more highly valued by teachers of non-mathematics classes than by mathematics faculty. Additionally, it is likely these will be valued more than other representations by teachers of non-mathematics classes. As there have been multiple stated concerns with calculus instruction and curriculum as they currently stand (e.g., Bressoud, 2021; Bressoud et al., 2015, Dray et al., 2019; Tallman et al., 2021; Teague, 2017), this study can help determine how mainstream calculus I curricula can be improved to better prepare students for future non-mathematics classes. Specifically, this study can help determine how calculus I instruction can be made more authentic, to potentially better help prepare professionals to use calculus concepts in their fields.

Calculus: A Problematic Filter

There are many potential reasons for this failure to reform calculus classes. One concern postulated by researchers is that mathematics classes privilege those who know the "rules of the game" of math education rather than prepare students to use math outside of math class (Black & Hernandez-Martinez, 2016; Williams, 2012; Williams & Choudry, 2016). This suggests that proficiency in mathematics classes, as evidenced by good grades, is not of value for use in future classes or careers, but as a form of exchange that can be leveraged to enter competitive fields or prestigious post-secondary institutions (Williams, 2012). This form of exchange has been dubbed "mathematics capital" (Williams, 2012).

This notion of mathematics classes acting more as producers of mathematical capital rather than transferable skill is concerning considering results found by Tallman et al. (2021). In their study, they reviewed 254 calculus final exams to gain a better understanding of how calculus students were assessed. Tallman et al. found that the calculus final exams they reviewed did not generally assess students' understanding of calculus concepts, but their abilities to use mathematical procedures to answer particular types of calculus questions. Additionally, few questions in the final exams allowed students to engage meaningfully with real-world contexts.

The results found by Tallman et al. (2021) along with Williams' (2012) notion of mathematical capital suggest that calculus classes are not acting as a pump but as a filter that does not filter for attributes that help students succeed in science and engineering degrees. Some suggest this may be a problem as the number of engineering graduates has not seen real gains over the last three decades despite calls from political and advocacy groups for more students to obtain such degrees (Bressoud et al., 2017). Additionally, there are concerns that mathematics classes as they currently stand reinforce existing inequities rather than make it possible for all students, including those from marginalized populations, to succeed in science and engineering careers (Williams, 2012; Williams & Choudry, 2016). As students from marginalized populations are generally more likely to struggle in calculus classes (Bressoud et al., 2015), the filtering done by calculus classes, in their current form, presents serious concerns for educational equity.

These issues show that mainstream calculus is in need of improvement. For such improvement to happen, the content of calculus classes must be better examined. Some science education researchers, in conjunction with math education researchers, have pointed out that mathematicians and scientists often utilize different representations and understandings of important calculus concepts (Dray & Manogue, 2005; Dray et al., 2019). As noted by Dray and Manogue (2005), "The way mathematicians view and teach mathematics, and the way mathematics is used by physicists and other scientists, are completely different; we speak different languages, or at least different dialects" (p. 2). This suggests that calculus content should focus on future applications of calculus. However, more information is needed to determine which applications should be included in an introductory calculus class. This study aimed to begin the process of determining which applications should be included through a quantitative survey.

Theoretical Framework: Multiple Representations of the Derivative

Since mainstream calculus focuses mostly on using the derivative, this study will examine how the derivative is represented by calculus teachers, as well as by teachers of STEM classes. As noted previously, researchers have observed differences in the ways scientists and mathematicians use and discuss derivatives (Dray et al., 2019; Dray & Manogue, 2005). Although the formal definition of the derivative is given using limits, this definition is often not directly used when determining a derivative from real world data. Roundy et al. (2015) saw this when they asked groups of mathematicians, physicists, and engineers to find the derivative of a certain rate of change in a mechanical machine created for the purpose of the case study. The physicists and engineers found approximations of the derivative by looking at ratios of small changes in the input and output variables and were thus able to find "good enough" approximations of the derivative to the point they described their answers as "the derivative" rather than as an approximation of the derivative. However, the mathematicians were unable to find a derivative and were unsure of the approximation they were able to generate.

In later work, Dray et al. (2019) described this issue seen by Roundy et al. (2015) as an overreliance, by the mathematicians, on the limit definition of the derivative. Along with their firsthand experiences in working with derivatives in their research and in upper-level physics classes, Dray et al. (2019) used this difference between the results of the mathematicians and the physicists and engineers in Roundy et al. (2015) to develop the notion of a "thick derivative." A "thick derivative" is a derivative function or value developed using numerical data to approximate the formal limit process. Dray et al. (2019) postulated that this notion of a thick derivative is used by scientists and engineers in their work as an approximation of the limit definition of the derivative.

To operationalize these differences, Dray et al. (2019) created a framework describing the multiple representations of the derivative they encountered in their professional work. This framework was an extension of a framework developed by Zandieh (2000). The framework of Dray et al. (2019) lists five main representations of the derivative: (a) graphical, (b) verbal, (c) symbolic, (d) numerical, and (e) physical. These representations are all considered process-objects (Sfard, 1991) that begin as ratios that are then reified into limits and functions. This framework was used to help determine which of these five primary representations of the derivative are favored by post-secondary teachers in majors that require students to take calculus.

Methods

For this study, a quantitative, correlational study design was used (Field, 2018). Correlational studies are used to determine if there is a relationship between sets of independent and dependent variables. In this study, I specifically examined the relationship between the subject domain of a teacher and the value they ascribe to different representations of the derivative. As such, I considered the subject domain of collegiate teachers surveyed as the independent variable for this study. This independent variable is categorical. There are six dependent variables, each representing the value a teacher places on a certain representation of the derivative. These variables follow from the representations of the derivative described by Dray et al. (2019). Although Dray et al. describe only five representations of the derivative, the graphical, verbal, symbolic, numerical, and experimental representations, they do divide their symbolic representation into two parts. There is the symbolic representation of using a limit to determine a derivative and the symbolic representation of using derivative rules to find derivatives of known functions. Since derivative rules play a key role in calculus I classes (Tallman et al., 2021), I considered the limit representation of the derivative and derivative rules used to find derivative functions separately within this study. This resulted in a survey examining six representations, the graphical, verbal, symbolic, rules, numerical, and experimental representations. As the value respondents ascribe to each representation will be determined using Likert-scale questions, the value respondents assign to each variable can be considered scale variables (Field, 2018).

Data Analysis

Since the data collected consisted of one categorical independent variable and multiple dependent scale variables, data was analyzed using a multivariable analysis of variance (MANOVA) (Fields, 2018; Huck, 2012). This analysis is appropriate as it prevents possible type I errors that may result from repeated uses of an analysis of variance procedure for each separate dependent variable (Fields, 2018). Additionally, MANOVA can be used to reveal possible relationships between the dependent variables. To further analyze differences for the representations between individual subject areas, I used Tukey's post-hoc test.

To help measure the reliability of the items used to assess the value ascribed to each representation of the derivative, Cronbach's alpha was calculated for each set of items used to create the normalized representation scores (Fields, 2018; Huck, 2012). All analyses were carried out using SPSS.

Participants

For this study, I surveyed Wyoming public community college and university faculty who teach in a major that includes calculus as a requirement. Of those who were sent the survey, seventy responded and completed the survey.

Although surveying teachers within the state of Wyoming does not strictly represent a random sample, this sample is still representative of post-secondary teachers across the country. All colleges in the state of Wyoming are accredited by a national accrediting body (Higher Learning Commission, 2019), and thus educational requirements for these positions are the same as at other institutions in the United States. These colleges recruit faculty from all around the country, with some faculty even coming from international sources.

Participant anonymity was protected by collecting no personally identifying information. Furthermore, only I had access to the data on a password-protected cloud storage system. This research was also protected by having the study approved by the institutional review board of the University of Wyoming.

Data Sources

Respondents participated in this study by completing a survey I created. This survey was created by designing Likert-scale items based on the framework of Dray and colleagues (2019) previously described. Multiple items were created for each conception described in the framework. These questions were items to elicit respondents' values of each process-object layer for each conception. For each item, respondents were asked to share how important they thought various concepts were for students to understand at the end of an introductory calculus class. For example, respondents were asked how important it was for students to memorize basic derivative rules. For each statement, respondents could rank the statement, "Not at all important," "Slightly important," "Moderately important," "Very important," or "Extremely important."

I created this survey based on Dray and colleagues (2019) framework due to its suitability as a framework of the mathematical knowledge to teach derivatives, as discussed in the literature review. Since an overwhelming majority of calculus students have been found to declare non-mathematics majors (Bressoud, 2015), this framework is especially well-suited to assess the value non-mathematics teachers place on different conceptions of the derivative.

Results

As noted earlier, this survey had 70 responses. Participant breakdown by subject area is as follows: (a) Mathematics: 22 respondents; (b) Biology: 6 respondents; (c) Chemistry and physics: 8 respondents; (d) Engineering and computer science: 9 respondents; and (e) other: 25 respondents.

Reliability Results

Each subscale of this survey, the graphical, verbal, symbolic, rules, numerical, and experimental subscales, had high reliability scores. Additionally, to meet the assumptions of MANOVA, the graphical and verbal subscales were combined. This new, larger subscale also had high reliability scores. This resulted in five representations analyzed as part of the MANOVA: the graphical & verbal representation, the symbolic representation, the rules representation, the numerical representation, and the experimental representation. Each of these representations had a reliability score of 0.891 or better.

Test Results

Based on Pillai's trace, there was a significant association of subject area with the value ascribed to different representations of the derivative, $V = 0.758, F(20,256) = 2.690, p < 0.001$. For each representation, the mathematicians yielded the highest value for their mean score. In other words, mathematicians in this study valued each representation more than their counterparts. Separate univariate tests for each representation yielded significant associations within each representation as well. Tukey's Post-Hoc test was used to consider subject areas pairwise and determine which had significantly different values ascribed to the representations. Most notably, mathematics and biology teachers differed significantly on the graphical & verbal and rules representation ($p = 0.018$ and $p = 0.042$ respectively), with the mathematicians valuing each representation more than their biologist counterparts.

Discussion

Assuming the differences found in the values ascribed to different representations found in this survey are accurate, there are two main ways to address these differences to improve calculus I classes; curricular adjustments and creating calculus classes specifically for certain majors, often termed "siloed classes" (Ellis et al., 2021; Luque et al., 2022; Voigt et al., 2020).

Curricular Adjustments

A call to adjust the curriculum of calculus I is not new. There have been attempts to reduce the calculus curriculum in the past to focus less on rote skills and more on relational understanding (Douglas, 1986). More recent research, however, indicate that these reductions have not yet occurred (Jones & Watson, 2018; Tallman et al., 2021). Despite this lack of reduction, researchers involved in more recent studies still expressed a desire to reduce and focus the calculus curriculum. Jones and Watson (2018) suggested focusing on Zandieh's (2000) version of the derivative representation framework to help focus instruction, while Tallman et al. (2021) suggested that calculus exams should assess relational understanding of the derivative rather than solving specific types of calculus problems.

The results from this study lend additional credence to the suggestions of Jones and Watson (2018) and Tallman et al. (2021). Scholars often suggest lessening the emphasis on complex uses of rote procedures, especially with the advent of computer technology that can complete these procedures more accurately and efficiently than humans (Douglas, 1986; Gravemeijer et al., 2017; Tallman et al., 2021).

As mentioned before, non-mathematicians do not view such procedures as unimportant; they merely view them as less important. These data do not suggest a complete removal of rote procedures from calculus I curricula; instead, they suggest a partial removal of such material only. Furthermore, research literature suggests that building fluency with these procedures through relational understanding of these procedures, rather than through extensive practice of complex combinations of such procedures, can help ensure future professionals can effectively use technology to assist them with such procedures in the future (Gravemeijer et al., 2017; Hoyle et al., 2013; Tallman et al., 2021; van der Wal et al., 2017).

Siloed Classes

The significant difference in the rules category between mathematicians and biologists is both striking and practically important. As a reminder, the mathematicians reported valuing the rules category more than the biologists, with a difference of 1.5076. These differences between the biology and mathematics teachers is made practically important by the number of students from these majors in mainstream calculus. Based on a large national survey, about 30% of calculus I students are biology or life science majors (Bressoud et al., 2015). This group is second only to engineering majors, who make up about 31% of calculus I students. The group with the next highest percentage is business majors, with 7% of calculus I students. Thus, this disparity where biologists value the Rules category much less than mathematicians, while the engineers answer quite similarly to the mathematicians in that category, leads to a conundrum that is difficult to solve in a class serving both populations.

One possible solution to this conundrum is to create siloed calculus classes (Ellis et al., 2021; Klingbeil & Bourne, 2013; Luque et al., 2022; Voigt et al., 2020). These calculus classes are variations on the traditional calculus curriculum that focus on using calculus in a particular subject area. There are many types of siloed classes, but one that has received significant attention is a calculus class for future biologists and other life scientists. These commonly referenced siloed classes parallel the large numbers of such students in calculus I classes as well as the results of this study.

Research into siloed classes has shown such classes can lead to lower failure rates in calculus classes, especially those for biology and life science majors (Luque et al., 2022; Voigt et al., 2020). Siloed classes overall seem to have helped students who were less prepared for college math (Klingbeil & Bourne, 2013; Voigt et al., 2020). In one study, the drop, failure, and withdrawal rate (DFW) for such students was equal to that of their colleagues who entered college with better math skills, suggesting that siloed classes "levelled the playing field for less prepared students" (Voigt et al., 2020, p. 868). Siloed classes also tend to lead to lower failure rates as well as increased enrollment in such classes and majors (Klingbeil & Bourne, 2013; Luque et al., 2022). These findings suggest that siloed classes have the potential to help students proceed past calculus into major coursework.

This study adds additional evidence to the need for siloed classes especially for biology majors. The significant difference found between the value ascribed to the Graphical and Verbal representation and Rules representation between the mathematicians and biologists suggests mainstream calculus classes may not be properly serving biology majors. Further research, including targeted interviews with course coordinators, is needed to validate this notion.

Future Research

This study opens the door to several avenues of future research. In many ways, this study can be considered a pilot study for the derivative representations survey used herein. As mentioned before, the framework by Dray and colleagues (2019) used to design this survey has been used in the past to analyze differences in the ways mathematicians and non-mathematicians approach differentiation tasks in task-based settings. As piloted in this study, such differences can continue to be analyzed among larger groups of professionals using the derivative representations survey. However, before such research could be conducted, improvements would need to be made to the survey as it currently stands.

Finding Elements of Exploration in a Ritualized Calculus Discourse

Mark Watford
Florida State University

Undergraduate mathematics classrooms continue to experiment with active learning strategies as an alternative to the traditional lecture-based teaching model. This paper investigates one student's (Jacob) engagement in a poster session activity in a Calculus 1 course and explores how he reasoned about calculus concepts in this non-standard learning environment. Informed by Sfard's theory of commognition, an analysis of Jacob's discursive routines reveals a complex interplay between ritualized and explorative discourse. While Jacob's poster presentations appear highly ritualized on the surface, with routines recycled from class, indications of explorative activities emerged in his preparation with a partner, reflecting an active search for suitable routines. This research emphasizes the importance of considering the entire ritual-exploration continuum in mathematics education and raises questions about facilitating the transition from ritualized to explorative discourse.

Keywords: Commognition, Routines, Calculus, Exploration, Rituals

Introduction

In undergraduate mathematics education, there is a growing trend of incorporating forms of learning which differ from the standard lecture model. One notable study reported calculus instructors being encouraged to employ *active learning* strategies in their classroom (Rasmussen et al., 2014) as one of seven characteristics of successful calculus programs of doctoral granting institutions in the country. However, the term *active learning* is vague and has varying interpretations. Generally, it can refer to any form of student engagement in class which differs from the standard lecture model, ranging from the incorporation of worksheets to engaging in group discussions and problem solving (Freeman et al., 2014). Nevertheless, there have been recent calls to incorporate such strategies in tertiary mathematics learning (e.g., CBMS, 2016; Saxe & Braddy, 2015) and a call to investigate such "interventions in practice" (Rasmussen et al., 2014, p. 509). At Barrow University[1], a large research-intensive university in the southeastern United States, one intervention has been implemented in the Calculus 1 courses for several years and serves as the context for this research project. The weekly activity of students engaging in poster sessions (further described in the "Methods" section) was designed to have students become expert at solving one problem and then communicating their solution to their peers. Because communication is at the forefront of this activity, Sfard's (2008) theory of commognition, which considers thinking is communicating, is fitting to study how students reason about calculus concepts, especially in a non-standard learning environment. For the purposes of this paper, I focus on the discursive routines of one student, Jacob, and how he situated the poster session activity as explorative or ritualized. Preliminary findings indicate that the presentation of the poster was highly ritualized, yet there were moments of exploration evidenced in Jacob's discourse when speaking with his instructor. As well, there was also an indication that Jacob engaged in more explorative routines when designing the poster he presented, but the constraints of the assignment may have funneled Jacob into a ritualized routine.

[1] All names in this paper are pseudonyms.

Literature Review

Commognition has gained popularity recently with the framing's tenet that students' thinking is revealed in their communication. Sfard (2016) promoted that analyzing discursive activities stands in stark contrast to a more cognitivist approach which has "the tendency to view communication as a mere window to something else" (p. 41). With a commognitive lens, thinking *is* communicating and vice versa. Since its inception, a wide range of aspects of commognition have been trialed in various forms in the research of undergraduate mathematics education, particularly with intervening learning activities that disrupt the standard lecture model. Most recently, Kontorovich (2023) critically examined the panacea-like collaborative learning structure by attending to a triad of cognitive, social, and affective aspects of students' collaboration as they studied linear algebra. His research explored how two students, Jan and Sai, were able to position themselves as mathematizers (or not as mathematizers) and how they perceived each other as such. The careful commognitive analysis of the dynamics between the two students illuminated a great need for further research into how the triad of mechanisms plays a role in collaborative learning situations.

Another avenue of study in which the lecture model is disrupted through varying forms of classroom activity is the continuum of routines. Lavie et al. (2019) operationalized routines with a commognitive lens and made a distinction between rituals (process-oriented routines) and explorations (product-oriented routines). Whereas rituals typically are guided by the question, "how do I proceed," explorations are guided by the question, "what is it that I want to get" (Lavie et al., 2019, p. 166). Rituals should be in no way absent from a novice mathematics learner's discourse. They are the foundation of transitioning to an explorative discourse. Therefore, as a mathematics learner becomes a full-fledged member of the mathematics community, they undergo a gradual de-ritualization of their routines and move toward the exploration end of the spectrum. In fact, certain curriculum materials which are "explicitly designed to promote student-centered activities that shift classroom discourse away from lectures" (Barnett, 2022, p. 1579), such as Primary Source Projects (PSPs), were analyzed for their potential to de-ritualize mathematical discourse at the tertiary level. Barnett (2022) showed how the task situations in PSPs ranged on the whole of the ritual-exploration continuum and may be used to fuel the de-ritualization process (depending on how the PSPs are implemented).

Similarly, Nachlieli and Tabach (2019) and Sfard (2016) proposed that the nature of routines in which students engage is highly dependent on the ways in which a lesson or activity is implemented. Nachlieli and Tabach (2019) developed a framework to analyze mathematical learning tasks as either ritual-enabling opportunities to learn (OTL) or exploration-requiring OTL. They, too, stated that rituals are essential for students to enter the discourse because rituals help to develop students' object-level and meta-level discourse which is the foundation of explorative activities. However, Sfard (2016) analyzed the discursive routines of a teacher during a lesson and subsequently the routines of his students as they solved similar problems. She found that they mirrored his ritualized routines and exhibited some of the same features of his routines. Thus, it is not surprising that it should be essential to consider the routines afforded by and exhibited in such classroom activities.

Theoretical Framework: Commognitive Routines

Researchers of mathematical discourse are no stranger to Sfard's (2008) theory of *commognition*, a concatenation of *communication* and *cognition*, which posits that thinking and communication are one in the same. Sfard (2008) proposed that mathematical discourse is a special form of discourse that can be characterized by four properties: word use, visual mediators, narratives which can be composed of key words and visual mediators, and routines. Both word use and visual mediators may be rather trivially conceptualized as those special words and symbols we use to communicate mathematics and which are exclusive to mathematical discourse. For instance, in the context of evaluating a limit, key words and visual mediators may include the words *indeterminate form* and algebraic symbols like $\frac{\infty}{\infty}$ or graphs that show the end behavior of a function. Narratives are the stories we tell about mathematical objects using the key words and visual mediators (e.g., $\lim_{x\to\infty}\left(\frac{2^3}{3}\right)^x = \infty$ because $\frac{2^3}{3} > 1$). Finally, routines are the repetitive patterns found in mathematical discourse (e.g., evaluating a limit using algebra). For the purposes of this paper, routines will be characterized as explorative or ritualized.

Explorations may be considered by many in the professional mathematical community as the true form of "doing mathematics." That is, the goal of an exploration is to produce a narrative about mathematical objects which the mathematical community generally accepts as true. Thus, explorations may be considered as product-oriented routines (Lavie et al., 2019). On the opposite end of the routinization spectrum is the ritual. Those who perform rituals are completing discursive actions with the goal of "creating and sustaining a bond with other people" (Sfard, 2008, p. 241) and may not be concerned about telling stories about mathematical objects. A ritual is "appreciated for its performance and not for its product" (Lavie et al., 2019, p. 166) and therefore is considered a process-oriented routine.

Because pure rituals and explorations are truly rare in mathematics classrooms (Lavie et al., 2019), I will characterize elements of the mathematical discourse of a student presenting a poster to his peers and instructor as ritualized or explorative and seek to answer the question:

How might a student engage in discursive routines in the context of a Calculus 1 poster session?

Methods

Context of the course and poster session

Data from this study were collected from a Calculus and Analytic Geometry 1 course taught in the Spring 2023 semester at a large southeastern research-intensive university. The mathematics department employs graduate teaching assistants as instructors of record for the four-credit hour calculus course as well as a specialized teaching faculty member who serves as the course mentor and collaborates with TAs to implement a unified curriculum. Members of the teaching team are expected to adhere to the same schedule, covering specified content and implementing a hallmark classroom activity, poster presentations, weekly. The poster activity consists of students collaborating with a partner outside of class to solve one calculus problem and then presenting their solution as a poster during class. The problems on which students collaborate are comparable to what they may be given as a homework problem and are directly related to the content of a recent lecture. As stated in the activity description given to students, they are expected to become "expert" at solving the problem. Their expertise is demonstrated through the inclusion of four mandatory components of the poster: detailed steps to solve the problem, the "final answer" to the problem, clues from the problem that may lead to the solution, and mistakes made or mistakes students anticipate others might make while solving the problem. Once per week, the class engaged in two rounds of poster sessions. In the first round, one person from each pair stood at their respective poster while the partner visited other posters. The person standing explained their problem to anyone who visited and should have been able to answer any questions posed by their visitors. After 10–15 minutes, partners switched places, and the second round commenced. The poster session from which this analysis was taken occurred in the third week of the semester and consisted of problems related to calculating limits and finding the derivative at a point.

Data Collection

The episode analyzed for this paper is part of a larger research project in which 24 of 29 students consented to have their classroom interactions audio/video recorded and copies of their coursework collected as data. Field notes and recordings of the class lectures were captured. Additionally, six of the 24 consenting students participated in an interview designed to expand on their mathematical routines observed in the class. This paper focuses on one consenting student, Jacob, who also participated in an interview. Although Jacob initially enrolled in the course to be eligible for entrance in the computer science program, he revealed that after a few weeks of being in the course, he realized that he wanted to progress in a different direction entirely and major in Chinese Language and Culture. By personal admission, Jacob said that a heavy course load was one factor contributing to his change of heart. The other factor was a newfound interest in learning about Chinese culture. The episode of analysis is from Jacob's second poster session in which he was tasked with evaluating the limit using algebra: $\lim_{x \to \infty} \frac{2^{3x+1}}{3^{x+3}}$.

Data Analysis

When analyzing the poster episode, I drew upon Sfard's (2016) and Lavie et al.'s (2019) notion of the routine as a spectrum ranging from ritual to exploration. According to Sfard (2016), there are three main features of a routine that need to be considered when determining whether an episode may be explorative. First, the subjects of the narratives are typically abstract objects rather than more concrete symbols and signifiers. Second, the source of mathematical narratives in an explorative discourse "can be logically deduced from stories already endorsed" (Sfard, 2016, p. 45) as opposed to relying on memory or an authoritative source, such as the instructor or textbook. Lastly, the goals of mathematical activity must be considered. As described above, the goal of an exploration is to tell a story about mathematical objects while the goal of a ritual is to engage in the process itself. The data sources which inform the following analysis are the interview transcript, the poster presentation transcript, and the poster artifact.

Results

The following episode is taken from Jacob's poster presentation in which he presented to 13 persons including the instructor (Ms. Rebecca) and the researcher (Mark). Jacob's poster monologue was roughly the same for each presentation. He admitted in the interview that he did not rehearse a script, however, he said:

> as the poster session gets going, I do say like a similar spiel…. obviously, the prompts are laid out step by step; I go step by step. And, I say pretty much the same thing, although sometimes I change the wording a bit to make it a bit more interesting to myself.

Therefore, the components of his mathematical discourse are virtually identical in each presentation. Below is one representative example of Jacob's presentation which he would begin once a visitor appeared before him.

We have [the problem][2] find the limit of *x* to infinity of two to that over three to that [pointing in the general area of the upper left-hand corner of the poster]. So yes, and put very simply, no matter what we tried, we ended up with the indefinite[3] form. So, we went [with] *undefined*. We tried to divide by the conjugate because of those pesky exponents. And yeah, we still got infinity over infinity, so we went with *undefined*. To be honest, [we are] not sure if it's correct.

Figure 1 displays the poster that Jacob and his partner, Rachel, created to present their solution to the limit problem.

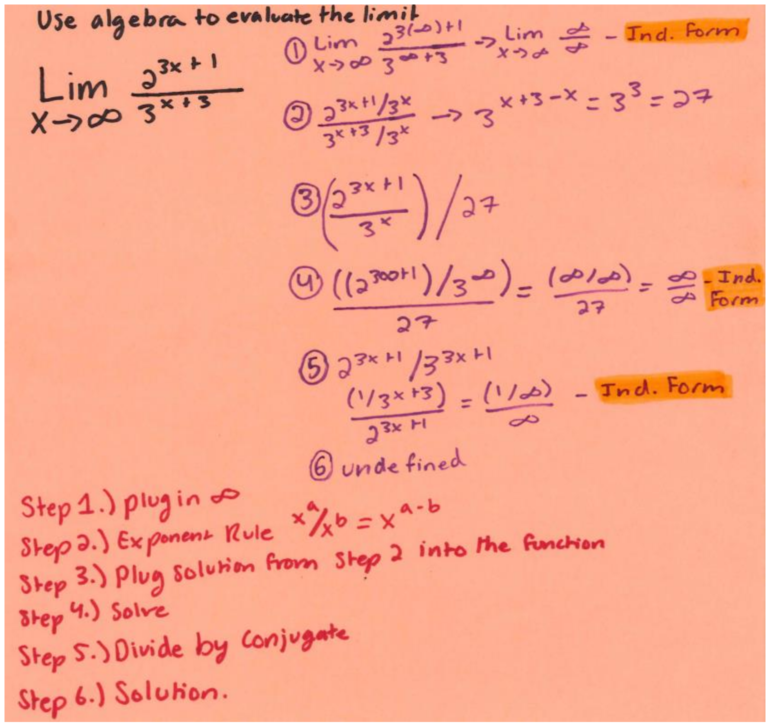

Figure 1. Jacob and Rachel's poster detailing their three attempts at evaluating the limit.

Objects of Mathematical Discourse

One distinctive component of mathematical discourse is characterized by how discursants communicate about mathematical objects. The objects of mathematical discourse were coded as either concrete or abstract. This distinction was dependent not only on the key word itself but also how the discursant communicated about the object. In other words, concrete objects were treated by the discursant as something tangible and that could be operated on by a person, whereas abstract objects existed primarily in the discourse and could take on discursive actions. For example, Jacob spoke about $\lim_{x \to \infty} \frac{2^{3x+1}}{3^{x+3}}$ as something "we have" in terms of a concrete problem which needed a solution. There is no perceptible indication that Jacob considered the

---

[2] Words in brackets clarify Jacob's meaning based on his other instances of delivering virtually the same monologue.

[3] Jacob consistently used "indefinite" in place of "indeterminate." This seemed to have no bearing on what Jacob meant by the "indefinite" form. In fact, his instructor and his partner both used this term when speaking about the indeterminate form while reasoning through Jacob's poster. However, the instructor did not use "indefinite form" while lecturing.

function inside the limit notation as a quotient of exponential functions with certain properties. In fact, Jacob further concretized the limit in his recitation of the function by referring to the exponents as “that” and “that.” The reason for this word choice is not apparent; however, I conjecture that this was a form of colloquial discourse in which Jacob felt comfortable engaging with his classmates. This is supported by the fact that Jacob changed his discourse once I (who established myself as a researcher in the class) visited his poster. While explaining the poster to the me, Jacob recited the entirety of the exponents as “two to the three *x* plus one over three to the *x* plus three.” Jacob may have perceived me as a person with whom it would be inappropriate to engage in colloquial discourse. However, once I left, Jacob adopted this practice of reciting the exponents as he did for me in subsequent presentations to both students and the instructor. Regardless of the reason for the word choice, Jacob still treated the exponents as “things” rather than mathematical objects with special properties.

Perhaps the most concrete of objects Jacob mentioned were “those pesky exponents.” Jacob spoke of the exponents in terms of being physical obstacles imbued with the ability to cause trouble. More characteristic of an explorative discourse would be how Ms. Rebecca spoke about the exponents when she was trying to help Jacob reason through evaluating the limit. Ms. Rebecca posed the question, “are the exponents actually growing faster in the top or the bottom [of the fraction]” as if to model the types of questions her students should be asking when solving a problem. The way in which she spoke about the behavior of exponents and how that behavior affects the overall function is more indicative of discourse with abstract objects. Although Jacob’s discourse appeared highly ritualized in the poster sessions based on how he communicated about mathematical objects, the source of his narratives and the goals of his mathematical activity may shed light in a different direction.

Sources of Mathematical Narratives

The source of Jacob’s mathematical narratives both within the poster and the poster session itself was predominantly a recycled routine. This is more indicative of ritualized routines. Jacob’s poster showed that he and his partner tried to recycle three routines they learned in class: substituting a value for the variable, using exponent rules to simplify the expression, and multiplying by a quotient of conjugates. Although it may be a mere observation that Jacob and his partner attempted to recycle three routines, this was confirmed in Jacob’s admission to his instructor that he was looking for the appropriate routine to recycle but did not find one that matched the current situation. He said, “I don’t know if we’ve had a problem where we just straight up said *undefined*; so, that’s why I was kind of suspicious.” This explains why Jacob felt the need to end each of his presentations with a word of caution about the accuracy of his solution.

Moreover, Jacob verified this in his interview as an almost instinctive normal practice when completing the poster each week. When working on a poster problem, he would sometimes refer to his notes, “comparing it to previous examples of problems” which were similar or “problems that use similar methods.” This may not be an unfamiliar practice to professional mathematicians nor to the commognition literature (see Lavie et al.’s (2019) discussion on *precedents*), but Jacob’s seemingly automatic trial of the three routines based on key features of the problem (the presence of infinity, exponents, and a sum in a quotient function) suggests that he was acting without much purpose. Furthermore, it appears from “Step 5” (Figure 1) that Jacob and his partner were not entirely certain of what a conjugate is or how it may be used to help evaluate limits. This may be typical of a novice in the mathematical discourse who recognizes that some discursive action is necessary, but it is not apparent what the discursive action should be.

In contrast to Jacob's seemingly highly ritualized poster presentation, there was some indication that he engaged in a more explorative activity when preparing the poster with his partner. Jacob consistently said that he "tried" different routines showing that the source of these narratives was not entirely automatic recall; rather, he and his partner were actively searching for an appropriate routine that corresponded to a non-indeterminate form solution. Because the routine of ending with an indeterminate form was unacceptable according to Jacob's previously encountered routines, he knew that he needed to engage in a different routine. The actual "how" of that routine and "which" routine was unclear to him. This trialing of routines shows a mixture of Jacob asking the questions that Lavie et al. (2019) characterized as explorative and ritualized. Jacob appeared to be asking *how to proceed to get* a non-indeterminate form.

Goals of Mathematical Activity

The third aspect of a routine that can serve to distinguish between explorative and ritualized discourse is the goal of mathematical activity. According to Sfard (2016), the objective of performing a ritual is grounded in establishing or developing a relationship with another person and adhering to the goals set by others. The objective of engaging in an exploration is to know more about mathematical objects" (p. 44) and produce an endorsable narrative about those objects. The explorative goal is more intrinsically motivated while extrinsic motivation drives rituals. It is possible that Jacob and his partner "went [with] undefined," because providing a solution was one of the goals of the assignment. This is apparent because in four of Jacob's presentations, he ended with "we went with what we thought was best." In contrast, Jacob's discourse with his instructor showed that he genuinely wanted to know more about evaluating the limit in this case. Jacob began his poster presentation to his instructor by saying, "I'm pretty sure this is incorrect, so that's why I want to present it to you: to see if you can explain." There was no precedent that Jacob would be able to modify his poster to improve his grade, so the desire to know how to evaluate the limit in this case was more of an intrinsic motivation to simply "know more." Further evidence of this conjecture was found in Jacob's interview. When asked why he attempted to solve the poster problem, one of the reasons that Jacob gave was "part of it is showing to myself that, hey, I can actually do this stuff. You know, I'm actually not that bad at math, even though I feel like I am." The goal of mathematizing to establish and develop a relationship with his mathematical self is, by definition, ritualized discourse. Yet, it is apparent that the explorative spark is rooted in Jacob's discourse, and the ritualized discourse in which he engaged during the poster session was not wholly absent of mathematical exploration.

Discussion

This research offers insight into the complex nature of student engagement with mathematical concepts at the tertiary level and the role of discourse in shaping students' mathematical thinking. It underscores the importance of considering the entire ritual-exploration continuum in the mathematics classroom and highlights the interplay between the two extremes. Future research in this area could explore how instructors can design activities that intentionally promote the transition from ritualized to explorative discourse, such as PSPs (Barnett, 2022) or other exploration-requiring OTL (Nachlieli & Tabach, 2019). Additionally, investigating how students' discursive routines evolve over time as they progress in their mathematics learning would provide a deeper understanding of the developmental aspects of mathematical thinking.

Is it Possible to Instruct College Students in the Role of Inventors?
A Case Study of a Mathematics Instructor in India

Praveen Chhikara
University of Illinois at Urbana-Champaign

Rochelle Gutiérrez
University of Illinois at Urbana-Champaign

This qualitative case study attempts to understand instructional goals that a mathematics instructor in India sets and envisions for engaging students. The instructor participated in a professional development program provided by the authors on the active role of students in learning mathematics. The authors' interpretations from three interviews were guided by two theoretical lenses of Realistic Mathematics Education and Rehumanizing Mathematics. In return, the interpretations offer a context to imagine how the lenses might interact.

Keywords: Realistic Mathematics Education, Rehumanizing Mathematics, Undergraduate mathematics,

Today, a substantial number of students worldwide experience a disconnection from mathematics and adopt a passive role as mere recipients of knowledge in classrooms. What if our mathematics instruction was a journey of students' inventions built on situations experienced as "realistic" based on what they know, their intuition, and even their misconceptions (Van den Heuvel-Panhuizen & Drijvers, 2020)? What if we approached students' non-traditional conceptions as avenues to expand mathematical knowledge, as a form of rehumanizing mathematics (Gutiérrez, 2018)? Such an approach has the potential to enhance students' senses of connection with abstract mathematical concepts, foster active engagement and participation, and enable them to view themselves as "authors of mathematics" (Povey & Burton, 1999, p. 235). This study aims to investigate how a mathematics instructor in India, who has been provided professional development on the active role of students in learning mathematics, might conceive of engaging students in classrooms. As a qualitative case, this study seeks to shine light on the meaning that this one instructor made about his instructional aims while engaging in learning about ways to highlight the human nature of mathematics. The interpretations were guided by two theoretical lenses of Realistic Mathematics Education and Rehumanizing mathematics.

Literature Review and Theoretical Framework

Realistic Mathematics Education (RME), conceptualizes the use of "realistic" situations to teach mathematical knowledge (Artigue & Blomhøj, 2013; Gravemeijer, 2020; Van den Heuvel-Panhuizen & Drijvers, 2020). An underlying goal of RME is an instructional approach beyond just exposing the students to mathematics as ready-made, which makes it different from traditional instruction. Realistic Mathematics Education is theorized through six principles: activity, interactivity, reality, intertwinement, level, and guidance (Van den Heuvel-Panhuizen & Drijvers, 2020). Being focused on instructional practices, this study will center on the guidance principle or guided reinvention process, but not in isolation from other principles because other principles interact with and influence guided reinvention. Guided Reinvention (GR) theorizes how teachers can provide opportunities for students by selecting "realistic" contexts to facilitate them to reinvent "higher" level formal concepts individually and collaboratively. (Gravemeijer, 2008; Van den Heuvel-Panhuizen & Drijvers, 2020). Because GR appears to be a set of prescribed practices to teach predetermined concepts, is there room for instructors to be led more by "alternative conceptions" or student's conceptions that differ from or conflict with standard understanding of mathematics concepts (Fujii, 2020, p. 625)?

Rehumanizing Mathematics (RM) is a framework that centers queer BIPOC students, as they are most harmed by standard practices and forms of mathematics (Gutiérrez, 2018). RM seeks to correct for an overemphasis on abstraction, objectivity, and binary logic. The framework advocates for humane practices, such as the incorporation of the cultural and linguistic resources of the participants of school mathematics. RM involves eight dimensions: (a) participation/positioning, (b) cultures/histories, (c) windows/mirrors, (d) living practice/futures, (e) creation, (f) broadening mathematics, (g) body/emotions, and (h) ownership/stewardship. To understand how instructors might be led more by "alternative conceptions" or student's conceptions that differ from or conflict with standard understanding, we choose the Creation dimension of RM. The Creation dimension (Cr) acknowledges students' conceptions and diverse forms of expressing mathematics, which relates to possible students' conceptions in group discussions in GR (Gutiérrez, 2018). In this way, Cr along with GR can be considered as a more comprehensive way of being able to expand beyond traditional knowledge forms or representations and that can then feel humanizing for students who might possess other ways of knowing and viewing the world and help affirm their relationships with mathematics as authors/creators of mathematics. The overarching question – What are the perspectives and intentions of a mathematics instructor in India about his roles/goals in classroom instruction in terms of engaging in abstract concepts? More specifically, [GR] How does the instructor conceive of and facilitate students to learn abstract concepts of mathematics? [Cr] In what ways does the instructor respond to his students when their work and conceptions do not align traditional mathematics or when they could be perceived as "wrong"? (e.g., How does the instructor address students' responses that are "misconceptions"?)

Methods

India's new National Education Policy 2020 strongly emphasizes the achievement of "learning outcomes," which is evident from its repeated mention of the term in the document (Government of India, n.d., p. 3). The primary focus in traditional classrooms of India is often limited to demonstrating the prescribed curricula and preparing students for semester final exams (Venkataraman et al., 2012). As such, many instructors feel pressured to complete the curriculum, even though it is too much content to cover in a meaningful manner. Student-student and student-instructor interactions in these classrooms are usually minimal (Ramanujam, 2012). Thus, students tend to find themselves disconnected from the course content.

In order to build rapport and reciprocity, we organized an online professional development (PD) program consisting of seven interactive sessions (each 90-120 minutes long) for 10 college/university mathematics instructors in India. Inspired by RME and RM literature, we designed activities such as creating reinvention-style lesson plans and grading intuition-driven hypothetical student responses that conflict with standard ideas in order to facilitate participants to share their meanings around GR and Cr in their classroom practices. Five participants who volunteered to be part of the research study gave us permission to interview and record them as they reflected on their experiences in each workshop. The first author interviewed each research participant twice in two 60-minute semi-structured sessions conducted and recorded through Zoom. The first interview centered on Guided Reinvention included questions such as "How was the lesson plan activity with your group partner to create a lesson that can facilitate students to discover math concepts?" to probe how they make sense of reinvention-based instruction and their related instructional goals. The second interview, focusing on Creation, included questions such as, "In the workshop, you discussed with your group partner about 'wrong responses.' What were some important points that arose in the discussion?" to probe for participants' viewpoints for alternative conceptions."

Thus, the PD program served as the entry point for questions we developed for individuals based upon their work in groups and perceptions of the PD. The interview questions avoided evaluation and instead emphasized ways participants made meanings in the program sessions. We sought explanatory responses and offered interviewees a chance to share their perspectives and practices as a teacher and learner. Questions that asked participants to reflect on their experiences as learners offered them a chance to talk about "poor" or ineffective instructional practices without referring to themselves. For example, "In your career as a student and then as a teacher, can you recall an event when a learner's own ways of solving mathematics problems were supported or discouraged because of something? What was that?"

Data Analysis

After analyzing responses from the first two interviews, we selected one instructor, whom we call Aditya [pseudonym], to focus upon for a case study to fully engage and delve into more complexities of his identity and context in making pedagogical decisions (Yin, 2017). As a case study design, this study is not generalizable "from samples to universes" (Yin, 2017, p.20), but its findings might be "transferable" (Finfgeld‑Connett, 2010, p. 246) to other instructors' contexts. The final interview utilized a "Member Checking and Intervention Interview" protocol that was aimed (1) to determine the accuracy of interpretations of this instructor's identified practices in the first two interviews through member checking questions that consisted of summaries of our interpretations and (2) to extend/challenge the participants' practices toward GR and Cr through intervention questions or joint wonders that consisted of the interviewee's own perspectives about teaching and utilizing questions asked within the literature (Gambill, 2022). We wanted to honor the relational piece in research and promote collaborative wondering to make research more humane, empathetic, less extractive, and non-evaluative.

The data were analyzed in multiple phases. We first identified interesting segments and interpreted them with memos. When the authors had different interpretations, we attempted to reach a consensus or an "interrater reliability" (Belotto, 2018, p. 2625). We then labeled the segments and interpretations with short phrases of 3-4 words, which became sub-codes. These codes served as the basis of the findings we present below.

Findings

We found four themes: (a) Avoiding faulty foundations through correct proofs, (b) Offering exploratory opportunities through minimal-to-incremental guidance, (c) Encouraging student engagement by building upon their prior knowledge, and (d) Increasing motivation by providing the history of mathematical concepts. Due to space constrains, we present below the first two themes in this section and mainly the second in the discussion section later.

Avoiding faulty foundations through correct proofs

In this section, we will explore Aditya's role, which appeared in the data analysis, to instruct his students to refrain from faulty foundations through formal or correct proofs. Interestingly, with this goal in mind, he seemingly incorporates informality and motivates students to share diverse "guess[es]" or "wrong" conceptions. In his grading of a student's solution that included informal terms presented in our PD program, Aditya explained:

> [W]e [as students] **assume some results** are obvious or trivial. We simply **write** it down "clearly," "obviously." I forbid them [students] to **write** "obviously" or "clearly." I tell them that if it is so obvious or so clear to you, why don't you **produce**

> a proof because it's not at all obvious to me? … if I could not do it, then either there's a problem in my understanding … or … what we are trying to solve is not true.

Like many mathematics instructors, Aditya seems to consider his instructional role to "forbid" or prevent students to always rely upon intuition/informality ("assume some results") so that they can understand the value of proofs. He might be recognizing that ideas that seem to be true informally might not be the case when they try to prove those ideas formally. And, in this case, he seems to be invested in supporting his students to learn how to prove something, as it will be an important skill in learning mathematics. Even if he stresses formal proofs, Aditya appears quite different from many instructors who consistently ignore intuition/informality in instruction to understand his goals toward both informality and formality. When he says, "I forbid them to write obviously, or clearly," he seems to value mathematical symbolic or formal proofs, especially when it comes to *writing* proofs. But contrasting with the traditional emphasis *only* on formal procedures, Aditya acknowledges, at another instance during an interview, informality's role to get a global bird's eye view or an "overall idea" of proofs. These views appear to underscore informalities for *thinking* processes in students' heads when they prove formally or even when they have acquired formal concepts. The way Aditya "forbids" his students to prevent errors is not necessarily instant rejection of their thoughts. At another moment, Aditya appears to value an open classroom space by motivating his students to propose "guess[es]" or conjectures and to ask questions without thinking of them as trivial and incorrect. This might be one way to accomplish the goal effectively because Aditya is able to correct more "wrong" points or "faulty" foundations. Thinking that an understanding based on a student's "guess" can differ from or conflict with an instructor's understanding, the first author asked him about contradictory understandings. He said:

> [If two understandings] are contradictory, one of the concepts must be wrong because **in maths the answer [to a question] is just one [unique]**. … if I realized that I was completely wrong, [or] I was on the wrong track, … [then it] would stay with me always, and I would never make that **mistake** [again]…. If it's not contradictory, then there are scopes [or chances] of learning. Even if it is contradictory …or one of us [with contradictory understandings] is completely wrong, [then] you can think of it as a pin [or reminder] or some kind of marking that would always stay with the student and would help him **not to get it wrong the next time**.

Saying "in maths the answer is just one [unique]" and "not to get it wrong the next time," Aditya appears to value correcting his students' "mistakes" or conceptions, which might otherwise be "contradictory" and ambiguous. Such an instruction can highlight a limited exploration of "wrong" things though because the instruction is only about identifying "mistakes" so that the students do not repeat them. The students' exploration through "guesses" or "questions" requires instructor's facilitation and guidance, which we understand in the next theme.

Offering exploratory opportunities through minimal-to-incremental guidance

Aditya expects his instructional role to offer students exploratory opportunities through his minimal-to-incremental guidance that encompasses exposing the least content possible in the beginning and providing students hints when believed necessary. When asked about students' exploration opportunities in the classroom, Aditya said:

> [W]hat I feel I would … follow in the class actually [offer the] **least bit of help**. So, as if there are several pages [of hints]. You flip the first page, you have [a hint on the first page] if you can solve [the given problem] ... If you can't, then move to the next

page and see some **more hints or more suggestions** or some more help. So, step by step it's up to the students. … I get a feeling … how much **help they need**. So, depending on that I try to provide help, but at the very beginning. I would give them the minimum. … let them **struggle and learn**.

He appears to target his instruction by offering the "least bit of help" at first so that the students can "struggle and learn" and can get his support of "more hints or more suggestions" when they are perceived unable to complete the given tasks. Through such minimal-to-incremental guidance, as opposed to instructors who give them maximum guidance, his students are likely to first be given the opportunity to learn with guidance as per the extent of the "help they need." Aditya's exploratory and discovery-oriented goals for his students were also reflected in his epistemological perspective in the quote below:

[Exploring] Proof first then [getting at] theorem statement should be a way [to teach] because that means students always would be **curious**. … How can we get this theorem? It is a **reverse process**; you don't get to eat your meal until, unless you cook it. … That's the way it should be natural.

When asked, Aditya could not recall any particular example of such a "reverse process" at that time but it appears worthy to mention. This "reverse process" of getting a theorem statement after a proof differs from a widespread perception among mathematics professors and in mathematics textbooks to follow Definition – Theorem – Proof format. If directly taught, students might not feel supported to explore in the traditional format. On the other hand, with Aditya igniting "curious[ity]," students might come up with brand new conjectures because they are free to explore and build knowledge. However, the final interview's member checking revealed the strategy does not always play out in the ways he hopes and revealed that his students just wonder individually in their heads instead of contributing to proofs by sharing aloud with others. This is understandable because it might be difficult for students to understand what is expected of them. By practicing minimal-to-incremental guidance, he values neither complete absence of guidance by letting them explore without facilitation nor excessive guidance.

The analysis of the first two interviews highlights his emphasis on asking questions to the students, which can appear as "hints." Thus, in the final interview, we asked how he might model questions to students. Some questions such as "what-if" questions were found to be open-ended and promote exploration while others such as "this-and that" questions could guide students toward a particular line of thinking. He said:

[I]magine that I have **changed one condition** from there or the other condition from there **[in a known result]**. [Then I ask them] do you still think the result is true? So, some questions of this form [I would ask]. Can we remove these conditions or can we add [some], can we **weak[en]** them? So, with [their present] knowledge they [students] can come up with … counterexample[s] … You said that both A & B would hold? Almost probably A would hold or B would hold. **Can you guess which of them [A and B] would hold?** … They are just **interpolating [guessing] from what they know**.

When he says, "Can you guess which of them [A and B] would hold?", he appears to prompt the students to consider specific and important ideas or concepts by "interpolating from what they know." Such a binary question is important so that students can understand the intended goals of their instructor. Moreover, Aditya's "what-if" questions like "chang[ing] one condition … in a known result" in particular can be seen as open-ended questions and beyond mere yes/no questions because the "students can come up with … counterexamples" to justify and there can be brainstorming on tweaking conditional statements, like “weaken[ing] them” in his classroom. Thus, the what-if questions in Aditya’s classrooms are likely to provide support for exploration.

Discussion

Aditya had been introduced to the concepts of Guided Reinvention (GR) and Creation (Cr) through a series of PD sessions and was offered the opportunity to reflect on these concepts and how they (might) play out in his teaching. With the objective of how he makes sense of GR and Cr in mind, we identified four main themes through the teaching practices that he employs or conceives: (a) Avoiding faulty foundations through correct proofs, (b) Offering exploratory opportunities through minimal-to-incremental guidance, (c) Encouraging student engagement by building upon their prior knowledge, and (d) Increasing motivation by providing the history of mathematical concepts.

Due to space restraints, we mainly focus on the theme of *minimal-to-incremental guidance* in this section. Even so, we believe it is important to highlight some of the interactions between the themes and with the conceptual tools of GR and Cr. We found that Aditya envisions his responsibility to provide opportunities for exploration through an instructional strategy of giving minimum assistance in the beginning and increasing the assistance gradually through “hints” and questions as per the perceived need of the students. Through the instructor’s hints, such an approach has potential to empower students to reinvent intended concepts that GR contends. Due to the lack of expository teaching, the “curious” students might also have opportunities to *explore* and develop brand new conjectures in such a minimal-to-incremental guided instruction; thus, the instruction can be seen consistent with Cr. Aditya’s technique appears unique, given this type of guidance does not appear in Learning Outcomes based Curriculum Framework (LOCF) and the standard faculty induction program called GURU-DAKSHTA published by University Grants Commision (UGC), a statutory body in India. Aditya’ questioning strategy in the classroom supports both GR and Cr. The binary question, observed in the findings section, is important so that the students can understand the intended and clear goals of their instructor, which provides support for GR because RME-instruction sequences appear to have a clear specific path to follow. Moreover, Aditya’s open-ended questions like what-if questions appear consistent with King and Rosenshine (1993) who argue for “guided cooperative questioning strategy” in which teachers ask generic thought-provoking questions that can provide support for exploration and, thus, Creation. Such an approach is more process-oriented (as opposed to product-oriented), which makes it different from the learning outcomes approach highlighted in India’s education policy and GR’s “intended mathematics” goals (Gravemeijer, 1999).

A minimal guidance might facilitate students' exploration, but there are chances that such explorations can lead to students’ proofs that are not “correct” or to their “contradictory understandings” that are revealed in the theme on correct proofs. We note from Aditya’s practice that if guidance is increased too quickly, it might restrict exploration or discovery. In other words, if his students solve mathematics problems using informal or intuitive language that does not align with standard proofs, he might feel prompted to make them aware of the inaccuracy and tell them or motivate them to use formal proofs.

More than simply showing how Cr and GR arise in Aditya's views and instruction, his case highlights how the two conceptual tools Cr and GR relate and support or expand the other theoretically. Both concepts acknowledge: (a) students as mathematicians, (b) students participating and connecting with each other, and (c) instruction as process-oriented. Let’s consider how they expand each other. First, Cr expands GR in following ways: (a) The GR process aims to facilitate students to reinvent instructor's or curriculum's predetermined concepts. Cr acknowledges that the foundations of the predetermined concepts can be contextual, for example, following one of several appropriate sets of axioms or a collection of self-evident statements. In this way, Cr might go beyond just considering predetermined concepts in teaching and learning mathematics by taking into account the "misconceptions" as alternative, yet viable, ways to think about or develop a concept. (b) GR appears to be a linear sequence of levels starting from situation → referential → general → formal in "Model of - Model for: emergent modeling" (Gravemeijer et al., 2000; Streefland, 1985; Van den Heuvel-Panhuizen, 2003). Creation can inform us that instructional practices are not necessarily sequential due to the probable presence of an interaction between correct and "wrong" conceptions. Second, GR expands Cr in the following ways: (a) Goal-oriented: Cr does not speak about achieving specific goals that can indicate success. Considering GR with Cr can be helpful because GR appears goal-oriented by focusing on facilitating students to reinvent a predetermined concept. (b) Concrete practice: GR can offer instructional steps, for example the linear sequence of levels, should an instructor be confused or uncertain about how to approach Cr in the classroom. Thus, Cr and GR show the potential to expand each other.

There are several strengths of this study. The study was not extractive because we attempted to build through (a) the PD program before we generated data with Aditya and (b) the joint wonders during interviews that included the first author's teaching experience to identify the resistance in practicing GR and/or Cr in Aditya's instruction during the interview. Second, the interview protocols were tailored to the participant's responses and according to the examples and comments they provided in preceding interviews. Even so, there are some limitations to this study. For example, although several interviews were conducted with each participant, there is a single data source: interview responses from Aditya. Multiple data sources, such as classroom observations and comments from students during focal groups or interviews, or survey responses would have allowed for triangulation and increased credibility and a more comprehensive understanding.

Conclusion and Implications

This case study investigated how a mathematics instructor in India conceived of his practice in relation to facilitating abstraction and addressing students' conceptions. This study raises several issues for future researchers. In this study, Aditya described what he does and what he thinks about his teaching through interviews and, in that sense, his case offers researchers a glimpse of the potential approaches and challenges of incorporating GR and Cr into mathematics instruction at the college level. However, the data fail to capture how his students feel about his instructional practices. Future research might consider observing the classroom in an ethnographic study in order to get some evidence from students on how GR and Cr are experienced or might be supported in the classroom. This approach is especially important in the case of RM because instructors alone cannot determine if their pedagogy is being felt in rehumanizing ways (Gutiérrez, 2018). Potential research questions for the study might include: (a) How does a mathematics instructor practicing both GR and Cr know how much informality is appropriate during a course primarily based on abstract concepts or in courses that feature "pure" mathematics? (b) What instructional practices, such as debates in history, might offer Nepantla moments for students so they can appreciate conflicting conceptions in classrooms (Scott & Tuana, 2017)? and (c) How might seeing informality and formality as part of a larger cycle affect a mathematization process in GR during the instruction?

A Student's Self-Perceptions and Social Positions in an Undergraduate Precalculus Classroom

Jason Guglielmo
Arizona State University

Mathematics education research has linked students' development of positive mathematics identities to outcomes of academic success and persistence in STEM. I contribute to this research area by adopting a positional approach to identity development, focusing on the students' development of in-the-moment identities through the negotiation of acts and roles. To better understand the connection between the roles adopted by students in class and the students' mathematics identity development, I conducted classroom observations of an undergraduate precalculus classroom and interviewed four focal students on their beliefs about math and experiences in this course early and late in the semester. Student-instructor interactions from the observations were coded to produce positioning profiles for the focal students. Here, I present the positioning profile for one student, alongside a reflection of her transition from not identifying as a "math person" to identifying as one, as developed through narrative analysis of the interview data.

Keywords: positioning, identity, student-instructor interactions

Students' mathematics identity development has been a topic of mathematics education research, with studies linking the development of a positive math identity to students' academic success (e.g., Ma & Kishor, 1997; Lee & Anderson, 2009; Gonzalez et al., 2020) and persistence in STEM trajectories (e.g., Meece et al., 1990; Boaler & Greeno, 2000). This study intends to explore how student-instructor interactions in the classroom support or hinder the development of positive math identities. Identity has been conceived of in many different ways, and here I leverage perspectives with a focus on students' in-the-moment construction of their *positional identity* as they interact with others in math spaces, foregrounding the roles that students are allowed access to and choose to adopt in their math classes (Herbel-Eisenmann et al., 2015; Radovic et al., 2018). This positional take on identity has offered particular insights into the role of communication acts (Andersson & Wagner, 2019) and their associated power dynamics (Esmonde & Langer-Osuna, 2013) in affording (or denying) resources for students' participation in mathematical tasks.

In this contributed report, I utilize longitudinal classroom observation and interview data to describe the ways in which Olivia (pseudonym), a student in an undergraduate precalculus course, (a) adopted particular roles during interactions involving the instructor in the math class, and (b) experienced growth in her sense of self as a "math person" across the semester. The ultimate goal of this research is to better understand how an undergraduate student's positioning during interactions with their math instructor impacts the student's enduring sense of themself as a learner and doer of math. To that end, the next phase of analysis will involve linking repeated positions adopted by multiple students to changes in their self-perceived mathematics identity. A better understanding of the impacts of student positioning during instructor-led interactions on their more stable identification with math will support instructors' ability to consciously reframe their discussions (Louie, 2017) in ways to support their students' mathematics identity development.

Theoretical Framing and Relevant Literature

I define a participant's *positional identity* using Harré and van Langenhove's (1999) positioning theory. This perspective is focused on understanding the meanings behind different communication acts in an interaction through the storylines and positions available to participants. *Storylines* are sociocultural frames for interpreting the available rights and duties of participants in the interaction, and *positions* are the ways that elements of these storylines are taken up by the participants during the interaction to act in particular ways (Andersson & Wagner, 2019). One's identity is constructed through social interactions where (a) the individual acts to position themselves as having particular roles or qualities, and (b) others act to position the individual and accept (or reject) the individual's own acts of positioning (Langer-Osuna & Esmonde, 2017). With this understanding, I define an individual's *mathematics identity* as their personally held beliefs about their ability to participate appropriately in particular mathematics spaces. This framing of mathematics identity assumes a connection between students' acceptance (or rejection) of in-the-moment positions within the mathematics classroom, and their self-understandings about how they are supposed to participate in mathematics spaces.

Significant work has been done in K-12 mathematics education research to better understand students' identity development and the outcomes associated with it using a positional lens (Boaler & Greeno, 2000; Esmonde & Langer-Osuna, 2013; Bishop, 2012; Anderson, 2009; Andersson & Wagner, 2019; Gholson & Martin, 2019; Louie, 2017). In particular, the positional approach to identity has given researchers insights into students' enactment of different mathematics identities in the same local context (Bishop, 2012) and the positive influence of different positioning acts on students' engagement with certain mathematical practices (Esmonde & Langer-Osuna, 2013). However, this positional approach to mathematics identity has been uncommon in RUME (Radovic et al., 2018).

To characterize the varied positions that students could adopt in the classroom, I initially leveraged Andersson and Wagner's (2019) characterizations of high school math students, who highlighted three positions of *leader*, *follower*, and *rebel*. These archetypes focus on characterizing who is making requests and who is fulfilling those requests (or not), but they are somewhat limited. For instance, any interaction involving students and the instructor tends to position the instructor as the *leader* and the students as *followers*, given the nature of their formal relationship. As such, Andersson and Wagner's characterization of positions is more suited for student-student interactions and not student-instructor interactions. Additional approaches to characterizing positions from the literature range from lower inference documentation of the structure and function of an individual's communication actions (Bishop, 2012) to higher inference coding for the emotional content of actions (e.g., Heyd-Metzuyanim & Cooper, 2022). These various approaches to identifying students' positions in the math class collectively influenced the initial analytic coding process.

Methods

Data Collection and Context

Data for this preliminary report consist of (a) classroom observations of an undergraduate precalculus classroom, and (b) early- and late-semester interviews with one of four focal students and the instructor. The course was taught in Spring 2023 at a large research university in the Southwestern U.S. Class sessions were 75 minutes long, and students typically engaged in small group work at their tables while the instructor circulated the room, interspersed with whole class discussions (WCD). During WCD, the instructor frequently used an Initiation-Response-

Evaluation model for questioning (Mehan, 1979), where she initiated the interaction by asking a question to the class, a student responded to the instructor's question, and the instructor assessed and evaluated the student's response.

Three preliminary classroom visits occurred at the start of the semester, to identify and recruit focal students and to refine the video and audio recording setup. Following this, seven observations were conducted for study: three earlier in the semester and four later in the semester. After the preliminary classroom visits, students who had interacted with the instructor at least once were invited to participate in the study, and four students were chosen who had interacted with the instructor with varying frequency. Small group work was recorded visually using two tripod-mounted iPads and audibly using two recording devices placed on tables with the focal students; both visual and audio recording devices were adjusted throughout the class session to best capture student-instructor interactions in both small group and whole class discussions. While observing and recording class sessions, field notes were taken to provide context and to indicate times when there were interactions between the instructor and one of the focal students. The instructor was interviewed at the beginning and end of the semester to provide additional context regarding instructional practices and how she interacted with students.

The focal students were interviewed at the beginning and end of the semester, immediately following the early-term and late-term observations. All interviews were video- and audio-recorded using Zoom conferencing software; some interviews were conducted in-person while others were conducted over Zoom. Interviews were semi-structured, with questions about the students' (a) academic status and past experiences in math courses, (b) general interests in and beliefs about mathematics, (c) performance and participation in this particular course, and (d) perceptions of how they and significant others in their life and course (family, friends, instructor, classmates) viewed them as a "math person." At the end of each interview, participants were asked to reflect on particular moments from a recent class session, supported by clips from the class recording in which the participant was interacting with the instructor.

Analysis of Observation Data

Analysis of the observation data began with the identification of notable moments from class recordings. A *notable moment* is one where (a) an interaction occurred involving the instructor and a focal student, and (b) the interaction was *not* focused on course logistics (e.g., asking about exam dates). Although this report focuses on the notable moments involving one particular student, a total of 17 notable moments were identified between all four focal students, ranging from one to three minutes in length. These clips were transcribed using Descript software and manual cleaning, with notes added to indicate associated physical movements and gestures. Analysis of these notable moments was done in accordance with thematic analysis (Braun & Clarke, 2012) to develop roles for these focal students and the instructor. Following familiarization with the data, initial codes were assigned to each talk-turn, with multiple codes sometimes associated with the same turn. Codes were developed in a predominantly deductive fashion, where prior positioning studies were leveraged to construct (a) *structural codes* (Andersson & Wagner, 2019; Bishop, 2012) that capture the discursive function of the talk-turn in the interaction, and (b) *subjective codes* (Heyd-Metzuyanim & Cooper, 2022) that incorporate inferences about turn-taker's emotional hue. Though informed by the literature, these codes were refined through an iterative reflection with the data to more accurately capture the roles that were common in the class. Once refined, the position codes were grouped by student, and *positioning profiles* were created for each student and the instructor to reflect any patterns noted in the individual's positions throughout the class. In the next section, the developed codes are presented alongside a checklist to indicate if Olivia or her instructor adopted any of those roles during notable moments involving Olivia.

Analysis of Interview Data

Interview recordings were automatically transcribed by Zoom and manually checked. Analysis of interview data was conducted in accordance with narrative analysis (Polkinghorne, 1995) to configure the elements and events of Olivia's interview into a developmental account of her feelings as a "math person" throughout the semester. The use of "math person" here is due, in part, to prior findings that the term is associated with mathematics identity for some undergraduate students (Guglielmo et al., 2023). Initially, events relevant to Olivia's perceptions of herself as a learner and doer of math were identified and summarized. These events were then organized to construct an initial recounting of Olivia's math identity development from beginning to end of the semester. This narrative was refined through a recursive movement between the data and the emerging thematic plot, to ensure it succinctly brought meaning to the interview data while maintaining accuracy. In the next section, a condensed version of the narrative along with relevant excerpts from the interview transcript are presented.

Results

Olivia's Positioning Profile

Olivia was involved in six notable moments over four class periods (two early-class, two late-class). Five of these moments occurred while students were working in small groups, the sixth occurred during whole class discussion. Table 1 describes all nine position codes that were developed during analysis. In this table, both the position code and its description are provided, alongside a checklist that acknowledges if the instructor or Olivia exhibited that role during *any* of Olivia's six notable moments. The first six codes are structural codes and the last three are subjective codes.

Table 1. Codes developed for Olivia and the instructor's roles during Olivia's six notable moments, with a checklist for which individuals exhibited these roles in at least one notable moment.

Code: Description	**Instructor**	**Olivia**
Requester (general): Making a request expecting a response from members of a work group or the entire class.	x	
Requester (specific): Making a request expecting a response from a specific individual.	x	x
Requester (support): Making a request looking for approval or support for their prior responses or actions.	x	
Responder: Responding to a previous request by another individual, with or without justification for response.	x	x
Subject: Being the explicit or implicit subject of another individual's request or response.	x	x
Revoicer: Rephrasing or restating the response of another person out loud.	x	x

Approver: Responding to another individual's request or response, with explicit or implicit approval of some part of their contribution.	x	x
Critiquer: Responding to another individual's request or response, with explicit or implicit critique of some part of their contribution.	x	
Apologizer: Expressing regret for a prior response or action.	x	x

The following excerpt illustrates how these codes were applied, using a small group interaction between Olivia, the instructor, and StudentA (a non-focal student in Olivia's small group), discussing the domain of the sine function:

		Code [*Subject*]
Instructor	So, do we have any restriction on our angle measure?	Requester [*General*]
Olivia	Well, I was thinking, wouldn't, wouldn't it be like zero to two pi?	Responder [Instructor]
Instructor	Can we go (*upward vocal inflection*) above two pi?	Critiquer [Olivia] Requester [*General*]
StudentA	Yeah, yeah, if you do multiple rotations.	Responder [Instructor]
Instructor	Okay. Can we go the (*upward vocal inflection*) other direction?	Approver [StudentA] Critiquer [Olivia] Requester [*General*]
Olivia	Yeah.	Responder [Inst.]
Instructor	So (*expectant pause*)	Requester [*General*]
StudentA	Kind of (*pause*) infinity?	Responder [Instructor] Requester [Instructor]
Olivia	Okay.	Approver [StudentA]
Instructor	Yeah, we can go in both directions. We'll still get out something, right, from our function. Yeah, we haven't been working too much in terms of, like, more than one full rotation. But, um, we definitely can.	Approver [StudentA] Revoicer [*General*]

Initially, Olivia responds to the instructor's request for the domain of the sine function (talked about as an angle measure) as zero to two pi. The instructor, instead of approving Olivia's contribution, makes a request for further information from the whole group, implicitly critiquing Olivia's response. StudentA responds to the instructor's first request with support, and then Olivia responds to the instructor's second request without support. After the instructor's final request, StudentA provides a hesitant response that also functions as a request for support, to which both Olivia and the instructor approve. This was one of three notable moments where Olivia made a mathematical error in her response, and the instructor adopted a Critiquer role by questioning the student's response. In the two other instances, one similarly involved an implicit critique of the student's response mediated by another student, while the other was an explicit critique of the student's algebra.

Olivia's Narrative Reflection on Mathematics Identity

Olivia's mathematics identity narrative was constructed relative to three phases of Olivia's participation in her precalculus course: the pre-precalculus narrative, the initial reflections on precalculus, and the final reflections on precalculus. Before enrolling in her precalculus course, Olivia had some positive associations with mathematics, based on prior experiences in math courses and her own interests in the sciences. In high school, Olivia found particular math subjects interesting and "easy" (trigonometry, statistics), while also developing a preference for math classrooms with an active instructor who provides step-by-step explanations and examples. In her transition to university, mathematics played a peripheral role in her choice to major in biological sciences, with Olivia desiring a biology-focused major that was not "fully set on just math." In relation to her biology identity, Olivia views math as a useful tool for interpreting graphs, analyzing data, and making predictions, with its application to many areas and its integral role in the advancement of our society. In sum, Olivia has an appreciation for mathematics, an interest in learning (at least some areas) of mathematics, and a view of mathematics as significant (in some regards) to her future academic and career motivations.

Despite these positive associations with mathematics, Olivia explicitly did *not* describe herself as a math person during the initial interview, in which she said:

> **I want to be a math person**. I associate a lot of like math people, **they're really smart**. Like they're really smart. They think really well, like the way their minds work, they're very calculated […] whereas, like, with English, it's okay, there's more leniency in it […] I feel good knowing that, like, my family would probably see me as [a math person], but **I just don't see myself as it probably due to some, like, I see, I'm like, I'm hard on myself. I'm a pretty, like, when it comes to that, I have a pretty high standard**.

Olivia often contrasted her sense of being an "English person" with being a "math person" during this first interview, as noted in the excerpt above. She viewed herself as an English person, in part because it "just comes more naturally," while not viewing herself as a math person due to her own "high standard." During this first interview, Olivia thought of "math person" as a title reserved for "really smart" individuals, of which she did not view herself.

While reflecting on her classmates' perceptions of her as a math person during the first interview, Olivia noted the mixed perceptions they likely have. She mentioned some students in the class that likely *don't* view her as a math person due to her getting multiple answers wrong, but also one particular student who likely *does* view her as a math person, because Olivia opens up more around her and explains her process. This focus on opening up and reaching out to others was brought up multiple times by the student, mostly expressing a desire to contribute her ideas more during discussions. Specifically in previous math courses, Olivia acknowledged that she often would not speak out during class due to her "low self-esteem when it comes to math related subjects." However, with her precalculus course, Olivia stated that "[the instructor] makes it to where you wanna talk to the tables," and that "this is the perfect moment for me, in my mind, to like, try and branch out more." Though she still has to "fight the feeling" of being afraid to be wrong, Olivia acknowledges that she has started sharing her ideas more openly with others in her precalculus class, due in part to the interactive nature encouraged in the class.

During the second interview, and after asking Olivia "How has this class affected your level of interest in math as a whole?" Olivia immediately responded, "Okay, this is crazy, but I've actually, I went from thinking that I wasn't a math person to actually thinking I am a math person now." Throughout the interview, the reasons behind this change in the student's self-perception as a math person were explored. One particular reason, highlighted in the excerpt below, had to do with the students' shift in thinking about being wrong as necessary in the process of learning mathematics:

> I'm, I'm feeling a lot more comfortable with being wrong. Just like being able to discuss in groups, if I'm wrong, I kind of, I, I used to just care about it so much. **It was all I would think about. I, I was afraid of like speaking.** But like now it's, I don't know. I, I'm feeling a lot more comfortable in doing that, because **I've seen everyone get something wrong before and I'm like, I'm not the only one** […] It's not like I care that they got that wrong, so why would others care about me getting stuff wrong, you know? It's all part of the process. **It's all part of learning. That's why we're learning it**.

Olivia more explicitly notes her instructor's influence on this shift, through her "sweet and genuine" approach to teaching and her ability to "understand where [Olivia's] coming from." In contrast, Olivia states that with her current English instructor, "I'm afraid that if I say this, I'm gonna be wrong, and she's gonna scream at me." Unlike other classes, Olivia consistently looks forward to going to her precalculus lessons, sees the importance in them, and feels "happy" and "motivated" when she learns something new. Overall, Olivia now predominantly sees a math person as one who enjoys doing math and participating in math contexts. As such, she now views herself as a math person.

Discussion and Next Steps

During early- and late-semester class observations, Olivia adopted relatively consistent positions during interactions involving the instructor. In five of the six notable moments, Olivia made a mathematical error in her response to the instructor's request, and another individual would implicitly or explicitly critique her response. In these interactions across the semester, Olivia took on the role of a quiet yet persistent member of her precalculus class, whose contributions were open to critique by others. This prevalence of critiquing contributions was mirrored in Olivia's reflections during both interviews, where she often mentioned a fear she had of speaking out and being wrong in previous math classes. By the end of her precalculus course, Olivia saw the process of trying and getting things wrong as a necessary part of learning mathematics. This shift coincided with her coming to claim the title "math person," as Olivia found enjoyment and motivation in her precalculus class. In accordance with positioning theory (Harré & van Lagenhove, 1999) and mathematics identity, I conjecture a link between Olivia's frequent in-class role as the subject of others' critique and her development of understanding wrong answers as necessary for learning.

Additional positioning profiles and math identity narratives for the other focal members of this class will contribute to a broader understanding of ways in which students' mathematics identities may shift in relation to the positions they adopt during interactions with their instructor. These will inform future research intended to better understand the ways in which undergraduate students' positioning in their math class affects their mathematics identity development, including exploring the storylines from which they draw their various roles and classroom norms. Ultimately, this will lead to a more comprehensive understanding of the factors that influence the students' positioning and mathematics identity development.

University of Nebraska-Lincoln

Within secondary mathematics teacher preparation, recent scholarship points to the efficacy of strong links between university mathematics course content and secondary mathematics teaching practice. Studies aligned with this view typically focus on overarching course design, rather than instructional characteristics. This investigation builds on a prior such study that found improvements in teachers' potential competence for teaching across four different content areas. In the present study, we analyze 137 teachers' expectation for success in and valuing of core instructional practices and their gains in content knowledge for teaching, as well as a purposive sample of videos from 6 courses enrolling a subset of these teachers. Based on our analysis, we suggest that different aspects of university instruction may have differential influence on attitudinal and cognitive aspects of teachers' potential competence. Moreover, instructional practices that most benefit attitudinal aspects may be in tension with those that most benefit cognitive aspects.

Keywords: teaching practice, secondary mathematics teacher education, competence

For decades, the narrative of secondary mathematics education was one of disconnect. Klein (1924/1932, as cited in Kilpatrick, 2019) lamented a "discontinuity" between undergraduate mathematics experiences and secondary teaching. Empirical findings documented that many secondary teachers found their undergraduate mathematics courses irrelevant to their teaching (Goulding et al., 2003; Zazkis & Leikin, 2010). There is recent promise in an approach to designing mathematics courses for prospective secondary mathematics teachers that connects undergraduate course mathematics *content* to secondary mathematics *teaching practice* (see Lai et al., in press and Wasserman et al., 2023 for reviews). These results conclude that curricular materials that intentionally promote such connections beneficially serve prospective secondary mathematics teachers (PSMTs). However, these studies lack an investigation of the undergraduate pedagogy through which the intended curricula are enacted. Yet different enactments of the same curriculum may have differential impacts (Remillard, 2018).

Our purpose is to hypothesize teaching practices that may impact PSMTs' development of competence for teaching. We operationalize competence in terms of expectation for success and valuing of evidence-based teaching practices, and the development of content knowledge for teaching. In doing so, we account for relationships among these traits. We address: (RQ1) *To what degree do attitudinal and cognitive aspects of competence associate?* (RQ2) *What aspects of evidence-based teaching practice may most influence PSMTs' development of attitudinal and cognitive aspects of competence for teaching?* We analyzed teaching practices with the Mathematics Classroom Observation Protocol for Practices (MCOPP; Gleason et al., 2017) applied to a purposive sample of 6 instructors' videos. Hence, we contribute an analysis of relationships between PSMTs' development of competence and instructional practices they experienced.

Terminology. In this study, *secondary* refers to Grades 6-12, though we note that 90% of participants intended to teach Grades 9-12. *PSMT* refers to prospective secondary mathematics teachers, *instructor* refers to an undergraduate instructor, and *student* refers to a secondary student. *Content* refers to mathematics and statistics.

Conceptual Perspective

We take competence for teaching to include teachers' capacity to harness knowledge and attitudinal traits (Blömeke et al., 2015). With respect to knowledge, we focus here on *content knowledge for teaching* (*CKT)*, defined as disciplinary knowledge entailed in the recurrent work of teaching mathematics or statistics (Ball et al., 2008; Baumert et al., 2010; Thompson & Thompson, 1996). With respect to attitudinal traits, we focus on expectancy and value for enacting evidence-based teaching practices. A person's *expectancy* is their expectation of success at carrying out a task in a particular situation (Wigfield & Eccles, 2000). *Value* is the importance of carrying out a task well, and can encompass utility, enjoyment, and personal fulfillment (see Eccles & Wigfield, 2020, for a review). We use evidence-based teaching practices to refer to teaching practices that promote discussion and elicit student thinking about content in ways rooted in disciplinary norms (e.g., Gleason et al., 2017; Grossman et al., 2009). Such teaching practices are associated with instructional quality and student learning outcomes at the secondary levels (e.g., Baumert et al., 2010).

Competence is influenced by socialization (Eccles & Wigfield, 2020), and PSMTs' socialization includes their experiences in the mathematics courses they take (e.g., Buchholtz & Kaiser, 2013; Werler & Tahirsylaj, 2022). In this study, all participating PSMTs enrolled in courses using written curricula developed by the Mathematics Of Doing, Understanding, Learning and Educating for Secondary Schools (MODULE(S2)) project, which promoted explicit links between university course content and secondary mathematics teaching practice. We posit that even with this similarity across PSMTs' experiences, there may still be differences due to instructors' enactment of the written curriculum (Remillard, 2018).

One theme in studies of undergraduate mathematics instruction in the past decade has been the effectiveness of *evidence-based teaching practices*, particularly those consistent with inquiry-based mathematics education (Laursen & Rasmussen, 2019; Freeman et al., 2014). We operationalize the term "evidence-based teaching practices" as teaching for conceptual understanding, including opportunities to examine mathematical structure, through teacher interactions and students' engagement. One characterization of evidence-based teaching practices (among others) is represented by the Mathematics Classroom Observation Protocol for Practices (MCOPP), which has been validated to capture the presence of evidence-based practices in undergraduate mathematics instruction (Gleason et al., 2017). The principles behind MCOPP items are consistent with guidance at the elementary, secondary, and undergraduate levels for mathematics teaching (e.g., Mathematical Association of America, 2018; National Council of Teachers of Mathematics, 2014). Gleason et al. (2017) reported that MCOPP items fall into two dimensions: Teacher Facilitation and Student Engagement.

Background

Evaluation of effectiveness in instruction is typically conceptualized in a process-product paradigm: "the search for relations between classroom processes (instruction) and products (what students learn" (Gage & Needels, 1989, p. 254). For instance, one of the main results cited in support of evidence-based practices in undergraduate mathematics education is Freeman et al.'s (2014) meta-analysis. They concluded from their analysis of 225 studies that "active learning" pedagogies (process) increase undergraduates' scores on concept inventories and course examinations (product) in STEM fields. Indeed, the term "evidence-based practices" is rooted in this paradigm: they are teaching practices for which process-product research indicates positive impacts on student outcomes.

Studies assessing the impact of evidence-based teaching practices as a process tend to focus on one product at a time. For instance, Laursen et al. (2014) examined the impact of inquiry-based methods on undergraduates' assessments of their own learning gains. Johnson et el. (2020) investigated the effect of active learning methods on undergraduates' knowledge of group theory. Freeman et al. (2014) focused on outcomes in course examinations and concept inventories. These results do not account for the possibility that particular teaching practices may have differential impacts on different aspects of student outcomes, such as attitudinal in comparison to cognitive outcomes.

Although process-product studies of inquiry-based mathematics education have included mathematics courses for PSMTs in their data, their analyses typically consider PSMTs' experiences in aggregate with undergraduate mathematics students more generally (e.g., Laursen, et al., 2014). However, PSMTs have needs distinct from other undergraduate mathematics students, because content knowledge for teaching is different from content as needed in other mathematically-intensive careers (e.g., Krauss et al., 2008; Hill et al., 2007). Moreover, although prior studies in undergraduate mathematics education have examined undergraduates' attitudes toward mathematics, they have not addressed attitudes specific to future teaching practice.

This study addresses the gap in examining the potential for differential impacts as well as the need for studies specific to PSMTs. We analyze a combination of teaching practices experienced by PSMTs in a mathematics course, content knowledge for teaching, as well as expectancy and value for carrying out evidence-based teaching practices.

Data & Method

The context for this study is the MODULE(S2) project, a research and development effort that produced written curricular materials in algebra, geometry, mathematical modeling, and statistics. Materials for each content area are intended to span one term of a university mathematics course for PSMTs. All materials featured opportunities for PSMTs to apply course content to teaching situations such as responding to student ideas. In a previous study, the MODULE(S2) project examined pre- and post-term data for PSMTs' expectancy and value for enacting evidence-based teaching practices, and their CKT. This research found mean increases in PSMTs' outcomes across each of these constructs (Lai et al., 2023). Further, this prior study indicated that PSMTs noticed their instructors' enactment of evidence-based practices. One significant limitation of this prior study is that it examined instruction indirectly, using PSMTs' perception of the instruction they experienced.

There are two parts to the present study. For RQ1, we examined the association among PSMTs' gains in expectancy, value, and content knowledge for teaching. For RQ2, we compared ratings for videos of 6 instructors' use of evidence-based practices to mean gains of participating PSMTs enrolled in their courses. Our rationale was that if we were going to examine the impact of instructional practices on PSMTs' development of three different traits (expectancy, value, and content knowledge for teaching), we should also examine the relationship among these constructs in the population. If significantly associated, instructional processes influencing one trait may influence others in a similar way. If association is more limited, we may be looking for differences in the influence of instructional practices on traits.

Participants for RQ1 were 137 PSMTs enrolled in university courses using MODULE(S2) materials, with 50 in algebra, 25 in geometry, 16 in mathematical modeling, and 46 in statistics. For RQ2, we purposively sampled 6 instructors' courses in geometry and statistics, the areas with the most video data available for analysis. Following the process-product model, we posited that PSMTs' mean gains in CKT represented variation in instruction. Our purposive sample consisted of videos from instructors with high and low relative mean gains among participating PSMTs, resulting in a selection of 19 videos from 4 geometry instructors' courses (12 videos; mean CKT gains ranged from 10% to 19.50% of the maximum possible CKT score) and 2 statistics instructors' courses (7 videos; CKT gains 10.6% and 26.88%). Video lengths ranged from 40 minutes to 75 minutes and documented a single class period instruction.

As for instrumentation, we measured pre-/post-term expectancy and value for carrying out evidence-based practices using a Likert-item survey, whose phrasings were drawn from Wigfield and Eccles (2000). In the prior study, internal reliability (Cronbach's α) was $\alpha = 0.91$ for the expectancy assessment, and $\alpha = 0.79$ for the value assessment. A common guideline for Cronbach's α is to consider values over 0.7 as acceptable and values over 0.9 as excellent (Nunnally, 1978). We measured (CKT) in each area with instruments featuring applications of the specified content to teaching (see Lai et al., 2023 for more details on instrument validity for capturing PSMTs' CKT). We analyzed instructional videos using MCOPP, which consists of 20 items describing aspects of two categories: undergraduate student engagement (SE) (e.g., assessing strategies, communicating ideas to peers) and teacher facilitation (TF) (e.g., allows for wait time; encourages independent thinking) (Gleason et al., 2017). Each item is rated on a scale of 1 to 3, representing less to more intense enactment.

For RQ1, the first three authors analyzed relationships between PSMTs' expectancy, value, and CKT. To do so, we used Pearson's correlation coefficient r to measure effect size of correlations. We used p-values to determine if there is evidence of a non-zero correlation in the theoretical population, but focus on practical significance.

For RQ2, four researchers (including the fifth and sixth authors) coded videos with MCOPP items, reconciling in pairs any difficult evaluations. We intended to analyze relationships between these dimensions, items, and mean PSMT gains per course in expectancy, value, and CKT. We decided to focus solely on TF as the videos often followed the instructor, affording limited data on student engagement. Of note, after 2017, items addressing equitable teaching practices were added to MCOPP from outside the original factor analysis. Based on parallelism in phrasing, we posited how these items fell into the teacher facilitation dimension; we call this dimension *TF+*.

Here we emphasize the phrasing of RQ2: "What aspects of evidence-based teaching practice <u>may</u> most influence PSMTs' development of attitudinal and cognitive aspects of competence for teaching?" Although we use Pearson's correlation coefficient r in this analysis, we do so in an exploratory way. Our findings are potential hypotheses. We posited that $r \sim 0$ ($\sim 0.1 < r < \sim 0.1$) can be interpreted as the hypothesis that the MCOPP item or dimension has little relationship to the PSMT gain in the trait (expectancy, value, or CKT). Otherwise, positive r indicates a hypothesis that the teaching practices described in the MCOPP item or dimension benefits PSMTs' development in that trait. And negative r indicates a hypothesis that those teaching practices may have less benefit for PSMTs' development.

We also emphasize the study context: we already know that PSMTs on average gained expectancy, value, and CKT. Thus a negative correlation indicates that the dimension may have had less impact on the PSMTs' development than others for the specified trait, rather than indicating that the dimension is detrimental to the PSMTs' development.

Results

RQ1: PSMTs' Gains in CKT Versus Expectancy or Value Show Mostly Statistically Insignificant Correlations with Negligible Effects

The first three authors used Pearson's correlation coefficient *r* to analyze relationships between PSMTs' gains in CKT versus their gains in expectation to implement and valuation of core instructional practices. Each PSMT's scores on these metrics were first converted to a percent change from pre to post out of total possible points on the relevant assessment or survey. Figure 1 shows Pearson's correlation coefficient *r* and the p-values for this group of PSMTs, both partitioned by content area and as a whole group. Note that both results for the combined group were statistically significant with $p < 0.05$, though their *r* values were small. The only content-specific significant result was for statistics and value, with a higher *r* value of +0.41. These results imply that, for the most part, PSMTs' learning of mathematics content for teaching was separate from their expectation and valuation of core instructional practices.

	CKT vs. E *r* value	CKT vs. E p-value	CKT vs. V *r* value	CKT vs. V p-value
Algebra	+0.107	0.458	+0.022	0.882
Geometry	+0.137	0.514	+0.153	0.466
Modeling	+0.342	0.195	+0.336	0.203
Statistics	+0.188	0.212	+0.41	0.005
All Content Areas Combined	+0.168	0.0497	+0.199	0.019

Figure 1. Pearson's correlation coefficient r and the p-value for correlations between PSMT's gains in content knowledge for teaching (CKT) and gains in expectancy (E) or value (V). Statistically significant results are highlighted in green.

RQ2: We Hypothesize that the Process as a Whole (of Evidence-Based Practices) is the Sum of Parts in Tension

Overall, Pearson's correlation coefficients with the TF dimension with expectancy, value, and CKT ranged from 0.022 to +0.49. Our estimate for standard error over the 19 observations (for 19 videos) is 0.45 assuming independent observations. This assumption is necessary for the analysis even though these observations are not independent, with multiple videos originating from the same instructor. Nonetheless, we infer that these coefficients are relatively small. The exceptions are the correlations with gains in expectancy, which were +0.45 (TF) and +0.49 (TF+).

When examining correlation for individual MCOPP items with expectancy, value, and CKT, we find wider variation. With expectancy, *r* ranged from -0.12 to +0.73. With value, *r* ranged from 0.42 to 0.57 actual. With CKT, *r* ranged from -0.62 to +0.51. For some items with larger relative *r* in terms of absolute value (operationalized as $|r| > \sim 0.4$), the sign for the coefficient flipped between expectancy and CKT, or between value and CKT, or the coefficient for CKT was relatively small (for examples, see Figure 2).

	7) The teacher promoted modeling with math.	11) The teacher's talk encouraged student thinking	13) There was a climate of respect for what others had to say	14) In general, the teacher provided wait-time
E	-0.08	+0.18	+0.58	+0.73
V	-0.42	+0.42	+0.57	+0.56
CKT	+0.51	-0.62	-0.09	+0.01

Discussion

We examined pre/post-gains in PSMTs' expectancy, value, and CKT as well as instruction experienced by the PSMTs, for which our analysis found insignificant correlations between PSMTs' gains in these aspects. We also hypothesized that teacher facilitation would have the greatest additional impact on PSMTs' gains in expectancy, in the context that we know students on average experienced gains across each trait across all courses.

Our study was limited in several ways. The band of CKT gains that determined the purposive sampling was relatively narrow, limiting differences to detect. The videos coded, though purposively selected, may not represent the widest variation in instruction; the courses with the highest and lowest mean CKT gains in a content area sometimes had no video data available. Additionally, we completed coding in two of the four original content areas. For this reason, we view our results as hypotheses for further consideration.

One hypothesis we make is that in the presence of gains in competence, teaching practices may make more difference in expectancy for carrying out evidence-based teaching practices than other traits. One reason for this being that experiencing evidence-based teaching can foster confidence by providing a model for what such teaching looks and feels like.

We also hypothesize that different teaching practices have differential benefits to distinct intended outcomes for competence (gains in expectancy, value, and CKT). Here we distinguish teaching practice, conceived as the whole of a teacher's instruction, from teaching practices, conceived as routines and aspects within instruction (Lampert, 2010). Further, in any given moment, an instructor can only focus on so many individual practices; emphasizing one practice may necessitate doing so at the expense of another. How do we conceive of "effective" teaching practices when faced with these kinds of results? Perhaps effective teaching practice is composed of teaching practices in tension.

Connecting Unique Factorization Domains with the Teaching of High School Algebra in Approximations of Practice

Sthefania Espinosa

Younggon Bae
The University of Texas, Rio Grande Valley

We designed approximations of practice (AoPs; Grossman et al., 2009) that pose hypothetical classroom scenarios of high school students learning about factoring polynomials. We investigated the ways in which prospective and in-service teachers leverage their understanding of unique factorization domains to inform their teaching practices of attending, interpreting, and deciding how to respond to students' thinking in the AoPs with the goal of making explicit connections between abstract algebra and the teaching of secondary mathematics.

Keywords: approximations of practice, noticing, unique factorization domain, abstract algebra

Connecting secondary mathematics and abstract algebra can support in-service and pre-service teachers (IPSTs) in their teaching. For IPSTs to recognize advanced mathematics courses, like Abstract Algebra, as beneficial for their teaching, they should be explicitly given opportunities in their mathematics courses to reflect on how the advanced content is connected to secondary mathematics and how those connections can inform their teaching. Some researchers and teacher educators (e.g., Álvarez et al., 2020; Burroughs et al., 2023; Serbin & Bae, 2023) have provided such opportunities to IPSTs by using *Approximations of Practice* (AoPs) in advanced mathematics courses, which are activities situated in hypothetical classroom scenarios that require IPSTs to simulate certain teaching practices (Grossman et al., 2009). AoPs often include scripting tasks (Zazkis et al., 2013) and noticing tasks (Jacobs et al., 2010) that engage IPSTs in attending, interpreting, and deciding how to respond to students' thinking in samples of written student work or scripted class discussions.

Before teachers' understanding of connections between secondary and abstract algebra can become useful in their teaching or AoPs, those connections should first serve to fundamentally change the teachers' understandings of the content they teach (Wasserman, 2018). This principle guided our design of an instructional task sequence that guided IPSTs in reinventing (Gravemeijer, 1999) unique factorization domains (UFDs), connecting its properties to the factorization of integers and polynomials (commonly used in secondary algebra), and applying their understandings of those connections in AoPs. A *UFD* is an integral domain R in which every nonzero element $r \in R$ which is not a unit has the following two properties: (i) r can be written as a finite product of irreducibles p_i of R (not necessarily distinct): $r = p_1 p_2 \dots p_n$ and (ii) the decomposition in (i) is unique up to *associates*: namely, if $r = q_1 q_2 \dots q_m$ is another factorization of r into irreducibles, then $m = n$ and there is some renumbering of the factors so that p_i is associate to q_1 for $i = 1, 2, \dots, n$ (Dummit & Foote, 2003). After reinventing UFDs, the IPSTs were asked to complete a set of AoPs (Grossman et al., 2009) that were designed to lead them to use their understandings of UFDs and factorization while they noticed (attended to, interpreted, and decided how to respond to) student thinking or scripted class discussions in hypothetical classroom scenarios (Jacobs et al., 2010; Zazkis et al., 2013). We address this research question: *What aspects of IPSTs' understanding about UFDs do they leverage as they interpret and decide how to respond to students' mathematical thinking in AoPs?*

Literature Review

It is essential for teachers to have knowledge of the content they teach, as well as knowledge of advanced mathematics that is related to, but is still outside the scope of, secondary mathematics. Wasserman (2018) defines the mathematical knowledge outside of the scope that teachers teach as *nonlocal mathematics*. Nonlocal mathematics can influence the teachers' perceptions and interpretations of their students' thinking. Thus, it is important that preservice teachers are prepared beyond the local mathematics they plan to teach. However, it often occurs that IPSTs do not see any connections between the advanced mathematics courses they take with the secondary mathematics they eventually teach (Zazkis & Leikin, 2010).

Some researchers have tried to resolve this disconnect by studying how to support IPSTs in making connections between the content they learn and the content they teach on the secondary level (Alvarez et al., 2020; Wasserman, 2018; Wasserman et al., 2017; Larsen, 2013). However, there has not been much research done on how these connections actually influence the way graduate students teach mathematics (Wasserman et al., 2017). Abstract Algebra is one of the primary advanced mathematical courses required for IPSTs, where they can learn about algebraic structures (Pramasdyahsari, 2021; Ticknor, 2012). To make explicit connections between the abstract algebra and secondary mathematics, Álvarez et al. (2020) designed pedagogical tasks for use in abstract algebra courses that generated student-teacher interaction and helped students construct their own knowledge. Similarly, Zbiek & Heid (2018) proposed the Mathematical Understanding for Secondary Teaching framework where IPSTs connect abstract algebra and school algebra through the mathematical activities of mathematical noticing, mathematical reasoning and, mathematical creating, which leverage the practices of noticing structure and symbolic forms, proving and conjecturing, as well as representing and defining. Herbst et al. (2014) explored how AoPs using online learning can engage prospective secondary teachers as part of their practice-based teacher development. These studies exemplify efforts being made toward supporting IPSTs in connecting advanced mathematics to teaching.

Theoretical Background

Building Up From Practice – Stepping Down to Practice

To help teachers make connections between advanced and secondary mathematics, Wasserman et al. (2017) proposed the *building up-stepping down* model for a real analysis course. The model consists of providing IPSTs with pedagogical situation tasks that can help them recognize the utility of advanced mathematics, in this case, real analysis, in their teaching. Thus, they start from a practical scenario in the context of teaching mathematics and build up the advanced mathematical content from that practice. Once the students learn advanced mathematics, they step down to teaching practice, where the ideas of real analysis are explicitly connected to secondary mathematics, and IPSTs can use their knowledge about real analysis to support their teaching practices such as attending and responding to hypothetical students' ideas.

Approximations of Practice

Teaching requires multifaceted skills, like interpreting and responding to students' mathematical thinking, explaining mathematical definitions, posing questions, and responding to questions that can advance the students' reasoning (Álvarez et al. 2020). Therefore, it is crucial that IPSTs have opportunities to practice these skills without the complexity of teaching in a real-life scenario. Grossman et al. (2009) defined *AoPs* as "opportunities for novices to engage in practices that are more or less proximal to the practices of a profession" (p. 2058). AoPs, like scripting and noticing tasks, serve as practice for IPSTs to implement the pedagogical moves they learn (Crespo, 2018). For instance, Zaskis & Marmur (2018) argue that scripting tasks provide IPSTs the opportunity to "explore erroneous or incomplete approaches of a student, revisit and possibly enhance personal understanding of the mathematics involved and enrich the repertoire of potential responses to be used in future 'real' teaching" (p. 294). Scripting tasks also prompt prospective teachers to reflect and explain why they would continue the discussion in that manner (Campbell & Baldinger, 2021). By having these opportunities in advanced mathematics courses, IPSTs can develop teaching practices in connection to the advanced mathematical content they learn in the courses (Álvarez et al., 2020, Zaskis & Marmur, 2018).

Noticing Students' Mathematical Thinking

In our task design, we leveraged the three components of professional teacher noticing of mathematical thinking: attending students' mathematical thinking, interpreting students' understanding and deciding how to respond (Jacobs et al., 2010), as we consider them key pedagogical moves that teachers can implement to guide a class discussion and answer their students' questions. Zambak et al. (2023) recognize that "noticing provides pedagogical readiness for PSTs to correctly identify students' mathematical conceptions and misconceptions and guides their instructional strategies" (p. 4). In noticing tasks, prospective teachers are posed with a hypothetical classroom scenario where the mathematical activity and thinking of a student are described. The goal of such tasks is for IPSTs to attend, interpret, and decide how to respond to the student's ideas by reasoning about the strategies the student used to solve the given task. We investigate the aspects of IPSTs' understandings of UFDs that IPSTs leverage as they interpret and respond to students' mathematical thinking in AoPs.

Therefore, our study design is informed by Wasserman et al.'s (2017) *building up-stepping down* model for designing curricula that connects advanced mathematics to teaching, along with the instructional design theory of Realistic Mathematics Education (Gravemeijer, 1999), informed our creation of local instructional theory, in which we guided graduate student IPSTs' reinvention of UFDs. We connected the first tasks in the sequence to the teaching of factorization in high school algebra by using algebra tile manipulatives. We built up the advanced mathematical content by guiding the IPSTs to reinvent UFDs (see Bae et al., 2024). We then guided the IPSTs to step down to practice by using their understandings of UFDs in their responses to AoPs situated in hypothetical classroom situations. The design of the AoPs was informed by Grossman et al.'s (2009) AoPs and Jacobs et al.'s (2010) noticing framework.

Methods

We designed a sequence of tasks to guide IPSTs to reinvent the reducibles and irreducibles (Unit 1), reinvent the definition of UFD (Unit 2 & 3), and apply their knowledge to AoPs (Unit 4). In Unit 4, we created AoPs where IPSTs engaged in noticing students' mathematical reasoning about concepts related to factorizations of integers and polynomials. The tasks were designed to elicit IPSTs' use of their knowledge of UFD from the previous units as they attended to, interpreted, and decided how to respond to students' thinking in written work and class discussion scripts. In this paper, we focus on their work on the AoPs tasks in Unit 4.

We administered the AoPs to IPSTs in a teaching experiment (Steffe & Thompson, 2000) conducted in the Southern US. Six mathematics graduate student IPSTs participated in this study: Josie and Raul (Group A), Javier and Roberto (Group B), and Kim and Taylor (Group C) (pseudonyms). They all had taken an abstract algebra course but had not yet learned about UFDs. They had varied teaching experiences at different school and college levels ranging from student teaching to 20 years. Each group participated in five 90-minute sessions of teaching experiments with the research team. Groups A and B participated in person, and Group C participated in Zoom. We collected and transcribed the session recordings.

We implemented the AoPs in Figures 1, 2, and 3. The IPSTs responded to questions about their interpretation of what the students' approaches and understandings, and how they would respond to such student ideas if they were the students' teacher and how their responses were informed by their understanding of UFDs, providing us with evidence about how they used their knowledge about UFD to inform their pedagogical actions. We used inductive coding (Miles et al., 2013) to analyze how IPSTs use their knowledge about UFD as they worked on the AoPs. We coded the properties of UFDs the IPSTs referenced as they in noticed and responded to students' mathematical thinking, i.e., (Jacobs et al., 2010).

In Mr. Garcia's class, students were asked to factor a quadratic polynomial $-2x^2 - 4x + 6$ for solving a quadratic equation $-2x^2 - 4x + 6 = 0$. Mr. Garcia had four of his students, Aden, Brian, Cassy, and David come to the board and share how they factored the polynomial. The following is the solutions of the four students that involve different final forms of factorization of the polynomial $-2x^2 - 4x + 6$.

Aden	Brian	Cassy	David
$-2x^2 - 4x + 6$ $= -2(x^2 + 2x - 3)$ $= -2(x + 3)(x - 1)$	$-2x^2 - 4x + 6$ $= -(2x^2 + 4x - 6)$ $= -(x - 1)(2x + 6)$	$-2x^2 - 4x + 6$ $= x^2 + 2x - 3$ $= (x + 3)(x - 1)$	$-2x^2 - 4x + 6$ $= (-x + 1)(2x + 6)$ $= (-x + 1)2(x + 3)$

Jaime, one of the students in Mr. Garcia's class, said "So who's got it right? They all got it different, so someone must be wrong." Monica followed, "That doesn't matter, you have to check if they all give you the same roots".

Figure 1. Approximation of Practice Task 1 Scenario

1. In Ms. Gonzalez's last class, students went over problems that required factoring polynomials. Ms. Gonzalez wants her students to think about the factorization of polynomials. She said: "Today, we are going to explore how polynomials and integers are similar. What similarities do you think polynomials and integers have?"
2. A student Amy asked the following question to Ms. Gonzalez: That problem told us to factor a polynomial, and I was trying to remember where I saw factoring before. I remember that numbers have prime factorizations. Do polynomials have prime factorizations too? Or is that a different kind of factorization?

Figure 2. Approximation of Practice Task Scenarios from Task Set 2

The teacher asks students to find the factors of the polynomial $x^2 + 5x + 6$.
When asking the students to share their answers, he receives the following answer:
Luis: The factors are 3 and 2.
Teacher: Can you explain your answer?
Luis: The factors of 6 are 3 and 2 because 3·2 is equal to 6 and 3 plus 2 gives me 5 which matches the polynomial.
Alex: I think he's right, he just needs to add x, so we have $(x + 3)$ and $(x + 2)$.
Mia: I have $(x + 2)$ and $(x + 3)$. Does the order for this matter?

Figure 3. Approximation of Practice Scenario from Task Set 3

Results

Episode 1: Reasoning About the Uniqueness Axiom of UFD to Inform their Interpretation of and Response to Hypothetical Students' Thinking

In the AoP task set 1, four hypothetical students, Aiden, Brian, Cassy, and David obtained different factorizations $-2x^2 - 4x + 6$ (see Figure 1). In this hypothetical scenario, the students' work was on the classroom board, and the class was discussing the factorizations. Two students, Jaime and Monica, shared their ideas (see Figure 1). The participants were asked to attend to and interpret the student understanding evident in Jaime's and Monica's comments. Josie and Raul agreed that Jaime's comment was valid, arguing that his understanding of factoring is strong. For instance, Josie claimed: He knows that… *when you're factoring something to the irreducibles, it should be unique no matter what… The order doesn't matter, but it still should be unique factorization. So, they should still end up with the same solution if the task is to factor it out.* Josie recognized that Jaime thought only one of the distinct solutions from his classmates must be correct because he might know that the problem must have one unique solution. Raul interpreted Jaime's understanding of factorization as "*on point*" for this same reason. Both IPSTs connected Jaime's comment to the uniqueness axiom of the unique factorization domain.

The participants were prompted to decide how they would respond to the class following the comments by Jaime and Monica. Josie responded:

> Just check each student's solutions of like, you have student [work] on the board, and you might ask, who got it right? It's a two-part question, the factoring and solving the equation. So, to *check if you got the factoring right, distribute it, see if you got the original polynomial*. And then the second part of solving the equation, actually solve it. Set it equal to 0. Find the roots for each one. And that will give you the checkmark or the X for each one, whether they got both parts of the question right or wrong.

Josie and Raul decided that they would ask students to go back and check their classmates' answers for them to find whether the factorizations were correct.

Finally, the participants were asked how their understanding of UFD helped them interpret and decide how to respond to the students' thinking. Josie and Raul said:

> *Josie*: *It helps you address Jaime's comment, of the unique factorization domain tells us that the elements can be written as a unique product of irreducibles up to the order and associates of the elements*. So, it helps us address his comment right away of, *he understands that the factorizations should be unique*, so every student should have gotten the same factorization if the question is to factor it all the way down to irreducibles.
>
> *Raul*: [...]. So, I kind of push already for like, *you need to factorize it as much as possible, which is like this unique factorization idea, prime factorization idea*. Um, so, I guess my push is like, with this, with *this unique factorization domain idea in mind is that, we want it to be as small as possible, on what the product is that.* […]
>
> *Josie*: *Because we know… how the integral domain works, we can answer their question like well, but how? But why?* …I think that's the question. Which is why I thought that the question would be more like appropriately addressed to Jamie's comment, and maybe student Aiden for that matter too, that they understand that the factorization, you're going to get it down to like, *you want to break it down as much as possible, like the primes*. And that *factorization must be unique, which is the property of the UFD we're looking at***.**

Josie recognized that the way she could address the students' comments was by knowing how some mathematical structures such as rings and integral domains work. Specifically, she mentioned that the UFD axiom about uniqueness helped her respond to the students' mathematical thinking. Raul also referenced the UFD axiom regarding the existence of prime factorizations, as evident in his response of pushing students to "factorize it as much as possible" and "be as small as possible." Thus, Josie's and Raul's understandings of the axioms of UFDs informed their interpretation of and response to student thinking in this AoP.

Episode 2: Reasoning about the Reducibility and Irreducibility of Polynomials to Inform their Interpretation of and Response to Hypothetical Students' Thinking

In Task Set 2, the IPSTs were given the classroom scenario in Figure 2, where a teacher prompts her students to identify the similarities between integers and polynomials to help them develop an intuitive understanding of factoring polynomials. The IPSTs were asked to anticipate what similarities students might find between integers and polynomials. Taylor and Kim said that students would probably recognize that integers and polynomials have numbers, and they could do operations with them such as addition, subtraction, and multiplication. Both agreed that students would probably not think about factorization as a similarity between them. Kim and Taylor were then asked about how they would respond to these anticipated student ideas and how they could connect those ideas to the factorization of polynomials. Kim replied, "I think the big thing is… branching the ideas together. Right, okay, so…this is surface-level. Let's get a little bit deeper, to get the point of the factorization at least. Okay, yes, so you can factor polynomials." Next, they were asked about the characteristics of unique factorization domains that would help inform their response to students in this question. They answered as follows:

Kim: I think for that one, just the fact that you *had the unique factorization domain of like integers but also the ring of polynomials. Knowing that they are, that that is the same, inherently those structures, allows one I think to be more confident in saying, okay, they are similar, because they are the same structure*, right?

Taylor: *I still like the "breaking them down", that they can be broken down into irreducible things. […] Just knowing that you can break these things down*, I think that would be really beneficial, at least for that level. So that I guess the first point is the most important one for me, not so much that they're unique, but that you can do it to begin with.

Taylor related the reducibility of elements in UFDs as the main property that was connected to factoring polynomials, arguing that students could understand factoring as the action of "breaking things down" Therefore, Taylor's knowledge of the reducibility in UFDs helped her have an intuitive understanding of factoring in a high school setting and informed her way of sharing these ideas with the student.

The participants were next asked about how they would decide to respond Amy's question if they were her teacher (see task 2 in Figure 2). They replied as follows:

Taylor: Yeah, they do have prime factorizations, *and I don't think it's a different kind of factorization*. Because like, 2 and 3, you know, that's 6, but the factorization of 2 and 3 can be the same as a polynomial as long as you have the correct x value. So it's, I don't know if I would call it different kind of factorization. *I would say they're the same, but they're performed differently and for different reasons*.

Kim: …I just immediately am like…what do you mean by prime, right? Like prime, just give the definition of prime... You can't reduce it, right? So, *talk about reducibility, make that connection, and then you can get the polynomial to a reducibility* as well, kind of depending on like that factorization and with the root finding.

Taylor agrees with Amy's reasoning about the similarities between the prime factorizations of integers and polynomials, and Kim relates such property of polynomials to the reducibility in the elements of UFDs given that both integers and polynomials with integer coefficients are UFDs. We asked the participants what aspects of UFD informed their responses to students. Kim said:

Just knowing that the UFD is both a definition for the integers and the polynomials ring is, is important for this response, like with the last one. Because, okay, if you know they are the same, you can confidently say yes, of course, without having that doubt. Because if you have that… second of doubt of like, oh, are they the same or are they not? And you're discouraging the student from like, but they were right, and they had the right idea. *So setting a foundation of yes, I know for a fact, because it's the same structure, okay. And it instills confidence in the student as well.*

Kim's understanding of the structure of the integers and polynomials as UFDs gave her the confidence to assert that the factorizations the student Amy asked about were indeed similar because they have the same UFD structure. Having this understanding about the structure of factorization in $\mathbb{Z}$ and $\mathbb{Z}[x]$, informed Kim's response to the hypothetical student in the AoP.

Episode 3: Reasoning About the Commutativity of Polynomial Factors to Inform their Interpretation of and Response to Hypothetical Students' Thinking

The last set of tasks consisted of the hypothetical classroom scenario in Figure 3. When asked to interpret Mia's understanding, Javier replied*: "Mia's just trying to I guess clarify if commutativity is going to work here also."* We asked the participants how they would address and respond to the students' comments if they were their teacher. Javier and Roberto responded:

Javier: For Mia, *I'd probably just tell her to multiply those out,* $(x+2)(x+3)$*, and then multiply* $(x+3)(x+2)$*, to see if it really does matter if we multiply them in any order.*

Roberto: *…Mia to expand both terms and see if they give you the same answer*. I think the way the task is given is that I think she knows how to factor everything out. She knows how to get those two answers, but *she's just not sure if commutativity matters or not*. It can be solved just by *telling her to distribute*. *It doesn't matter in this case, it's the same*.

The IPSTs were asked about how their knowledge of unique factorization domains was informing their responses to students. Javier responded, "Seeing the commutativity in the tiles," and Roberto agreed. The IPSTs explained that their knowledge of the commutativity property of UFDs helped them explain with confidence why the order of the factors does not matter when factoring a quadratic. They both referred to the "uniqueness up to the order" of the factors, which results from the multiplicative commutativity that can be applied to the factors in a factorization.

Discussion and Conclusion

We exemplified how IPSTs' understandings of the connections between the abstract algebraic concept of UFD and the concepts of integer and polynomial factorization from secondary mathematics seemed to support them in their pedagogical practices. Specifically, we identified how the participating IPSTs seemed to leverage their reasoning about the existence and uniqueness axioms of UFDs to inform their responses to AoPs tasks that prompted them to interpret and decide how to respond to hypothetical students' thinking or classroom scenarios. Our work contributed to the literature on how IPSTs' knowledge of abstract algebraic concepts can inform their pedagogical practices. Our findings also contribute to the literature on the utility of AoPs in supporting IPSTs in connecting advanced and secondary mathematics. Álvarez et al. (2020) suggested that these AoPs can be "used both as a vehicle for bridging undergraduates' advanced mathematical knowledge to secondary school mathematics and for strengthening undergraduates' understanding of the advanced mathematics from an encounter with school mathematics" (p. 16). Additionally, AoPs can give IPSTs experience in using their knowledge of advanced mathematics in their teaching practices, which can contribute to improvements in their perceptions of advanced mathematics as being useful for their teaching of school mathematics (Serbin & Bae, 2023). Future research can address how IPSTs use their knowledge of other advanced mathematical concepts, as well as their pedagogical or mathematical practices (e.g., Wasserman, 2022), as they perform AoPs. Lastly, we propose that mathematics instructors who prepare IPSTs should implement AoPs in their assignments to support IPSTs in developing coherent understandings of the connections between abstract algebra and the teaching and learning of secondary mathematics.

In Transition from Undergraduate to Postgraduate Mathematics: A Case of Re-learning to Learn

Rox-Anne L'Italien-Bruneau
The University of Auckland

Igor' Kontorovich
The University of Auckland

The transition from undergraduate to postgraduate studies has been underexplored in mathematics education research. Several studies showed that this transition is challenging as it requires countless changes in familiar practices. In this paper, we present the case of Jordan—an honors student who was developing mathematical background as a stepping stone toward his research project. With the commognitive framework, we analyzed the data from three interviews to reveal Jordan's mathematical learning network of routines. The findings detail the network's components and illuminate the role of agency in Jordan's network development. Agency appears as necessary to navigate learning routines common in undergraduate studies and enables Jordan to be less dependent on externally provided resources shaping his learning.

Keywords: mathematics learning, postgraduate studies, commognition, learning routines

Introduction and Background

The preparation of new researchers is vital for the flourishment of any discipline. Mathematics departments initiate students to research through a range of programs such as honors, master's and doctorates. Each of these postgraduate contexts is distinct, and their structures differ substantially from what undergraduate students are used to. Thus, a shift from undergraduate to postgraduate mathematics constitutes a critical transition, that is, one that involves "a noticeable change of point of view […and] a necessity for entering into a different type of discourse […] or more broadly […] changing 'lenses'" (Yerushalmi, 2005, p. 37). Yet, research into students' experiences of the undergraduate–postgraduate transition in mathematics is scarce.

Higher education research identified important obstacles in students' transition to postgraduate studies. For instance, O'Donnell and colleagues challenged the assumption that undergraduates are experts in disciplinary practices and elaborated on multiple changes postgraduate students must navigate simultaneously (O'Donnell et al., 2009; Tobbell & O'Donnell, 2013a; Tobbell & O'Donnell, 2013b). Adjusting to a higher level of independence has been reported to be particularly challenging for students (Tobbell et al., 2010). Lovitts (2005, 2008) detailed a range of factors underpinning the complexity of the shift from being expected to "[learn] what others know and how they know it" to "conducting original research and creating knowledge" (p. 140). Among other factors, the microenvironment composed of the department, advisors, and peers appeared to have a significant impact on the shift to independent research. Overall, the growth of independence constitutes a central theme in the literature on the transition to postgraduate studies. While the existing findings are relevant to many postgraduate programs, they may be difficult to appreciate without accounting for the discipline within which the transition occurs. Therefore, the transition from undergraduate to postgraduate is a topic of interest for mathematics education research.

A few mathematics education studies discussed the experience of postgraduate students (e.g., Herzig, 2002, 2004; Morton & Thornley, 2001) and even fewer focused on the undergraduate–postgraduate transition. Duffin and Simpson (2006) listed a few differences between undergraduate and postgraduate studies. Within the former, students' learning mainly occurs through courses, where lecturers determine syllabi, teach the material, set problems for students to solve, and suggest textbooks and references. The research component features in some undergraduate programs, but it is typically small and comes with comprehensive support (Dorff, Henrich & Pudwell, 2019). In turn, postgraduate students are expected to learn in an independent and self-directed manner. While research supervision is a typical component of many postgraduate programs, this role differs from that of a course lecturer. Accordingly, students' adaptation to the circumstances of postgraduate mathematics learning appears unavoidable.

An example of such adaptations comes from Geraniou (2010). She observed different stages in students' doctoral studies and explored factors contributing to students' success. Geraniou describes the first stage, which she calls *adjustment*, as "reading and gaining the background knowledge so as to be in a position to start their research" (p. 286). As this study was undertaken in the UK, coursework was not required, and students experienced learning without the structured environment of courses. Geraniou reports that in the absence of clear learning aims and imposed assessments, the students drew on their personal interest in the material and turned to their supervisors for motivation and guidance.

Some studies addressed the distinctions between how undergraduates and postgraduate students carry out specific learning-oriented practices. For instance, Shepherd and van de Sande (2014) explored students' and mathematicians' learning from mathematical texts. The researchers found that undergraduates limit their attention to the provided reference, relying only on the material presented inside the text for support. Postgraduate students and mathematicians both used the provided reference and external resources when seeking clarifications.

The existing literature indicates that the undergraduate–postgraduate transition requires new ways to learn mathematics. This study was initiated to enrich the existing literature by exploring how these ways of learning come about. Specifically, we aim *to characterize the processes of students' adjustment to the learning of mathematics at the postgraduate level.* We pursue this aim in the case of an honors student who was developing mathematical background outside of courses as a preparation for his research project.

Theoretical Framework

Research has shown the usefulness of the commognitive framework (Sfard, 2008) in exploring mathematics learning and teaching in the university context (e.g., Nardi et al., 2014; Karavi et al., 2022; Kontorovich & Ovadiya, 2022). In this study, we rely on the framework to cast light on students' learning of mathematics at the postgraduate level.

Commognition construes different mathematical areas as *discourses*, defined as "different types of communication, set apart by their objects, the kinds of mediators used, and the rules followed by participants, thus defining different communities of communicating actors" (Sfard, 2008, p. 93). Consistently, *learning* is associated with one "becoming a participant in certain distinct activities" (Sfard, 2008, p. 23). This may be evident in one's capability to operate with broadly accepted discourse-specific narratives, such as definitions, theorems, and proofs.

Postgraduate studies are expected to prepare students to contribute to a targeted mathematical discourse. This preparation imposes expectations on students, but students are "contributors to their life circumstances, not just products of them" (Bandera, 2006, p.1). In the context of postgraduate studies, students' contributions are captured through *agentive learning.* Brennan (2012) defines a learner's agency as an "ability to define and pursue learning" (p. 24). Knowles (1975) maintains that agentive learners take initiative, are sensitive to their learning needs, set relevant goals, determine helpful resources, and monitor their learning outcomes. Similarly, Lavie et al. (2019) specify that growth in agentivity, the commognitive version of agency, can be identified via the increasing number of self-determined decisions. Lavie et al. highlight the importance of one initiating activities without invitations from others and in the capability to set "the relevant [tasks] for herself, in response to her own needs" (p. 170). These activities can be captured in terms of one's *routines*.

Commognition defines routines as patterned courses of action. Initially, the construct referred to capture one's participation in a specific mathematical discourse (Sfard, 2008). Lavie et al. (2019) expanded this approach, arguing that "whatever we do involves routines. From the simplest, most mundane of our activities to the most abstract and sophisticated of them, we cope with the task by repeating something that we did or have seen done before" (p. 154). Sfard (2023) demonstrated that one's routines of teaching can be construed as "a tightly interconnected system" (p. 5) or a *network*, where one routine feeds into another or where several routines constitute part of a greater routine. Sfard argues that networks have a fractal-like structure due to the recursive nature of routines. In her words, "routines are built from parts that, in themselves, constitute routines" (Sfard, 2023, p. 5).

Following Sfard's (2023) steps, we propose that *mathematics learning*, that is an activity targeted as becoming an insider to a mathematical discourse, can be considered through the lens of routines. Indeed, students' progression through school and university mathematics can be seen as a journey across different discourses and joining these discourses requires the performance of various routines of learning. Thus, we propose that learning involves a repertoire of routines students employ to come to grips with new mathematics time and again. In undergraduate studies, this repertoire may include engaging with the course resources, working on the assigned exercises, and consulting with the lecturer during office hours. Identifying what routines students employ to learn mathematics at the postgraduate level is at the heart of our study.

Sfard (2008) distinguishes between the "how" and the "when" of a routine. The former refers to the *procedure* or the course of action, whereas the latter captures applicability conditions within which one *initiates* a routine and brings it to *closure*. Lavie et al. (2019) proposed that an analysis of one's routines should account for the *task*—an interpretation of a goal a routine performer sets for themselves in a specific *task situation*, that is, in circumstances in which they consider themselves bound to act.

Lavie et al. (2019) maintain that in task situations, people replicate actions they either performed or observed others performing in circumstances they deem sufficiently similar to the current one. Common features of situations, called *precedents,* enable one to cope with unfamiliar task situations. As no two task situations are identical, drawing on precedents requires one to decide which aspects of past performance should be replicated as is and which elements need to be amended to new circumstances. Accordingly, the implementation of familiar routines still requires some degree of agency. It is especially needed when one realizes that existing routines are insufficient to navigate the current task situation. Routines must then be substantially revised or abandoned in favor of new habits. Given the systemic differences between undergraduate and postgraduate contexts, it seems reasonable to expect students to develop new learning routines deliberately and agentively. We attend to the agentive component when analyzing postgraduate students' routines when learning new mathematics.

Method

This study is part of the first author's doctoral research on mathematics students' transition from undergraduate studies to postgraduate research. In this paper, we report on the case of Jordan (pseudonym), a mathematics major enrolled in a one-year honors program. The study unfolded in a small department of mathematics at a research-intensive university in New Zealand. Jordan's program consisted of six semester-long graduate courses and a research project that he carried out in parallel under the guidance of two supervisors. Jordan's project revolved around group theory and topology. Group theory was part of Jordan's undergraduate and graduate coursework, but topology was not. Nonetheless, Jordan had to develop the mathematical background needed for his research project in the first few months of his program.

Our data came from three interviews, around 50 minutes each. The interviews took place when Jordan was in the third, fifth and sixth months of his program. The first interview focused on Jordan's work with the supervisors and his general impression of research so far. Through his responses, Jordan elaborated on his self-guided learning of topology, and we used the opportunity to delve into this process. In the following interview, Jordan elaborated on his typical practices of learning new content, now including group theory, and demonstrated some of them in the third interview.

We engaged with the interview transcripts with the commognitive apparatus, searching for routines Jordan employed to join new mathematical discourses. Our data mainly consisted of Jordan's reflections, and thus, we operated with *routines-narratives*, i.e. self-descriptions of patterned actions. Different routines-narratives varied in the level of detail, but we attempted to delineate Jordan's procedures and tasks where possible. In the last stage of the analysis, we structured the identified routines into a network, with particular attention to how Jordan's postgraduate learning routines compare to typical actions students employ in undergraduate mathematics courses.

Findings

To report our results on Jordan's adjustments to the learning of mathematics at the postgraduate level, we report on one network of learning routines central to Jordan's joining mathematical discourses. Building on the fractal nature of networks, we then zoom in on one component of this network, which is a network in its own right.

Agentive Navigation of Network of Learning Routines

As mentioned, Jordan had to develop the background needed for his research in topology and group theory. Thus, the overarching task of the learning network we identified was to become an insider of these discourses or, in Jordan's words, to "get the background knowledge." Here is an example of how Jordan described this endeavor in the case of topology:

> I spent the first couple of weeks learning some topology and I read [some] lecture notes from a graduate course. It's a sort of introduction to topological groups, and it had like exercises. So, yesterday, I met with my adviser, and we just went over the exercises that I did and checked if they were roughly correct, and tried to approach the ones that I didn't get correct or just didn't know how to do. This was all building up to this theorem called Van Dantzig theorem. The goal of the first couple weeks was to understand that because it's apparently a foundation theorem in this area of topological groups.

The synthesis of similar self-reflections and observations of Jordan's work showed that Jordan's learning activity included finding references online; engaging with them with a special attention to definitions, examples, and exercises; discussing selected exercises and their solutions with his supervisor; and writing up selected solutions in LaTeX. The activities had a patterned nature and fed into each other, giving rise to a network of learning routines.

Some elements of the network are not foreign to routines undergraduates employ to join mathematical discourses in their coursework. Indeed, it is not rare for students to engage with provided references, solve exercises, and attend office hours to clarify issues with the course lecturer. At some point in the first interview, Jordan reflected on this similarity explicitly:

> I remember when I was taking algebra and calculus theory, and you're doing line integrals or decomposition of matrices, I could just do exercises, and there were loads of exercises, like hundreds of exercises. I could just sort of go, do them quite quickly, and I would get a good understanding.

This excerpt suggests that engaging with exercises provided in lecture notes and textbooks was a routinized and valuable way for Jordan to learn in at least some of his undergraduate courses. Hence, we propose that features of undergraduate studies and the learning routines they shape constitute precedents informing Jordan's routines as he joins the topological discourse.

Notwithstanding, it is hard to ignore the differences between typical ways of learning in undergraduate courses and Jordan's learning network. During the first months of his program, Jordan studied topology and group theory in an independent, self-directed manner, without a teacher providing carefully selected readings, exercises, and assessments. This new situation did not enable the replication of routinized habits and necessitated Jordan to be agentive and make multiple decisions. Let us elaborate on some of them regarding his engagement with multiple references.

Engaging with multiple references The supervisors directed Jordan to the main concepts and theorems in the area, which focused on Jordan's search for references. Consider an example of Jordan reflecting on his engagement with one reference:

> *Jordan*: Right now I'm reading through this particular document [lecture notes]. I'll have like, 20 tabs opened on my computer, and it's a couple of different textbooks and this paper and I'm also looking up Wikipedia articles, looking up math stack exchange articles, or posts to explain certain things.
>
> *Rox-Anne*: And you use all those resources to understand better the notes that you have, right?
>
> *Jordan*: Yeah. It explains sparsely the notes [my supervisors] want me to go through. I have a couple of textbook PDFs that I have downloaded, and also a friend of mine in a course. He's doing a master's, and he has some notes on topology, so I'm also using his notes…just referencing all this stuff. Sometimes, I want a particular definition, so I have to go to another reference.

In an undergraduate course, students are typically offered single references to learn from. These resources cover the relevant material and provide explanations that lecturers deem satisfactory and appropriate to support students' learning. However, in the case of Jordan, he has to be the one to search for relevant references. The process occurs online, requiring particular search procedures (e.g., choosing keywords). Jordan needs to estimate the usefulness of each reference to decide whether to engage with it more deeply or search for an alternative. No single reference appears to totally fulfil Jordan's needs, which yields to search-engagement cycles. Furthermore, Jordan also has to be the one to decide when the reference has fulfilled its purpose. For instance, once "a particular definition" has been found, he can return to his main notes. In this way, we argue that Jordan's performance of search-for-references and engagement-with-references routines are more agentive than those typically expected from students in undergraduate courses. Agency pertains to all components of these routines, including their initiation, procedures, and closure.

Detachment from Externally Proposed Exercises in Favor of Self-Posed Ones

In the first interview, Jordan shared that working on exercises he finds in textbooks and lecture notes plays a major role in his learning. He also recognized the limitations of learning through exercises. In his words:

> I guess I am not really sure what I'm going to do when the exercises run out because that's kind of the main way I've always learned. So if there are no exercises, I don't really know, I'll have to ask my advisors to, like, create exercises for me or something, or maybe I'll just try to come up with it myself.

Working on externally assigned exercises constitutes a central component of Jordan's learning network. By engaging with them, Jordan puts himself in task situations he encountered at the undergraduate level: an authoritative source, such as a lecturer or a textbook, ensures that the exercise is well-formulated, relevant, and potentially contributes to students' learning. The relevant material that is sufficient to solve the exercise is typically presented in the preceding text, whereas some learning resources may even provide final answers, hints, or complete solutions. A self-generated solution is often interpreted as a marker of understanding and progress, whereas difficulties can be clarified with a course lecturer or a supervisor in Jordan's case. In this way, exercises contribute to Jordan's becoming a participant in his target mathematical discourse.

However, exercises also confine Jordan to a particular type of resource. Indeed, Jordan was cognizant that exercises are not characteristic of the literature found in postgraduate mathematics, or at least not in the way Jordan is used to. This may potentially impede his engagement with that literature since he is "not really sure [what] to do when the exercises run out." As in undergraduate courses, he considers the supervisors as potential setters of exercises in these cases. Jordan acknowledges the possibility of coming up with his own exercises, but this possibility was mentioned in passing.

Later interviews revealed a number of routines Jordan developed to reduce his dependency on externally set exercises. He labelled one of these routines as *filling in the gaps* and gave the following example:

> *Jordan*: For the Van Dantzig theorem, they say that the translation map is a continuous map and they just make a little remark about it, but the reason it works is because it comes from the fact that the product map is continuous as well.
>
> *Rox-Anne*: But it's not that obvious, right?
>
> *Jordan*: I mean, it kind of is, I don't know, I feel like I'll write it out for myself eventually. Just write out a little proof in full like we show that the translation is just a product of [continuous maps].

Filling in the gaps emerged as a network of routines where Jordan sets new task situations for himself. Within this network, Jordan engaged with a reference with attention to "gaps", such as statements that were not justified in full or inferences that were unclear to him. Then, he turned the generation of a justification or proof into a task for him to pursue. This routine was discussed more deeply as Jordan's research project became more oriented on group theory. To develop the background for his research, Jordan engaged with various scientific papers, and the new routine of filling in the gaps gained importance.

Jordan specified that he initially filled in gaps that the references' authors often indicated with phrases such as "we omitted the proof because it's not difficult." He interpreted these indicators as a "signal that ok, I should probably fill that in, for the details, to put in my research [thesis]". At some point, Jordan started to create gaps on his own by pausing his reading and attempting to prove or justify mathematical statements before engaging with how this was done in the reference. In his words, I "create exercises by looking at the statement, then [trying] to prove it, and then reading what their proof is." Gaps of this sort can be opened in any mathematical paper, turning it into a prolific source of learning-inducing task situations. Whether noticed or created, the routine of filling in the gaps enabled Jordan to distance his learning network from the dependence on externally set exercises.

Summary and Discussion

Mathematics departments invest considerable efforts and resources to involve their majoring students in mathematics research through postgraduate programs. However, only a few studies in mathematics education explored the transition from undergraduate to postgraduate studies. With all the research attention that transitions received in mathematics education (Gueudet, 2016), the undergraduate-postgraduate transition appears to be overlooked.

In this paper, we focused on Jordan—an honors student who was developing mathematical background on his own as a stepping stone toward his research project. Higher education research emphasizes the shift in independence in students' transition from undergraduate studies to postgraduate research (Lovitts, 2005, 2008). Jordan's case illustrates that undergraduate studies do not always prepare students to embark on research right away, and students may need to develop the necessary background related to their research area. Geraniou (2010) referred to such situations as the *adjustment* stage and also identified this stage among doctoral studies. Our study shows that an adjustment stage may also be necessary in transitioning to other types of postgraduate research.

Using the commognitive framework, we identified a network of learning routines Jordan employed and developed in his adjustment stage. We saw similarities between some network components and ways of learning students often employ in undergraduate courses. Instances of these similar network components are the engagement with resources and the discussions with the advisors who provided clarifications about the material. These correspondences are somewhat expected considering that Jordan majored only a few months ago and was offered learning aims similar to those found in undergraduate courses. Additionally, we note that the main reference used by Jordan when joining the topological discourse was lecture notes, which may have facilitated the replication of routines common in undergraduate courses. Nonetheless, a distinctive feature of Jordan's network pertained to agency. In particular, agency was needed to navigate the network routines since each required him to make decisions regarding the initiation of a routine, the course of action, and a decision that the targeted outcome was achieved. Initially, the network depended on Jordan having access to exercises from textbooks and lecture notes, which confined his learning opportunities to specific references. Then, he demonstrated agency when introducing the routine of filling in the gaps that enabled him to become a poser of his own exercises. This new routine had a major impact on the whole network, broadening its applicability and enabling Jordan to learn from research papers. Accordingly, we propose that in mathematics, the shift to independence mentioned by Lovitts (2005, 2008) may be characterized by a growing distance from externally provided resources supporting learning.

The network development we observed fully exemplifies what has been called agentive learning (Brenan, 2012; Knowles, 1975). Our findings show that in the case of Jordan, the shift to this kind of learning, which was required at the postgraduate level, was a gradual and time-consuming process and a part of his adjustment stage. This makes us wonder about the role of agentive learning in the transition from undergraduate to postgraduate mathematics, specifically considering students' expected contribution to research.

Reinventing the Definition of Unique Factorization Domains

In this study, we conducted a teaching experiment to test hypothetical learning trajectories of reinventing the definition of the unique factorization domain. Six graduate mathematics students who are preservice and in-service teachers were given experientially real tasks of examining factorizations of integers and quadratics using algebra tiles. The experiment showed that their intuitive and informal reasonings about the reducibility and unique factorization were leveraged to formalize two defining axioms of the unique factorization domain by the emergent model of algebra tiles and by the pedagogical moves of the teacher-researcher who led the sessions.

Keywords: Unique factorization domains, Mathematics for teachers, Defining, Conjecturing

The importance of making connections between advanced mathematics courses required in teaching preparation programs and the secondary mathematics that students may teach has been highlighted in recent research (Álvarez et al., 2020; Wasserman, 2018; Wasserman et al., 2017). Abstract Algebra is a course where students learn about algebraic structures, including the properties of number systems, sets, and operations, including those commonly found in secondary mathematics contexts. Abstract Algebra serves as a course where in-service and prospective teachers (IPSTs) can learn the structural and fundamental reasons why secondary mathematics works, e.g., why the factors of a polynomial $(a + b)(c + d)$ are equal to $(c + d)(a + b)$. One concept typically covered in a graduate algebra course is unique factorization domain (UFD), which is defined as an integral domain R such that for every nonzero non-unit element $r \in R$, (i) r can be written as a finite product of irreducibles p_i of R (not necessarily distinct): $r = p_1 p_2 \ldots p_n$ and (ii) the decomposition in (i) is unique up to *associates*: namely, if $r = q_1 q_2 \ldots q_m$ is another factorization of r into irreducibles, then $m = n$, and there is some renumbering of the factors such that p_i is associate to q_i for $i = 1, 2, \ldots, n$ (Dummit & Foote, 2004). The structure of UFD is commonly used in secondary mathematics contexts related to the fundamental theorem of arithmetic and the fundamental theorem of algebra.

There exists a gap in the literature on students' understanding and their reinvention of UFDs. In our study, grounded in the instructional design theory of Realistic Mathematics Education (RME; Freudenthal, 1973; Gravemeijer, 1999), we designed a local instructional theory (Gravemeijer, 2004) with the goal of students reinventing UFDs. This concept of UFD is particularly useful for IPSTs, as it can support them in understanding that polynomials and integers have similarities in their structure and properties, which can be useful knowledge in their teaching of high school and college algebra. In this paper, we describe two hypothetical learning trajectories that comprise this local instructional theory where graduate students, who are IPSTs, engage in the mathematical activities of conjecturing and defining UFD by intuitively reasoning about the side lengths of rectangles represented in arrays and quadratics represented with algebra tiles. The students construct the axiom about the factorization of an element into a product of irreducibles. This helps students recognize the structural similarities of factorization in Z and $Z[x]$, which leads them to understand that a factorization of an element reduced to a product of irreducibles is unique up to associates and the reordering of the factors. We aim to answer the following questions: *1) Which aspects of the task sequence and which teacher-researchers' pedagogical moves support students' reinvention of unique factorization domains? 2) As students engage in the task sequence, which ways of reasoning are productive to leverage to guide them toward reinventing unique factorization domains?*

Literature Review

One major strand of research in students' reasoning about abstract algebra is based on students' guided reinvention (Freudenthal, 1991) of algebraic structures. Larsen (2009; 2013) developed a local instructional theory by which undergraduate students were guided to reinvent the definitions of group and group isomorphism by reasoning about the properties of the group of symmetries of an equilateral triangle. Larsen and Lockwood (2013) extended this work by developing another local instructional theory by which undergraduate students were guided to reinvent quotient groups. Cook (2012) also developed a local instructional theory for students' reinvention of rings, integral domains, and fields. These studies illustrated how students' intuitive reasoning could be leveraged for reinventing and defining formal mathematical concepts in abstract algebra. Researchers have not yet developed local instructional theories for unique factorization domains. Our study, therefore, contributes to the literature through its design of a hypothetical learning trajectory of how IPSTs reinvent the defining axioms of a UFD.

There has been minimal research done on students' understanding of UFDs. UFDs are special kinds of integral domains that have additional axioms about the existence and uniqueness of the factorization of each nonzero, non-unit element as a product of irreducibles. When exploring students' understandings of the factorization of elements in algebraic structures, researchers have focused on investigating student thinking in UFDs including the integers, Z, and the polynomials with integer coefficients, $Z[x]$. They have demonstrated the productivity of students considering the juxtaposition of elements in these sets, as doing so led them to recognize the overarching structure shared by the sets of integers and polynomials (e.g., Lee, 2018; Lee & Heid, 2018). We leverage this same juxtaposition of integers and polynomials with integer coefficients in this study to help guide students to make conjectures about the properties that integers and polynomials with integer coefficients share, which can be generalized to other integral domains that also satisfy the axioms of UFDs. One of the defining axioms of UFDs is the uniqueness of a nonzero non-unit element's factorization. Conceptualizing the factorization of integers and polynomials as unique has been shown to be a non-trivial endeavor for students (Zazkis & Campbell, 1996) This uniqueness property of irreducible factorizations is essential for secondary teachers to understand, as it is commonly used in problems that relate to the fundamental theorem of arithmetic or the fundamental theorem of algebra. Our task sequence, therefore, focuses on supporting IPSTs in reinventing the existence and uniqueness properties of the factorizations of integers and polynomials that are commonly used in the secondary mathematics content that they may teach.

Theoretical Background

Design Research and RME

We ground our teaching experiment by the design research methodology (Gravemeijer, 1999) that consists of designing and implementing a set of tasks that will be tested and iteratively modified, so that the task sequence aligns with the research team's learning goals. We designed a task sequence consisting of four units. We refer to the collection of four units as a local instructional theory (LIT), and each individual unit as a hypothetical learning trajectory (HLT). Our LIT had the overall goal of guiding students to reinvent the concept of UFD, which is why our task sequence was designed guided by the heuristics of RME (Freudenthal, 1991) which involve implementing: a) experientially real tasks where students can solve context problems that develop their intuitive understanding and guide them to formalize their understanding, b) an emergent model that will serve as a *model-of* students' informal understanding that can become a *model-for* students' formal and generalized understanding of an object, and c) guided reinvention, where students construct their own knowledge through their intuitive understanding with the guide and scaffolding of the tasks and/or an instructor. Each of the HLTs of the LIT, describes the intended learning goals, the learning activities, and the hypothesized student's understanding and learning (Simon, 1995). Once researchers design a proposed task sequence, they implement it in a small-scale teaching experiment where the tasks are administered to pairs of students, who with the help of a teacher-researcher, complete the tasks. The researchers then analyze students' thinking, testing the effectiveness of the tasks depending on how the students engage in such tasks and accomplish the intended goals. Through this process, the HLTs are edited and modified accordingly to help the students meet the hypothesized learning outcomes. Once this occurs, the LIT can be implemented in a larger-scale teaching experiment. Through this process of designing, implementing, and revising HLTs, researchers can discover students' ways of thinking that anticipate formal mathematics and identify ways to evoke and leverage those ways of thinking to support students' development of formal concepts.

Defining and Conjecturing through Guided Reinvention

In order to leverage students' ways of thinking, students need to be engaged in mathematical activities that can help them come up with ideas that describe their informal activity. The tasks in an LIT contribute to this process, but the teacher-researcher in charge of guiding the LIT has the role of evoking and leveraging those mathematical practices. In our case, the participants engage in the process of reinventing an abstract algebraic concept. Dawkins (2015) defined a successful reinvention as "an instance of psychological explication whenever students already possess some intuitive or less formal understanding from which they construct formalized meanings" (p. 67). To achieve this reinvention, the students engage in mathematical activities of defining and conjecturing where students can sense mathematics as a human activity (Zandieh & Rasmussen, 2010). To guide students in the process of conjecturing, researchers can generate examples and counterexamples that can help students "enrich their concept images and enable them to judge the probable truth of conjectures" (Selden, 2012, p. 403). For definitions consisting of axioms, students axiomatize while transitioning from a model-of to model-for (Larsen, 2013), where students start to formalize their intuitive reasoning into a more structured and refined conjecture. Vroom and Alzaga Elizondo (2023) described college instructors' ways to guide students in the process of refining and editing a definition by suggesting an edit with implicit/explicit mathematical reasoning and by presenting students with problematic situations. We explore students' conjecturing and defining activities, as well as the pedagogical moves that scaffold those activities, in this study.

Methods

In this study, we designed RME-based HLTs with the goal of guiding IPSTs to reinvent the definition of UFD and to connect their knowledge to the teaching of mathematics. The HLTs include task sequences that are designed to guide students to reinvent the definition of reducibles and irreducibles (Unit 1), reinvent the definition of UFD (Unit 2 & 3), and apply their knowledge to pedagogical scenarios in hypothetical classroom situations (Unit 4). In this paper, we focus on the IPSTs' work in Units 2 and 3. The IPSTs were given experientially real tasks to guide their reinvention of the two defining axioms of UFD following the two HLTs that we initially hypothesized in the task design stage of this research. They were asked to investigate composite integers and factorable quadratics using algebra tiles and generate conjectures about the reducibility of elements in Z and $Z[x]$ in Unit 2. They were asked to examine different factorizations of the same elements that are essentially the same and conjectured about the uniqueness of factorization in Z and $Z[x]$ in Unit 3.

We tested the HLTs by administering tasks to IPSTs in a teaching experiment (Steffe & Thompson, 2000) conducted in a Hispanic-serving institution in the Southern US. Six mathematics graduate student IPSTs participated in this study: Josie and Raul (Group A), Javier and Roberto (Group B), and Kim and Taylor (Group C). They took abstract algebra courses at the undergraduate and/or graduate levels but had not learned UFD in their coursework. Each group participated in five 90-minute sessions of teaching experiments with the research team including a teacher-researcher (TR), secondary instructor, and research assistant. The TR's role was to guide the session, provide students with prompts to work on, and ask follow-up questions to better understand and clarify the IPSTs' thinking. The research assistant operated the video camera and took field notes. The secondary instructor observed the sessions, took field notes, and asked questions to the IPSTs when needed. Groups A and B participated in person, and Group C participated on Zoom due to their availability. In-person groups were given printouts with physical algebra tiles, and the virtual group was provided with an online whiteboard with tasks and virtual algebra tile manipulatives.

We collected and transcribed the video recordings of fifteen 90-minute teaching experiment sessions. The groups' written work on handouts and virtual whiteboards were collected. We used inductive coding (Miles et al., 2013) to analyze how IPSTs engaged in conjecturing and defining as they were guided to reinvent the definition of UFD. We focused our analysis on their ways of reasoning that were leveraged by using the algebra tiles and by interacting with the TR.

Results

Reducibility of Elements in Z, $Z[x]$, and UFD

In the first task set of Unit 2 (see Figure 1), the IPSTs observed side lengths of rectangular arrays of algebra tiles that represent 12 and its factors. They were asked to keep reducing the side lengths of rectangular arrays and to conjecture about the reducibility of integers. For instance, groups arranged tiles to represent $12 = 3\times4$ or $12 = 2\times6$ then reduced the composite factors of 12 into other rectangular arrays such as $4 = 2\times2$ and $6 = 3\times2$. The IPSTs transitioned their use of the emergent model (i.e., algebra tiles) from being a model of factoring integers to a model for abstracting the reducibility property of composite integers. IPSTs initially conjectured *reducible integers can be reduced to a product of irreducible integers*. Their reasoning was leveraged when prompted to think of counterexamples to their conjectures. When needed, the TR suggested what to consider such as 0 and units in Z (1 and -1). This also involves referencing the definition of irreducibles from the previous unit where units and zero are not included. The IPSTs found that *the zero and units cannot be represented as a product of irreducibles because they are not irreducibles by the definition*. This investigation allowed them to revise their conjectures by limiting the scope of integers in the statement: *all non-zero, non-unit integers can be reduced to a product of irreducible integers*. Examining precise definitions of irreducibles and products (of elements) was productive to leverage their reasoning in revising their conjectures. For instance, they observed 2×1 arrangement of algebra tiles and asked if this could be a product of irreducibles. It allowed them to consolidate their definitions of irreducibles (e.g., irreducibles do not include units and zero) and products (e.g., a product can be a single element). In sum, IPSTs' initial conjectures about the reducibility of integers were elicited and leveraged by the prompts in the task sequence with support from the TR when needed. Counterexamples and formal definitions were useful resources for their progression in the practices of conjecturing and revising their conjectures.

Task Set 1	1. Look at the side lengths of the rectangles of 12. Are those side lengths (factors) of 12 reducible or irreducible? How do you know? 2. If the side length is a reducible, arrange the tiles representing that side length into a rectangular array. Are those side lengths of the new rectangle reducible or irreducible? 3. What do you notice about the reducibility of integers? Make a conjecture. 4. Can we always write an integer as a product of irreducibles? Try to find a counterexample where an integer cannot be factored into a product of irreducibles.
Task Set 2	1. Look at the side lengths of the rectangles that represent these quadratics. Note that we consider polynomials with integer coefficients only: (a) $3x^2 + 9x$, (b) $x^2 + 3x + 3$, (c) $2x^2 + 4x$, (d) $x^2 + 4x + 3$, (e) $x^2 + 5x + 7$. Are those factors of the quadratic reducible or irreducible? How do you know? 2. If the side length is a reducible polynomial, arrange that side length polynomial into a rectangular array. Are those new side lengths reducible or irreducible? 3. Create a conjecture about the reducibility of quadratics. 4. Can we always write a quadratic as a product of irreducibles? Try to find a counterexample where a reducible cannot be factored into a product of irreducibles. 5. What about a higher degree polynomial? Can we write any polynomial as a product of irreducibles? Try to find a counterexample where a reducible cannot be factored into a product of irreducibles.
Task Set 3	1. The Common Cores State Standards of Mathematics suggest that students should "Understand that polynomials form a system analogous to the integers." Thus, polynomials have similar structure to the integers. In what ways are polynomials and integers similar? 2. Integers and rings of polynomials with integer coefficients are special kinds of integral domains with special properties about their elements' reducibility. Let's make a conjecture about the reducibility of integers and polynomials. What similarities do you see between these examples of the side lengths of the rectangular array that represents an integer and the side lengths of the rectangular arrangements of algebra tiles that represent quadratics?

Figure 1. Unit 2 task sequence

Task Set 2 used the same structure of the task sequence to guide IPSTs to conjecture about the reducibility of quadratics over $Z[x]$ (see Figure 1). This time, they used algebra tiles to represent quadratics and their factorizations if they are reducibles. For instance, IPSTs reduced $3x^2 + 9x$ into $3x\times(x + 3)$, then further reduced $3x$ into $3\times x$ using algebra tiles (see Figure 2). The progression in their reasoning seemed similar to those from the previous unit: generating initial conjectures, looking for counterexamples (e.g., units and zero), and refining their conjectures by eliminating units and zero from the initial conjectures. When examining the array of $x\times1$ that cannot be reduced further, the IPSTs needed the precise definition of units in a ring to determine if x is a unit in $Z[x]$ or not. The TR guided the IPSTs to reference the definition and pushed them for precision in their conclusion that x is not a unit because its multiplicative inverse $1/x$ does not exist in $Z[x]$.

TR: ... why is x not a unit?

Kim: x is not a unit because, um, its multiplicative inverse, it does not have one that is within that ring. Because the power of x would need to be outside of the natural numbers, so it would not be the unit.

In this task set, the IPSTs' reasoning was leveraged along the task sequences with the support of the TR and the emergent model of the algebra tiles. In particular, those supports were productive in identifying non-unit and non-zero elements in $Z[x]$ that were less explicit for them than those in Z. So, the IPSTs concluded the conjectures about the reducibility of integers in Z and polynomials in $Z[x]$ with essentially the same structure: *A non-zero, non-unit element in R can be written as a product of irreducible elements in R.*

In Task Set 3, the IPSTs were asked to identify common algebraic properties of Z and $Z[x]$ and write a conjecture of the reducibility in UFDs that works for both Z and $Z[x]$. The TR supported the IPSTs to recall and synthesize algebraic properties of Z and $Z[x]$ and formalize their final conjecture. In sum, the task design in Unit 2 used algebra tiles, and the TR's pedagogical moves leveraged the IPSTs' reasoning of generating, revising, and abstracting conjectures of the reducibility in the respective algebraic structures.

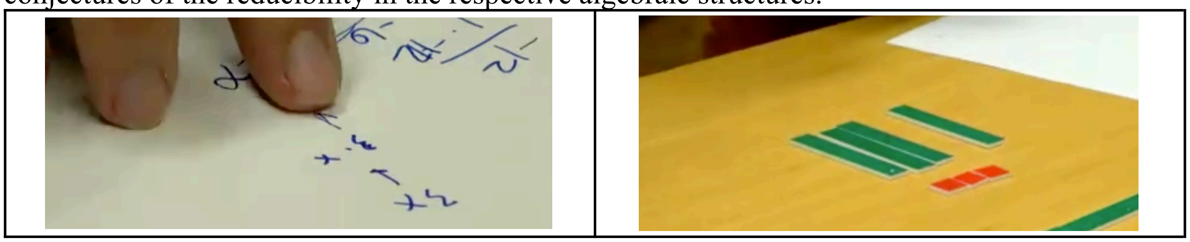

Figure 2. Group A used algebra tiles to represent the factorization of $3x = 3\times x$

Unique Factorization of Elements in Z, $Z[x]$, and UFD

Unit 3 tasks began with investigating two factorizations of an integer or a quadratic that differ by the order of factors in the products or by -1. Then, the IPSTs were guided to reinvent the concept of the uniqueness of factorizations, i.e., determine when two factorizations are essentially the same. For example, when asked to convince why two factorizations $(x + 3)(x + 2)$ and $(-x - 3)(-x - 2)$ are essentially the same, the IPSTs showed algebraic procedure to convert one into the other by using $(-1)^2 = 1$. They initially conjectured *two factorizations of a quadratic in* $Z[x]$ *are essentially same when a factor in one factorization is the negative of the respective factor in the other factorization.* This reasoning was leveraged in the following set of tasks that guided them to reinvent the definition of associates. Later, it allowed the IPSTs to use the formal language to capture their ideas about the relationship between factors in two essentially the same factorizations. When defining associates, the TR helped the IPSTs to generalize 1 and -1 to units for a general integral domain when they wrote the formal definition. The TR suggested to generalize their initial definitions, asked a leading question, and provided scaffolding. For instance, Javier (Group B) first wrote a conjecture that non-zero and non-unit elements a and b in an integral domain are associates if and only if their greatest common factors are 1 and -1. The TR leveraged his reasoning about associates with common factors of 1 and -1 but also pointed out a limitation of the conjecture by providing counterexamples.

TR: […] the only divisor I guess, the 1 and -1, then we could have something like $x + 3$ and $x + 2$ are associates? […] So you're right in that they do have this shared factor of 1 and -1, and it could be that it's just $a = 1\times b$ or it could be that $a = 1\times(-b)$. So it's looking like there's this shared kind of structure here, where a is equal to something times b. So now we have to figure out, what's that something?

Group B wrote a formal definition of associates using the idea of $a = ub$ where u is a unit in R that generalizes their initial conjecture to work for arbitrary integral domains (see Figure 3a). Following the problems in Task Set 2, the IPSTs revised their conjectures of the uniqueness of factorizations by using the definition of associates: *Two factorizations of an element in an integral domain are essentially the same if one factorization can be converted to the other by rearranging the order of factors or by replacing factors with their associates*. This involves using symbolic notations representing two possible factorizations $a_1 \cdot a_2 \cdots a_n$ and $b_1 \cdot b_2 \cdots b_m$ to express their reasoning of the uniqueness up to the associations and the order of factors. The TR helped the IPSTs to come up with precise subscripts in their writing. For instance, the TR suggested different subscripts n and m for the last factors in the given factorizations, a_n and b_m and different subscripts i and k for arbitrary factors from each factorization that are associates to each other, a_i and b_k. The TR pointed out an unintended assumption of correspondence between a_i and b_i when using the same subscripts for associates that are not necessarily ordered the same way (see Figure 3b).

TR: I like how you symbolized that, the $r = a_1 a_2 \cdots a_i$ and then the $u_1 b_1 u_2 b_2 \cdots u_i b_i$. So you're kind of pairing the a_1 with the b_1 and the u_1. So you're numbering them, that's kind of implying there's this correspondence between the a_i and the b_i.

This pedagogical move of the TR elicited the IPSTs' attention to the precision in mathematical language and leveraged their reasoning of what it means two arbitrary factorizations are essentially the same in the context as well as how to express precisely. The IPSTs' reasoning about the reducibility and the uniqueness of factorizations in Z and $Z[x]$ were leveraged in Task Set 3 where they were asked to synthesize two conjectures they made about the existence and uniqueness of factorizations of elements as a product of irreducibles to create the two axioms in the definition of UFD. The TR guided them to formalize their statements for the axioms in this process and helped them with making sense of the definition they created by using examples and non-examples (e.g., $Z[\sqrt{5}i]$) of UFD.

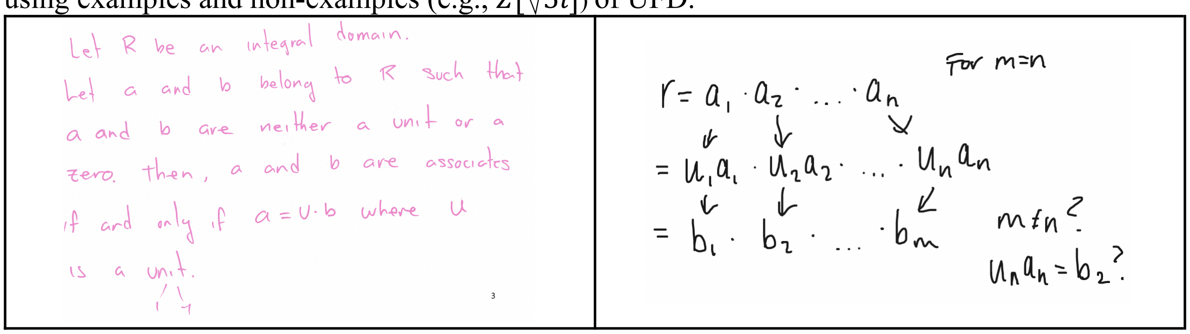

Figure 3. (a) Roberto's final definition of associates (left), (b) Kim's use of symbolic notations for two arbitrary factorizations that are essentially the same (right).

Conclusion

The findings of this study showed evidence of HLTs (Simon, 1995) in reinventing the definition of UFD by leveraging students' reasoning of the reducibility and the unique factorization of elements in Z and $Z[x]$. The sequence of experientially real tasks provided guiding prompts for the IPSTs' mathematical activities of conjecturing and defining in the progression of reinventing the two defining axioms of UFD. The emergent model of algebra tiles served as a *model-for* structuring and formalizing their intuitive reasoning about factorizations of integers and quadratics. The TR's pedagogical moves provided sociomathematical scaffolding that facilitates the IPSTs' horizontal and vertical mathematization (Gravemeijer & Doorman, 1999) of their informal reasoning and mathematical language. We plan to continue the design research on refining the hypotheses of student reasoning and task design of the HLTs in the following iterations of teaching experiments and classroom implementation.

This study explores the instructional practices of four graduate teaching assistants (GTAs) – Ursula, Ava, Phoenix, and Cole – in an active learning Calculus I course. Each GTA's unique pedagogical background is discussed in relation to their teaching methods and their students' classroom actions. Ursula, a seasoned high school math teacher, brings a wealth of experience in active teaching, while Ava, having encountered active learning as a student, reflects on her positive experiences. Phoenix, a novice GTA, emphasizes group work and individual student exploration, while Cole, with limited teaching and active learning experience, promotes student independent work. The contrasting approaches of these GTAs within the same purposefully designed active learning environment provides valuable insight into the connection between previous educational experiences and teaching practice, especially with respect to student engagement in a Calculus classroom.

Keywords: Active Learning, Calculus, Teaching Practices, Graduate Teaching Assistants

Calculus teaching and learning is an important and much-discussed topic in post-secondary mathematics education. Many educators and administrators are concerned about high DFW (the percentage of students who receive a D, an F, or withdraw) rates in introductory mathematics courses. Up to 50% of students nationally fail their first mathematics course, and 50% of students who struggle in mathematics courses in their first year leave STEM majors (APLU, n.d.). One way that institutions have attempted to combat these high DWF rates is through the introduction of active learning into first-year mathematics courses (APLU, n.d.). The Conference Board of the Mathematical Sciences (CBMS) defines active learning as "classroom practices that engage students in activities, such as reading, writing, discussion, or problem solving, that promote higher-order thinking" (CBMS, 2016, para. 1). Building on this, we define active learning as a productive learning environment that provides meaningful mathematical learning opportunities for all students. Such active learning environments include three key components: the inclusion of cognitively demanding mathematical tasks, the delivery of high-quality mathematics instruction, and the promotion of both small and whole-group discussions.

While much of the focus of active learning is on students – especially engagement and higher-order thinking – active learning also requires instructors to take on a prominent role. This role differs significantly from a traditional role in a lecture-based classroom. Instructors must choose rich tasks which promote higher-order thinking, facilitate classroom discussions, and manage a classroom in which student-centered activities occur. This shift often presents a challenge, as most university instructors have not experienced this type of classroom in either prior professional settings or their own education.

At large universities, Graduate Teaching Assistants (GTAs) are a significant part of the implementation of active learning. Consequently, there has been a push to provide GTAs with professional development opportunities to help them make the transition to facilitators of active learning in their classrooms (Deshler et al., 2015). Significantly, "effective training of graduate teaching assistants" is one of the seven characteristics of a successful calculus program, as put forth by Bressoud and Rasmussen (2015, p. 145). GTAs have an important role in implementing student-centered pedagogy and active learning. Therefore, it is important to understand how the GTAs themselves enact and support active learning in the classroom. It is particularly important to understand how their backgrounds may influence their actions. This leads to the question we explore in this study: what teaching actions do GTAs with different pedagogical backgrounds take in an active learning Calculus I course and how do they discuss these actions?

Literature Review

Because of the current focus on student-centered activities in entry-level mathematics classes, much has been written on active learning strategies and their effect on student learning (Freeman et al., 2014; Kim et al., 2013). As GTAs play an important role in enacting active learning, there has been a focus on GTA professional development (PD). GTA PD programs provide an important opportunity for GTAs to engage with and understand research-based instructional strategies, including exposure to active and student-centered pedagogy (Archie et al., 2022, Deshler et al., 2015). Many GTAs come into programs with little to no teaching experience, and both pedagogical content knowledge and knowledge of student thinking are important for GTAs' transition from learner to teacher (Kung & Speer, 2009). GTA PD provides them with opportunities to develop this knowledge and connected skills.

Regardless of whether they have participated in a PD program, GTAs may not have experienced active-learning approaches as learners in their own coursework, leading to a limited comfort with using these approaches in their teaching (Deshler et al., 2015). Patrick et al. (2021) studied GTAs across a College of Science and College of Engineering to determine their perceptions and practice of active learning strategies as a student and teacher. They found that GTAs' ranking of teaching strategies changed depending on whether they were thinking about their learning or their teaching. "TAs were currently teaching differently from the way they preferred to learn and how they thought undergraduates learned best" (Patrick, et al., 2021, p. 11). GTAs reported a desire for more active learning strategies in their own classes and felt that they should use more active learning strategies in their own teaching (Patrick, et al., 2021). However, GTAs' feelings about active learning were not sufficiently reflected in their classroom practices. While the link between experience and teaching practices seems to be straightforward, empirical evidence on mathematics GTAs' implementation of active learning based on their perspectives about and background with active learning is sparse.

Even experienced instructors can encounter challenges when implementing active learning strategies, requiring deep understanding of effective teaching practices and productive pedagogical strategies. The Mathematics Association of America National Study on College Calculus calls teaching which incorporates active learning ambitious teaching, stating that "they are ambitious in the sense that they require substantial institutional supports and advanced knowledge, skills, and beliefs on the part of instructors" (Larsen et al., 2015, p. 104). These complexities in implementing active learning also affect GTAs, who play pivotal roles in undergraduate mathematics courses. GTAs, often lacking training and prior classroom experience, face these challenges despite the growing emphasis on active learning in undergraduate mathematics education, as their own exposure to active learning is limited

(Manzanares et al., 2023). Therefore, we need studies that focus on GTAs conceptions and teaching practices of active learning.

Methods

Active Learning Context

This study takes place within a wider research effort to transform introductory courses in STEM at a large public university in the northeast USA. This study represents one component of the overall project and examines the actions and ideas of GTAs as they integrate active learning into their Calculus I teaching. The course follows a lecture-recitation model of instruction in which students attend a large lecture (~150 students) taught by a faculty member and a smaller recitation (~20 students) taught by a GTA. Implementation of active learning was purposefully focused on recitation sections and included a new classroom structure (introduction, small group work, class discussion), researcher-designed activities, and near-peer tutors called Learning Assistants (LAs). GTAs were given the freedom to implement these active learning methods in whatever way they saw fit.

While all recitations involved active learning, there were six special researcher-designed activities spread over the course of the 15-week semester. These activities were designed to foster the core practices of quantitative reasoning (Thompson, 1994) and representational fluency (Fonger, 2019). Students worked on these activities in small groups of three to four students, supported by the GTA and LA. The GTA was responsible for leading the class, meaning they facilitated the introduction and class discussion and were responsible for administrative tasks such as proctoring quizzes and collecting homework. The LAs' responsibility was to facilitate small group discussion, typically by asking students questions and attending to student ideas.

Data Collection and Analysis

Data for this study includes video recordings of recitation sessions and interviews with GTAs. Recitations were recorded six times throughout the semester on the days the researcher-designed activities were implemented. Structured interviews with GTAs were conducted at the beginning and the end of the course and were focused on GTAs' experiences with and ideas about active learning. This analysis focuses on a subset of these recordings for four GTAs. These four GTAs were selected for this analysis because they highlight distinct ways in which classroom actions and conceptions of teaching manifest in this active learning context.

To capture the classroom actions of these GTAs across the semester, two video recordings (one from the first half of the semester and one from the last three weeks) were analyzed for each GTA using the Classroom Observation Protocol for Undergraduate STEM (COPUS) (Lund et al., 2015). The COPUS framework describes the types of activities both instructors (Figure 1) and students (Figure 2) are engaged in throughout a lesson. Codes from this framework were applied to every two-minute interval of the recorded video. For each GTA, the codes were aggregated across the two videos, and the percentage of each coding category out of total number of codes was calculated. For robust descriptions of the COPUS action codes used in this study see Lund et al. (2015). Each lesson was coded by at least two members of the research team and disagreements were resolved by consensus of the team.

Interviews were analyzed in order to contextualize each GTAs' conceptions of their practice in the reformed classroom. These interviews were analyzed through open coding and thematic analysis to capture GTAs' definitions of and experiences with active learning (Miles et al., 2018; Strauss & Corbin, 1998).

Results

In this section, we will introduce the background of four GTAs, Ursula, Ava, Phoenix, and Cole, compare their instructional actions (Figure 1), and examine the classroom actions of their students (Figure 2). We aim to understand the teaching approaches adopted by the GTAs with diverse pedagogical backgrounds and explore how they discuss these actions.

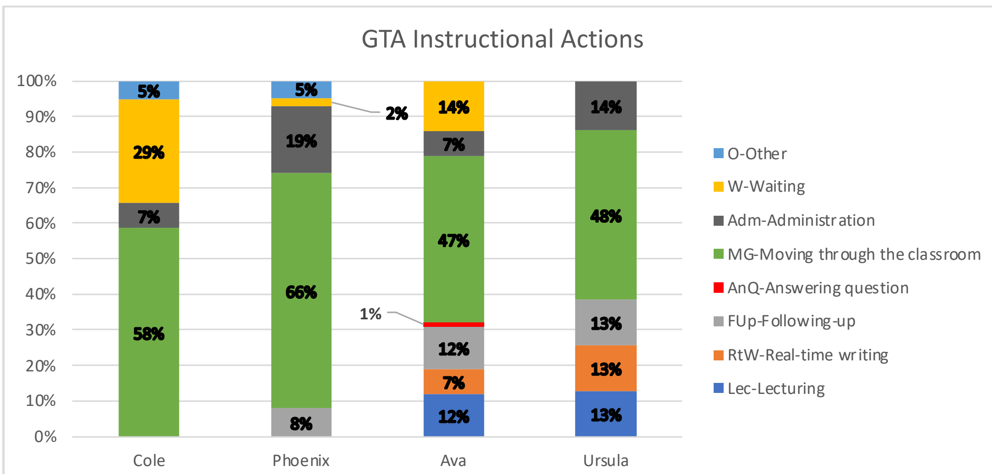

Figure 1: Instructional Actions of each GTA

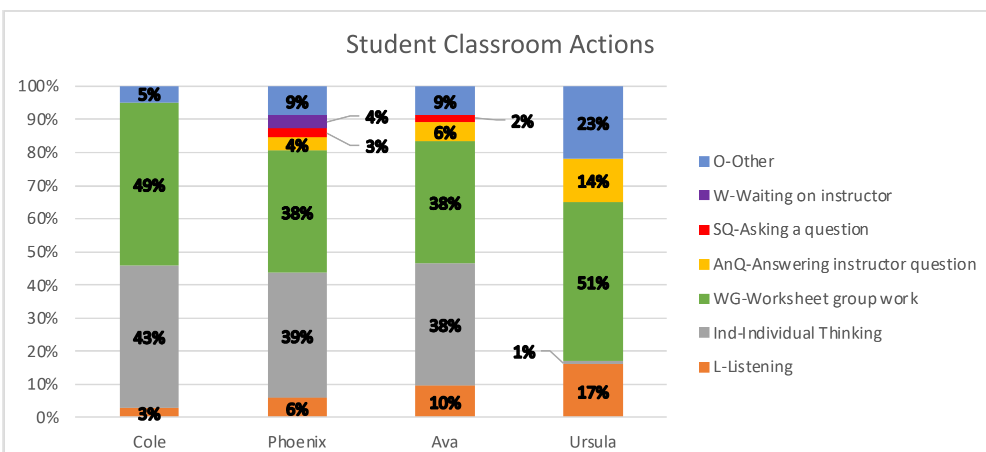

Figure 2: Actions of Students in each GTA's classroom

Ursula

Ursula was a graduate student in the Mathematics Education Ph.D. program and in her fifth year as a GTA at the university. Prior to her GTA experience, Ursula had substantial experience teaching mathematics to high school students. She described her high school teaching practice as "active" and said that she often had students work in groups or work independently. In Figure 1, we see that approximately half of classroom action codes are *moving*, meaning that she devotes significant attention to facilitating student work on activities in the classroom. She described that, when she moves through the classroom, “I’m not going to solve the activity for them, but if they got stuck I will ask them the question to lead them to the next step”.

Outside of facilitating group work, Ursula’s actions are still notably student centered; 13% of her actions were coded as *following-up,* meaning that she responded to student ideas in front of the class. Even though 12% and 13% of her actions are respectively focused on *lecture* and *real time writing*, these codes primarily occur during the lesson introduction. Ursula explained that, in this introduction, she “reviews concepts” and “examples” to make students more “comfortable” participating in group work by fostering “confidence” in their mathematical knowledge. While lecturing and writing are not typically considered as active, Ursula used them selectively and strategically in her teaching to support the more active portions of the lesson and to create a “balance between the instructors and the student”. While a significant number of codes were *administration,* even these actions were frequently student-centered, consisting of such things as organizing student groups and assigning students problems to write on the whiteboard.

This emphasis on group engagement and instructor collaboration was also reflected through the actions of students in Ursula’s classroom (Figure 2). Her students’ actions were primarily worksheet *group work,* indicating that students typically worked together on class activities. Also, the students in Ursula’s classroom were *answering instructor questions* (14%) and *listening* (17%) meaning that they shared their ideas in front of their peers and listened to one another and to Ursula. The *other* (23%) category in this case represents students writing work on the classroom whiteboards, again emphasizing the opportunities for students to share their mathematical ideas in this classroom.

Overall, Ursula’s conceptions and practices typify how a GTA with previous active-learning teaching experience was able to effectively implement such methods at the undergraduate level and provide reasons why such methods are appropriate for supporting student learning.

Ava

Ava was a mathematics Ph.D. student who at the time of the study was in her third year as a GTA at the university. Unlike Ursula, she had no previous independent teaching experience, but Ava did encounter active learning several times as an undergraduate student. She described that she “struggled” to interpret mathematical content independently as a learner in a flipped classroom, but she had more positive experience in a class where “the teacher would present the material, and then we'd work on it in groups”.

In her own practice as a GTA, Ava’s actions as a teacher mirror her positive experiences as a student. We see that her actions as a teacher are similar to Ursula’s (Figure 1), but 14% of Ava’s actions are *waiting,* meaning that she was merely standing on the side during class time. This presence of wait time could be because Ava frames active learning as “when students bounce ideas off of each other” and hinges upon “the student thinking more deeply about the topic”. Since student thinking is central to active learning in her view, Ava allowed students time to work on their own without her intervention.

Additionally, we see that Ursula and Ava’s students primarily engage in the same types of activities (Figure 2), except that Ava’s students engage in *independent thinking* (38%) while Ursula’s students rarely work independently. Again, this is probably rooted in their different conceptualizations of active learning; Ava has a broad view of active student engagement while Ursula takes group work as essential in such an environment.

From Ava's actions and discussion of these actions, we see that she used her own experiences as a student with active learning to guide her teaching as a GTA in an active environment. Because of her own positive experiences with group work and guided work during class, she implements such practices in her classroom, supporting students to work in groups or independently on classroom activities.

Phoenix

Phoenix was a graduate student in the mathematics education PhD program; in her second semester as a GTA. She began the graduate program directly following her undergraduate degree at the same institution, meaning that she had no independent teaching experience prior to her time as a GTA. She did, however, have experience as a peer-tutor and had taken several university-level courses focusing on teaching and learning.

Phoenix's teaching actions are notably distinct from the relatively similar pattern seen in the actions of Ursula and Ava. Unlike these two, Phoenix did not lecture or write on the board; she was mostly involved in *moving* (66%) and *administration* (19%). That is, Phoenix's classroom actions primarily focus on working with students and organizing student groups, rather than instructing students from the board. This is reminiscent of her own experiences with active learning as a student as she and her peers spent time "working in groups and kind of investigating the material ourselves". She further explained that she views active learning as rooted in "the students and the students wanting to learn the material" with her role being to "help each individual student" through this process. Phoenix recognized her responsibility as an instructor to guide student thinking, but she provided this support at an individual and group level, while Ursula and Ava provided support at the classroom level through short periods of direct instruction at the board.

While Phoenix's actions are distinct from Ursula and Ava's, we see that her students' actions are relatively similar to Ava's students (Figure 2). We do see that Phoenix's students are *listening* less than Ava's students (6% vs 10%), which reflects Phoenix's emphasis on group work time. Similar to Ava, we see that Phoenix's students had the opportunity to share their thinking as they are engaged in *asking questions* and *answering instructor questions.*

Through these actions and commentary, we see that Phoenix's status as a novice GTA with limited active learning experience led to a strong emphasis on group work in her classroom. While Ava and Ursula, who have more experience with active learning, chose to provide their students with some direct instruction, Phoenix chose to provide students more time to work on their own or in groups. While this alternate focus in teaching actions was not coupled with major shifts in student actions, these alternate approaches of GTAs in the same environment are notable.

Cole

Cole was a first-year Ph.D. student in statistics and, like Phoenix, was in his second semester as a GTA at the university. Cole had some online experience as a one-on-one tutor before his time as a GTA, but, unlike the other GTAs discussed in this study, he had no experience with active learning as a teacher nor as a student. He stated that in his time as a student he would "pretty much study alone, individually" and "usually just listen to the teachers and copy, paste" notes written on the board.

Accompanying this difference in experience, we see that Cole's classroom actions were distinct from those of Ursula, Ava, and Phoenix. While Cole's proportion of *moving* is similar to the other GTAs, he has a much higher proportion of *waiting* (29%) than the other GTAs. It is also important to note that Cole's *other* code marked times when he left the classroom entirely, contrary to other GTAs for whom the *other* code was content related, representing such activities as discussing study skills and reviewing student work. Again, these actions reflect Cole's view of active learning; he describes active learning as "communicating with others... exchanging your thoughts" making his role in the classroom "more like a tutor". Cole's actions are consistent with this idea of active learning as he lets students work with a high degree of independence and intervenes in this process sparingly. This strong emphasis on student independence could also be a reactionary effort to move away from his "copy, paste" experience as a learner.

Similarly, we see differences in the actions of Cole's students in comparison to the students of the other three GTAs. Cole's students are almost always engaged in *worksheet group work* or *individual thinking* (92%). Again, this echoes Cole's conceptualization of active learning as students working without much direct instruction.

Overall, Cole's actions show one way in which active learning can be enacted by a GTA with little prior experience with such methods as a student or as a teacher. In Cole's classroom, active learning manifests as student independence, with Cole offering students support at the individual or group level, rather than providing direct instruction.

Discussion

From the four GTAs examined above, we see that there is a connection between previous active learning experiences and instructional practices. Ursula, a GTA with experience teaching in an active learning setting, gives attention to students' work within groups, but supports this work through some direct instruction and following up on group work in front of the class. Ava and Phoenix, who had some experience with active learning as students, still emphasize group work, but allow students to work individually. Cole, a GTA without previous active learning experience, attends solely to group work, occasionally leaving students to their own devices.

While all GTAs in this study were provided with the same active learning teaching guidelines and supports (i.e., LAs, researcher-designed activities, suggested classroom structure), we observe that GTA actions and the actions of their students are distinct within each classroom. Previous literature acknowledges the need for GTAs pedagogical training, but we emphasize that GTAs educational needs as teachers vary depending on their previous experiences as both teachers and learners. That is, "effective training" (Bressoud & Rasmussen, 2015, p. 145) of GTAs must account for the lived educational experiences and resulting pedagogical ideas of GTAs. Without such background taken into account, GTAs may have difficulty implementing active learning practices in the classroom.

Since GTAs often serve important roles in facilitating student-centered instruction within Calculus courses, it is important to acknowledge factors which enable or inhibit them accomplishing this type of instruction. Here, we identify background experiences with active learning as one such factor and encourage both researchers and educators to pursue practical means of integrating GTAs' previous educational experiences into GTA pedagogical training.

Instructor and Coordinator Perspectives within First-Year Mathematics Courses

Paul Regier	Ashley Berger	Allison Dorko
University of Science and Arts of Oklahoma	University of Oklahoma	Oklahoma State University

The perspectives, habits, and mindsets of experienced instructors and coordinators serving within course coordination systems are valuable for effective coordination. In this paper, we present perspectives and recommendations from coordinators and instructors being coordinated with the goal of helping those who are new to coordination. We utilize Martinez et al.'s (2022) work on two coordinator orientations, Humanistic-Growth and Knowledge-Managerial, to frame the common perspectives of instructors and coordinators of first-year mathematics courses. Most participants gave reasonings for their decisions surrounding coordination with a healthy balance of Humanistic and Managerial considerations in mind.

Keywords: Course coordination, first-year mathematics, coordinator orientations

Research on course coordination has defined the ways in which perspectives, habits, and mindsets of coordinators can improve student and instructor experience and outcomes. In this paper, we synthesize the perspectives of mathematics course coordinators and instructors across one region, for the purpose of supporting (a) instructors and coordinators with little prior experience with course coordination, (b) math departments seeking to build/improve course coordination, and (c) for instructors and coordinators seeking to improve coordination.

The paper contributes to the research of course coordination by providing replication and expansion of Rasmussen & Ellis's (2015) work exploring coordination at universities with successful calculus programs and Martinez et al.'s (2022) work on coordinator orientations. There have been calls in the field for more replication studies (e.g., Melhuish, 2018; Melhusih & Thanheiser, 2018) and published replication studies (e.g., Borji et al., 2022; Melhuish, 2018) indicate that the field values replication studies. Our work replicates Rasmussen and Ellis' (2015) and Martinez et al.'s (2022) work by studying common perspectives of coordinators and instructors who work under coordinators within a regional but expanded context of first-year mathematics courses. These instructors' voices are critical for understanding what makes coordination successful.

Literature Review

As part of an extensive research project involving five PhD-granting universities known for having successful calculus coordination programs, Rasmussen and Ellis (2015) characterized aspects of effective course coordination in Calculus I. Their work highlights the role of one serving as a coordinator as someone who serves in a multi-year or semi-permanent position, is knowledgeable and respected in teaching, and who is oriented to serve both as a resource and facilitator. Rasmussen and Ellis describe the importance of coordination in which the course is viewed as community property with concrete actions taken to this end. Regular meetings are held to focus on the needs and priorities of the instructors, compare progress, share difficulties and ideas for problems, and develop common grading practices. Additionally, drawing on work in behavioral economics (Thaler & Sunstein, 2008), Rasmussen and Ellis identify the role of effective coordinators in serving as a choice architect - "someone who is responsible for organizing the context in which people make decisions" (p. 112), not someone who makes decisions for others. They identified the role of coordinators in (a) making life easier by setting default options (providing resources), (b) providing feedback to users, (c) making mappings easy to understand, and (d) providing information about what others are doing. "If many people do something or think something, their actions, and their thoughts convey information about what might be best for you to do or think" (Thaler & Sunstein, 2008; p. 54)

Martinez et al. (2022) extended this work to studying coordinator *orientations* or views that "give a sense of direction for what one does, implicitly or explicitly" (p. 330). In their analysis of interviews with course coordinators and instructors, Martinez identified two coordinator orientations: a Humanistic-Growth Orientation and a Knowledge-Managerial Orientation (referred to here as *Humanistic* and *Managerial* orientations for simplicity). Each orientation was characterized by five themes. The Humanistic orientation involves the following five themes: (a) attending to student experience, primarily in receiving the same opportunity to succeed, (b) being concerned about others and expressing concern for others, (c) seeking to build community as a form of professional support, (d) being attentive to instructor differences in that "one size does not fit all", and (e) providing instructor support through professional development opportunities and as a resource for general concerns. The Managerial orientation involves (a) drawing on knowledge of the course, department, and institution, (b) bringing knowledge and experience of a variety of pedagogical practices, (c) providing materials related to content and curriculum, (d) communicating clearly, end (e) exhibiting strong communication skills. Martinez et al. (2022) conjecture that "a combination of both coordinator orientations and their corresponding professional development approaches (community-based and material-based) is more likely to lead to substantive and sustained improvement" (p. 344).

Both Martinez et al.'s (2022) and Rasmussen and Ellis' (2015) results draw from an extensive data corpus (over 92 interviews and 95 hours of audio recordings) of programs with established and effective support for course coordination. This study serves as a smaller-scale replication study (Melhuish, 2018) in studying the ways in which regional perspectives regarding course coordination are consistent with broader theoretical perspectives. In particular, this paper explores a broader category of mathematics course coordination in which there may be less structure or departmental support for course coordination, yet a growing local community of support for course coordination within and across mathematics departments.

Research Questions

In this context of both structured and semi-structured course coordination, we ask the following research questions:

1. What activities do coordinators devote their time and attention to in coordinating a course?
2. What perspectives, habits, and mindsets do coordinators and coordinated instructors find most conducive to effective course coordination?
3. In what ways do perspectives shared regarding coordination embody theoretical perspectives of Humanistic and Managerial coordinator orientations?

Methods

The authors of this paper recruited 14 instructors teaching and/or coordinating courses from five medium to large-enrollment universities in Oklahoma. Participants were recruited through an initial survey of participants of their primary role as coordinator or instructor. Of these instructors, a first subgroup of five instructors also served as coordinators of courses with structured coordination. These instructors were involved in coordinating various aspects of their course throughout the semester. A second subgroup of four instructors served as coordinators of courses involving semi-structured coordination, where coordinators were part of a team that mostly made decisions before a semester as opposed to during it. A third group of participants involved instructors who have taught one or more coordinated courses with structured coordination.

The authors lead focus-group-style interviews in 6 separate sessions of 1-5 participants per session. Interviews were conducted on Zoom and recorded, running about 1.25 hours each. The authors recorded field notes of responses to each question. Recorded detailed interview field notes, along with transcriptions of targeted segments of the interviews were transcribed. The first author open-coded responses based on the intended context of the perspective and advice offered (Strauss & Corbin, 1998). After this, a second cycle of axial coding was used to segment comments by similar perspectives (Saldaña, 2013). A third round of coding involved identifying instructor perspectives, habits, and mindsets aligned with themes of Martinez et al.'s (2022) coordinator orientations. Finally, a cross-comparison across the second and third round of coding were analyzed.

Results

The following sections provide a summary of what coordinators and instructors shared regarding (a) the purpose and affordances of coordination, (b) the structure and roles of coordination, (c) the goals of coordination meetings, and (d) recommendations for coordinators and instructors in both structured and semi-structured coordination courses. Following this, we provide the cross-comparison of these four categories of perspectives with Martinez et al.'s (2022) coordinator orientations.

Purpose and Affordances of Coordination

One of the primary purposes cited by coordinators for developing a coordinated structure for a course was to increase consistency of course content and delivery. One coordinator cited that before coordination, "students had wildly different experiences." Across contexts of coordination, instructors described how coordination enables a range of instructors to "bring the rigor [of the course] more closely together." Coordinators also described coordination as a factor in improving the quality of course materials and design.

Instructors described the importance of coordination in providing resources for improving teaching and learning, as well as handling student issues. Coordination appeared to be a factor in increasing instructors' competence in teaching by providing support for instructional development and a community for discussing and handling issues of concern. One instructor stated, "If the course hadn't been coordinated, I would not have survived my first semester." Another instructor stated that the coordinated structure "helped me focus more on teaching [and] what kind of questions I was asking; was I allowing enough time to absorb the material?"

All instructors described having an increased sense of relatedness to other instructors because of the coordination. They said coordination provided a venue to talk and ask questions of other instructors which was very beneficial. One instructor said they felt very appreciated by their coordinator, but not by the department's administration. This instructor had worked hard to flip the class, but in the following semester, was placed in a corequisite section where he was not allowed to flip the class. In the face of this loss of autonomy, he said "I'm a creative person, but I cannot bring this to the students - what I want to bring to them will not work out." Regarding the increased structure and loss of control, another instructor said she felt like she still had enough autonomy, and another instructor said the added support of coordination afforded more autonomy to work on what she wanted.

Structure and Roles of Coordination

We acknowledge that coordination presents itself in a variety of ways, from the selection of a textbook and topics only, to more heavily coordinated courses where the vast majority of aspects are decided on by instructors. From the pre-interview survey, the coordinator participants indicated coordinating textbooks, topics, pacing, syllabi, exams, online homework, grading schemes, rubrics, written homework, and quizzes. They also cited responsibilities of instructor training, instructor observation, and feedback, fielding student complaints, instructor mentorship, instructor evaluation, setting up LMS, communicating with an accessibility resource office, administering makeup assessments, and scheduling exam rooms. In the interviews, several coordinators took particular concern for instructor training and mentorship for graduate students and new teachers. When concerns regarding teachers' instruction and behavior arose, one coordinator described these as opportunities for professional development and learning, assuring responsive instructors that they were not in trouble and that "this is all normal."

Coordinators who held regular coordination meetings spoke in detail about how they conducted these meetings since it was a primary form of communication between coordinators and instructors. Thus, the following section describes the goals coordinators held regarding meetings and how they approached them.

Goals and Approaches for Coordination Meetings

One of the primary ways of developing and carrying out coordination was through instructor meetings. While some coordinators preferred online communication and one-on-one meetings with instructors, the majority of coordinators focused substantial time and care on coordination meetings. Coordinators used coordination meetings weekly, biweekly, or monthly to (a) discuss course policies, (b) guide instructors, (c) provide training on the use of course materials or technology, (d) provide opportunities for professional support, and (e) distribute feedback. Some coordinators described the importance of using meetings to convey a vision or overarching story for the course that they wanted instructors to see and follow. Coordinators described using the start of meetings to check in, to "Look everyone in the eye and make sure they are doing what they are supposed to be doing. 'You all are in the same place? Good! Let's go on.'"

In their discussion, coordinators agreed that they wanted instructors to perceive meetings as necessary and helpful in meeting practical needs. To this end, they discussed the importance of planning and sending out an agenda prior to the meeting so that instructors can offer suggestions on what to add. However, meetings also furthered the humanistic goals of building relationships and providing mutual learning opportunities. One coordinator emphasized that she was "not 'the one' with the answers." Although the "young ones" were learning and observing what other instructors were doing, discussions often focused on sharing ideas, experiences, and suggestions in an environment where everyone could ask questions about the course and learn and buy into why the course was set up in the way it was. One coordinator emphasized being sensitive to people's time; if meetings are becoming off track or unproductive, they sought to address the cause individually or change the structure of the meetings.

Specific Recommendations

Advice for Coordinators. In addition to advice for meetings, coordinators and instructors alike shared advice directly related to organization, interpersonal skills, getting feedback and support, and beginning a new coordinator position. Instructors gave emphatic advice that coordinators work on organizational skills by building detailed lists of what tasks were important at what time of the semester. One instructor described how important it was to receive resources in a timely way so that they could have sufficient time to prepare for class.

Coordinators advised focusing on interpersonal skills, especially in valuing the people you are working with, and discerning when to give ground to instructors and when to hold your line. Some coordinators described the importance as a coordinator of staying humble, asking questions, and continuing to learn from other instructors and coordinators. One coordinator advised framing the coordinator structure of their course as beneficial to new instructors. She said, "I am doing this to make things easier for you, and make things fair for students."

Coordinators also emphasized the value of collecting feedback from instructors. One advised that "especially when you have inexperienced instructors who may chafe under authority, get administrators on board with this." One instructor found instructor evaluations helpful for seeking feedback on what they did well and what didn't, which spurred them to also seek feedback outside the formal system of evaluations.

Two coordinators described the complexity and burden of the responsibilities in their first year as coordinators, advising new coordinators to be careful about what they take on. One coordinator advised: "Come in and get your bearings first. Try it out the way it exists, if it's not broken." Another coordinator echoed this advice: "Learn what the prior person did, and just do it; wait to start making changes until after the first and second semester."

Advice for those working in semi-structured coordination. While the above perspectives and principles may apply to a broad range of contexts, several course coordinators offered advice, particularly for those working in contexts where structured course coordination doesn't yet exist. In seeking the benefits of coordination (aligning the content and rigor of courses, improving course resources, and increasing collaborative support), they shared some lower-stakes ways to add coordination into a course. One instructor suggested in addition to a common textbook and syllabus, providing suggested homework assignments, and problems that could be used as a guide to new instructors, but would not restrict established instructors. Another suggested collaboratively working on building a common final exam. One coordinator was chair of a committee of those who regularly teach a course and hold monthly meetings; she suggested that if instructors find meetings effective and helpful, they can lead to small but beneficial iterative changes in the course. Another coordinator suggested, "Don't be afraid to add one thing per semester. And then keep it up."

Advice for Instructors. Since coordination offers affordances and constraints that differ from teaching without coordination, coordinators offered the following advice for instructors teaching within a coordinated structure: "Don't mistake the coordinator structure of the course for needed preparation," and "Don't underestimate the amount of time needed to properly prepare."

When offering advice to those teaching a coordinated course for the first time, they emphasized asking questions and talking to other instructors. One instructor said, "It doesn't matter how many years you have been teaching, you will encounter things that will miserably fail." This instructor emphasized how, as new instructors, we forget how to explain the basics and are not used to commanding attention and creating rapport with students: "Anything that you don't know how to do, it is helpful to have a team to talk to."

Advice to both instructors and coordinators. One instructor noted that both instructors and coordinators share the common goal of working well with students clearly communicating expectations. Thus, he advised both instructors and coordinators to see themselves as a team and work as a team.

Cross-Coding of the Results with Coordinator Orientations

Of a total of 308 comments assigned specific codes, 292 spoke positively of various aspects of coordination, and 16 spoke negatively of the coordinated structure. Of these 16, seven comments negatively described the specific structure and roles of the curriculum in relation to student experience (e.g., regarding the instructor's loss of autonomy in being assigned by the department a corequisite section in which he was not allowed to flip his classroom). The remaining 297 comments were distributed as presented in Table 1, which are further discussed in the next section. Table 2 provides a legend of the coordinator orientation codes used in Table 1.

Table 1: Cross-coding of coordinator orientations with axial coding of positive perspectives (number of instances coded with a positive perspective of coordination)

		Coordinator Orientations											
		H1	H2	H3	H4	H5	M1	M2	M3	M4	M5	NA	Total
Axial Coding	Purpose & affordances	9	2	3	4	6	2	4	6	1	2	9	48
	Structure & roles	10	7	5	7	14	5	2	24	4	7	3	88
	Coordination meetings	4	5	8	5	13	0	2	3	1	4	4	49
	Recommendations	3	3	6	2	3	5	2	1	2	11	6	44
	NA (no cross code)	13	4	4	9	6	1	3	8	6	9		63
	Total	39	21	26	27	42	13	13	42	14	33	22	292

Table 2: Codes of Coordinator Orientations (Martinez et al., 2022)

Humanistic-Growth	Knowledge-Managerial
H1: Attends to student experience	M1: Draws on knowledge of the course, department, & institution
H2: Concerned about others	M2: Demonstrates experience & knowledge of teaching the course
H3: Takes action to build community	M3: Provides material related to content & curriculum
H4: Attentive to instructor differences	M4: Communicates clearly
H5: Provides instructor support	M5: Exhibits strong administrative skills

Discussion

The above cross-coding of common perspectives regarding coordination and Martinez et al.'s (2022) coordinator orientations highlight the following in regard to this particular sample of instructors and coordinators. In describing the purpose, affordances, structure, and roles of coordination, these instructors particularly valued orientations of attending to student experience (H1), providing instructor support (H5), and providing course materials (M3). When offering explicit advice for coordinators and instructors, participants were more likely to emphasize attitudes and behaviors reflecting the importance of coordinators having strong administrative skills.

The most frequent theme found in the cross-coding was the Structures & Roles theme coupled with M3: Provides material related to content & curriculum. This is unsurprising in that a primary requirement of coordination in the context studied is that materials of some kind are provided. What may be more interesting within the Structure & Roles theme, however, is the noticeable presence of Humanistic perspectives. The coordinators spent a significant portion of time discussing how their decisions affected the students' experiences and whether or not they supported their instructors. The key role of coordination in how it affects the student experience was about keeping the course fair for all students, regardless of which instructor they had. The coordinator's concern for supporting their instructors was evident in how they discussed teacher training, observations of classes, and management of assessments and the LMS.

Course coordination meetings have the potential to emphasize Managerial aspects of coordination; however, Table 1 shows that the participants viewed the purpose of meetings more in terms of Humanistic perspectives. The purpose of the meetings for the participants was more about support and building a community than it was about relaying materials and rules for the course. Both coordinators and instructors were eager to offer recommendations for future coordinators and instructors. Frequently, their advice involved administrative skills that a coordinator needs to have in order to be effective and they made practical suggestions like making explicit to-do lists for each semester.

In their experiences with coordination, instructors described, in varying degrees, gaining an increased sense of competence, autonomy, and relatedness for teaching. However, in one case, coordination constrained an instructor's sense of autonomy, and in turn their creative engagement and motivation for teaching. Thus, it can be especially important for coordinators to give attention to specific decisions that may impact instructors' sense of autonomy. While decisions of course assignments and scheduling decisions may never be perfect, fostering a team mindset can mitigate negative attitudes regarding loss of autonomy. This instructor's experience also highlights the importance of coordinators holding team meetings and building relationships in which instructors can express and feel supported in their concerns. In line with Martinez et al.'s (2022) conjecture that a combination of coordinator orientations is more likely to lead to improvements, the participants in this study described effective coordination as involving decisions led by both coordinator orientations.

Conclusion

Research serves to provide a context for instructors and coordinators with little prior experience with coordination for understanding how to understand the affordances and constraints of coordination and to quickly and effectively adapt efforts within this system. Therefore, one of the purposes of this work is to create a practical guide for those coordinating for the first time, as well as for those teaching a coordinated course for the first time. We hope that categorizing the participants' perspectives by coordinator orientations can help others with new coordination systems and navigating initial decisions.

Coordination can support first-time instructors to progressively focus their attention on where they can grow the most in their effectiveness as instructors, by focusing first on (a) their own roles and responsibilities as an instructor, then as questions/issues arise, (b) their role in relationship to coordination, and ultimately (c) their role in as part of a team of instructors delivering consistent and quality instruction. Coordination also supports coordinators to allocate energy most effectively at various stages in their service as coordinators. Especially in light of the cyclical nature of course-coordinator-responsibilities (pre-semester preparation, course implementation, post-semester reflection and evaluation, revision, repeat), these perspectives can help coordinators evaluate where their skills, expertise, and experience can help people the most.

A recent movement has developed to emphasize the importance of inclusive teaching practices in undergraduate STEM education. Mathematics courses have one of the largest impacts on students' persistence and success in STEM majors, making efforts to improve diversity and inclusion in these classes all the more important. In this paper, we discuss our initial steps to develop a measure of students' perceptions of instructor behaviors that promote inclusivity in their classrooms. This paper briefly discusses the initial development of items for our measure and focuses on our exploratory analysis of the latent factor structure and our process for defining these latent factors in the context of math instructors' actions.

Keywords: Mathematics, instructor behaviors, factor analysis, instrument development, inclusion

Introduction

Efforts to diversify STEM fields, both in academia and industry, will benefit from efforts to cultivate inclusive introductory STEM courses. Mathematics courses in particular are notorious for contributing to disparities as they are often required in order for STEM undergraduates to graduate (Ellis et al., 2016; Leyva et al., 2021, Battey et al., 2022). Multiple efforts to promote inclusive teaching practices in higher STEM education have tackled aspects such as curricula, classroom interpersonal relationships, and pedagogy. (Dewsbury & Brame, 2019; Hogan & Sathy, 2022; Inclusive STEM Teaching Project, 2023; Johnson, 2019; Kachani et al., 2020; Tanner, 2013). While these works highlight the importance of inclusion in STEM classrooms, we find little work done to identify and functionally measure aspects of inclusivity in post-secondary STEM classrooms. This report details our team's effort to develop an instrument that would capture students' perceptions of how their instructor's behaviors support or diminish inclusivity in undergraduate mathematics classrooms. For our work, we conceptualize inclusiveness as students' feeling that they belong in and can achieve success in the math class. Our current findings are part of a long-term instrument development project (a more detailed description is available in Brown et. al. (2023)). The aim of this project is to create an instrument that can be used primarily for research purposes in investigating relationships between students' feelings of inclusion and other student-level variables (sense of belonging, mathematical confidence, etc.) or for instructors' personal use in improving their teaching practice. Our instrument should not be used for institutional assessment of instructors as such an application is likely to introduce racial and gender bias, among other concerns. In this report, we present an abbreviated description of the exploratory process for developing the 28-item Fundamental Instructor Behaviors for Inclusion (FIBI) instrument followed by the details of the exploratory factor structure, our process of naming the latent factors, and concludes with a discussion of future work.

Methods and Data Collection

Instrument

Development of the FIBI instrument began with the creation of 79 items that started with the common stem "My mathematics instructor…". Each item required a response on a 5-point Likert scale (1-Strongly Disagree, 2-Disagree, 3-Neither agree nor disagree, 4-Agree, 5-Strongly Agree). We created these items based on students' responses during focus groups discussions of the following questions:

- What has your instructor done or said that conveyed a sense you can succeed in math?
- What have they done or said that conveyed a sense you can't succeed in math?
- What have they done or said that conveyed a sense you belong in math?
- What have they done or said that conveyed a sense you don't belong in math?

(Focus groups are more fully reported in Brown et. al. (2023).) In addition to these items, we included nine items from two published instruments for measuring teacher behaviors: the Teacher Communication Behavior Questionnaire (TCBQ; She & Fisher, 2002) and the Questionnaire on Teacher Interaction (QTI; Wubbels et al., 1991). We included those items which covered behaviors not specifically mentioned by our focus groups, but that we thought could also impact students' feelings of inclusion in their classroom. These items were modified to fit the sentence structure of our previous 79 items before being added to the instrument, bringing the total number of items to 88.

Data Collection

In the Fall 2021, we collected data using the 88 items as well as demographic questions at a large, predominantly white, research-intensive university in the Northeastern United States. We intentionally recruited students from introductory chemistry and biology courses but asked them to provide responses based on their current mathematics instructor. Our goal for this strategy was to reduce the students' potential fears/concerns that their mathematics instructor would have access to their responses and to encourage students to provide honest responses to the items. Participants in the study received extra credit (equivalent to 0.5% of final grade) in their biology or chemistry course for completing the study. A total of 1,276 students participated in the study.

Due to the predominantly white makeup of this university and our desire to center the voices of students underrepresented in STEM classrooms, namely women and persons excluded because of their ethnicity or race (PEERs; Asai, 2020), we implemented a secondary strategy to specifically recruit PEER participants from other universities via emails to university chapters of student organizations such as the National Society of Black Engineers (NSBE) and the Society for the Advancement of Chicanos/Hispanics and Native Americans in Science (SACNAS) as well as colleagues at other institutions. Participants in this wave of recruitment were incentivized with a raffle for Amazon gift cards (20 $50 prizes, five $100 prizes, and two $250 prizes). This recruitment led to an additional 149 responses, bringing the total number of participants to 1,425.

Following the data collection, we cleaned the data by removing participants who (a) did not consent to participate (n = 161), (b) did not complete all FIBI items (n = 72), (c) were not enrolled in a mathematics course in Fall 2021 (n = 260), and (d) any responses identified as duplicates via student emails (n = 62). Thus, 870 participants remained in our sample. While the majority of our sample identified as female (n = 551), we still had a lack of participation from students who identify as PEERs (21%; n = 185). Approximately 71% of participants (n = 614) identified with at least one of these two groups.

Methods

To conduct our exploratory factor analysis (EFA), we used two sets of software: SPSS (version 28) and R (version 4.2.0). Analysis of the data was completed using multiple factor extraction methods (principal components analysis and principal axes) as well as using both Pearson and polychoric correlations (Holgado–Tello et al., 2010) to investigate the impacts of these choices on our analyses and to understand the FIBI instrument's structure in more detail. Across these different design choices, we consistently used an oblique rotation method (promax) to allow for correlations between factors which we suspected from our prior work with student focus groups (Brown et. al., 2023). In addition to considering multiple methodological choices, we were also interested in any potential differences in the factor structure for the subsets of women, PEERs, and the combined subset of women and PEERs and thus, we repeated these analyses for each subset as well as the whole sample. Due to the limited sample size, analysis of the PEER subgroup failed to converge. However, the other three analyses produced generally similar results (similar factor structure, number of factors, primary loading of items, and factor correlations). Thus, only the results for the whole sample are reported here.

Our EFA relied on several heuristics in tandem to determine the appropriate number of latent factors to retain including (a) the Kaiser-Gutman criterion (eigenvalues greater than one), (b) parallel analysis (Horn, 1965), and (c) analysis of Scree plots (R. A. Johnson & Wichern, 2007). After using these heuristics to limit the number of factors to consider, we then eliminated any items which did not have a factor loading with a magnitude greater than 0.4 to any of the remaining factors (Stevens, 1992). Following these removals via benchmarks, we moved into more detailed item-to-item analysis where we investigated the Pearson and polychoric correlations between items with primary loadings on the same factor. In doing so, we identified clusters of items containing correlations with magnitude of 0.6 or higher and then selected representative items from each cluster to remain in the instrument while removing the others. (See Brown et. al., 2023) for our guiding principles for examining item clusters.) Our process of exploratory analysis and item reduction was iterative to ensure the stability of the measure. Thus, after each wave of item removal by item benchmarks and item-to-item analysis, EFA was rerun on the subset of items to ensure similar performance (factor structure—item assignment to factors—and cumulative variance explained) after the removal of those items.

Results

Exploratory Factor Analysis and Item Reduction

For our initial EFA containing all 88 items, the Kaiser-Gutman criterion suggested a 12-factor solution which explained approximately 63% of the total variance in responses while parallel analysis suggested a slightly less complex, 10-factor model which explained 56% of the total variance. Unfortunately, with such a large number of factors, our initial benchmark for removal (magnitude of the factor loading greater than 0.4) only flagged 9 items for removal. Due to our desire for a more parsimonious model, we considered the Scree plot of our factors, which suggested a model containing four to six factors, and thus we conservatively chose to include six factors. With this smaller subset of factors, our benchmark for factor loadings identified a total of 23 items for removal while still explaining approximately 55% of the total variance. After the removal of these items, we began analysis of item-to-item correlations and using our research team’s guiding principles we identified another 23 items for removal, leaving 42 items left after our first wave of EFA and item reduction.

After completing the first wave of analysis, EFA was re-run to confirm that items remained in similar clusters and the number of factors was as we expected after removing those items. Scree plot analysis now suggested a seven-factor model. However, the seventh factor contained only a single item while the other six factors remained thematically intact from our previous analysis. Thus, the item was removed, and we retained the six-factor structure which still explained approximately 55% of the total variance. Again, employing the factor loading benchmark of 0.4, we identified 7 additional items for removal which no longer loaded significantly onto any of the factors. Item-to-item analysis was used again to identify six final items for elimination, resulting in a 28-item instrument.

Once more, to ensure our factor structure was stable, we conducted EFA on the subset of 28 items. Again, we arrived at the same six-factor model which explained 55% of the variation in responses. All items remained in their initial factors from the previous wave, except for the item, “My mathematics instructor talks too fast.” Additionally, the item “My mathematics instructor gives exams which are hard to finish in the allotted time,” now had a factor loading of 0.339, which did not meet the original benchmark of 0.4. However, our research team believed that the item provided student perceptions that were not equally addressed by any other items in the instrument and thus chose to retain the item. The details of the factor structure for the final 28-item instrument are discussed in the following section.

Resulting Exploratory Factor Structure

Following our iterative EFA process followed by item reduction, we arrived at a six-factor solution containing 28 items and explaining approximately 55% of the total variation in responses. A summary of the variation explained by each factor can be seen in Table 1. Factor labels (Factor 1, 2, …) were assigned in order based on the proportion of variance explained by the factor in the 28-item EFA. After reducing the instrument to 28 items, we see that Factor 1 explains the most variation in responses (12.7%) with Factor 2 explaining a similar amount of variation (12.6%). We note that Factor 1 and Factor 2 contain strictly negatively worded or positively worded items respectively, but both emphasize the irritation/willingness that instructors may exhibit when it comes to engaging with students and their questions which may have resulted in both factors explaining essentially identical amounts of variation.

Table 1: Summary of 6-Factor Solution on 28 Item Instrument

	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5	Factor 6
SS Loadings	3.55	3.52	2.74	1.95	1.92	1.59
Proportion of Variance Explained	0.127	0.126	0.098	0.070	0.069	0.057
Cumulative Variance Explained	0.127	0.253	0.351	0.421	0.490	0.547

Factor are labeled (Factor 1, 2, …) in order based on the proportion of variance explained in the 28 item EFA.

Unlike the other factors, Factor 3, which explained 9.8% of the variation in responses, was the only factor to contain both positively and negatively worded items. Item assignments as well as their factor loadings are provided in Table 2. For Factor 3, we can see that both negatively worded items associated with this factor, Q20 and Q21, have negative factor loadings while all other items have positive loadings, which is consistent with our expectation that negatively

Table 2: Primary Factor Loadings 6-Factor Solution

Question	Factor Loading	Question	Factor Loading
Factor 1: My math instructor is disrespectful to us sometimes.		Factor 4: My math instructor models the math-person archetype.	
Q28: Blames us when we don't understand something.	0.816	Q22: Gives overly complex or technical explanations.	0.680
Q5: Puts us down.	0.694	Q1: Teaches too fast.	0.601
Q6: Criticizes our answers to their questions.	0.761	Q12: Is too advanced to be teaching this course.	0.535
Q25: Smirks or laughs at our questions.	0.781	Q18: Gives exams which are hard to finish in the allotted time	0.339
Q26: Says the material is simple, easy, or obvious.	0.458	Factor 5: My math instructor doesn't prioritize teaching us.	
Q27: Seems annoyed, frustrated, or exasperated by our questions.	0.766	Q14: Doesn't manage class time well.	0.611
Factor 2: My math instructor is open and adaptable to us.		Q11: Makes mistakes which confuse students.	0.469
Q15: Makes sure all questions get answered before moving on.	0.831	Q13: Pays more attention to some students than others.	0.495
Q2: Explains things in different ways when we ask.	0.675	Q17: Takes too long to grade and/or return homework, quizzes and/or exams	0.534
Q3: Pauses to let us absorb material or formulate questions.	0.522	Factor 6: My math instructor does more than just lecture at us.	
Q9: Teaches to all students, not just those who've already seen this material.	0.562	Q19: Checks in on us when we work in groups.	0.758
Q10: Is helpful during office hours.	0.586	Q8: Encourages us to work together.	0.745
Q16: Makes us feel comfortable asking questions.	0.592	Q23: Provides supplementary materials like handouts or worksheets.	0.508
Factor 3: My math instructor isn't apathetic toward us.			
Q4: Jokes with the class.	0.858		
Q7: Talks enthusiastically about math.	0.699		
Q20: Has little or no enthusiasm for teaching.	-0.728		
Q21: Has little or no interest in students' success.	-0.410		
Q24: Engages in small talk with the class.	0.661		

Item labels (Q1, Q2,…) are the item order in the survey. The first item listed for each factor has the largest factor loading for the factor; subsequent items are listed in order by item label.

worded items would have a negative relationship with an overall positive factor. When naming the factors, we devised a positively framed name for this factor, incorporating the antithesis of Q20 and Q21 as themes within the factor. For example, we considered “an interest in student success” as a theme defining Factor 3 rather than the lack of interest.

Based on the item-factor associations presented in Table 2, our team took a collaborative approach to develop names to define our latent factors. To begin this process, each team member created their own name/phrase to describe each factor. Then, as a team, we discussed the proposed names/phrases, identifying consistencies between them and any potential weaknesses. Our aim was to create a unified name that could unite all items under a common theme rather than naming based on a few of the higher loading items. Thus, after creating a group name for a factor, each item was compared to the factor name to ensure that the name represented the item well. As we continued this process for multiple factors, our team decided to implement a common structure for each factor name to emphasize that these factors represent students’ perceptions of their instructor. Thus, each factor name is written using the same structure as the FIBI items: “My mathematics instructor …” This commonality is meant to provide FIBI users with six collective statements, from the students’ perspective, about their instructor’s behaviors that may be increasing/decreasing the students’ feeling of inclusion in their classroom. In this respect, we phrased the titles to not be a definitive judgement of the instructor, but rather a current understanding that the students have developed with respect to their own class. For example, for Factor 5, a few of our initial phrases defining the factor were: “poor time management” and “inattentive to teaching.” As we worked to incorporate both the issues of timing in Q14 and Q17 and attention to details in Q11 and Q13, our discussion turned to the idea of having priorities above providing quality instruction for students. While the factor could have been given a definitive title such as, “My mathematics instructor doesn’t know how to manage their time well,” we wanted to avoid the declaration that an instructor “doesn’t know” or “lacks” some ability or effort. Instead, we chose the title, “My math instructor doesn’t prioritize teaching us,” because it addresses the students’ current perception of their instructor’s lack of attention and time management skills through the lens of “having priorities other than teaching” which an instructor can then address without feeling as if they have been labeled as “inattentive”.

Table 3: Factor Correlations for 6-Factor Solution

	Factor 1 (–)	Factor 2 (+)	Factor 3 (+)	Factor 4 (–)	Factor 5 (–)	Factor 6 (+)
Factor 1 (–)	1	-0.61	-0.44	0.51	0.62	-0.33
Factor 2 (+)		1	0.71	-0.59	-0.58	0.65
Factor 3 (+)			1	-0.35	-0.31	0.6
Factor 4 (–)				1	0.51	-0.46
Factor 5 (–)					1	-0.43
Factor 6 (+)						1

(+)/(–) after each factor denotes whether the factor emphasizes positive/ negative impacts on inclusivity.

After providing names for each of our factors, we have three positively framed and three negatively framed factors. Based on previous work, we expected the factors of inclusion to be dependent on each other. Thus, we also investigated the correlations between our factors which are presented in Table 3. Of our six factors, three are focused on positive behaviors to support inclusion and the other three address negative behaviors that may inhibit feelings of inclusion in a mathematics classroom. So, we expected that factors addressing negative behaviors will have an inverse relationship with positively focused factors. Moreover, two factors that are both positively (negatively) focused were expected to have a positive association between the two factors. This relationship did indeed present itself in our data. Additionally, we note that the magnitude of the associations between factors ranged from 0.31 to 0.71, suggesting that all of our factors are moderately dependent on one another and thus the different aspects of students' perceptions of inclusive instructor behaviors are linked to each other.

Discussion

This paper addresses the beginning stages of development for the FIBI instrument, a measure of students' perceptions of inclusive instructor behaviors in undergraduate mathematics classrooms. Development of this instrument began with an emphasis on the inclusion of women and PEER students in defining inclusive practices through targeted focus groups which became the basis for items included in the FIBI instrument. After developing these items, we proceeded through an iterative process of exploratory factor analysis and item reduction to arrive at our current 28-item instrument which contains six factors, of which three describe instructor behaviors that promote inclusion and three describe behaviors that inhibit feelings of inclusion.

One limitation of our work is the lack of diversity present in our sample. Although we were able to obtain a majority of our responses from women, our sample did not contain enough students who identified as PEERs to assess the factor structure for this subgroup alone. Additionally, other underrepresented identities such as Indigenous, Native Hawai'ian, Pacific Islander, non-binary gender identities, are not well represented in our sample and we did not investigate sexual identity as an identifier for underrepresented students in mathematics class. It may be possible that students from these groups would identify alternative factors which we did not see in this study. However, for our future confirmatory work, we plan to make a more targeted effort to include more PEER participants and to understand any possible differences in the factor structure. Another limitation of our study comes from our focus on deriving items from the responses of students in our focus groups. Because many students have only experienced traditional, lecture-based classrooms, it is doubtful that they have experienced any teaching strategies that may promote feelings of inclusion. Hence, we have aimed our instrument at defining only "fundamental" behaviors that may be present in a wide variety of teaching styles.

While this paper has presented a basic factor structure for the FIBI instrument, future analysis is needed to confirm this factor structure. Thus, our future steps for instrument development include a secondary data collection to use for confirmatory factor analyses (CFA) to validate our factor structure. Additionally, to continue centering women and PEERs in defining inclusive practices, we plan to run a multiple groups CFA model to analytically compare the factor structures and factor loadings based on gender and race/ethnicity. Finally, the FIBI instrument must be compared to other measures of similar constructs to assess construct validity and we plan to investigate the relationship between FIBI factor scores and other constructs such as math confidence, belonging, as well as course grades. These next steps will be crucial for establishing the validity of the FIBI so it can then be used by instructors aiming to assess and improve feelings of inclusion in their math classrooms.

Teaching Proofs in a Second Linear Algebra Course: A Mathematician's Resources, Orientations, Goals, and Continual Decision Makings

Jeffrey S. Meyer — California State University, San Bernardino
Sepideh Stewart — University of Oklahoma
Avery Madden — University of Oklahoma

In this research study, we employed Schoenfeld's (2010) theory of Resources, Orientations, and Goals (ROGs) to examine an instructor's (and co-author's) textbook in a second course in linear algebra. The course was proof-based and the instructor anticipated that many students would have difficulty. Having the knowledge of students' difficulties from a first course in linear algebra they created tailored resources with many hints and pedagogical attributes for their students. The instructor's goal was to encourage students to construct their own proofs to understand and learn the materials, hence promoting exploration, conjecturing, and proving mental mathematical actions.

Keywords: linear algebra, proof, second course, belief, pedagogy, knowledge of content and students, mathematical knowledge for teaching

Literature Review

Linear algebra is a key topic for many mathematics majors and other fields. The Linear Algebra Curriculum Study Group (LACSG) recommended that "at least one second course in matrix theory/linear algebra should be a high priority for every mathematics curriculum" (Carlson, Johnson, Lay, & Porter, 1993, p. 45). The LACSG 2.0 recommends that mathematics departments offer a variety of second courses (e.g., numerical linear algebra) and include wider topics (Stewart et al., 2022). However, research on topics in second courses of linear algebra, which contain more abstract content, is rare. In addition, in a survey paper by Stewart, Andrews-Larson, and Zandieh (2019), the authors found that more research on how students make sense of linear algebra proofs are needed. Hence, in this paper, we focus our attention on linear algebra proofs. For example, Stewart and Thomas (2019) aimed to uncover linear algebra students' perceptions of proofs in a first course. The results revealed that many students expressed their need for understanding. Studies also showed that the number of new definitions which linear algebra students must learn to begin writing proofs is overwhelming and makes learning proofs difficult (Hannah, 2017; Britton & Henderson, 2009). Malek and Movshovitz-Hadar (2011) employed one-on-one workshops to examine the effect of using their Transparent Pseudo Proofs (TPPs) in teaching first-year linear algebra proofs. They found for non-algorithmic proofs, students with familiarities in the TPPs wrote more in-depth and satisfactory answers than students who learned proofs traditionally, however, both groups of students performed equally for algorithmic proofs. Uhlig (2002) developed a novel approach compared to the traditional Definition, Lemma, Proof, Theorem, Proof, Corollary (DLPTPC) to teach linear algebra proofs. He posed the following questions: "What happens if? Why does it happen? How do different cases occur? What is true here?" (p. 338). He believed "Such a WWHWT sequence of presentation quickly leads students to understand, construct, reason through, enjoy, and actually demand 'salient point' type proofs" (p. 338).

Further expanding on the ideas of proof education, Melhuish et al. (2022) synthesized 104 papers from a range of countries and methods to describe what is known about proof-based learning and what is still missing. In their exploration, they uncovered that two schools of thought existed for teaching proofs, lecture-based proofs and student-centered learning. They concluded that while student-based learning is promising, a large gap remained in "understanding of the theoretical mechanisms which specific instructor moves may encourage or scaffold student activity is only beginning to emerge" (Melhuish et al., 2022, p. 17). Attempting to understand the theoretical mechanisms of an instructor is not something that is entirely new despite not being well explored. Using Schoenfeld's (2010) Resources, Orientations, and Goals (ROGs) framework, Hannah, Stewart, and Thomas (2011) attempted to describe the instructors' overarching goals to present linear algebra topics to their students. The paper found that analyzing the instructor's goals proved useful in uncovering his decision making and how the instructor approached teaching the "big picture." These results validated the instructor's decision making as a useful tool for improving the teaching ability of the instructor. Furthermore, the feedback from the students in this case of reflective teaching was positive, reinforcing the idea that this analysis provided enrichment for the instructor and students.

Theoretical Framework

The theoretical aspects of this study are based on Schoenfeld's (2010) Resources, Orientations and Goals (ROGs). He claims that "if you know enough about a teacher's knowledge, goals and beliefs, you can explain every decision that he or she makes, in the midst of teaching" (2012, p. 343). By resources Schoenfeld focuses mainly on knowledge, which they define "as the information that he or she has potentially available to bring to bear in order to solve problems, achieve goals, or perform other such tasks" (2010, p. 25). Goals are defined as what the individual wants to achieve. The term orientations refer to "dispositions, beliefs, values, tastes, and preferences" (2010, p. 29). Although, the theory was originally applied on school teaching, (e.g., Aguirre & Speer, 2000; Thomas & Yoon, 2011; Törner, Rolke, Rösken, & Sriraman, 2010), it also has applicability to teaching at university (e.g., Hannah, Stewart & Thomas, 2011; Paterson, Thomas & Taylor, 2011; Stewart, Troup, & Plaxco, 2018). In addition, as we are interested in understanding the teaching and learning of proof in a formal second linear algebra course, we approach this problem with the Mathematical Knowledge for Teaching framework (MKT) by Ball, Thames, and Phelps (2008). This framework identifies several distinct domains of knowledge that instructors must use when they teach mathematical content.

In particular, for this paper, we restrict ourselves to one domain: *knowledge of content and students (KCS).* According to Ball et al., (2008, p. 401):

> *[K]nowledge of content and students (KCS)*, is knowledge that combines knowing about students and knowing about mathematics. Teachers must anticipate what students are likely to think and what they will find confusing. When choosing an example, teachers need to predict what students will find interesting and motivating. When assigning a task, teachers need to anticipate what students are likely to do with it and whether they will find it easy or hard. … Each of these tasks requires an interaction between specific mathematical understanding and familiarity with students and their mathematical thinking.

In this study, our goal is to network these theories by associating Ball's instructor anticipation KCS and Schoenfeld's instructor beliefs about student resources. The research question guiding this research is: What knowledge of content and students do experienced instructors leverage for teaching proofs in linear algebra?

Methods

This narrative study (Creswell, 2013) is part of a larger study working with a mathematician (the instructor and first author), whose research is in geometry and algebra, and his linear algebra students. In the rest of the paper, we shall refer to the mathematician as "the instructor." The research team consisted of the instructor, a mathematics education researcher in linear algebra education, and a graduate student who is working on linear algebra education. The course was self-contained, proof-based, and constructed the theory of formal linear algebra from basic set-theoretic assumptions. Incoming students all had experience with formal proofs in other courses. The author approached this course with the core pedagogical perspective that *students should have the opportunity to construct all proofs themselves*.

Students were supplied with a self-contained textbook written by the instructor that had all definitions, propositions, and reflections, carefully sequenced, that students would progress through during the entire term. Recognizing the difficulty of creating proofs on their own, the instructor supplied *scaffolding* (via hints, questions, and reflections) to support the students in the completion of the proofs without reducing the cognitive demand of the proofs themselves.

Class met twice a week for 75 minutes. Class time was split into three components: lecture (~15min), group time (~45min), and presentations (~15min). Throughout lecture, the instructor would recall concepts from the past class and introduce new ideas for that day's investigations. During group time, groups would work, while standing up at and writing on white boards, to construct (and convince one another) of proofs to that day's propositions. During this time, the author would walk among the groups, attempting to facilitate discussions and provide hints for groups that were stuck. Towards the end of this time, the author would recruit groups to share their thinking for their proofs. During presentations, groups would present their proofs (complete or incomplete) to the class for discussion.

Each week, students were then required to LaTeX up and submit all proofs in their "course journal," a single cumulative document. Students were not allowed to look up proofs from other resources, but they were encouraged to work with classmates outside of class.

Data collection and analysis

We collected data from the textbook created by the instructor, videos of the instructor during lecture, videos of the students presenting, videos of student board work, and the final course journal submissions for each student. In this paper we only analyzed the instructor's textbook. The team wanted to look at a small sample and identify structures of linear algebra proofs. The members of the team collectively decided to analyze Investigation 12 (Linear Combinations and Span), both because it related to previous work (Madden et al 2023) and the team determined it was the first instance of propositions which contained sophisticated linear algebraic reasoning. The team then determined it was beneficial to also analyze Investigation 9 (Subspaces), as Investigation 12 frequently referenced it. The research team individually analyzed the data, identified emergent themes, and then the team met to share, discuss, and settle upon identified themes. The team was especially interested in the hints. The team continually consulted with the instructor to gain insights into his knowledge and beliefs that led him to make the decisions that were observed in the investigations. In this paper, we will only analyze the instructor's beliefs.

Results and Discussion

We analyzed two investigations on subspaces and span that the instructor provided his students (see Figures 2, 3, and 4). These investigations, as well as relevant references to earlier investigations, are provided below (see also Figure 1). These investigations were created by the instructor prior to his students using them. As such, these investigations contain a significant amount of information about the instructor's knowledge and beliefs about the content, his students, and teaching the subject, as well as his goals.

Instructor's Knowledge and Beliefs About Learning Proof in a Student-Centric Course

The instructor has taught a proof-based second course in linear algebra many times, and based upon those experiences, wrote his own self-contained textbook that he based his course upon and that he distributed to his students. As a consequence of his experiences teaching such a course, together with his beliefs concerning how people learn, the instructor came to hold certain beliefs regarding the structure of such a second course, and which caused him to make certain teaching decisions regarding the nature and structure of his textbook. Here are some of the instructor's beliefs and corresponding teaching decisions.

Belief (B1). Students should learn formal linear algebra in a student-centric course, which would include that the students should have the opportunity to construct all proofs themselves. Belief B1 resulted in the teaching decision (TD1): he created a self-contained textbook that contained no proofs, but rather a collection of carefully sequenced propositions and reflections.

Belief (B2). Teachers play an important role in student learning by (1) providing students with cognitively demanding problems and (2) helping students access knowledge and heuristics to solve the problem. In this context, the problems provided were proofs and Belief B2 resulted in teaching decision (TD2): for each proof, anticipating where students would struggle, he carefully wrote hints, which typically included a suggestion for the type of proof to pursue, the definitions to retrieve, and some intermediate results to prove. This can be observed in Figure 4 in the hints to the proofs of Propositions 4.48 and 4.50.

Belief (B3). Central to the story of a proof-based second course in linear algebra is (1) a solid understanding of linear algebra for the object $\mathbf{R}^n$, and (2) continual enactment of structural abstraction (Tall, 2013). Belief B3 resulted in the teaching decision (TD3): prior to a (formal) object being constructed, the antecedent object in $\mathbf{R}^n$ was revisited and discussed, as was explicitly the action of structural abstraction. The terminology of structural abstraction was introduced early in the textbook (see Figure 1) and then continually used throughout the term.

> A fundamental mathematical action is **structural abstraction**, in which we take a *specific* object within a *specific* context, observe its meaningful structures, and then construct an abstract object endowed with these structures, no more and no less. We then may mentally act upon this new abstract object, bringing it to life as a new mathematical entity, of which our original object is now a mere example.

Figure 1. Excerpt from Investigation 3 of the instructor's textbook.

Teaching decision 3 (TD3) can be seen having been implemented in the introduction to subspaces (see Figure 2).

> **Investigation 9**. **Subspaces.** Once again, think back to your first course in linear algebra. We were constantly looking at spans and solving matrix equations. Geometrically, we were looking it, lines, planes, and more generally, k-planes, through the origin. We now perform a structural abstraction on these objects, which we now formalize with subspaces.
>
> **Definition 4.24.** If V is a vector space over the field F, then a **vector subspace** of V is a subset $W \subset V$ satisfying:
>
> **(S1)** W is nonempty,
> **(S2)** W closed under addition: if $\mathbf{w}_1, \mathbf{w}_2 \in W$, then $\mathbf{w}_1 + \mathbf{w}_2 \in W$,
> **(S3)** W is closed under scaling: if $a \in F$ and $\mathbf{w} \in W$, then $a\mathbf{w} \in W$.
>
> I will often use the symbol W for a subspace.

Figure 2. Excerpt from Investigation 9 of the instructor's textbook.

Instructor's Knowledge and Beliefs About the Learning of Mathematical Mental Actions

Belief (B4). There are many distinct types of mathematical mental actions, including proving, conjecturing, generalizing, abstracting, modeling, and interpreting (Harel, 2008). It is a goal of the instructor that in a formal course such as this, students internalize these actions.

Beliefs (B5-B7) of the instructor is that students (1) come into such a course not being explicitly aware of such mental actions, (2) students are more likely to internalize such actions if these actions are explicitly named and discussed, and (3) students are more likely to internalize such actions if they have opportunities to engage in them.

Reflection 4.30. Is $\mathbb{R}^2$ a subspace of $\mathbb{R}^3$? Carefully explain your thinking.

Proposition 4.31. *If F is a field, $n \in \mathbb{Z}_+$, and $i \in \{1,2,\dots,n\}$, then the set* $W_i := \left\{ \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_n \end{bmatrix} \in F^n \;\middle|\; v_i = 0 \right\}$ *is a vector subspace of F^n.*

Generalization is another important mathematical action we perform, distinct from, but related to structural abstraction. See, for example, the work of Harel and Tall, The General, the Abstract, and the Generic in Advanced Mathematics. Roughly speaking, **expansive generalization** occurs when you *expand the applicability* of an object or process with which you are already familiar.

Reflection 4.32. A common example of expansive generalization is given by the movement from linear combinations of vectors in $\mathbb{R}^2$ to linear combination of vectors in $\mathbb{R}^n$. Carefully explain the process of finding linear combinations in $\mathbb{R}^2$. Then, explain how this familiar process is expanded to $\mathbb{R}^3$, and eventually, $\mathbb{R}^n$. Explain how this fits the criteria for expansive generalization.

Reflection 4.33. Compare and contrast expansive generalization with structural abstraction. You may find it useful to use as examples, $\mathbb{R}^2 \to \mathbb{R}^n$ for expansive generalization and $\mathbb{R}^n$ to an abstract vector space V for structural abstraction.

Explore-Conjecture-Prove 4.34. Using expansive generalization upon the subspaces $W_i \subset F^n$ in Proposition 4.31, find, clearly conjecture, and then verify a more general collection of subspaces of F^n.

Figure 3. Excerpt from Investigation 9 of the instructor's textbook.

The course is built around proving, however, the instructor identified and highlighted other mental actions where he could. In this instance (Figure 3), the instructor made the teaching decision (TD4) to have students reflect upon and practice generalizing and conjecturing. This sequence comes at the end of the initial investigation into subspaces. Here, in Proposition 4.31, students are initially asked to prove that the subset W_i of F^n, where the ith entry is zero, is a subspace. The instructor provided a hyperlink to a mathematics education resource to reflect upon expansive generalization by Harel and Tall (1989) and then asked students to use expansive generalization to conjecture and then prove new propositions (see Figure 3). More precisely, students are asked to reflect upon the method in which they proved Proposition 4.31, and then in Explore-Conjecture-Prove 4.34 to determine other subsets that are subspaces. Here students were free to consider many generalizations, the two most obvious being: (1) if the ith entry is held a different (nonzero) constant (which will not be a subspace) or (2) if more than one entry is held to be zero (which is a subspace).

Investigation 12. **Linear Combinations and Span.** One core idea of linear algebra is *mixture*. Vector space axioms were were precisely the structures necessary to allow for mixtures, which we describe formally as linear combinations.

Throughout this investigation, V will denote a vector space over the field F.

Definition 4.45. If $S = \{\mathbf{v}_1, \dots, \mathbf{v}_n\} \subset V$, then a **linear combination** of S is an expression of the form

$$x_1\mathbf{v}_1 + \cdots + x_n\mathbf{v}_n,$$

where $x_1, x_2, \dots, x_n \in F$.

Note that we only take *finite sums* in linear combinations.

Definition 4.46. The **trivial** linear combination is the one with all 0 scalars. Otherwise it is **nontrivial**.

Definition 4.47. The **span** of S, denoted $\text{span}(S)$, is the set of all linear combinations of vectors in S. (Note that S can be infinite, but the combinations are finite.) In symbols,

$$\text{span}(S) := \{x_1\mathbf{v}_1 + \cdots + x_n\mathbf{v}_n \mid \mathbf{v}_1, \dots, \mathbf{v}_n \in S \text{ and } x_1, x_2, \dots, x_n \in F\}.$$

Sometimes if $\mathbf{v} \in V$, then I will write $\text{span}(\{\mathbf{v}\})$ as $F\mathbf{v}$ which reminds us that the span of a single vector is just the line created by all possible scalings of that vector.

Proposition 4.48. *If $S \subset V$ is nonempty, then* $\text{span}(S)$ *is a vector subspace.*
(Hint: Try a direct proof. Show that $\text{span}(S)$ satisfies (S1)-(S3). To show (S2), you will need to show that, if $\mathbf{w}_1, \mathbf{w}_2 \in \text{span}(S)$, then $\mathbf{w}_1 + \mathbf{w}_2 \in \text{span}(S)$. To do this, you need to interpret and unravel definitions. Similar for (S3). You may find Definition 4.47, Definition 4.45, Definition 4.24, and Definition 4.1 useful.)

A useful alternative characterization of span is that it is the *smallest* subspace containing S, which is made precise by the following proposition.

Lemma 4.49. *If $S \subset V$ is nonempty, $W \subset V$ is a subspace, and $S \subset W$, then* $\text{span}(S) \subset W$.
(Hint: Try a direct proof. You need to show that any linear combination of vectors in S is contained within W. You may find Definition 4.47, Definition 4.45 and Definition 4.24 useful.)

Proposition 4.50. *If $S \subset V$ is nonempty, then* $\text{span}(S)$ *is equal to the intersection of all subspaces of V which contain S.*
(Hint: Try a direct proof. Let $\mathscr{A}$ denote the collection of all subspaces of V containing S. In symbols, $\mathscr{A} = \{W \subset V \mid W \text{ is a subspace and } S \subset W\}$. Then you want to show $\text{span}(S) = \cap_{W \in \mathscr{A}} W$. You will need to show both inclusions. To show that $\cap_{W \in \mathscr{S}} W \subset \text{span}(S)$ is immediate (why???). To show the other inclusion, observe S is in each W for which $W \in \mathscr{A}$, and deduce $\text{span}(S) \subset W$ (how???). You may find Proposition 4.48, Lemma 4.49, and Definition 2.5 useful.)

Figure 4. Excerpt from Investigation 12 of the instructor's textbook.

Instructor's Knowledge and Beliefs About the Learning of Span

The instructor identified two characterizations of the concept of the span of a set of vectors S, span(S), as we now outline.

The first conception of span is a "bottom-up" construction. One first conceives of a linear combination. Based on the instructor's APOS (Dubinsky & McDonald, 2001) theoretical knowledge, the action of computing an explicit linear combination of vectors in $\mathbf{R}^n$ for small n, is a task that is introduced early in a first course in linear algebra. Through repeating this action, a student may internalize this action to create an internalized procedure. Eventually the student may encapsulate this procedure as a single object on its own. Only once a student has internalized the notion of a single linear combination as an object can the students conceive of many linear combinations of S at once. The student is then asked to conceive of not one, nor two nor three, but all linear combinations at once. They are asked to hold within their mind the infinitude of all such objects. That is span, built from the bottom up.

The second conception of span is a “top-down” construction. Here, one first conceives of a subspace. Unlike the above pathway, a subspace begins life as a formal object, defined in terms of properties. Furthermore, instantiations of this formal object are themselves typically infinite and there is no finite construction in the way there is for a linear combination. Once a student has internalized the formal object of subspace, the student can then begin to conceive of many subspaces at once. The student is then asked to conceive of not one, nor two, nor three, but all subspaces containing S at once. They are asked to hold within their mind the infinitude of all such objects and conceive of their intersection. That is span, built from the top down.

Both approaches, linear combination and subspace, are mathematically advantageous in appropriate contexts. For example, the former is useful for computation, while the latter is more tractable for formal proofs. The mathematician uses both. The student typically only confronts the first conception of span in their first course.

Concluding Remarks

This study examined a linear algebra instructor’s textbook through the lens of ROGs, and, in particular, the instructor’s beliefs and their knowledge of content and students. The instructor’s textbook is a product, an accumulation of a sequence of numerous teaching decisions, motivated by their beliefs and in line with their goals to help students succeed in understanding linear algebra, to promote mental mathematical actions, namely, exploration, conjecturing, and proving.

When tasked with problem solving, the instructor had knowledge from his experiences as a mathematician of the importance of being able to sort through and retrieve relevant knowledge (in particular, definitions and propositions) in the context of proving. Furthermore, from his experiences teaching, as well as familiarity with mathematics education literature, the instructor anticipated that students would significantly struggle (to the detriment of their learning) with the spontaneous retrieval of relevant definitions and propositions. The instructor therefore made the teaching decision to include these references in the hints. Anticipating the complexity of certain full proofs, the instructor made the decision to recommend specific intermediate results in the hints. Based on their beliefs as a mathematician and their knowledge of mathematics education literature and teaching experiences, the instructor made the decision to make pedagogical content knowledge available to their students. We question, what impact engagement with mathematics education literature might have on student learning (metacognition)?

The instructor got the impression that the hints, in harmony with their other teaching actions, had some long-term impact upon (1) students’ understandings of linear algebraic concepts and (2) how students approach proofs. Certain common definitions and propositions, such as the definition of subspace (Definition 4.24 in Figure 2) were invoked often throughout the term, and the students seemed to internalize them and speak of them fluently. After the course, students told the instructor that they learned that a well-written proof should include proper invocation of definitions and propositions.

Currently we are in the process of analyzing students’ data, for example, the course journals, and exit surveys. The team intends to look at the structure of students’ proofs, and how they constructed their proofs from the provided hints/resources. Without a doubt, proof is an important component of an abstract second course in linear algebra and more research on instructors and students is needed.

“Really, you’re a math major?!”: Students’ Descriptions of Racial and Gendered Microaggressions and Sense of Belonging in Mathematics

Anne Cawley
Cal Poly Pomona

Robin Wilson
Loyola Marymount University

Microaggressions (MAs) are intentional or unintentional messages that communicate hostile, derogatory, or negative messages towards a recipient (Sue et al., 2007). MAs that students receive in a math class can impact a students’ learning experience and can often lead to feelings of exclusion (Cawley et al., 2023). This paper expands on previous work, discussing two types of MAs—racial and gendered—while also discussing students’ overall sense of belonging in a math classroom. This study analyzes the reflections of 133 undergraduate math students who were asked to reflect on an article about mathematical MAs (Su, 2015). Findings show that a majority of students have felt like they do not belong in the math classroom, and that racial and gendered MAs contribute to this. This research supports the need to develop initiatives at departmental and institutional levels to encourage more inclusive spaces in math classrooms.

Keywords: Microaggressions in the Mathematics Classroom, Sense of Belonging

There is much research related to microaggressions, and their impact within society. *Microaggressions* (MAs) have been characterized as the intentional or unintentional forms of insulting, disrespectful communications that occur during everyday exchanges (Yang & Carrol, 2018). These indignities can communicate “hostile, derogatory, or negative” messages that target a person and/or their marginalized group (Sue et al., 2007). The concept of *MAs* was introduced by Pierce and colleagues in the 1970’s to describe “subtle, stunning, often automatic, and non-verbal exchanges which are ‘put downs’ of Blacks by offenders” (Pierce et al., 1977, p.65). While these offenses themselves can be innocuous, they have a cumulative effect on the victim. Pierce felt that these MAs were essential to understanding how African Americans experience racism (Pierce, n.d.). While MAs were founded to describe experiences that Black people faced within society, these have expanded to other racial and ethnic groups such as Latine[1], Asian Americans, and indigenous people. In recent years other types of MAs that people have experienced have been identified by researchers to include women, persons with disabilities, ethnic and religious minority groups, and LGBTQ people (Nadal, 2011).

MAs have been studied within education to understand their effect on a students’ sense of belonging. Sense of belonging pertains to a person’s belief that they are an accepted member of an academic community, whose presence and contributions are valued (Good et al., 2012). The experience of mattering or feeling cared about, accepted, respected, valued by, and important to the classroom and campus community define ways that students feel a sense of belonging (Strayhorn, 2018). When thinking of students within a university context, sense of belonging can also include the perceived social support a student has while pursuing their degree. Steele (1997) implied that it is important for students to feel a sense of belonging to a domain, in other words, an area of study like math or STEM. Yet, Steele also highlighted how societal barriers, such as stereotypes around race or gender, actively reduce feelings of being accepted or valued. MAs have been well reported as widespread in academic spaces and detrimental to student outcomes

[1]*Latine* is a gender-neutral replacement of the term Latino. It has been used as a more linguistically natural alternative to Latinx or Latin@ for Spanish-speakers (Celis Carbajal, 2020).

(Sue et al., 2009). This paper focuses on three types of MAs that STEM students face—racial, gendered, and mathematical—which we discuss in more detail below.

Sue and colleagues (2007) defined *racial microaggressions* as "brief and commonplace daily verbal, behavioral, and environmental indignities, whether intentional or unintentional, that communicate hostile, derogatory, or negative racial slights and insults to the target person or group" (p. 271). Solórzano and colleagues (2000) revealed that MAs were prevalent in classrooms and inhibit students' sense of belonging, especially for students coming from marginalized groups. Nadal and colleagues (2014) reported that racial MAs negatively impact student self-esteem and self-worth which in turn can impact mental health and student achievement. Students' reports of racial MAs within STEM departments are distinctive, which is problematic as many STEM departments already face issues in representation from marginalized communities (Burke, 2007; McGee, 2016). Students of color, especially Black students, report racial MAs from STEM instructors, advisors, and peers (Lee et al., 2020). Specifically focusing on STEM contexts, Marshall et al. (2021) noted that MAs especially impact students who have been historically excluded on the basis of race/ethnicity.

Gendered microaggressions are defined as "nuanced and brief everyday exchanges that communicate sexist denigration and slights toward women, which can be conveyed verbally and/or nonverbally through expression, gaze, and other gestures (Yang & Carroll, 2018). Rainey et al. (2018) found that women more often lacked a sense of belonging in STEM and left the major at higher rates than men, citing reasons such as feeling socially different or feeling like they did not fit in. Sekaquaptewa (2019) shared that while receiving a gendered MA can greatly impact a person, witnessing other women receive MAs can also have a negative impact on a student. Intersections of gender and race create a nuanced space where women of color experience an even more elevated exposure to MAs during their college experience (Lewis et al., 2013; McGee & Bentley, 2017).

As an extension from discussions of racial MAs, Su (2015) used the term *mathematical microaggression*, which refers to the subtle ways that mathematical authorities (such as instructors, classmates, or textbook authors) communicate that one does not belong in math. Su offered examples such as "It is obvious/clear/trivial that…" and "The rest is just algebra," and elaborated that such comments can convey negative messages towards students (e.g., their knowledge is lacking, their questions are unwelcome, their potential in math is limited). Cawley and colleagues (2023) documented three different types of mathematical MAs students experienced, which included microslights, microinsults, and environmental MAs. They found that most students did experience a mathematical MA, and that these were often received from both their instructors and peers.

Our study focuses on the types of racial or gendered MAs that students share they have experienced in their math learning experiences. Specifically, this paper focuses on the following research questions: 1) How do math students describe experiencing racial or gendered microaggressions? 2) How have math students been made to feel like they do not belong in a math class?

Methods

This study took place at a large public university on the West Coast of the U.S., designated as a Hispanic-Serving Institution. Data for this paper were collected between Fall 2019 and Spring 2022. The sample included 133 participants enrolled in calculus 1 (46 students) or abstract algebra (87 students), taught by the same instructor (Author 2). Course modalities included both in-person and virtual instruction. These classes incorporated inquiry-based learning and active learning and provided a significant amount of time for student collaboration and discussion during instruction. Based on institutional data of the 133 students[2], 46% were female, 54% were male, and one student was non-binary. Table 1 shows the racial/ethnic demographics of the students in the study. Students in the study were mostly STEM majors.

Table 1. Student Demographics

	Female (N = 61)		**Male (N = 72)**		**Non-Binary (N = 1)**		**Total (N=134)**	
	Total	%	Total	%	Total	%		
Latine	33	55%	28	38.9%	1	100%	62	46.6%
Black	1	1.6%	5	6.9%			6	4.5%
Asian	10	16.6%	15	20.8%			25	18.7%
Native	0	0%	1	1.4%			1	0.7%
White	11	18.3%	10	13.9%			21	15.8%
Mixed Race	1	1.6%	3	4.2%			4	3.0%
Unknown	4	6.6%	10	13.9%			9	6.7%
Total	**60**		**72**		**1**		**133**	

Throughout the course, students were asked to submit reflection assignments. In one of these assignments, students were asked to read Su's (2015) article on mathematical MAs, to reflect on the paper, and to respond to the following prompt: Have you ever been made to feel like you don't belong in a math class? Students could reflect on any moments in their math experience. The 133 reflections form the data set for this study.

The data were analyzed using constant comparative methods (Corbin & Strauss, 2008). In the first round of coding, all de-identified reflections were coded to identify if the student had explicitly written if they had ever been made to feel like they do not belong in the math classroom. We categorized it as 1) yes, they have been made to feel they do not belong, 2) no, they have never been made to feel like they do not belong, and 3) does not say. After reviewing the data, we completed a second round of deductive coding to identify MAs that students experienced in STEM, specifically mathematical, racial, and gendered MAs. We marked a MA as present if a student wrote about an incident that related to any of the three types of MAs. The authors coded the journals in sets of 20, meeting to discuss coding to ensure agreement.

Findings

This section is separated into two parts. First, we will share about how students wrote about racial and gendered MAs. 21 students discussed racial MAs while 13 students wrote about experiencing a gendered MA. Seven students discussed how both racial and gendered MAs impacted them. Then, we discuss the ways that students have shared whether they have/have not been made to feel like they do not belong in a math classroom.

Racial Microaggressions

21 students discussed racial MAs in their writing. The racial identities of the students included Latine, Asian American, Black, and unknown race/ethnicity. Seven students explicitly

[2] Because racial- and gender-identity data were not collected during the course each semester, the authors used institutional data provided for each student to identify race/ethnicity and sex. This may not properly reflect the students' gender-identity or racial/ethnic identity.

mentioned how they related to Su's experience as an Asian American in Texas explaining scenarios that were similar to those that Su shared about himself. Each student shared some sort of experience that affected their sense of belonging. Most of these racial MAs represented experiences in the math classroom, while others reflected general experiences that they had.

A majority of the responses were written by Latine and Asian American identifying students. Three of these students expressed comments that reflected the Model Minority Stereotype (Chou & Feagin, 2008), indicating that they have experienced the notion that because they are Asian American, they should be good at math. Some students' writing reflected experiences they faced with MAs both inside and outside of the classroom. For example, Alan, an Asian American math major described many ways his intelligence was assumed based on his race.

> Math aside, microaggressions suck. One thing I've heard until I was a senior in high school was, "oh you're Asian, you should [just] be good at math." And lately (as of 2020) as a mathematician among engineers, my new boss has said "you're a math major, you should be able to do [algebra] in your head." Albeit that these examples aren't exactly like Su's examples, hearing these statements made me feel anything but a positive emotion.

Alan acknowledged how these comments negatively affected him, appearing to follow him in many aspects of his schooling and career. Another student, Lucia, a Latine female math major shared an experience where being a math major was questioned.

> I remember speaking to a man about where I go to school and what major I was studying. I don't know if it was because I was in my Domino's Pizza uniform, my ethnicity, being a woman, or a combination of all three, but the man's response was "really?! You go to [university name]? You're a Math major?!! Isn't that major super hard and for smart people?" I remember feeling really annoyed and almost anger at the response.

Lucia faced incredulous remarks from strangers regarding her major, and described how her complex intersectionality made it appear that she could not possibly be a math major.

Gendered Microaggressions

Thirteen female students wrote about experiencing a gendered MAs. Two main themes occurred in this group: 1) female students noticed how male-dominated the STEM space is and 2) how male peers do not take them seriously and often do not believe that they are capable of doing math. Almost half of the women coded with a gendered MA described the memory of being one of only a few in their math classes. Monica, a Latine female math major explained her feeling of being the only female student,

> As a female in a male-dominated field, there have been times that I have felt I do not belong in the classroom. One of the first times was my first quarter…in my Calc 3 class. My Calc 3 had 30 students and only 3 were female. I did not feel unwanted but I will say that it felt uncomfortable at times.

This sensation of being one of the only women in the math classroom amplified other MAs. Six students described ways in which their male peers made them feel as though they were not capable of contributing to the math space, often not taking them seriously. Flor, a Latine female engineering major expressed ways that she coped with this type of treatment.

> [My pre-calculus] class was predominantly male students, with just a handful of us female. From what I remember, after lecture, it seemed as if all the guys just "got it". Myself and the other five girls usually sat together because it took us longer to get the material. We felt more comfortable sitting next to each other because we all knew we wouldn't judge each other for it. It was as if we created a safe place for ourselves within our pre-calculus class; we could ask each other questions rather than asking our teacher

or the guys, who'd just make us feel stupid. That was the class that made me hate math again. I struggled the entire semester, but with the help and support of the other girls, I'd managed to pass with a C.

Other women shared similar experiences as Flor, describing how in group work their contributions would often be overlooked, or their male peers would get exasperated when they would ask clarifying questions.

Racial, Gendered, and Mathematical Microaggressions

Seven students listed having experienced all three of types of MAs, all of which were female students of color. These women identified different moments within their educational experiences that relate to these MAs. Leticia and Claudia, both Latine female math majors, wrote about how the choice of name that the instructor uses for an example can demonstrate a lack of diversity and inclusion. Leticia wrote,

> Choosing male white/European names was a weird thing in my opinion because when names are used in class the teacher tends to just say the first name that comes to mind, and I assume it is the same when making homework/test problems. Many of my non-white and/or female teachers just use the basic names (i.e., Ann, John, Max, Julie, etc.) because that isn't the important part of the problem.

Leticia implies that the names selected for word problems or examples usually relate to European names. What is more, she indicated that even her marginalized instructors, who she may assume would diversify this component, also use these types of names. Claudia shared that "as a person of color and a female in STEM, I have constantly felt like I didn't belong in my field or in college." She explained that utilizing more diverse examples in class would help to alleviate this feeling, and that it "is important to the students of color who are constantly told that they do not belong in higher education because the statistics said so or because society keeps showing the negative stereotypes of the community."

Shenise and Nina, both women of color, expressed the challenges of being a math major. Shenise shared her concerns of being both black and a woman in math.

> I know as a black woman in the Math field, white men or men in general don't think you're capable of understanding the material the way that they do. There are countless times where I had ideas or different approaches to a problem and was ignored or overlooked and would eventually have to do it the way that I had suggested. They treat women as if we did not take the same classes to get where we are now.

Shenise's experiences reflected how men in math radiate the sense that she, and others like her, do not belong in math. Being ignored is a MA against the person contributing ideas and approaches, especially in a math class; this is amplified when Shenise explained that it was because she is a black woman. Nina shared,

> It is especially hard to feel like I belong as a Latinx woman. Walking into a class and seeing that you are one of maybe 2 or 3 girls in the class is both interesting and scary. Interesting because now I realize that I am seeing the "leaky pipeline" happen in real-time, and scary because I remember when my previous math classes would have at least 8-9 girls in them. Women and minorities are still underrepresented in STEM fields and the numbers have not been exponentially growing even as the years have changed and people have gotten far more progressive.

Nina explained how she felt seeing few women, which is known as an environmental MA (Marshall et al., 2021), relating to MAs that occur in the environment in which a person exists, not directly received by another individual.

Sense of Belonging

72 students indicated that they have been made to feel like they do not belong in a math classroom while 19 students indicated that they have never been made to feel like they do not belong. We will refer to the first group as Low Sense of Belonging (LSB) and the second group as High Sense of Belonging (HSB). 43 students did not indicate an explicit answer. We discuss each of these groups in this order.

86% of students that indicated LSB also discussed a mathematical MA. Only ten students who stated they had LSB did not include any examples of receiving or witnessing a mathematical MA. Ezekial, a male student (whose race/ethnicity was unknown), shared an experience where a math teacher actively tried to push him out of the STEM field. He shared,

> In the summer before my senior year of high school, after my retake of algebra 2, the teacher called me aside and asked me what my plans were for the future. He told me that he would only give me a passing grade if I didn't plan to major in anything involving math. While I remember my grade was a 66, and of course I should consider it an act of benevolence that he moved me up to a 70, I know I didn't deserve it. I felt like a fraud.

At the time of writing this, Ezekial was in his final semester as an economics major, a field that required a lot of mathematical skill and reasoning. His reflection indicates that his teacher provided a kind act, to provide him with a passing grade. However, he reflects that this act made him feel a LSB because he did not feel like he belonged in math.

Twelve students who indicated LSB also described instances of racial MAs while five students described gendered MAs. Carson, a Black male student majoring in physics and minoring in math explained how being one of a small minority of Black students creates LSB.

> Being an underrepresented minority is difficult enough, as there are so few that we feel we do not belong. The lack of inclusive language in these subjects creates a subconscious feeling that we do not belong. It is interesting with microaggressions, those who inflict them often don't know that their statement or attitude was harmful. I have been told by others that I speak so well after doing presentations, and while they meant it as a compliment, it creates the feeling that they weren't expecting me to speak well.

Carson highlights that inclusive language is valuable to feeling a sense of belonging. He continues to say, "Mathematics, and Physics, tends to be full of language that is discouraging." While he persisted with the degree, he acknowledged that he did not feel as though he belonged.

Interestingly, of the 19 students who indicated HSB, 15 documented having received mathematical MAs while four did not express any examples of having received or witnessed a mathematical MA. This implies that while students experience mathematical MAs, they can still have HSB in the classroom. This number is very small, only representing 11% of students. Aron, a Latine male, described why he feels HSB,

> I may have felt discouraged but not as if I didn't belong. I have always had a passion for math, and no one can ever take that away from me. At times it has proven to be challenging. However, that is part of the beauty. I don't think there is any other place I do belong in.

Aron finds a sense of belonging within the subject itself – he finds that a strong part of his identity is tied to the beauty of math itself.

While three people with HSB were coded as discussing racial MAs, they still felt like they belonged in the math class. Dane, an Asian American male student described,

> I have not ever felt that I didn't belong in a math class. Being an Asian American there are a lot of stereotypes revolving around my ability to do math solely because of my race.

> Growing up I was somewhat decent in math whether or not it was my genetics giving me an advantage or the cultural upbringing that came with being Asian.

Dane expressed that an awareness of the Model Minority Stereotype, yet persisted in his math endeavors maintaining a sense of belonging in the classroom. None of the students who described a gendered MA indicated HSB.

43 students did not state explicitly whether they had been made to feel like they don't belong. However, a majority of these students described mathematical MAs that they directly experienced; only five of these students did not write about a mathematical MA. Leticia, who did not explicitly say if she had LSB wrote,

> The calculus three teacher I had should be required to read this five times. He is an aero-space engineer teacher that likes to make math majors feel awful about themselves if they aren't doing well or have questions. One other math student asked if he wrote an *r* or an *n* and he gave the most sarcastic answer. I was never the target because when he asked who was a math major he didn't see my hand…There is nothing worse than feeling belittled when you are learning something difficult.

Leticia described here a moment that felt like a macroaggression, where she and her peers experienced very direct interactions from a faculty member, creating an experience where many may not have felt a sense of belonging in the classroom. She points out that the Su (2015) paper would be a useful tool for some faculty to read to understand the possible experiences a student may have when trying to learn such a difficult subject. Paired with her acknowledgement earlier of the use of white, European names in math word problems, Leticia made clear how she may not have experienced a sense of belonging in math.

Discussion

Our study showed that students experience traumatizing MAs in their math learning experiences. While the frequency was low regarding racial (16%) and gendered (10%) MAs discussed in the journals, the fact that these experiences still exist implies a dire need to reflect and consider our classroom spaces and the math field in general. When considering all students who enroll in math courses, this affects many students. These are also the accounts of students who "made it"; what would we see if we collected data from students who left STEM or never made it Calculus 1? What is more, over half of the students in this study indicated that they have been made to feel like they do not belong in math. Many more wrote accounts that would indicate the same but did not state explicitly whether or not they have been made to feel that way. If we consider those who did not explicitly say it yet implied it in their writing, it *could* be possible that at some point in time about 85% of students have been made to feel like they do not belong in a math classroom. While this is an important finding, future work will explore the frequency and longevity with which students feel LSB in their math classrooms.

Understanding the racial, gendered, and mathematical MAs that students face in classrooms may help us to understand ways to make students feel a strong sense of belonging in their math classes. Leyva and colleagues (2021) have documented instructional mechanisms that may impact a students' experience in college math, which include limiting within-group peer support as well as activating exclusionary ideas of who belongs in STEM (p. 27). As we continue to develop best practices for supporting students, we need to keep in mind the ways to develop a stronger sense of belonging for math students. We note here that the intersectionality of students' identities as both women and students of color is an important aspect to consider, as negative experiences at the intersection of these identities can amplify the lack of sense of belonging (Crenshaw, 1991), specifically in math.

Exploring the Adoption of Research-Based Instructional Strategies in Undergraduate Mathematics with the Teacher Centered Systematic Reform Model

Timothy J. Weston
University of Colorado

Sandra L. Laursen
University of Colorado

Tim Archie
University of Colorado

Studies show that Research-Based Instructional Strategies (RBIS) help students learn, however their adoption has been slow. The Teacher Centered Systematic Reform Model (TCRM) is a general model for organizing enablers and barriers to adoption of new teaching methods that includes departmental, personal and teacher thinking factors. We used the TCRM model as a framework to assess the amount of formal lecture reported by 634 mathematics instructors in their undergraduate courses. Regression analyses found that instructors who participated in Project NExT (a professional development workshop) during their early careers were less likely to use lecture than non-participants. Other significant predictors of lecture less included evaluation expectations emphasizing active teaching methods, involvement in equity and diversity efforts, and prior experience with RBIS. Factors with a positive correlational association with lecture included evaluation efforts by departments where lecture was expected. Results confirmed some prior models in different disciplines.

Keywords: Undergraduate Education, Adoption of New Teaching Practices, Research Based Teaching Strategies, Mathematics Education, Inquiry-Based Learning

Reaching back over twenty years, many studies show that Research-Based Instructional Strategies (RBIS) help students learn in college, but that adoption and integration into undergraduate classrooms is stubbornly limited (American Association for the Advancement of Science, 2013; Laursen et al., 2019; Stains et al., 2018). While the use of RBIS can help provide student understanding of STEM (and other disciplines), their effectiveness is limited if their use is constrained. The Teacher Centered Systematic Reform Model (TCSR) provides a general structural model to assess incentives and barriers to adoption of RBIS (Gess-Newsome, 2003). The broad categories of enablers and barriers to adoption in this model include contextual, personal, and teacher thinking; these factors have been researched in studies that assess the relative contribution of factors in the implementation of active learning in college classrooms (Yik et al., 2022).

The departmental context is an important focus of many adoption studies. Departmental norms and expectations, both supporting and hindering active learning, have been studied as one factor for instructors adopting active teaching methods (Hora & Anderson, 2012). Some of the factors constraining adoption were related to teaching load and a lack of time to prepare lessons, perhaps related to prevailing practices in university departments (Henderson & Darcy, 2007). Pressures to achieve tenure and to publish, found in more research-intensive universities, act to constrain the amount of effort instructors can devote to course design (Lund & Stains, 2015). Prevailing norms and expectations linked to academic evaluation can also encourage or limit adoption of RBIS; if teaching is not valued or if alternative teaching methods are discouraged, instructors may be less willing to take risks with new teaching methods. More practically, classroom context, mainly large class sizes and classroom layout (e.g., places designed for group work), have also worked against adoption (Yik et al., 2022).

The personal characteristic of university instructors also plays into implementation decisions. These can include prior experience with active teaching, participation in professional development and beliefs and values related to teaching. Instructors who experienced or practiced inquiry-based teaching as graduate students were more likely to teach the same way later (Fukawa-Connelly et al., 2016), as are instructors who experienced RBIS as students (Yik et al., 2022). Participation in larger professional development initiatives such as Chem Connections, National Academies Summer Institutes on Undergraduate Education, or POGIL have been linked to greater use of active teaching methods (Dertling et al., 2016). Our current study used data from Project NExT (PN), a teaching initiative in mathematics. Participation in more short-term professional development efforts, usually conducted on college campus, have also been linked to greater adoption and implementation of alternative pedagogies.

While many studies have been conducted on factors influencing adoption, there are few that focus on teaching undergraduate mathematics. Yik et al. (2022) conducted the largest quantitative study to date on adoption, testing a wide range of factors from the TCSR model. These researchers compared the amount of lecture used by instructors in mathematics to chemistry and physics. While physics instructors spent significantly less time lecturing than mathematics instructors, instructors in mathematics lectured at similar rates to those who taught chemistry. However, no separate or interactive models were made to learn how other factors worked within the mathematics discipline. Johnson et al. (2019) examined many of the same factors found in the TCSR model with survey data from 219 algebra instructors, although they did not incorporate a regression model in their analysis. The researchers made comparisons between high, medium and low lecturing groups on a range of variables from the TCSR model. Significant group comparisons were found in teacher beliefs about student learning (e.g., "I think students learn better when they struggle with the ideas prior to me explaining the material to them."). Johnson's team found only small differences for departmental support between lecture groups, with instructors who were given more latitude in course design lecturing at lower rates than instructors whose teaching was more constrained by their departments.

Rationale for Study & Research Questions

Widespread adoption and implementation of RBIS provide the key to their effective use. Understanding what helps and hinders this adoption may spur adoption by addressing policies and practices that may encourage or stymie the use of more active instruction. Our research questions included:

1) What factors related to the TCRM model are associated with the amount of time instructors engage in formal lecture in their mathematics courses?
2) Is participation in the professional development workshop Project NExT associated with the amount of time instructors engage in formal lecture in their mathematics courses?

Method

Participants

Six-hundred-thirty-four (634) mathematics instructors answered the Alumni Survey, 492 former participants in Project NExT and 142 from a comparison group. On the survey, participants were asked to choose one course they had taught recently and report on their teaching practices. Calculus was the most frequently chosen course (31%), followed by Special Topics (e.g., higher division mathematics), Algebra (12%), and Other courses (28%). Demographically, participants were white (79%), with Asian (4.6%), Hispanic (3%) and Black instructors (1.1%) making up only a small percentage of respondents. Gender representation was nearly even with 50% of those answering the survey identifying as male, 44% as female and another 6% non-binary or preferring not to answer. Instructors reported teaching at the college level from three to 44 years with an average teaching career of 18 years. Of those instructors responding, 28% of respondents had been department chairs at one time during their time teaching, but only 3% had been deans. Having an advanced degree was a requirement for entering Project NExT; 96% indicated their terminal degree was a Ph.D.

Instrument

The Project NExT Alumni Survey was administered to a list of 1532 Project NExT Alumni obtained from the project with a response rate of (71%). The sampling frame for the Alumni Comparison Group Survey contained 882 names with response rate of 28%. While 902 mathematics instructors answered the survey, the current analyses used only 643 responses of those providing complete information about their teaching and described in-person and non-virtual classes. The survey was administered during the winter and spring of 2022.

The survey contained 47 items (many items with long lists of choices) asking about a range of topics related to careers as math instructors. These included: 1) the benefits of Project NExT or an alternate professional development project, 2) academic career activities, 3) participation in professional development, 4) participation in professional societies, 5) involvement in receiving grant money and research, and 6) expectations for evaluation of their work from their department, and a parallel section asking about the activities that brought respondents personal career fulfillment. The teaching component of the survey was based on the TAMI-S survey developed by our research team (Hayward et. al., 2017) and asked instructors to choose a course they had taught recently and estimate the amount of time they spent in a range of teaching activities (e.g., Lecture or Group Work). We also asked basic demographic questions as well as questions about time spent teaching at the college level, and the characteristics of their institution.

Analysis

Ordinary Least Squares (OLS) Linear Regression was used to estimate the individual contribution of variables on instructor responses to the item: *Please choose a course you have taught that represents your best teaching. What approximates the amount of time you spend in Formal lecture? (1, Did not use this activity, 1/3 or less, 1/3 to 2/3, 2/3 to all of class time).* The dependent variable was similar to that used in Yik et al. (2022) which asked instructors to report percentages of time spent in lecture.

The final regression model used 564 listwise responses from 26 variables. These variables were included as representing components of the TCSR model. For the sake of space, we reported only statistically significant predictors, and listed other variables tested but which were not statistically significant. We also compared both raw and adjusted mean differences for Project NExT using a simple ANCOVA procedure, adjusting the means for each group with the propensity covariate. We used the covariate in this manner only after checking the assumptions of the ANCOVA procedure.

The survey took place in the context of research on professional development at project NExT. As well as selection of PN Alumni, we selected a comparison group of instructors. These respondents were chosen through the Math Genealogy Project, a website that tracks the history of mathematics Ph.D's and their advisors. Instructors were chosen for the sampling frame by matching PN alumni with their graduate school colleagues who shared the same advisor and attended the same university program at the nearly the same time.

For comparisons between PN Alumni and the comparison group mentioned below, we used a propensity matching analysis to control for differences between groups (Benedetto et al., 2018). The propensity model provided information on how groups differed along many of the same variables used in the main analysis.

Results

Fifteen variables entered the regression model; the resulting R-squared value was $R^2 = 0.34$. Five-hundred and sixty-four (564) cases were used in the regression model. The greatest inverse predictors of time spent lecturing were academic evaluation expectations to use techniques other than lecture (Beta= -0.22) and participation in Project NExT (Beta = -0.19). Evaluation expectations to lecture (Beta= 0.15) and to use a variety of teaching methods were associated with greater use of formal lecture. Lecture was used less frequently in courses for education majors or non-majors (Beta = -0.13), and instructors who used active or inquiry-based methods during their early career tended to lecture less (Beta = -0.09). Other inverse predictors of lecture included involvement in equity and diversity in department or institution (Beta = -0.12) and collaborating with other instructors to promote changes in math teaching practices (Beta = -0.12). The number of campus professional development workshops instructors participated in predicted greater use of lecture (Beta = 0.08). Table 1 presents the Linear Regression Model for class time spent in formal lecture.

Other variables were tested from the TCSR model but did not enter our regression model. Non-significant variables included: Years teaching at college/university level, Department head or chair (past or present), Gender, Academic Department Expectation: Receiving High Evaluations of Teaching from Students (as evaluation criterion), Tenure Track Position, Teaching Load, Member of Minoritized Population, Highest Degree Offered at Institution, Member of (Specific) Professional Societies, and Participation in (Specific) Campus Professional Development efforts.

To better assess the association of participation in Project NExT with formal lecture we created a propensity matching model. This model used logistic regression to predict group membership in PN or the comparison group. The resulting probabilities of group membership derived from the logistic model were then used as a covariate in an Analysis of Covariance model (ANCOVA) that tests the differences in the mean estimates of time spent lecturing between groups and adjusts each mean to reflect the logistic probabilities. The propensity logistic model found statistically significant differences between groups favoring the PN group for the following variables: Served on National Committee, and Participation in Campus Professional Development. The variables favoring the comparison group in the propensity model included Highest Degree Offered, Receiving an Endowed Professorship or Other Honorary Post, and Years Teaching at University Level.

The ANCOVA comparison returned a statistically significant result for the main effect for program status (PN or Comparison) of $F = 16.02$, df 1,497, $p < .0001$**. This result tested the difference in means for Formal Lecture between groups with PN = 2.01 and Comparison = 2.94. These means were adjusted by the covariate to PN = 2.09 and Comparison = 2.62. As effect sizes, the difference between raw means was ES = -0.88; for adjusted means the effect size was

ES = -0.50. The result indicated that having participated in Project NExT was associated with less use of formal lecture in the classroom.

Table 1 Linear Regression Model Predicting Class time Spent in Formal Lecture

Discussion

The analysis of the Project NExT Alumni Survey data found significant effects predicting the amount of time instructors reported using formal lecture for a range of variables related to departmental expectations, personal expectations, campus professional development, course content and equity and diversity. The results support some of the previous findings related to the TCSR model (Gess Newsome, 2003).

The large attenuated effect seen for participation in the workshop professional development Project NExT reflected those seen in Yik et al. (2022) and various other research about teacher focused professional development (Dertling et al., 2016). Although this comparison cannot be considered causal in any way, the effect for participation in the PN program suggests that those who have participated in NExT tend to lecture less than those from the matched comparison group. This counters a previous assessment of the program that found little or no benefits for the PN program (Fukawa-Connelly et al., 2016). Participation in campus wide professional development was not predictive of lecture time by specific program although those participating in more types of professional development were slightly more likely to lecture. This countered findings from Benabentos et al. (2021) who found higher uptake of research-based methods for those using campus professional development services. Our result may have been related to the type of professional development we asked about including training in non-teaching activities such as grant writing.

Perceived departmental expectations for active teaching were also predictive of less time spent lecturing. Instructors who reported that their department evaluated them with the "expectation to use techniques other than lecture" lectured less. Conversely, departments with expectations for lecture reported lecturing more. Johnson et al. (2019) found only small effects for departmental expectations for instructors in designing their own courses, with those having more latitude less likely to lecture. This was similar to the small effect for our agree/disagree survey item: "In my department, I am mostly free to teach however I want". The findings that departmental evaluation criteria are predictive of time spent lecturing was seen in work by Seymour et al. (2011), generally with instructors feeling blocked from implementing active learning due to a lack of incentives for doing so and pressure to publish for tenure. Items asking about activities that instructors find personally fulfilling were also predictive of time spent lecturing including valuing "Teaching in more active and engaging ways". Other practical teaching expectations such as teaching load, tenure status and the importance of student teaching evaluations did not enter into our regression model, a result mostly consonant with the Yik et al. study (2022).

Collaboration with others was also found to be predictive of lecture time. Those who collaborated with colleagues to promote changes in math teaching practices were less likely to lecture. This reflects other studies on professional development and teaching practices (Bressoud & Rasmussen, 2015) where instructors shared experiences with innovative pedagogical practices. This perhaps extends to other areas of collaboration such as promoting student equity and diversity; those instructors who were involved in these efforts with colleagues were also less likely to lecture. Early career experiences seemed to impact current teaching for those who took our survey. Those agreeing with the statement : "I taught using active or inquiry-based methods during my early career" tended to lecture less, and those who agreed with "I taught large introductory-level courses during my early career" lectured more. The influence of early career experiences on teaching style is found in studies by Yik et al.(2022) and Lund and Stains (2015).

Like many models ours is under-identified. Because of constraints on data collection, we were not able to gather information about teaching thinking related to student growth mindset, an important part of the TCSR model (Gess Newsome, 2003) and a significant predictor of less lecture time in Yik et al. (2022). Similarly, variables of class size and class layout were not included in our model but were found to predict greater use of lecture in previous studies (Lund & Stains, 2015; Yik et al.,2022). Inclusion of these factors in future research would provide a more complete picture of enablers and barriers to implementation of active learning.

U-Substitution through Quantitative Reasoning: A Conceptual Analysis

Steven R. Jones
Brigham Young University

Leilani C. Fonbuena
Brigham Young University

Research has shown how crucial quantities-based meanings are for calculus concepts. While past work has developed important quantitative approaches to integration, the major topic of u-substitution typically has not been fully detailed in these paradigms. This theoretical paper extends this past work to clearly define and elaborate u-substitution through a quantitative perspective. We use conceptual analysis based on quantities, starting with a concrete example of a solar panel producing energy. We abstract from this example to define u-substitution as a transformation from one quantitative relationship, via nested multivariation, to another quantitative relationship. We also detail a three-part structure within this transformation.

Keywords: calculus, integrals, u-substitution, quantitative reasoning, conceptual analysis

A growing body of work has established that quantitatively-based meanings for calculus concepts such as derivatives and integrals are essential for robust student understanding and productive usage outside of math classes (Byerley, 2019; Jones & Ely, 2023; Oehrtman & Simmons, 2023; Thompson, 1994). For integrals, this means moving away from the purely "area under a curve" meaning in favor of a "sum of small bits" meaning (Ely, 2017; Jones, 2015; Sealey, 2006). Much work has been done in introducing integrals through this meaning and in helping students reason and model with integrals (Bajracharya et al., 2023; Blomhøj & Kjeldsen, 2007; Chhetri & Oehrtman, 2015; Sealey, 2014; Stevens & Jones, 2023; Von Korff & Rebello, 2012). Yet, integration chapters typically conclude with the major "u-substitution" method, which is the first in a long line of substitution techniques, and which is also utilized in the sciences and engineering to convert between quantitative expressions (see Koretsky, 2012). Unfortunately, the current literature does not adequately depict how to incorporate u-substitution into a quantitative paradigm. It would be detrimental to work toward quantitative meanings for integrals only to have this major method exist outside them. Treating u-substitution quantitatively would not only allow students to effectively *use* it, but to understand the mechanisms for *why* it works. To build on the important prior work on quantitative reasoning in calculus, in this paper we induct u-substitution into it as well. As the first key step, this paper focuses on the *theoretical* side of a quantitatively-based approach to u-substitution. We use a quantities-based conceptual analysis to define the quantitative relationships within u-substitution and its three-part quantitative structure. In a separate paper, we build on this theoretical work to engage in empirical examinations of learning u-substitution through a quantitative approach.

Brief Review of Closely Related Literature

There is a proposed quantitative structure for definite integrals called *adding up pieces* (AUP) (Jones, 2013; Jones & Ely, 2023). AUP is comprised of three parts: *partition*, *target quantity*, and *sum* (see also Dray & Manogue, 2023; Sealey, 2014; Von Korff & Rebello, 2012). *Partition* is taking a quantitative object (e.g., a length, a space, a time duration) and segmenting it into tiny pieces. If the pieces are essentially infinitesimal in size, they are called "differentials" and are denoted with a "*d*", as in dx or dt (Ely, 2020). In other words, a dx or dt can be thought of as an incredibly tiny Δx or Δt. While differentials can be rigorously formalized through limits or hyperreals (see Jones & Ely, 2023), the more loosely-defined "essentially infinitesimal" is quite common across the sciences and is a crucial idea for quantitative reasoning, even if no specific threshold is defined for passing from "Δ" to "*d*" (Amos & Heckler, 2015; Hu & Rebello, 2013; Pina & Loverude, 2019; Thompson & Dreyfus, 2016; Von Korff & Rebello, 2014).

Target quantity refers to determining the sought-after quantity within each partition piece (Jones & Ely, 2023). For example, if one is determining the distance travelled under variable velocity, and time has been partitioned into infinitesimal *dt* pieces, one conceptualizes that each *dt* piece corresponds to a tiny bit of distance travelled, *dD*. In AUP, any quantitative relationship can be used to determine the target quantity. The distance example uses a simple product, $D = v \cdot t$, but other quantitative relationships can be used when appropriate (Simmons & Oehrtman, 2017). Oehrtman and Simmons (2023) called the quantitative relationship that holds for constant values, such as $D = v \cdot t$, the *basic model*. If some quantities vary, such as a varying velocity, the essentially infinitesimal nature of the partition pieces allows this quantity to be considered essentially constant over each piece. Thus, the basic model can be applied to the infinitesimal partition piece, as in $dD = v \cdot dt$, which Oehrtman and Simmons (2023) called the *local model*.

With a conceptualization of tiny bits of the target quantity in each essentially-infinitesimal partition piece, *sum* refers to the literal summation of these target quantity bits to obtain the total amount of the target quantity. We follow Leibniz's convention (Katz, 2009) in using the integral symbol, $\int$, as a literal "sum" symbol. As an example, $\int_a^b v(t)dt$ is the summation of tiny distances (produced by $v \cdot dt$) across the many *dt* pieces, yielding the total distance.

Theoretical Lens: Quantitative Relationships and Multivariation

Thompson (Smith & Thompson, 2007; Thompson, 1990) defined a "quantitative relationship" as a system of three quantities where any two can determine the third. Thompson's three-quantity relationships can be represented as a triangle with a quantity on each vertex (Figure 1a). Jones (2022) elaborated on these quantitative relationships to create a set of distinct relationship types called *multivariation* (MV) relationships (though MV can also include relationships with more than three quantities). One MV relationship type is *independent MV*, where multiple inputs influence a single output, but where the inputs are independent from each other (Figure 1b). Another type is *dependent MV*, where all the quantities are co-dependent and a change in a single quantity implies changes in all others (Figure 1c). A third type is *nested MV*, where the quantities are structured in a chain of influence, congruent to the structure in function composition (Figure 1d). Our conceptual analysis of u-substitution in this paper relies heavily on Thompson's idea of a quantitative relationship and on the dependent MV and nested MV types.

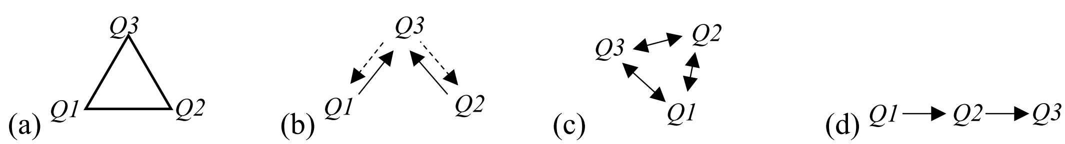

Figure 1. (a) Thompson's quant. relationship; with Jones' (b) independent MV, (c) dependent MV, (d) nested MV

Conceptual Analysis of U-Substitution: Starting with an Example Context

We begin our conceptual analysis with an example, from which we can abstract the general relationships. For our example, consider Figure 2a of a solar panel, with the sun rising at 6 am and reaching its zenith at 12 pm. The main quantities in this context are time (in hours, hr), the energy produced by the solar panel over a period of time (in kilojoules, kJ), and the power, or the rate at which energy is generated over time (in kilojoules per hour, kJ/hr). While a "watt" is a standard power unit (joules per second), we use kJ/hr to match the unit of time (hr), and to make the rate structure more obvious. Time, power, and energy are related by $E = P \cdot t$ (Figure 2b).

Notice that early in the morning there is less power because the sun makes a shallow angle with the panel. The power increases as the sun approaches its zenith, meaning that power is a function of time. In fact, we call time the main *input quantity* because it is an input both for the power, $P(t)$, and for the energy, $E(P, t)$. For this context, if we let 6:00 am be $t = 0$, we can use $P(t) = 1500 \sin\left(\frac{\pi}{12} t\right)$ kJ/hr as a reasonable model. The sine function suits the sun's increasing angle over time: it is zero at $t = 0$, increases from $0 \le t \le 6$, and is maximized at $t = 6$.

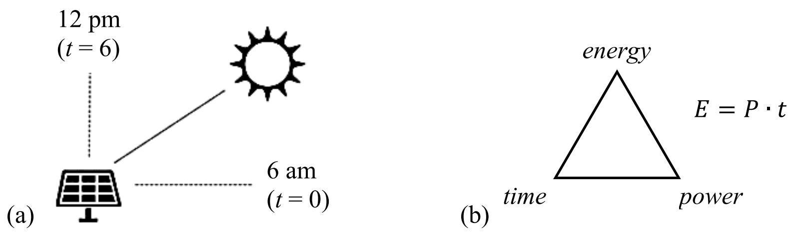

Figure 2. (a) A solar panel with varying power as the sun rises, and (b) the quantitative relationship in this context

The following initial question leads to a regular definite integral: How much energy is produced by the solar panel in this six-hour window? If power were constant over the six hours, we could use the basic model to calculate it: $E = P \cdot t$. But because power varies, we use the quantitative AUP structure to set up an integral. If we partition the six hour interval into essentially infinitesimal time intervals, *dt*, then we can assume power to be essentially constant over each interval. We can then use the local model $dE = P \cdot dt$ to capture the tiny bit of energy generated over a *dt* interval. Power, $P(t)$, is determined by a *t* value associated with the *dt* interval, so we can write our local model as: $dE = 1500 \sin\left(\frac{\pi}{12} t\right) \cdot dt$. We can then add up these bits of energy between $t = 0$ and $t = 6$ to find the total energy: $E = \int_{t=0}^{t=6} 1500 \sin\left(\frac{\pi}{12} t\right) dt$.

With this definite integral in place, we can now ask a different question that leads to u-substitution: What if we wanted to track the total energy in terms of the *angle* the sun makes with the horizon (in radians), rather than the time on the clock? This is the fundamental quantitative question we claim u-substitution is based on: How do you convert from one main *input quantity* to a different main *input quantity*? This conversion affects each of the three parts of the AUP structure. For the first part (partition), we need to determine what each infinitesimal *dt* piece corresponds to in terms of infinitesimal angles, *dθ*. For this conversion, notice that six hours corresponds to $\pi/2$ radians, three hours to $\pi/6$ radians, one hour to $\pi/12$ radians, and so on. In fact, for any time interval, the corresponding angle will always be $\pi/12$ as big, even at very small scales. Thus, $d\theta = \frac{\pi}{12} dt$, or equivalently $dt = \frac{12}{\pi} d\theta$, where the conversion factor $\frac{12}{\pi}$ has units of $\frac{\text{hr}}{\text{rad}}$. Switching from time pieces to angle pieces gives: $E = \int_{t=0}^{t=6} 1500 \sin\left(\frac{\pi}{12} t\right) \cdot \frac{12}{\pi} d\theta$. Of course, for this simpler context, the relationship between time and angle is linear at all scales. Later in the paper we examine a context where the relationship is *not* linear at all scales.

In tracking the units up to this point, we have $\left[1500 \sin\left(\frac{\pi}{12} t\right)\right] \frac{\text{kJ}}{\text{hr}} \cdot \left[\frac{12}{\pi}\right] \frac{\text{hr}}{\text{rad}} \cdot [d\theta]$ rad, which still yields a measure of kJ. This is valid quantitatively, though there is now a mismatch between defining part of the integral (the integrand) in terms of time and another part (the differential) in terms of angles. We also want to convert from power defined by time to power defined by angles. To do so, we note the nested MV relationship from *time → angle → power*, given by the function composition $\theta(t) = \frac{\pi}{12}t$ and $P(\theta(t)) = 1500\sin(\theta(t))$. However, if we no longer care about time, and only want to track the power in angles, this can become $P(\theta) = 1500\sin(\theta)$, leading to the integral expression: $E = \int_{t=0}^{t=6} 1500\sin(\theta)\frac{12}{\pi}\,d\theta$. Note that $1500\sin(\theta)$ still has units of kJ/hr, with the kJ/hr rate now determined by the angle. The factor 12/π still has units of hr/rad, so it is the entire "$1500\sin(\theta)\cdot 12/\pi$" that has units of kJ/rad.

While energy bits are now determined purely through the angle, $dE = 1500\sin(\theta)\cdot\frac{12}{\pi}d\theta$, the sum itself is still defined in terms of time. We want the sum to also be described in terms of the angle. Because $0 \le t \le 6$ hours corresponds to $0 \le \theta \le \frac{\pi}{2}$ radians, a sum running across *dt* pieces between $0 \le t \le 6$ hours covers the same ground as a sum running across $d\theta$ pieces between $0 \le \theta \le \frac{\pi}{2}$ radians. Thus, $E = \int_{\theta=0}^{\theta=\pi/2} 1500\sin(\theta)\frac{12}{\pi}\,d\theta$ and we have successfully described the total energy completely in terms of the *angle* as opposed to *time*.

Abstracting from the Example to a Quantitative Definition of U-Substitution

Before proceeding, we make some terminology clear. We have already used the term *input quantity* for the quantity that the other two depend on and that gets partitioned into infinitesimal pieces (*time*, in our example). We have also used *target quantity* to represent the quantity whose bits are added up by the integral and whose total amount is given by the value of the integral (*energy*, in our example). We introduce a new term, *integrand quantity*, for the quantity that functionally depends on the input quantity and that also combines with the input quantity to produce the target quantity. In our example, the integrand quantity was *power*.

With this terminology in place, recall that a definite integral answers the following question: If a target quantity is some combination of an input quantity and an integrand quantity, how can we determine its total amount if the integrand quantity varies over the input quantity? Relatedly, we claim that u-substitution now answers this question: How can we determine the total amount of the target quantity if we want to switch from tracking it in terms of the original input quantity to a new, different input quantity? This conversion is based on an inherent nested MV structure going from *original input → new input → integrand quantity*. In our solar panel example, the nested MV was $time \rightarrow angle \rightarrow power$, described by the function composition $P(\theta(t))$.

To provide a clear quantitative definition, we wish to use generic symbols for these quantities that are not specific to any context. We use "*a*" for the original input, "*b*" for the new input, "*Q*" for the integrand quantity, and "*T*" for the target quantity. In our solar panel example, "*a*" was time, "*b*" was angles, "*Q*" was power, and "*T*" was energy. Recall that for a basic integral, *a*, *Q*, and *T* are in a dependent MV quantitative relationship described by a Thompson triangle (Figure 3a). The nested MV relationship resides along the triangle's edge between the input quantity and the integrand quantity: *a* → *b* → *Q* (Figure 3b). Thus, *b* is always an intermediary between *a* and *Q*. We can now define u-substitution quantitatively as the act of shifting the vertex "*a*" of the

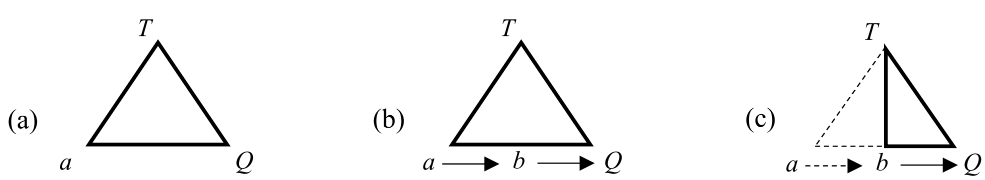

Figure 3. U-substitution as the transformation of the original dependent MV relationship (a); through the nested MV relationship between a, b, and Q (b); to a new dependent MV relationship (c).

original three-quantity triangle to the new input along this edge, “*b*,” thereby creating a new three-quantity triangle between *b, Q,* and *T* (Figure 3c).

The Three-part Structure within this Quantitative Definition

Having defined u-substitution as a transformation from one quantitative relationship to another closely-related quantitative relationship, as in Figure 3, we now examine the detailed structure contained within this transformation. Recall that the quantitative AUP structure for definite integrals contains three parts: *partition*, *target quantity*, and *sum*. U-substitution similarly contains a three-part structure, with the three parts corresponding to those in AUP.

The first part corresponds to AUP’s *partition* and involves converting the partition pieces from the original input quantity to *equivalent* partition pieces for the new input quantity. In the solar panel example, we saw that one cannot simply substitute *dθ* for *dt*, because it would change the size of the partition pieces. That is, a 0.001 second interval is not equivalent to a 0.001 radian interval, and a product between power and a 0.001 second interval does not yield the same energy as the product between power and a 0.001 radian interval. Rather, one must determine how big an infinitesimal piece of the new input quantity is in relation to an infinitesimal piece of the original input quantity. We call this part of the u-substitution structure: *differential* (Table 1).

The second part corresponds to AUP’s *target quantity*. It involves taking the integrand quantity that functionally depends on the original input and converting it to a functional relation based on the *new* input. In the solar panel example, power was dependent on time, and we converted it to a functional dependency on angle. This conversion permits the infinitesimal bits of the target quantity in each partition piece to be completely determined by the new input quantity, since both differential and integrand are now in terms of the new input quantity. We call this second part of the u-substitution structure: *integrand* (Table 1).

The third part is to re-describe the *summation*. The original sum is in terms of infinitesimal pieces of the original input quantity, and we need to instead describe it in terms of the new input quantity. In the solar panel example, we originally summed across infinitesimal time pieces between $0 \leq t \leq 6$, and we needed to switch to an equivalent sum across infinitesimal angle segments between $0 \leq \theta \leq \frac{\pi}{2}$. We call this third part of the structure: *bounds* (Table 1).

These three parts are exactly what enable the transformation from the original quantitative relationship to the new quantitative relationship by shifting the triangle’s vertex from *a* to *b*. If only some of these parts are enacted, the original input still exists as a vertex in the triangle, making it a four-quantity relationship in the triangle. While this is not incorrect, it creates issues for computation. In the solar panel example, when the differential in time was converted to a differential in angle, the quantitative structure still worked, but it was odd to have parts of the integral defined in one input quantity with other parts defined in another input quantity. Once the

Table 1. The three-part u-substitution structure, with original input a, new input b, and integrand quantity Q

Initial AUP parts	Corresponding parts in the u-substitution structure	
1. Partition: da	1. Differential: Convert partition from *da* pieces to equivalently-sized pieces in *db*.	$da \rightarrow [conversion]db$
2. Target quantity: $Q \cdot da$	2. Integrand: Convert integrand quantity, *Q*, from depending on *a* to depending on *b*. Target quantity now determined entirely by new input.	$Q(a) \rightarrow Q(b)$ $Q(a)da \rightarrow Q(b)[conv]db$
3. Sum: $\int_{a1}^{a2} Q(a)da$	3. Bounds: Convert sum from running across original input pieces to new input pieces.	$a_1 \leq a \leq a_2 \rightarrow$ $b_1 \leq b \leq b_2$

three parts of the u-substitution structure are enacted, the original input quantity's vertex is eliminated and the triangle transforms to the new vertex. Table 1 summarizes this three-part structure of u-substitution. Of course, we are quick to point out that in reasoning about u-substitution, one does *not* need to follow these three parts in a specific, prescribed order. Rather, it is possible to work through them in any order (see Oehrtman & Simmons, 2023).

Applying this Definition and Structure to Another (Non-Linear) Example

Having exposited the quantitative theory, we feel it beneficial to zoom back out to another contextual example to apply our quantitative definition and the three-part structure of the quantitative relationship transformation. We also use a context in which the relationship between the original input and the new input is *not* linear. Suppose a sphere is growing over time and we want to know the accumulated volume between $t = 5$ and $t = 10$ mins (Figure 4a, below). Note that at a given time the volume will grow at a rate proportional to its surface area, meaning there is a three-quantity relationship between *time*, *surface area*, and *volume* (Figure 4b). Here, time is the *input quantity*, volume is the *target quantity*, and surface area is the *integrand quantity*. Just to have something to work with, suppose the sphere's radius (in cm) is given by the function of time: $r(t) = t^2 + 5$ cm. Thus, surface area at any moment is $S(t) = 4\pi(t^2 + 5)^2$. Also, the instantaneous rate of radius growth is $dr/dt = 2t$ cm/min, so that for an essentially infinitesimal interval of time, dt, the radius grows by $dr = 2t \cdot dt$ cm. To more quickly get to u-substitution, we simply state that for an infinitesimal dt, volume will grow by the product of the surface area and the corresponding change in radius, leading to the integral: $V = \int_{t=5}^{t=10} 4\pi(t^2 + 5)^2\, 2t\, dt$.

We now ask the question specifically relevant to u-substitution: While volume grows over time, could we track its accumulation with respect to growth in the *radius* rather than *time*? This question is exactly what we claimed the domain of u-substitution to be. That is, we want to determine the total amount of the target quantity (volume), but we want to switch from one main *input quantity* (time) to another main *input quantity* (radius). Further, there is a nested MV relationship between *time* → *radius* → *surface area*, or $S(r(t))$ (Figure 4c). U-substitution will transform the original quantitative relationship into the new desired relationship (Figure 4d).

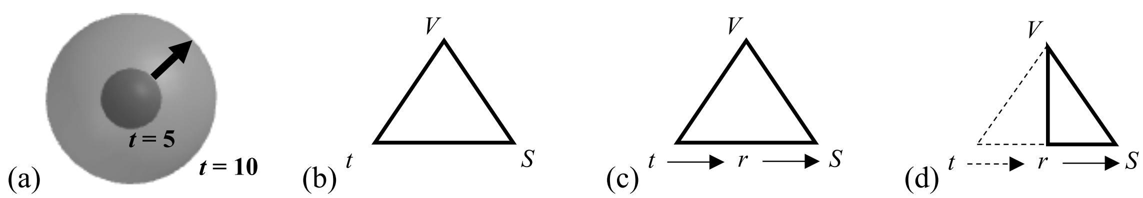

Figure 4. (a) growing sphere context; (b) time, surface area, volume quantitative relationship, (c) nested MV relationship between time, radius, and surface area, and (d) transformation to the new quantitative relationship

How do we enact this transformation? By using the three-part structure we proposed for u-substitution based on AUP. To show these can be done in any order, we purposefully use a different order here than for the solar panel example. First, the summation currently runs over *dt* pieces from $5 \leq t \leq 10$ min, but we could cover the exact same ground if we instead ran a summation over *dr* pieces from $30 \leq r \leq 105$ cm. This is the "*bounds*" part, making the integral so far: $V = \int_{r=30}^{r=105} 4\pi(t^2 + 5)^2\, 2t\, dt$. But the sum now is in terms of the radius, while all else is still described in terms of time. Second, we could re-describe the *integrand quantity* in terms of the radius. From the nested MV relationship, we have $4\pi(t^2 + 5)^2 = 4\pi\big(r(t)\big)^2 = S\big(r(t)\big)$, but since we want to eliminate time, we can rewrite this dependence simply as $S(r) = 4\pi r^2$. This is the "*integrand*" part, and makes the integral: $V = \int_{r=30}^{r=105} 4\pi r^2\ 2t\ dt$. Lastly, we need to convert the partition pieces in *dt* to partition pieces in *dr*. As explained before, a *dr* piece is not equivalent to a *dt* piece, so we need to know the conversion factor. While *t* and *r* do not have a linear relationship, we know that for any time *t*, dr will be exactly 2*t* times as big as *dt*: $dr = 2t \cdot dt$. This is the *differential* part and we now have a fully transformed integral from the original input quantity to the new input quantity: $V = \int_{r=30}^{r=105} 4\pi r^2\ dr$ (see Figure 4b-d).

Comparison to "Pure Math" U-Substitution

In a traditional "pure math" sense, u-substitution is depicted as undoing the chain rule: $\int_{x_1}^{x_2} f'\big(g(x)\big)g'(x)dx$. The procedure is to label the "inside" function, $g(x)$, as an arbitrary symbol "u", and to label $du = g'(x)dx$ in order to get $\int_{u_1}^{u_2} f'(u)\ du = f(u_1) - f(u_2)$. However, these symbols tend to be just notational conveniences and have little (if any) meaning, especially *du*. Here we show how our quantitative definition for u-substitution corresponds to this pure-math procedure and how it can provide conceptual meaning. If we think of *x*, f', and f as representing three quantities in a relationship, *u* is an intermediary quantity between *x* and f'. This is why *u* is always in a nested MV relationship with *x* and f', as in $x \rightarrow u \rightarrow f'$. In the quantitative paradigm, instead of *du* being just a notational convenience, $du = g'(x)dx$ actually represents the conversion factor from *dx* partition pieces to *du* partition pieces. Lastly, since we are converting from one input quantity to another, the switching of the bounds indicates a re-describing of the sum as it now ranges across infinitesimal pieces of the *new* input quantity.

Discussion

The contribution of this theoretical paper is to induct u-substitution into a quantitative paradigm, thereby extending the crucial prior work on quantitative reasoning in calculus (Jones & Ely, 2023; Oehrtman & Simmons, 2023; Thompson, 1994). In short, u-substitution deals with taking a quantitative relationship (Smith & Thompson, 2007; Thompson, 1990) in a definite integral and re-describing it through a *new* input quantity, where a nested MV exists between *original input → new input → integrand quantity* (Jones, 2022). We defined u-substitution as transforming this quantitative relationship by sliding the vertex from the original input to the new input. To fully accomplish this transformation, we described a three-part structure for u-substitution (*differential, integrand,* and *bounds*) that correspond to the three-part quantitative structure of AUP for definite integrals (Jones & Ely, 2023). These parts do not need to be executed in one specific order (Oehrtman & Simmons, 2023). In fact, a benefit to quantitative reasoning is actually reasoning about the context to flexibly carry out operations (Ely, 2017).

Our contribution allows for a quantitative reasoning paradigm in calculus based on informal infinitesimals (Ely, 2020) and AUP (Jones & Ely, 2023) to extend all the way through the introductory calculus curriculum, including u-substitution. This extension permits coherence across the entirety of the calculus course, founded on a reasoning type that has been shown to be extremely important for understanding and productive usage (Jones, 2015; Nguyen & Rebello, 2011; Oehrtman & Simmons, 2023; Pina & Loverude, 2019; Von Korff & Rebello, 2012). We are also building on this theoretical work through teaching experiments, teaching students u-substitution based on these quantitative meanings (which we report on in a separate paper). We believe that understanding u-substitution quantitatively in this way will enable students to actually understand the mechanisms behind it and to become more flexible users of it, as they can see what it means and the three-part structure for executing the quantitative transformation.

A Framework for Time and Covariational Reasoning

Kevin C. Moore
University of Georgia

Within the line of work on students' quantitative reasoning, researchers have alluded to the significance of time in constructing covariational relationships. I draw on this body of literature and return to Piaget's perspective on time to provide a framework for the role of time in students' (co)variational relationships. The framework also clarifies the nature of the multiplicative objects underlying students' (co)variational relationships. In support of illustrating the framework and capturing its emergence from building second-order models of students' mathematics, I also describe a task and how its design reflects the framework.

Keywords: Covariational Reasoning, Time, Piaget, Quantitative Reasoning

Time has long been a topic of contemplation for researchers and philosophers, and ontological and epistemological considerations of time are certainly not restricted to the academy. Kant (1781/2003) considered time to be so ubiquitous as to be given a priori. Differing from Kant, Piaget viewed time as a concept an individual constructs. Accordingly, Piaget dedicated several studies to developing conceptual models of that construction (e.g., Piaget, 1954; Piaget, 1970). Based on his findings, Piaget proposed that the mental operations involved in constructing time are inseparable from space, motion, and objects (Piaget, 1970; von Glasersfeld, 1984). Building on researchers who have alluded to covariational reasoning being connected to time, I return to Piaget's (1970) conceptual models for time to further develop the role of time in students' (co)variational reasoning. In doing so, I elaborate on the constructs of *experiential time* and *conceptual time* (Castillo-Garsow, 2012; Thompson & Carlson, 2017) to provide a framework for characterizing students' (co)variational reasoning in relation to concepts of time. Reflecting its empirical roots, I illustrate the framework by describing a task designed to provide insights into the role of time with respect to students' (co)variational reasoning.

Covariational Reasoning and Time

The connection between motion, variation, and the concept of time has been indicated within work on students' covariational reasoning (e.g., Ellis et al., 2020; Johnson, 2015b; Paoletti & Moore, 2017; Patterson & McGraw, 2018; Stalvey & Vidakovic, 2015; Thompson & Carlson, 2017). Covariational reasoning—defined as the cognitive activities involved in reasoning about how quantities vary in tandem (Carlson et al., 2002; Saldanha & Thompson, 1998)—is an emergent area of research within the landscape of quantitative reasoning. Researchers exploring covariational reasoning have illustrated its importance for the learning of concepts spanning middle, secondary, and undergraduate mathematics (Byerley & Thompson, 2017; Carlson & Oehrtman, 2004; Ellis, 2011; Ellis et al., 2015; Johnson, 2015a, 2015b; Moore, 2014; Paoletti et al., 2023; Thompson et al., 2017), with other researchers identifying its broader importance in STEM (Gantt et al., 2023; Rodriguez et al., 2019; Sokolowski, 2020; Yoon et al., 2021).

With respect to relationships between time and covariation or function, researchers have primarily focused on time as a parameter (Keene, 2007; Kertil et al., 2019; Paoletti & Moore, 2017; Patterson & McGraw, 2018; Stalvey & Vidakovic, 2015; Trigueros, 2004). These researchers have focused on the extent to which time is held implicitly or explicitly in mind by students as they construct and reason about relationships between quantities. For instance, Patterson and McGraw (2018) explored student meanings in the context of dynamic situations and their graphing quantitative relationships that did not include elapsed time as a graphed quantity. Relatedly, Paoletti and Moore (2017) explored how graphing experiences with quantitative relationships not explicitly involving elapsed time can create an intellectual need for time as a parameter. Taking a different approach, Stalvey and Vidakovic (2015) focused explicitly on students constructing relationships between elapsed time and two other quantities, and then their subsequent construction of a relationship between those two quantities.

Some of the aforementioned studies drew on notions of conceptual and experiential time, which Castillo-Garsow (2012) and Thompson (2011, 2012) introduced to characterize students' (co)variation. Having roots in Piaget's (1970) framing of time and Newtonian mathematics (Thompson, 2012), conceptual and experiential time are akin but not identical to explicit and implicit parametric distinctions. Whereas parametric distinctions focus on time as a distinct quantity, conceptual and experiential time are organic to quantities' (co)variation. Rather than framing time as implicit or explicit attribute in and of itself, time is framed as an emergent, intrinsic property of (co)variation that differs based on the (co)variation conception. Thompson (2012) described experiential time as "felt time that [passes]" in an experience, while conceptual time is part of the "flowing" of quantities and "Not time on a clock, but an imagined, smoothly changing, quantified time—a measured duration that grows in extent" (p. 147). The distinction between experiential and conceptual time is situated in how a phenomenon's attributes are conceived, reflecting Piaget's (1970) distinction between intuitive time and operational time.

Linking Piaget's Cognitive Account of Time and Covariation

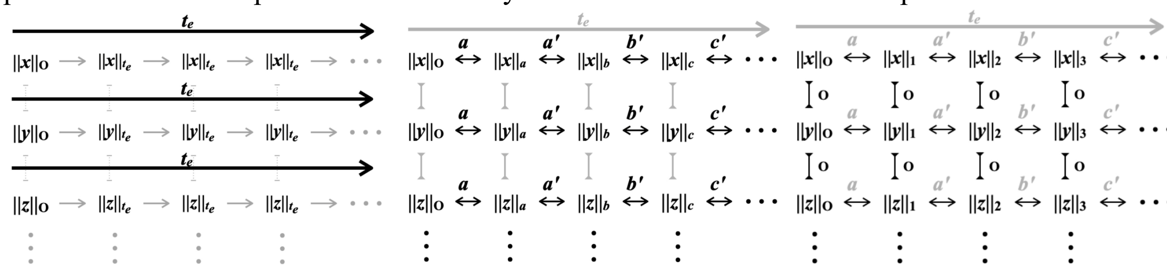
"We are far too readily tempted to speak of intuitive ideas of time, as if time, or for that matter space, could be perceived and conceived apart from the entities or the events that fill it" (Piaget, 1970, p. 1). Piaget considered time to be an emergent property of the co-ordination of simultaneous positions and the co-ordination of successive, spatial states. He referred to these co-ordinations as simultaneity and succession (with displacement), respectively, with their development occurring in the context of motions with different velocities. Piaget's view of time's link to conceptions of space and motion reflects his stance that concepts arise from the coordination and abstraction of mental actions. To Piaget, our temporal experience and memory of a situation are constructions subject to mental actions. We transition from intuitive to operative conceptions of time as we develop ways for organizing our experience that foreground operative forms of thought over experiential or figurative forms of thought (Piaget, 1970).

$$\begin{array}{ccccccccc}
\mathbf{O_1} & \xrightarrow{a} & \mathbf{A_1} & \xrightarrow{a'} & \mathbf{B_1} & \xrightarrow{b'} & \mathbf{C_1} & \xrightarrow{c'} & \cdots \\
\downarrow o & & \downarrow o & & \downarrow o & & \downarrow o & & \\
\mathbf{O_2} & \xrightarrow{a} & \mathbf{A_2} & \xrightarrow{a'} & \mathbf{B_2} & \xrightarrow{b'} & \mathbf{C_2} & \xrightarrow{c'} & \cdots \\
\downarrow o & & \downarrow o & & \downarrow o & & \downarrow o & & \\
\mathbf{O_3} & \xrightarrow{a} & \mathbf{A_3} & \xrightarrow{a'} & \mathbf{B_3} & \xrightarrow{b'} & \mathbf{C_3} & \xrightarrow{c'} & \cdots \\
\vdots & & \vdots & & \vdots & & \vdots & &
\end{array}$$

Figure 1. Piaget's co-seriation model of events, simultaneity, and succession. (Piaget, 1970, p. 264)

Piaget (1970) formalized the construction of simultaneity and succession of events as a grouping (i.e., co-seriation) shown Figure 1. $O_{\#}$ represents the initial state of event # (e.g., an attribute of an object/phenomenon like position in visual field, weight, or color). $A_{\#}$, $B_{\#}$, $C_{\#}$, and so on represent successive states of event #. a, a', b', c', and so on represent durations such that $b = a + a'$, $c = b + b'$, and so on. Piaget used $\downarrow o$ to link states of events occurring simultaneously (e.g., an object's weight and height), which can be thought of as a null vector due to the events' simultaneity. Piaget's (1970) model captures the multiplicative basis of co-seriation, in which events are united to form a *multiplicative object*—the cognitive uniting of attributes so that an object is simultaneously all of them (Inhelder & Piaget, 1964). As I illustrate below, constructing such an object is fundamental to the covariation of quantities (Saldanha & Thompson, 1998).

Drawing on Piaget's model of time and the simultaneity and succession of events, I present three conceptual models of time as it relates to an individual's conception of a phenomenon that entails quantities' magnitudes varying (e.g., $||x||$, $||y||$, $||z||$,…). The first model (Figure 2a) conveys a conception tied to experiential time. The second and third models (Figure 2b-c) each convey a conception tied to conceptual time. The second foregrounds the quantities as conceived with respect to elapsed time, while the third involves disembedding the quantities from the phenomenon and elapsed time so that they exist in an invariant relationship with each other.



(a) (b) (c)

Figure 2. Conceiving a phenomenon and quantities (a) with respect to experiential time, (b) with respect to conceptual, elapsed time, and (c) so they are disembedded with respect to time and understood in terms of their invariant relationship.

Adopting expression notation and restricting the focus to two quantities, we can represent Figure 2a, Figure 2b, and Figure 2c with $||x||_{t_e} \vee ||y||_{t_e}$, $(||x||_t \vee ||y||_t)$, and $(||x||_\Delta \wedge ||y||_\Delta)$, respectively. I use $||x||_{t_e} \vee ||y||_{t_e}$ with $\vee$ (OR) and no parentheses to indicate that when a phenomenon and its constituent quantities are conceived with respect to experiential time, the quantities are both understood as present and varying in experience. They are observed to co-occur, but they are not cognitively linked beyond that. A conception of their relationship involves sequentially recalling and possibly, but not necessarily, comparing the intuitive, in-the-moment experience of each quantity's variation. This is captured by the weak link between $||x||$ and $||y||$ in Figure 2a and foregrounding experiential time, t_e, with each quantity's variation.

I use $(||x||_t \vee ||y||_t)$ and $(||x||_\Delta \wedge ||y||_\Delta)$ to indicate a phenomenon and its constituent quantities conceived with respect to conceptual time, whether elapsed (t) or their relationship disembedded and understood with respect to variation (Δ) from another state. With respect to $(||x||_t \vee ||y||_t)$, I use parentheses to indicate that the quantities are understood as occurring simultaneously, but I use $\vee$ to indicate that elapsed time is the driver of the relationship such that each quantity exists in a multiplicative object with elapsed time but not with each other. The two quantities are related through their sharing a relationship with elapsed time. This is captured by the link between $||x||$ and $||y||$ in Figure 2b, which is stronger than that in Figure 2a but mitigated by the connection to elapsed time. With respect to $(||x||_\Delta \wedge ||y||_\Delta)$, I use $\wedge$ (AND) and parentheses to indicate that the quantities are understood as occurring simultaneously and persistently. One quantity's magnitude is held in mind with the "immediate, explicit, and persistent realization that, at every [magnitude], the other quantity also has a [magnitude]" (Saldanha & Thompson, 1998, p. 298). The quantities' magnitudes are the driver of the relationship, and thus properties of the relationship are understood as defining the multiplicative object formed by joining the two quantities' magnitudes and thus are sustained irrespective of elapsed time or figurative aspects of experience. This is captured by the link between $||x||$ and $||y||$ in Figure 2c, which indicates their simultaneous and persistent co-existence so that their covariation is defined precisely by their simultaneous variations. Figure 2b and Figure 2c each indicates a bi-directional relationship between states to reflect the operational nature of conceptual time (Piaget, 1970). Figure 2c indicates measured durations fade to the background so the relationship is not tied to any particular experience or measured duration.

Illustrating the Framework - Time and Task Design

The task illustrated here emerged during a teaching experiment with undergraduate mathematics education students as part of a larger project focused on capturing middle grades and undergraduate students' reasoning within dynamic situations (see Liang and Moore (2021), Lee et al. (2019), Tasova and Moore (2020), and Moore et al. (2019)). With respect to the task below, the project team drew on two sources of inspiration beyond the second-order models of student thinking that emerged during the teaching experiment (Steffe & Thompson, 2000; Thompson, 2008). As one source, we drew on the tasks demonstrated by Saldanha and Thompson (1998) and Carlson et al. (2002) that involve covarying quantities other than time. Tasks that prompt students to construct graphs with respect to time make it difficult for a researcher to tease out whether the student is reasoning with respect to conceptual or experiential time (Thompson & Carlson, 2017). The task below includes two distances (i.e., magnitude bars that provide figurative material to enact quantitative and covariational operations) with no reference to elapsed time. Piaget's (1970) aforementioned work on time provided the second source of inspiration for the task. Piaget described, "It is only by the co-ordination of at least two motions with different velocities that purely temporal relationships can be distinguished from spatial relationships or from intuitive ideas about motion" (p. 26). The task foregrounds relations of simultaneity and succession via prompting the participants to coordinate two objects in motion, with the two objects varying at different rates with respect to elapsed time.

The Task: Which One? – Going Around Gainesville (GAG)

"Which One? – GAG" is from a series of tasks titled "Which One?" A "Which One?" task is designed to be implemented after a participant constructs a covariational relationship within phenomenon or a graphical representation (Liang & Moore, 2021). A "Which One?" task provides several representations of covariational relationships, including magnitude bar sets that vary simultaneously or a collection of static or dynamic graphs. With the representations provided, the researcher asks the participant which of the representations, from none to all, accurately capture the relationship they identified previously (whence the name, "Which One?").

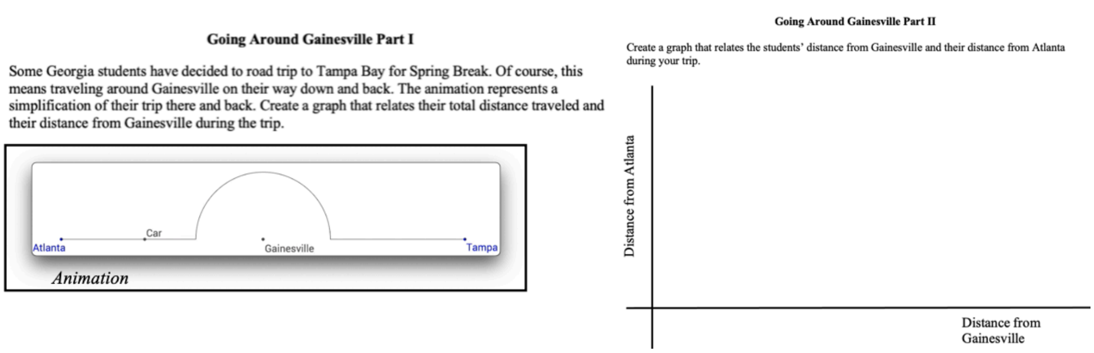


Figure 3. The Going Around Gainesville (GAG) task, video at: https://youtu.be/v2yc55Z9WV8.

The part preceding "Which One? – GAG" involves a video depicting a car starting in Atlanta and traveling back and forth from Tampa (Figure 3, see Moore et al. (2022) and Moore et al. (2019) for empirical data). After viewing the animation, the participant is sequentially asked two graphing tasks (Figure 3). After a participant engages in each part and has constructed what the research team perceives to be a stable understanding of the covariational relationship, the researcher implements the three-part task "Which One? – GAG". Each part consists of three pairs of magnitude bars presented in a *dynamic geometry environment* (DGE). As support for the reader, https://tinyurl.com/4v9ma7pc hosts videos illustrating each part and pair of the task. For Part I of the task (see Figure 4a for a snapshot), the participant is presented with three tabs, each containing a pair of magnitude bars. For each pair, one magnitude bar represents the *distance from Atlanta* (*dfA*) and one magnitude bar represents the *distance from Gainesville* (*dfG*). For each pair, the student can push "Drive" to start or stop the bars changing together, and the student can push "Reset" to return the pair to a zero-magnitude *dfA* and corresponding initial *dfG*. The participant is tasked with determining which, if any, of the pairs covary as to accurately capture the determined relationship between the *dfA* and the *dfG*. Table 1 describes the design of each magnitude pair. Pair B and C capture the normative relationship between the two distances.

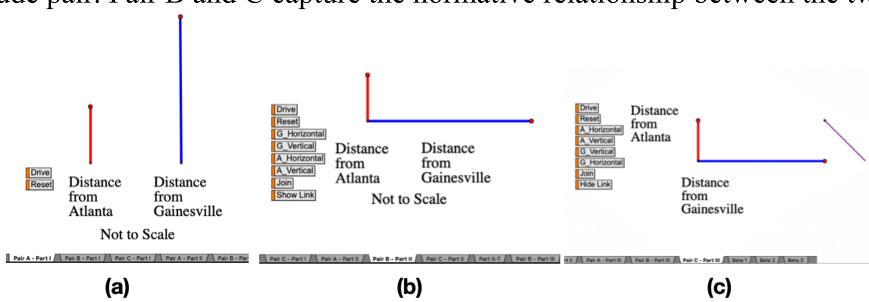

Figure 4. Example still shots for (a) Pair A – Part I, (b) Pair B – Part II, and (c) Pair C – Part III.

Table 1. The design of "Which One? – GAG".

RELATIONSHIP DESIGN	PART III
Pair A: With respect to *dfA*: *dfG* decreases at an increasing rate, decreases at a decreasing rate, remains constant, increases at a decreasing rate, and then increases at an increasing rate. When Drive is pushed, with respect to elapsed time: (i) *dfA* increases at a decreasing rate, increases at an increasing rate, increases at a decreasing rate, increases at an increasing rate, and then increases at a decreasing rate. (ii) *dfG* decreases at a constant rate, remains constant, and then increases at a constant rate.	Pair B: With respect to *dfA*: *dfG* decreases at a constant rate, remains constant, and increases at a constant rate. When Drive is pushed, with respect to elapsed time: (i) *dfA* increases at a decreasing rate, increases at an increasing rate, increases at a decreasing rate, increases at an increasing rate, and then increases at a decreasing rate. (ii) *dfG* decreases at a decreasing rate, decreases at an increasing rate, remains constant, increases at an increasing rate, and then increases at a decreasing rate.	Pair C: With respect to *dfA*: *dfG* decreases at a constant rate, remains constant, and increases at a constant rate. When Drive is pushed, with respect to elapsed time: (i) *dfA* increases at a constant rate. (ii) *dfG* decreases at a constant rate, remains constant, and then increases at a constant rate.	
Part II of the task (see Figure 4b for a snapshot) presents the same three pairs of magnitude bars, but they can reorient the magnitude bars, join then, and show a "link" between them. This link represents the process of joining two orthogonal magnitudes to form a Cartesian point. A participant is told that each pair matches its respective pair from Part I (e.g., Pair A in Part I, II, and III covary equivalently), and that Part II of the dynamic sketch is designed to help them further explore the extent the two magnitude bars capture the determined relationship between the two distances. For Part III of the task (see Figure 4c for a snapshot), the participant is again presented with the same three pairs of magnitude bars. In this case, each pair is oriented orthogonally, a Cartesian point is displayed, and a trace of the point is recorded as the magnitude bars covary. Like Part II, the participants are told that each pair matches its respective pair from Part I, and that Part III is to aid further exploring the extent the two magnitude bars capture the appropriate relationship between the two distances. During Part II and Part III, a participant is also prompted to reflect on and describe any changes in their assessment of the paired magnitudes. They can return to the previous parts if desired. They are also asked to reflect on difficulties from previous parts and how subsequent parts assist their assessment. Said frankly, Part I is intended to be difficult, both conceptually and in functional design, with the hopes of both eliciting their thinking and affording spontaneous requests for other representations.

Connecting the Task to the Framework

First focusing on Figure 2a (i.e., $||x||_{t_e} \vee ||y||_{t_e}$), and reflecting quantities' variations occurring in experiential time, a student reasoning in such a way attends to the variation of each magnitude separately, and they primarily do so through the experience of watching the DGE animated continuously using "Drive". With respect to Pair A, the student might conclude that *dfG* varies appropriately due to its smooth decrease, constancy, and then increase, while concluding that *dfA* varies incorrectly. For the latter, they anticipate that *dfA* increase at a smooth rate, which reflects the manner in which it increases during the experience of watching the road trip animation. With respect to Pair B, and consistent with their response to Pair A, the student might conclude that *dfG* and *dfA* vary inappropriately due to anticipating both increases or decreases at smooth rates, again reflecting how they experience the variations with the road trip animation. With respect to Pair C, the student is likely to conclude that both *dfG* and *dfA* vary appropriately due to the smooth variation of each. Across all of the pairs, the student primarily focuses on each magnitude separately and draws on intuitive or experiential notions of rate to draw conclusions.

For Figure 2b (i.e., $(||x||_t \vee ||y||_t)$), due to the basis in conceptual time, a student reasoning in such a way attends to the variation of each magnitude separately, but they coordinate the variation of each using successive durations of elapsed time. This might be accomplished by stepping through states of the DGE and tracking the variation of each quantity with anticipated properties in mind. With respect to Pair A, as the student tracks through successive, equal duration states of the DGE, the student might conclude that although *dfG* varies by constant amounts, *dfA* does not vary by constant amounts and thus the magnitude bars do not capture the appropriate relationship. With respect to Pair B, the student might comment on the difficulty assessing the pair using the DGE and thus seek to step through the DGE state by state. Reflecting that the quantities are cognitively linked through their shared relationship with elapsed time in this form of covariation, the student might attempt to "Drive" the bars for equal durations of time and then compare the variations of the magnitudes to each other. With respect to Pair C, the student is likely to conclude that the pair covaries appropriately due to the smooth variation of each, and they might further test this by using successive, equal durations of "Drive". Across all of the pairs, the student coordinates each magnitude with equal durations in order to draw comparisons across the magnitudes. Because of this, Pair B can lead to a perturbation that stems from the student anticipating equal variations in each quantity for equal variations in duration due to the piecewise linear relationship between *dfG* and *dfA*.

For Figure 2c (i.e., $(||x||_\Delta \wedge ||y||_\Delta)$), due to the basis in a disembedded invariant relationship, a student reasoning in such a way foregrounds coordinating a quantity's variation with respect to the other quantity's variation. Whether Pair A, B, or C, the student is likely to attempt to vary one quantity's magnitude in a systematic way while tracking the variations in the other quantity's magnitude. For instance, the student might use "Drive" to step *dfA* through successive, equal increases, and then assess the appropriateness of the pair by investigating whether the *dfG* magnitude follows the pattern of constant decrease, constant, and constant increase. A student engaging in such covariational reasoning might experience a perturbation stemming from the functionality of the DGE (e.g., it is difficult to use "Drive" to step through equal amounts of *dfA* increase), but they would not be significantly perturbed by how a single bar varies as the animation plays. They persistently foreground how the bars simultaneously covary, which can lead to expressing annoyance at Part I and motivating a need for Parts II-III and a graph.

Closing

The three forms of (co)variational reasoning differentiate (co)variation based on the role of time and, hence, the extent a multiplicative object is formed between the two quantities. The three forms invite questions regarding their developmental and hierarchical nature. The three forms emerged from work conducted primarily with undergraduate students, and I do not have second-order models of their developmental trajectory and relationships. I hypothesize the continued work by colleagues such as Ellis, Johnson, Lee, Paoletti, and Tasova will provide such insights. With respect to hierarchy, there is a relative increase in sophistication and generativity from Figure 2a to Figure 2c that is reflected in Piaget's exposition of time, as well as Carlson, Castillo-Garsow, Saldanha, and Thompson's descriptions of (co)variation. This relativeness is captured by Patterson and McGraw (2018), who described,

> We hypothesize that it is advantageous to be able to envision the covariation between two dynamically changing quantities and, to some degree, decouple this image of covariation from a unidirectional, experiential image of the passage of time. This process is essential for developing an understanding of an invariant relationship between two quantities and explaining how changes in one variable constrain changes in another variable. (p. 320)

The authors hedge in their hypothesis, as the process of decoupling quantities' covariation from experiential time is intrinsic to the form of covariation captured in Figure 2c and, more broadly, that suggested by Carlson, Castillo-Garsow, Saldanha, and Thompson. Constructing a multiplicative object between quantities' magnitudes necessarily involves decoupling images of variation from experiential or specific passages of elapsed time. It is then that two quantities' variations are taken as objects of thought and united so that an invariant relationship is constructed to constrain the two quantities' simultaneous variations. Although the forms have a hierarchical nature, the implications of such remain an open question. This is particularly true as it relates to how the forms of (co)variation play a role in students constructing concepts in which covariational reasoning provides a foundation, such as rate of change and accumulation.

Genre Theories and Their Potential for Studying Proof

Valentin A. B. Küchle
Auburn University

Paul C. Dawkins
Texas State University

In this theoretical report, we outline several major traditions of genre theory, argue that proof qualifies as a genre as defined by these traditions, and propose how genre analyses could be used to further our field's understanding of proof.

Keywords: genre, genre theory, proof, move analysis, critical genre analysis

Mathematics education researchers have engaged intensively with proof and the learning and teaching thereof, but rarely have they drawn on genre theories in this pursuit. In this theoretical report, we outline several major traditions of genre theory, argue that in line with these traditions proof is a genre, and propose how genre analyses could be used to further our field's understanding of proof.

A Brief Overview of Genre Theories

Since the 1980s, "genre" has received significant attention in the Anglophone world of applied linguistics from scholars of three research areas: English for Specific Purposes (ESP), Rhetorical Genre Studies (RGS) (sometimes referred to as "New Rhetoric" studies), and Systemic Functional Linguistics (SFL) (sometimes referred to as the "Sydney School") (Hyon, 1996, 2018b; Swales, 2012). All three traditions are united in viewing genre as a social practice (Tardy, 2012): ESP scholars define genre as communicative events (within discourse communities) with shared communicative purpose(s) (Swales, 1990), RGS scholars define genre in terms of the "action it is used to accomplish" (Miller, 1984, p. 151), and SFL scholars define genre as "a staged, goal oriented social process" (Martin et al., 1987, p. 59). As Tardy (2011) summarized:

> [The three traditions] agree on several general characteristics of genre as a category of discourse:
> - Genres are primarily a rhetorical category
> - Genres are socially situated
> - Genres are intertextual, not isolated
> - Genres are carried out in multiple—and often mixed—modes of communication
> - Genres reflect and enforce existing structures of power. (p. 55)

That said, the three traditions continue to differ, for example, in terms of: (a) the genres studied, (b) the attention paid to linguistic features, (c) the attention paid to institutional contexts, and (d) methods employed (Hyon, 1996, 2018b).

In addition to the three aforementioned traditions for studying genre (i.e., ESP, RGS, SFL), Swales (2012)—father of ESP genre theory—noted that there also exist "[t]he Brazilian approach to genre (Vian, 2012) and the Academic Literacies movement, sometimes known as the 'New London School'" (p. 113). Although it is incorrect to think of the Brazilian tradition as a monolith (Vian, 2012), it is correct to note that genre research in Brazil has been heavily influenced by Bakhtin's (1986b) work on genre (Gomes-Santos, 2003) and, albeit it to a lesser extent, socio-discursive interactionism (Bronckart, 1997). The Academic Literacies movement finds the ESP tradition too textual and pushes for a greater focus on academic practices (Swales, 2012). For discussion of further traditions of genre theory, see Vian (2012).

The Genre of Proof

In this section, we argue that proof satisfies Tardy's (2011) five characteristics of genre. We thereby wish to justify applying genre theories (particularly ESP, RGS, and SFL) and genre analyses to the genre of proof.

Proof Is Primarily a Rhetorical Category

By being "primarily a rhetorical category," Tardy (2011) meant that "what makes a text a genre is not its linguistic form but the rhetorical action that it carries out in response to the dynamics of a social context" (p. 55). As Hanna (2000) listed, proofs can be used to, for example, verify, explain, systematize, discover, communicate, construct, explore, and incorporate.[1] And, Hanna (1989) argued, some of these functions (i.e., rhetorical actions) may be more appropriate in certain social contexts—"proofs that explain should be favored in mathematics education over those that merely prove" (p. 45). That dynamics of different social contexts can lead to different rhetorical actions was also demonstrated by Schifter (2009): In one elementary school classroom, students used a proof as an aid to understanding; in the other, students used a proof to convince. In short, we argue that proofs serve a set of communicative purposes that depend on the discourse community in question, that is, as primarily a rhetorical category.

Proof Are Socially Situated

To assert that proofs are "socially situated" according to Tardy (2011), we should be able to observe that conventionalized forms of proof are tied to their socio-rhetorical context (e.g., a class of 4th graders and their teacher, Poisson geometers). Stylianides's (2007) frequently cited definition of proof acknowledges this centrality of the socio-rhetorical context by qualifying that accepted forms of statements, modes of argumentation, and modes of argument representation used in proofs are only "accepted" in that they are endorsed *by the classroom community*—or, as we would amend using ESP terminology, a given discourse community.

To underline that proofs are socially situated and that their form is tied to their socio-rhetorical context, consider the following three examples: (a) a two-column proof in a high school geometry classroom, (b) a proof by Gauß in *Disquisitiones Arithmeticae*, and (c) a proof told as a first-person singular narrative (e.g., "First, I noticed that if you take …") in an elementary school classroom. All three proofs vary significantly in form but, assuming their veracity, are valid forms of proof within their socio-rhetorical contexts.

Proof Are Intertextual, Not Isolated

"[T]he communicative work that genres do is almost never carried out by isolated, single texts. Rather genres work in coordination to accomplish complex tasks and social goals" (Tardy, 2011, p. 58). Below, we outline two ways in which proofs are intertextual.

First, proofs often explicitly reference previously proven statements (e.g., "By Proposition 4.2, …"). Thus, deliberate connections are made in proofs to other texts. All such intertextual references in proofs must be carefully organized so as to avoid circular reasoning. More generally, all proofs implicitly reference axioms and/or previously proven statements due to how mathematical theories are logically organized as inverted pyramids.[2]

---

[1] We acknowledge that although "verifying" is not the only communicative purpose of the genre of proof, it is a central one, and it is hard to make sense of proof without thinking about proving that a statement is true or false.

[2] In this analogy, the point of the inverted pyramid is axioms, upon which a progressively broader set of theorems is built.

Second, proofs are intertextual in that they work in coordination with other genres, such as definitions, theorems, and remarks. (Mariotti, 2006, argued that proofs must be understood as a triad of proof, statement, and background theory.) Often, a definition is followed by the statement of a theorem (or proposition or lemma) about the just-defined object or property, which is then proven. After the proof, an author may make a remark, which offers, for instance, observations about the just-finished proof. (For a genre analysis of remarks that illustrates different communicative purposes of remarks, see Küchle, 2023.) Sequences of definitions, theorems, proofs, remarks, and other mathematical genres (e.g., examples, exposition) can combine to form larger narratives (e.g., a sequence culminating in Lagrange's Theorem)—narratives that university instructors can backwards engineer.

Proofs Are Carried Out in Multiple—and Often Mixed—Modes of Communication

As O'Halloran (2015) noted, mathematics is multimodal: Mathematics uses linguistic, symbolic, and visual forms of representation. We assert that proof is also multimodal: Proofs consist of words, symbols, and images (e.g., graphs, diagrams). Yet, we acknowledge that although the value of images during proof-production has been suggested (e.g., Alcock & Weber, 2008; Weber & Alcock, 2004), the question remains to what extent a valid proof may be visual. Larvor (2019) addressed this question by showing that although not all types of diagrammatic inferences are typically allowed in proofs, there is a class of such inferences that are often allowed. In addition to satisfying certain diagram characteristics (Larvor, 2019), we believe that a proof's socio-rhetorical context—context that includes level and subdiscipline of mathematics—contributes to the permissibility of images in proof.

Proofs Reflect and Enforce Existing Structures of Power

As Dawkins and Weber (2017) noted, there are values and norms at play in proof-writing. Further, where there are values and norms at play, power dynamics emerge. Thus, Tardy (2011) deduced, "[genres] must be viewed as not just a reflection but also a reinforcement of the power structures that exist in the community within which they are used" (p. 60). Indeed:

> Genres are forms of "symbolic power" (Bourdieu, 1991, p. 163) and could be forms of "symbolic violence" (Bourdieu, 1991, p. 139) if they create time/spaces that work against their users' best interests and their users perceive them as naturalized or "just the way we do things around here." (Schryer, 2002, p. 76)

Thinking about the educational setting, Tardy (2011) observed: "School genres […] inherently situate students in low-power positions, subject to the evaluation and preferences of teachers, who serve as gatekeepers" (p. 60).

Tardy's (2011) observation about school genres also holds for proofs in educational settings. Even proofs written by research mathematicians for publication are subject to a power difference between the authors in low-power positions and the editors and reviewers as gatekeepers. In educational and academic settings, the person(s) in high-power positions uses their set of values and norms to evaluate the proof of the person(s) in low-power positions (see Tanswell & Rittberg, 2020). For instance, a proof may be considered "too verbose" or "make too many omissions." That these types of critiques are subject to bias and can (re)enforce existing structures of power—in our case, white supremacist capitalist patriarchy (hooks, 2015)—can be seen by considering the example of Su's (2020) student Akemi, whose proofs stopped receiving full marks once the teaching assistant found out Akemi was a woman.

To see how proofs may reflect existing structures of power, consider the language in which they are written:

> [T]he mode in which mathematic is usually written and spoken is one of advocacy, of claims and assertions, one which generally ignores its audience. It is a language which I feel is more easily adopted by men than women, if we can believe what we are told about women using fewer declarative sentences in conversation. And it is a language, which particularly, when spoken, is frequently abused with impatience, frustration, and defensiveness. (Keith, 1988, p. 8)

Thus, proofs—and the language they are written in—may reflect stereotypical traits of masculinity (Hottinger, 2016; Weber & Melhuish, 2022).

Summary

We contend that proof satisfies Tardy's (2011) list of five genre characteristics on which the three central Anglophone traditions of genre theory can agree. Thus, we feel justified in applying these theories' genre analysis tools to the genre of proof.

Analysis Possibilities

In this section, we explore two types of genre analysis from the three traditions and see how they could be applied to the genre of proof.

Move Analysis

In the ESP tradition, a genre is often studied by conducting a move analysis, which focuses on moves, "those textual segments that make up a genre's organizational structure and help the genre achieve its purposes" (Hyon, 2018a, p. 27). They are functional units (i.e., they are not about what a text is saying but about what the text is doing) and can be thought of as mini communicative purposes (Hyon, 2018a). For example, a common move in research article introductions is "establishing a niche," which can be realized by, for instance, indicating a gap in research (Swales, 1990). As Bhatia (1993) noted, moves need not occur linearly; they can also be interactive (e.g., in legislative texts, legislating and specifying can be thought of as a two-part interactive move).

A common goal of performing a move analysis is to determine a move structure that can be shared with students to aid their learning (Hyon, 2018a). To this end, mathematics education researchers could use, for example, Hyon's (2018a) stages of a move analysis—based on Biber et al.'s (2007) and Upton and Cohen's (2009) approaches. A move such an analysis might yield is *indicating deduction*, which authors realize in many ways (e.g., "[X]. Thus/hence/therefore, [Y]", "Since/Because [X], (it follows that) [Y]", "If [X], then [Y]", "From [X], we get that [Y]", or "[X] implies that [Y]"). This move can serve several common communicative purposes of proof: by *indicating deduction*, the author is able to more easily *convince* the reader since the text has been *systematized* and aids the reader's *verifying*. Other example moves might include setting a goal or initiating a proof technique.

A move analysis may also shed light on cross-cultural differences, be they differences between, what Holliday (1999) termed, "large cultures" (e.g., proofs in Germany versus those in the U.S.A) or "small cultures" (e.g., proofs by undergraduates in an introduction to proof [ITP] course versus those by research mathematicians) (Hyon, 2018a).

To illustrate what a cross-cultural difference might look like, consider our following informal observation. While skim-reading proofs in research papers and in first-year lecture notes, we noticed that mathematicians-as-teachers frequently *(re)express the statement to be proved*—a move seen but once in the research papers. Consider the following examples from Linear Algebra, Abstract Algebra, and an ITP course:

Proposition 5.3. Let $T : U \to V$ be a linear map. Then:
(*i*) im(T) is a subspace of V;
(*ii*) ker(T) is a subspace of U.
Proof. For (*i*), we must show that im(T) is closed under addition and scalar multiplication. […]

Theorem VI.6. *Let G be a group and a, b* $\in G$. *Then* $(ab)^{-1} = b^{-1}a^{-1}$.
[…]
PROOF. We're being asked to prove that $b^{-1}a^{-1}$ is the inverse of ab. So we want to show that $(b^{-1}a^{-1})(ab) = 1 = (ab)(b^{-1}a^{-1})$. […]

Example 8.11. State whether the following sets are bounded or unbounded and prove your answer. […]
(b) $B = (-\infty, \sqrt{2})$. […]
Solution: […]
(b) $B = (-\infty, \sqrt{2})$ is unbounded. We will prove this by showing that for all $M \in \mathbb{R}$ we can find $x_0 \in B$ such that $|x_0| > M$. […]

(Re)expressing the statement to be proved seems pedagogical in nature as it breaks down what needs to be shown. Although this move may seem innocuous, we would like to point out its potential for "deceiving" the student into thinking that nothing has happened. Yet, (re)expressing, or "unpacking," what needs to be shown is often a key step in first-year proofs, which frequently amount to rewriting/seeing something in a new way. Therefore, this move can significantly simplify the proof. Although the move might be thought of as the instructor modeling "good" proof behavior, it also removes the opportunity for students to do this work themselves. The study of e-Proofs suggests that in the interplay between work done for the student reader by the author and work done by the student reader to make sense of the proof, sometimes learning is supported better when the student reader's work is not co-opted by the text (Alcock et al., 2015).

In short, given differences in intended audience and discourse community, proofs written by mathematicians-as-researchers and mathematicians-as-teachers will serve slightly different communicative purposes—recall Hanna (1989) asserting that "proofs that explain should be favored in mathematics education over those that merely prove" (p. 45). Differences in communicative purposes entail differences in moves (i.e., mini communicative purposes), and we posit that the field of mathematics education may benefit from studying mathematicians-as-teachers' proof moves and the extent to which these indeed facilitate student learning.

Critical Genre Analysis

As argued above, the genre of proof reflects and enforces existing structures of power. To study how genres do so, some genre researchers have performed critical genre analyses (e.g., Hyatt, 2005; Levina & Orlikowski, 2009). Rather than being a singular type of analysis, critical genre analyses differ in their methodologies but are connected by their focus on power structures, relations, and imbalances. For example:

- Hyatt (2005) performed a corpus analysis of tutor feedback (and noted the potential for a critical discourse analysis [Fairclough, 2003] to complement the analysis);

- Levina and Orlikowski (2009) performed a qualitative study, as part of which they identified genres in the management consulting field and then "examin[ed] how control over genre enactment was exercised […], as well as who had competence in and participated in the various genre enactments, and how." (p. 678); and
- Schryer (2002) combined a rhetorical analysis with a critical discourse analysis (Hodge & Kress, 1993) to create a chronotopic (Bakhtin, 1981) analysis of "bad news" letters by an insurance company.[3]

Below, we discuss bias and author–reader–proof-text relations[4], before offering our thoughts on what a critical genre analysis of proof could look like.

First, consider that different readers receive a text differently, that is, a text is not reader-independent. A reader's past experiences with a genre shape their expectations for contemporary realizations of the genre. More broadly, discourse communities have and use their own genres, which are understood against a horizon of expectations that has developed over time (Swales, 2016). In addition to a reader's past experiences with a genre, Akemi's example from before suggests that the reader–author relation (shaped by the reader's context and biases) also affects the reader's reading of text. Given how heavily U.S. mathematics departments lean non-Hispanic White (77%) and male (70%) (Blair et al., 2018)[5], women and people of color are most likely to be targeted by readers' implicit and explicit biases.[6]

"Properties" of proof—like *convincing*, *transparent*, or *perspicuous* (Czocher & Weber, 2020)—are not so much properties as they are author–reader–text relations. They can be used to weave a set of contradictions that will always ensure that a proof is not good enough for a biased reader. The reader might claim the proof was unconvincing because it was too short or that the proof—perhaps amended and increased in length—is not perspicuous and untransparent. Minoritized students receiving negative (and possibly contradictory) feedback is concerning as it can lead to a loss of confidence and contribute to an unsupportive culture—reasons identified as leading to undergraduate and graduate students leaving STEM, particularly minoritized students (Herzig, 2004; Thiry et al., 2019).

Second, note that an author's awareness of the (hypothetical) reader(s) shapes their writing. SFL scholars would observe that proofs do not merely serve an ideational function but also an *interpersonal* function (and a textual function). ESP scholars would note that a communicative purpose is shaped by *discourse community* and *intended audience*. RGS scholars would point to genre being a *social* action. Finally, Bakhtinian scholars would point to the importance of an utterance's *addressivity*. For example: An author of a journal article will be trying to convince the reader that the proof is novel, important, and gives due credit to prior work, whereas a student seeks not only to convince the instructor of the veracity of their proof, but also of their knowledge. In short, regardless of how much proof genre conventions suppress agency, a proof is not author-independent, and the author's shaping of the text is affected by their awareness of the (hypothetical) reader(s). (Whether the shaping achieves the author's goals is a different matter.)

---

[3] Although Schryer (2002) did not label her work a critical genre analysis, she termed it a "critical approach to genre theory" (p. 76) and a way to "address the issue of genre and power" (p. 76).

[4] The triangle of author–reader–text relations (within contexts) is sometimes referred to as the rhetorical triangle.

[5] Percentages refer to full-time faculty in mathematics departments of four-year colleges and universities in fall 2015.

[6] Proof readers' bias is not just concerning with regard to university students, but also with regard to researchers. Single-blind journals are prevalent in mathematics alongside a culture of publishing preprints on arXiv. As a research mathematician friend of ours remarked, "I've never reviewed a paper I didn't know the author of."

Combining our observations about readers' biases and authors' awareness of their (hypothetical) reader(s), we note that an author's awareness may also include an awareness of their (hypothetical) reader(s)'s biases. For example: A friend of ours vividly remembers changing a proof to include more "powerful" mathematical ideas ("sledgehammers") to make her proof more convincing and beyond (anticipated) reproach.

Given the breadth of what constitutes a critical genre analysis, there are many possible avenues to pursue with the goal of studying power structures, relations, and imbalances as they pertain to the genre of proof. Drawing on our above observations and the view that criteria such as "convincing," "perspicuous," and "transparent" are prone to biased application, we believe it might be fruitful to ask: "What criteria do readers of proof apply when evaluating proofs, and how do they apply these in biased ways?" By studying the feedback that proof readers give—and to whom they give it—awareness can be fostered for the subjective nature of proof evaluation criteria. Further, revealing how biases interact with the application of proof evaluation criteria can provide a starting point for raising awareness of this problem within the discourse community of (research) mathematicians.

Finally, as aforementioned, proofs may reflect existing structures of power and stereotypical traits of, among others, masculinity (Hottinger, 2016; Weber & Melhuish, 2022). This observation raises the question of how proofs can be reenvisioned and rehumanized (Gutiérrez, 2018). For some examples thereof, consider Harron (2016), Sinclair (2005), Leron (1985), and Tymoczko (1993). A critical genre analysis could be used to identify the (invisible) constraints of the genre of proof (which hinder reenvisioning and rehumanizing proof) and how they reflect and enforce existing structures of power (e.g., Bowers & Küchle, 2020).

Conclusion

In this theoretical report, we hope to have given the reader a brief overview of contemporary genre theories, argued that proof is a genre for the purposes of (at least) three major genre theories, and outlined the potential of move analyses and critical genre analyses for advancing the field of mathematics education. But there are many more types of genre analysis mathematics educators could pursue, such as:

- a rhetorical appeals analysis (i.e., appeals to logos, pathos, and ethos);
- a lexico-grammatical analysis (e.g., of frame markers, attitude markers, hedges, and boosters) (SFL, in particular, offers a plethora of lexico-grammatical analysis tools);
- a historical or diachronic study of genre to understand the evolution of a genre;
- an ethnography to learn about the relevant discourse community;
- a genre systems analysis (or genre network analysis) to learn about the relationship among genres (and the relationship between genres and community);
- an intertextual analysis to, for example, understand references to other texts;
- a multimodal genre analysis. (Tardy, 2011)

Further, Bakhtin (1981, 1986a) has served as inspiration to genre theorists—particularly of the Brazilian tradition—and offered a whole set of possibly useful concepts, such as, carnivalesque, chronotope, dialogism, heteroglossia, and polyphony. In short, genre theories offer a whole host of analytic tools that, we argue, may be applied to the genre of proof to advance our field.

Student Happiness in Mathematics: Antecedents of Positive Emotions

Fern Van Vliet
Arizona State University

S. Katherine Nelson-Coffey
Arizona State University

Students often express negative emotions in mathematics classes. Positive emotions feel good, but they are important beyond just feeling good. Positive emotions can benefit learning, attitudes, and perceptions of mathematics. In this paper, we discuss why positive emotions are beneficial along with a literature review of common themes which are associated with positive emotions among students. For example, increases in students' perceptions of personal control and value in the classroom have been associated with increased positive emotions. Many practices already encouraged by mathematics education researchers (e.g. teaching conceptually, helping students find mathematics important) have the added benefit of potentially increasing positive emotions in students. Positive emotions have been shown to be associated with engagement and motivation in mathematics. By increasing positive emotions in the classroom, instructors can encourage the gradual growth of positive attitudes and beliefs about mathematics to students which are currently lacking among many students.

Keywords: positive emotions, affect, happiness

Happiness and wellbeing in education have become increasingly emphasized in psychological and educational research. The Programme for International Student Assessment (PISA) has been including measures for student affect and wellbeing in their assessments of students around the world since 2015 (Govorova et al., 2020). In a recent survey of 21,678 US high school students, 75% of students reported that they typically experience negative feelings at school, with the most frequently mentioned feelings including tired, stressed and bored (Moeller et al., 2020).

It is well documented that students have similar negative feelings towards mathematics. For example, students report finding mathematics boring, unimportant to their lives, and a generally negative experience (Brown et al., 2008; Hernandez-Martinez & Vos, 2018; Zazkis, 2015). Emotions in the classroom have been found to be connected to engagement and motivation with mathematics and attitudes towards mathematics both in the short and long term (Brown et al., 2008; Middleton et al., 2017; Middleton et al., 2023). Negative emotions have been associated with reduced motivation and negative attitudes (Brown et al., 2008; Middleton et al., 2023). While, positive emotions have been connected to increased motivation (Middleton et al., 2023). Given the prevalence and potential consequences of negative emotions about mathematics, more work is needed to consider how students' emotions about and during mathematics can be improved. We suggest that cultivating positive emotions in mathematics would offer new perspectives for this pervasive problem.

Robust evidence demonstrates the positive association between positive emotions and achievement (Camacho-Morles et al., 2021; Coffey, 2020; Villavicencio & Bernardo, 2016). For example, Coffey (2020) found that positive affect at at age 1.5 years directly predicted higher educational attainment at age 29. In a meta analysis of 68 studies, Camacho-Morles et al. (2021) found a positive relationship between enjoyment and academic performance. Thus, positive emotions are associated with lasting benefits for academic achievement.

The benefits of positive emotions in mathematics likely accrue over time. According to the Broaden and Build Theory, positive emotions are associated with two categories of benefits (Fredrickson, 2001). First, positive emotions *broaden* awareness. People experiencing positive emotions are more aware of the "big picture" and able to take in a wider range of information. For example, smiles have been associated with increased breadth of attention (Johnson et al., 2010). Second, when in a broadened state of awareness from positive emotions, people are able to *build* more resources for themselves. This building of rescources has been associated with greater cognitive flexibility in an experimental task among participants in a positive emotion condition (Wang et al., 2017). Further, genuine smiles (Duchenne smiles) have been shown to predict increased flexibility in attention on an orienting task (Johnson et al., 2010).

Given these potential benefits of positive emotions in mathematics, an important area of research also involves understanding the factors that may predict positive emotions. We now review existing literature exploring the correlates of positive emotions in educational settings, which may inform strategies for educators or researchers interested in promoting positive emotions in mathematics classrooms. We begin by discussing student characteristics on an individual level that are associated with positive emotions. Then, we zoom out and discuss predictors within the classroom environment which are associated with positive emotions.

Student Cognitive Appraisals of Control and Value

Control Value Theory (CVT) posits that students' personal appraisals of a) *control* and b) *value* of the material are proximal antecedents of emotions related to achievement (Pekrun, 2006; Pekrun, 2021). Students' control appraisals describe how much control or influence students perceive they have over events, and value appraisals describe how much importance or worth students give to a particular object of focus (e.g. an exam, mathematics in general; Pekrun, 2006; Pekrun, 2021). Control and value appraisals can operate independently; thus, students can experience a combination of high and low appraisals of control and value. For example, a student may feel that they are able to answer every question on their homework assignment easily (high control), but the same student may feel that the homework is boring and unimportant (low value). According to CVT, students experience more positive emotions when they have high levels of both control and value (Pekrun, 2006; Pekrun, 2021).

Control Appraisals

Higher perceptions of control are generally associated with more positive emotions from students in math classes (Bieg et al., 2017; Bieleke et al., 2023; Buff, 2014; Buff et al., 2017). However, students on average report low feelings of control in the classroom (Bieg et al., 2017). These reported low feelings of control may be related to the many aspects of the classroom that are decided by teachers or administrators (e.g. assignments, exams; Bieg et al., 2017; Boehme et al., 2017). Research has shown that changes in perceived control are positively associated with changes in enjoyment of learning (Buff et al., 2017). Thus, perhaps interventions to increase student perceived control may have benefits by increasing positive emotions. For example, Bieg and colleagues (2017) demonstrated that working in groups and working individually increases perceived control when compared to learning from direct instruction.

However, it is important to note that too much control can lead to negative feelings for students (Buff et al., 2011; Pekrun, 2006, 2021). For example, if a student has very high control over what is happening in the classroom, they may feel bored and unengaged in mathematics (Pekrun, 2006). Buff and colleagues (2011) demonstrated that the relationship between control and positive emotions is nonlinear with the benefits of control tapering off at the highest levels.

Value Appraisals

Similar to control, it has been demonstrated that changes in perceived value are positively predictive of changes in enjoyment of learning (Buff, 2014; Buff et al., 2017). Math students generally report low values for math and feel that math is unimportant to their lives and boring (Brown et al., 2008; Hernandez-Martinez & Vos, 2018). Low value for math is associated with lower levels of motivation as well which contributes to negative emotions (Brown et al., 2008). Thus, interventions to increase student value could be beneficial to increase positive emotions for students.

However, just as with feelings of control, increasing value appraisals too much may be damaging to some students which has been demonstrated empirically (Boehem et al., 2017; Lauermann et al., 2017). High levels of value among families was associated with greater math anxiety in one study (Boehme et al., 2017). This view is also supported theoretically by CVT. For example, a student who believes succeeding in math is necessary for success in their future career has a high value of math, and anything that gets in the way of the success that they feel is necessary could lead to anxiety.

Control and Value Appraisals Occur Together

As discussed above, appraisals of control and value should not be increased for every student. Potential intervention studies are made more nuanced by the fact that control and value appraisals often co-occur. Thus, control and value appraisals become a type of optimization problem. For each student, there is a different optimal level of control and value which leads to the most success and positive emotions in the class. For example, Boehme et al. (2017) found that high family values of math were associated with test anxiety, yet high family values were associated with lower test anxiety through increased feelings of control among students. This finding suggests that increasing only value may worsen math anxiety; however, when an increase in value occurs with an increase in control, students may experience less math anxiety. Similarly, students with high math anxiety may benefit from an increase in control in the classroom while gifted students may benefit from classroom practices designed to decrease feelings of control as this may reduce feelings of boredom and increase positive emotions (Pekrun et al., 2010).

Classroom Environment Predictors of Positive Emotions

Research has also shown many factors within the classroom environment that can contribute to students experiencing positive emotions.

Learner-Oriented Instruction

General education research has demonstrated the benefits of learner-oriented teaching practices (e.g. group work, project based learning; Bruder & Prescott, 2013; Cevikbas & Kaiser, 2020; Laursen et al., 2014). However, direct instruction in a lecture format is still one of the most common teaching practices (Bieg et al., 2017; Jiang et al., 2021; Stigler & Hiebert, 2009). Direct instruction has also been shown to be associated with negative emotions in students (Bieg et al., 2017; Jiang et al., 2021). However, learner-oriented instruction, like working in pairs or small groups) has been shown to give students more feelings of control (e.g. control over discussions, control over pace of the material; Bieg et al., 2017).

Bieg et al. (2017) used experience-sampling methodology to measure students' emotions during math class. Students received notifications sent to an iPod Touch with surveys to complete during class. The survey asked them to report the current type of instruction (e.g. lecture, small group work), feelings of control in the moment, and current emotions (enjoyment, pride, anger, anxiety, and boredom). Results revealed that working in groups or working individually was associated with greater student enjoyment and perceived student control.

Collaborative work through learner-oriented instruction also offers the benefits of encouraging positive social interaction among students. Working in groups and having positive interactions with others is associated with positive emotions in math classes (Satyam, 2020). Also, giving students the opportunity to work in groups allows students to experience mathematics in a way similar to mathematicians, who also collaborate frequently (Burton, 1998). This approach is consistent with current approaches to science education, which has been dedicating more attention to cultivating experiences for students to make them feel like scientists (Jaber & Hammer, 2016). Burton (1998) reports that mathematicians report feeling increased joy and creativity through their collaborative work. Thus, group work could have a twofold effect of increasing positive emotions and allowing students the opportunity to work in ways similar to mathematicians and experts.

Learning Materials and Curriculum

Just as instruction type can influence student emotions, classroom activities and curriculum can influence student engagement which in turn can influence student emotions (Middleton et al., 2017). For example, giving students opportunities to work on challenging problems has been associated with more positive emotions and fewer negative emotions (Dettmers et al., 2011; Greensfeld & Deutsch, 2016; Greensfeld & Deutsch, 2022; Liljedahl, 2005; Satyam, 2020; Schukajlow & Rakoczy, 2016). For example, Dettmers et al. (2011) found that when students perceived homework assignments as challenging with well-selected problems, students put more effort into their homework and experienced fewer negative emotions.

Satyam (2020) describes “satisfying moments” as moments that create significant positive emotions for an individual. Eleven undergraduate students in a transition-to-proof class were interviewed to determine moments of satisfaction. The most common satisfying moments included overcoming a challenge. Thus, overcoming difficulties may create positive moments for students.

Alternative forms of curriculum and assessment can also decrease the common negative emotion of test related anxiety (Krispenz et al., 2019; Walen & Williams, 2002). Walden and Williams (2002) found that their participants had anxiety specific to timed assessments. These undergraduate students enjoyed mathematics, but the time limit of exams created anxiety. Further, using timed assessments likely deters students from using a problem solving approach as procedural methods will likely lead to faster solutions (Walden & Williams, 2002). So, even if teachers are teaching conceptual lessons and using well developed materials with challenging problems, timed assessments may undermine the work that went into those lessons and create more negative emotions for students as well.

Conclusion

Many practices already encouraged by mathematics education researchers (e.g. teaching conceptually, helping students find mathematics important) have the added benefit of potentially increasing positive emotions in students. By increasing positive emotions in the classroom, instructors can encourage the gradual growth of positive attitudes and beliefs about mathematics to students which are currently lacking among many students (Brown et al., 2008; Zazkis, 2015).

Although we have focused on positive emotions for this paper, it is important to not neglect the prevalence of negative emotions in the classroom as well (Deshler et al., 2019; Di Leo et al., 2019; Di Leo et al., 2020; D’Mello et al., 2014; Zazkis, 2015). Research has demonstrated that negative emotions can also be beneficial for students' learning (D'Mello et al., 2014). For example, although being confused is an uncomfortable feeling, and thus a negative emotional state, confusion has been shown to be beneficial to learning if the confusion is resolved (D'Mello et al., 2014). In D'Mello et al. (2014), the participants who experienced confusion were more successful in remembering information presented to them than participants who learned without experiencing confusion. Anxiety has also been found to have a positive relationship with student performance when students have high prior knowledge of mathematics (Schukajlow et al., 2021).

Just as negative emotions can be beneficial, positive emotions can also be detrimental. Villavicencio et al. (2016) found that pride among engineering students in the Phillipenes had a negative association with final course grades. Studies have also shown that positive emotions such as excitement and enjoyment can be barriers to perseverance in mathematical reasoning (Barnes, 2021; Ben-Eliyahu & Linnenbrink-Garcia, 2015).

Thus, there are benefits and detriments to both positive and negative emotions. However, on average, positive emotions have been shown to have more beneficial effects in mathematics learning than negative emotions (Bieg et al., 2017; Greensfeld & Deutsch, 2022; Greensfeld & Deutsch, 2016; Jiang et al., 2021; Liljedahl, 2005; Middleton et al., 2023; Satyam, 2020; Schukajlow & Rakocy, 2016). For example, Middleton et al (2023) found that positive emotions were associated with more motivational outcomes than negative emotions. Thus, in this study, perhaps an intervention to increase positive emotions would provide more benefit than an intervention to decrease negative emotions. With an increased focus on increasing positive emotions in the classroom, mathematics may become a more enjoyable place for students filled with creativity and curiosity.

A Framework for Characterizing and Identifying Playful Mathematical Experiences

Jeremy Bernier
Arizona State University

Play has been recognized as a component of mathematical practice; accordingly, this manuscript explores the potential role of play in undergraduate mathematics education. The manuscript introduces a novel framework for characterizing play, wherein a person is said to be playing in a scenario if they are (1) making non-routine, voluntary, and free choices/actions, (2) experiencing an appropriate level of challenge/uncertainty, and (3) experiencing amusement, satisfaction, or excitement. This framework is applied to provide a definition of playful mathematical experiences and consider how playful mathematical experiences relate to other concepts, like mathematical play and authentic mathematics.

Keywords: mathematical play, characteristics of play, rehumanizing mathematics

In the traditional mathematics classroom, students learn mathematics through some combination of teacher demonstration and repetitive practice of key computational skills While there is no consensus as to what mathematics *is*, articulations of the nature of mathematics tend to refer to concepts like problem solving, logical reasoning, modeling, or creative exercise (Halmos, 1980; Mura, 1993; Sfard, 1998; Strauss, 2011) – characterizations which stand in stark contrast to the operation of traditional mathematics classrooms (Boaler, 2002; Mann, 2006). Many approaches under the umbrella of Inquiry-Based Mathematics Education (IBME) have sought to incorporate more components of authentic (cf. Brown et al., 1989) mathematical practice – i.e., ways mathematicians do mathematics – into undergraduate mathematics classrooms as part of larger efforts to improve undergraduate mathematics instruction and learning (Laursen & Rasmussen, 2019).

One component of authentic mathematical practice – that is, something which mathematicians actually *do* – not included in Laursen and Rasmussen's (2019) synthesis of IBME approaches is the notion of *play*. Play is a near-universal human experience, and also one with much ambiguity (Sutton-Smith, 1997); much of the remainder of this manuscript will be dedicated to characterizing it more fully. When mathematicians like Su (2020) and Lockhart (2008) discuss play as part of mathematical practice, they refer to the pleasure and whimsy of freely exploring mathematical structures. Su (2022) argues that "contemplating patterns, playing with ideas, exploring what's true, and enjoying the surprises that arise along the way" (p. 53) is key to mathematical research, while Lockhart (2008) states that in mathematics, "we get to play and imagine whatever we want and make patterns and ask questions about them" (p. 4). Beyond mathematicians' descriptions of their own practice, Horne et al. (2023) recently examined the problem-solving practices of professional mathematicians and found evidence that playfulness is at least sometimes invoked within their mathematical practice.

Now, play being a part of authentic mathematical practice does not necessitate the inclusion of play at all levels of learning mathematics. Reviewing journal articles and attending faculty meetings are practices of mathematicians, but I suspect most would agree that first year undergraduate students need not participate in these practices. So, while I *assert* that play is legitimate for inclusion in mathematics classes due to its role in authentic mathematical practice (Holton et al., 2001; Horne et al., 2023; Lockhart, 2008; Su, 2020), I go further and *conjecture* that play may be a useful element to introduce to undergraduate mathematics classrooms for reasons beyond its validity.

My evidence for this conjecture is the current status of participation in STEM. Many more students enter college with interests in STEM than complete degrees in STEM fields (Bressoud, 2020; Seymour & Hunter, 2019). One reason for this is that undergraduate mathematics classrooms can be dehumanizing (cf. Gutiérrez, 2018) spaces where students are not able to interact with mathematics as their whole authentic selves; this is especially so for students from minoritized groups (Leyva et al., 2021, 2022). Recently, Caldwell et al. (2023) have argued that play can contribute to rehumanizing mathematics classrooms. According to their argument, play can challenge traditional mathematics classroom practices and create space for students to assert their own understandings of mathematics (Caldwell et al., 2023). While Caldwell et al. (2023) placed their work in the context of elementary schools, the fact that people of any age can and do engage in play means the same ideas may apply to the undergraduate mathematics classroom.

So far in this manuscript, I have provided a brief overview of *why* we might want to integrate play into undergraduate mathematics classrooms. Before we can proceed to fully considering *how* play might be integrated into undergraduate mathematics classrooms, further clarity is needed on *what* play actually *is* and how I suggest we should operationalize it in this context. The remainder of this manuscript serves to articulate a framework for play oriented towards identifying whether someone is playing or not in a given scenario, using that framework to define *playful mathematical experiences*, and considering how this definition relates to and differs from existing work on play in mathematics.

Characterizing and Contextualizing Play in Mathematics

Characterizing exactly what play *is* is a challenge. The conceptual ambiguity of play makes it difficult to define in a way which captures all applications of the word while being operationalizable. As a result, diverse definitions and frameworks exist which vary greatly depending on both the backgrounds of the authors developing the frameworks, as well as the audience they are speaking to (Sutton-Smith, 1997; Salen and Zimmerman, 2004; Bergen, 2015). Zoologists, philosophers, psychologists, and game designers all study play, each emphasizing different aspects of it which are particularly relevant to their domains and motivations. Some characterizations of play conflict somewhat with the idea of play in the classroom – for example, Huizinga (1949) articulates that play must be separate from “ordinary life” and involves no material gain. As a further complication, within mathematics, the concept of mathematical play exists and has been operationalized differently by different researchers (Holton et al., 2001; Horne et al., 2023; Williams-Pierce, 2019), but typically as a very specific type of play.

As a transdisciplinary scholar, I felt it was important to leverage the collective knowledge about play from diverse perspectives. Moreover, as I examined many frameworks of play, I found that they often were oriented to be describing the environment that a person was playing in as much as the actions of the player – and in some cases, seemed to imply that environments which meet certain conditions demand play. Under certain understandings of play, this is sensible. However, this orientation is not useful if one’s goal – as mine is – is to clearly evaluate the extent to which the design and implementation of an activity intended to be playful results in playful experiences. In other words, in the environment of the undergraduate mathematics classroom (or indeed, any classroom), where both playful and non-playful behaviors are possible, how do we differentiate between those? So, to resolve this, I have pragmatically drawn on articulations of what play is from diverse authors and perspectives (Bergen, 2015; Callois, 2001/1961; Csikszentmihalyi & Bennett, 1971; Henricks, 2008; Holton et al., 2001; Huizinga, 1949; Salen & Zimmerman, 2004; Sutton-Smith, 1997; Sylva et al., 1976; Williams-Pierce & Thevenow-Harrison, 2021) to develop a framework of characteristics of play.

The Framework

Within any given scenario – whether designed or naturalistic – a person is likely engaging in play if, at some point, their interaction with the scenario meets each of the following criteria:

1. The person is making non-routine, voluntary, and free choices and/or actions.
2. The person is experiencing an appropriate level of challenge and/or uncertainty.
3. The person is experiencing amusement, satisfaction, or excitement.

In the following subsections, I describe in more detail how these characteristics draw on existing literature on play from multiple disciplines and authors. I also suggest (non-exhaustively) a few actions we may observe that would indicate that each characteristic is met in a scenario.

Making Non-Routine, Voluntary, and Free Choices and Actions. Across diverse authors and contexts, play is strongly associated with the idea of freedom (Henricks, 2008; Holton et al., 2001; Huizinga, 1949; Salen & Zimmerman, 2004; Williams-Pierce & Thevenow-Harrison, 2021). Although play is always bound by some sort of structure – be it an implicit societal structure or the more explicit rules of mathematics and games – play is defined by the player's ability to interact with that structure in ways that they choose. Moreover, for these choices to be truly free, they must be made voluntarily – they must not be imposed upon the potential player by an outside source (Huizinga, 1949; Williams-Pierce & Thevenow-Harrison, 2021). Of course, the degree to which a choice or action is taken freely and voluntarily may be challenging to determine as an observer. Observing kids at a playground at a public park, perhaps we could assume that their choices are all free and voluntary. In a classroom or even a playground attached to a school, this is a harder assumption to make – the rules of schools and classrooms make them spaces where students' freedom and agency are inherently reduced.

To allow for identification of playful behaviors under these environments of reduced freedom, I draw particularly on discussion by Sylva et al. (1976) about the relationship between routines and play. Sylva et al. (1976) articulate this by stating that play offers an "invitation to the possibilities inherent in things and events. It's the freedom to notice seemingly irrelevant detail" (p. 396). When operating under a routine, we do not give ourselves space to notice alternate possibilities (Sylva et al., 1976). In the undergraduate mathematics classroom, this is reflected in the difference between exercises and problems (cf. Schoenfeld, 1985): exercises, like completing a worksheet of u-substitution integration tasks after instruction on the technique, involve implementing routines and therefore have less space for freedom. Problems, like asking students who have not yet learned about integration to estimate the area under a curve, are non-routine and create more space for students to freely choose their strategy.

This is not to say that play never involves routine behaviors. Consider a pitcher's role in a baseball game – while the pitcher has practiced their routine for throwing fastballs and curveballs, how they implement these pitches in response to the state of the game and the actions of the offense is, at least occasionally, non-routine. In the undergraduate mathematics classroom, consider the prior example of asking students to estimate the area under a curve. As part of this task, students will likely compute the areas of figures they have well-established routines for – but the choices of how to deploy those routines is subject to students' choices. So, the notion of non-routine is useful to identify actions which are done freely and voluntarily in environments with reduced freedom, like the undergraduate mathematics classroom.

At this stage, I suggest three observable actions which would indicate to me that the person is making non-routine, voluntary, and free choices and/or actions. The first is when a person takes an action with an indication that the action is exploratory and that the outcome will be unknown. Routine actions inherently have at least expected outcomes, so an action taken with an explicit reference to uncertainty of outcome is indicative of a non-routine action. Second is when a person takes actions to test or push the bounds of a scenario. Testing and potentially adjusting the limitations of a scenario is reflective of asserting freedom over the scenario by specifically challenging it. An example of this is in the case of Calvin and the educational mathematical game *Boone's Meadow* (Wisittanawat & Gresalfi, 2021). While playing the game, Calvin tested the bounds of the scenario by seeing if he could hijack a vehicle and flying in different ways to see how the outcome of the game changed. Finally, the creation of individual goals would also indicate free action. These goals could be expressed explicitly as a goal or could be any desire to accomplish something that is not specifically implicated by the scenario.

Appropriate Level of Challenge or Uncertainty. In order to engage in playful behavior in a scenario, a person should find some challenge within that scenario (Csikszentmihalyi & Bennett, 1971; Salen & Zimmerman, 2004) or some uncertainty of how to act within that scenario (Holton et al., 2001; Salen & Zimmerman, 2004). Whether the play is provoked by challenge or by uncertainty roughly corresponds to Callois' concepts of ludus and paidia (2001/1961). When the play is provoked by challenge, the player is trying to accomplish some sort of specific goal within (and to some extent, perhaps against) the scenario – which is inclusive of the rule-based play of ludus. Conversely, if the play is provoked by uncertainty, the player may simply be trying to explore or understand the scenario and what the bounds of the scenario are – which would be more in alignment with the improvisational play of paidia. Of course, these are not mutually exclusive. How challenging a scenario is can fluctuate depending on a person's uncertainty, and the process of exploring uncertainty may lead to finding or creating challenges.

For this, I assert three observable actions which may indicate that a person is experiencing an appropriate level of challenge or uncertainty. The first is self-explanatory: a direct statement or express that they are experiencing challenge or uncertainty, like saying "this is so hard" or "I'm not sure if this will work." The second regards the potential of frustration. Sylva et al. (1976) indicate that play comes with a "moratorium on frustration" (p. 245), but Holton et al. (2001) suggest that frustration is actually a common feature of play. Indeed, in my own experiences, it is typical that working on appropriately challenging tasks will involve some frustration, even as it gives way to excitement when a 'lightbulb moment' is achieved. So, I draw on Holton et al. (2001) to suggest that frustration may be experienced while engaging playfully in a scenario – but, if it is experienced, it is not an obstacle to the person's engagement. What this would manifest as, then, is that a person showing signs of frustration persists in the task. Finally, I suggest that if the person makes multiple attempts at interacting with the scenario – by changing an action midcourse, somehow resetting the scenario, or otherwise repeating their experience with the scenario – this indicates an appropriate level of challenge and/or uncertainty. In the world of games, this may be reflected in restarting a level or loading an earlier save file before a certain action was taken; in the world of mathematical problems, this could involve crumpling up a sheet of paper or erasing everything on a whiteboard up to a certain point.

Experiencing Amusement, Satisfaction, or Excitement. The affective component of play – that is, the idea that play is fun – is broadly acknowledged (Csikszentmihalyi & Bennett, 1971; Henricks, 2008; Sutton-Smith, 1997). In my view, it is minimized and under-addressed in importance in most frameworks of play. Indeed, many of the definitions and frameworks did not mention fun; some who did mention fun did so only to state that fun alone is insufficient to understand play (Csikszentmihalyi & Bennett, 1971). I would argue, however, that if a person is engaging in free action and experiencing a challenge or uncertainty, but is not "having fun," then they are not engaging in play. Therefore, if the goal of observing an experience is to determine if that experience was playful, then whether they are having fun ought to be considered. Of course, fun is too broad a concept, so I suggest that having fun can be operationalized as experiencing amusement, satisfaction, or excitement.

These do not represent the total of all feelings that can be experienced during play – I have already mentioned frustration, and other emotions like annoyance or even sadness can occur while playing. My exclusion of these experiences in this framework is not to say that they are never part of play. However, if the experience of frustration, annoyance, or sadness *never* gives way to amusement, satisfaction, or excitement, that it would be incorrect to characterize that activity as play. In other words, play need not *always* be fun, but *at some point*, it must.

Even just with the experiences of amusement, satisfaction, and excitement, there are limits to how I might observe these. People do not always outwardly express these emotions even as they are experiencing them. Moreover, the way emotions are expressed and recognized varies from culture to culture and person to person (Elfenbein & Ambady, 2003), although there is some evidence that expressions of joy may be broadly recognized (Sauter et al., 2010). Observing for this may be particularly challenging, and is the part of this framework most in need of further development. For now, I draw on things I am likely to do when I am enjoying my experience of playing a game and/or solving a mathematical problem: smiling, laughing, and engaging in celebratory moves (e.g. a fist pump, a 'woop', or self-applause).

Playful Mathematical Experiences, Mathematical Play, and Mathematical Problem Solving

Given my framework for play, I define a playful mathematical experience as an experience where a person or group of persons is (a) interacting with mathematical rules, ideas, and objects, and (b) where their interaction otherwise meets each of the three characteristics in the prior subsection. Playful mathematical experiences thus overlap with several different kinds of experiences discussed in this manuscript (Figure 1). Here, I wish to interrogate the relationship

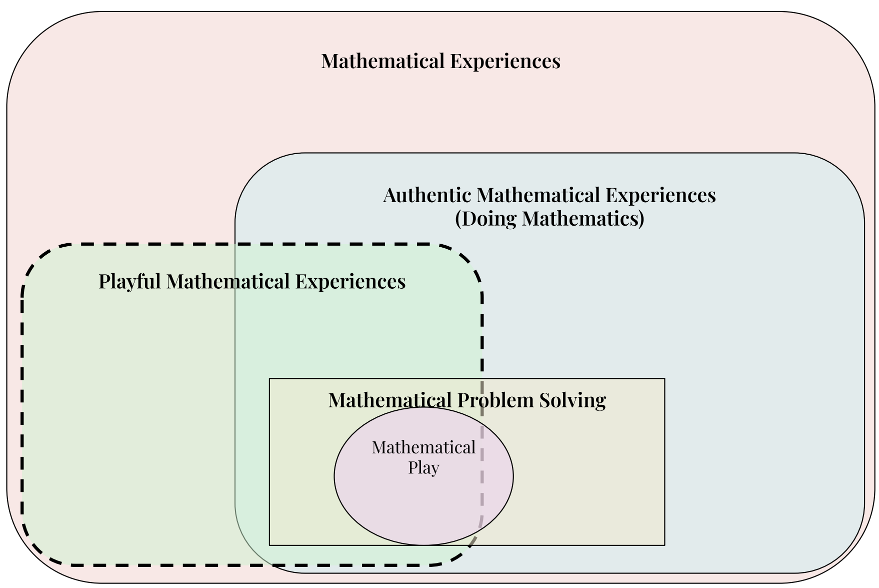

Figure 1. An Euler diagram showing the relationship between playful mathematical experiences (dashed lines) and other concepts discussed in this manuscript.

between playful mathematical experiences and mathematical play, and how these relate to authentic mathematical experiences.

Mathematical play is conceptualized differently by different scholars (Holton et al., 2001; Horne et al., 2023; Williams-Pierce, 2019). I start by considering those of Williams-Pierce (2019) and Holton et al. (2001), which I see as having the most differences from my definition of playful mathematical experiences. Williams-Pierce (2019) defines mathematical play as "voluntary engagement in cycles of mathematical hypotheses with occurrences of failure," (p. 591), where cycles of mathematical hypotheses entails "shift[ing] regularly between generalizing activity and generalizations…in which players learn to adjust their behavior and conceptualization" (p. 592). Holton et al. (2001) conceptualize it more generally:

> By mathematical play we mean that part of the process used to solve mathematical problems, which involves both experimentation and creativity to generate ideas, and using the formal rules of mathematics to follow any ideas to some sort of a conclusion. Mathematical play involves pushing the limits of the situation and following thoughts and ideas wherever they may lead. (p. 403)

Both of these invoke ideas of freedom and exploration within mathematics, specifically with the solving of mathematical problems or development of mathematical concepts. I drew on both characterizations of mathematical play articulate in developing my own understanding of playful mathematical experiences.

Horne et al. (2023), meanwhile, operationalize mathematical play (reframed as playful math) in a way which is very well-aligned with my framework. In examining mathematicians' problem solving for evidence of play, they looked for evidence of three characteristics: "(a) agency in exploration or goal accomplishment, (b) self-selection of mathematical goals, and (c) a state of immersion, investment, and/or enjoyment" (Horne et al., 2023, p. 99). The first two of these characteristics align with my first characteristic of play, and their third characteristic lines up well with my third characteristic.

However, each of Williams-Pierce (2019), Holton et al. (2001), and Horne et al. (2023) specifically locate mathematical play within or very tightly adjacent to mathematical problem solving. While mathematical problem solving is a fertile ground for playful mathematical experiences, my definition for playful mathematical experiences is more broad. By way of example, consider a group of people who are telling a series of mathematical jokes to one another. Their experience may be playful in that (a) creating the jokes to tell is likely a non-routine process involving free exploration of different ideas, (b) the group members may view it as a "challenge" to try to get a bigger laugh with each joke, and (c) the shared laughter is an indication of their enjoyment of the situation. Since making jokes about mathematics involves interacting, in some manner, with mathematics, this would qualify as a playful mathematical experience. But, unless the jokes also represent a sequence of well-reasoned mathematical argumentation, it would likely not be construed as mathematical play.

I am motivated by the authenticity of play to mathematics. Based on the substantial overlap between these different characterizations, it seems to me that nearly any playful mathematical experience which involves doing mathematics (i.e., that is an authentic mathematical experience) would necessarily fit these definitions of mathematical play. Indeed, as I proceed in developing this framework, I am looking to mathematical problem solving experiences to better understand what play might look like in mathematics. However, I think it is important to include other ways of playing with mathematics, like my previous joke-making example, within the definition of playful mathematical experiences for two reasons.

First, students may hold beliefs about mathematics which preclude the possibility of playing in mathematics classrooms (cf. the case of Keegan in Wisittanawat & Gresalfi, 2021) or have anxiety about mathematics. Such students may not be 'ready' to engage playfully with mathematics while doing mathematics until they become more comfortable with doing mathematics itself. If playfulness is a goal, it may be useful to use activities which provoke playfulness but which are not necessarily authentic to mathematics as a bridge. In the classroom, this could involve an activity sequence which first prompts students to play more generally, then adding mathematics to their play, before finally inviting them to engage in mathematical play through mathematical problem solving.

Second, in a humanized mathematics classroom, students must be able to "draw upon all of their cultural and linguistic resources" and to "see aspects of themselves" (Gutiérrez, 2018, p. 1) in their mathematical work. To me, this means that students are not just invited to participate in existing practices of mathematicians, but are also invited to bring practices from other communities to bear on mathematics. Since one of my motivations for integrating play into undergraduate mathematics classrooms is to contribute to rehumanizing them, then it seems appropriate to include space for playful mathematical experiences beyond doing mathematics.

Discussion

The framework of play and definition of playful mathematical experiences in this manuscript started being developed when I, as a mathematics educator and gamer, first noticed that the traits of many of my favorite games were much the same as those of my favorite mathematical experiences. Since then, I have developed my understanding of play and playful mathematical experiences through the careful transdisciplinary examination of diverse sources of literature. While this has been a substantive endeavor, this is still an early draft of this framework, and further development is needed before it is used in the evaluation of designed learning activities. Even in between my first articulation of this framework and the writing of this manuscript, recently-published works (i.e., Caldwell et al., 2023; Horne et al., 2023; Su, 2020) led me to further develop my ideas.

The greatest weakness of my framework for play and my associated definition of playful mathematical experiences is that they are informed primarily by research literature and secondarily by my own experiences, and they are not yet informed by data. To address this, I am presently in the process of conducting a study which will use this framework to examine students' interactions with digital puzzle games and mathematical problems in a clinical interview environment. From this process, I expect this framework will evolve and deepen greatly. In particular, this process should allow me to better understand the relationship between playful experiences in general, playful mathematical experiences, and mathematical play, by examining how student interactions are similar and different in more- and less-explicitly mathematical situations. Even as a work in progress, I present this framework with the intent to prompt mathematicians, mathematics educators, and researchers of mathematics education to consider for themselves: what is, can be, and should be the role of play in undergraduate mathematics classrooms?

Acknowledgments

I must thank Elisabeth Gee, Michelle Zandieh, Brian Nelson, and Naneh Apkarian for mentoring the development of this framework as my dissertation committee. I also wish to thank Zac Bettersworth and Jason Guglielmo for providing valuable feedback on this manuscript.

Conceptualizing Students' Ways of Understanding Bijections in Combinatorics

Dru Horne
University of Georgia

Pairing and one-to-one correspondences are natural activities, which can be formalized using bijections. Despite bijections being central to mathematics, few studies have explicitly attended to how students construct, understand, and use them. Because bijections show up naturally in combinatorial arguments, I situate this work in combinatorics. In this theoretical paper, I propose three ways of understanding bijections in combinatorics—relabeling, representational, and relational bijections—and discuss possible affordances and constraints of each. I also provide combinatorial examples using binomial coefficients to exemplify each way of understanding.

Keywords: Combinatorics, bijection, ways of understanding

In elementary combinatorics there are two main proof techniques: double counting and constructing a bijection or correspondence (Benjamin & Quinn, 2003; Mazur, 2010). While there has been work done with counting arguments (Lockwood, 2013; Lockwood et al., 2015; Lockwood & Purdy, 2019; Lockwood & Reed, 2020) and double counting proofs (Engelke Infante & CadwalladerOlsker, 2011; Engelke & CadwalladerOlsker, 2010; Erickson & Lockwood, 2021; Lockwood et al., 2021), there has been little work done with bijections in combinatorics. In this theoretical paper, I define a bijective way of thinking and introduce three ways of understanding (Harel, 2008a) bijections in combinatorics: *relabeling bijections*, *representational bijections*, and *relational bijections*. For each of these, I provide one or more examples to illustrate the way of understanding and discuss the potential affordances and constraints.

Literature Review

In early childhood, one-to-one correspondences play an important role in children learning number concepts such as the cardinality principle and exact number. Mix (2002) found that children 12-38 months can experience and use one-to-one correspondences in a wide range of contexts and that certain types of correspondences may serve as bridging activities for students to develop numerical equivalence. For example, pairing objects that have some conceptual relationship, such as frogs and lily pads, serve as cues of equinumerosity for young children (Muldoon et al., 2005). Different types of correspondences may foster different skills. For example, item-to-item correspondences help with set pairing, whereas word-to-item correspondences help children with cardinality (Muldoon et al., 2009). However, just because children can understand cardinality does not mean they understand exact number, i.e., cardinality is an invariant for equinumerous sets (Muldoon et al., 2009). In fact, the relationship between exact number, cardinality, and one-to-one correspondences is complex (e.g., Izard et al., 2014; Sarnecka & Carey, 2008; Sarnecka & Gelman, 2004; Sarnecka & Wright, 2013).

As students progress in mathematics, one-to-one correspondences are formalized as the study of bijections, which are important for discussing cardinality of infinite sets, defining equivalent mathematical objects via isomorphism, and in making combinatorial arguments. In regards to infinite sets, research has found that students experience paradoxes related to arithmetic with infinite sets (Mamolo, 2014), which may arise because students rely on their knowledge of finite sets to reason about infinite sets (Fischbein et al., 1981; Tirosh, 1991). Moreover, students can often hold multiple conflicting criteria for comparing infinite sets, including bijection, single infinity, and subset inclusion (Tsamir, 1999). In fact, the presentation of two infinite sets can affect whether students reason using bijections or some other criterion (Tirosh & Tsamir, 1996; Tsamir & Tirosh, 1992). Even when students use bijections as a comparison method, they often rely on informal arguments rather can constructing explicit bijections (Hamza & O'Shea, 2011), which may be because students are limited in the bijections they can construct based on the functions they know (Tsamir & Dreyfus, 2005).

In combinatorial contexts, the research show mixed results related to students' bijective reasoning. Muter and Uptegrove (2011) found that a group of high school students could recognize and connect different combinatorial problems, such as pizza toppings and block towers, by constructing bijections, whereas Mamona-Downs and Downs (2004) found that students did not construct bijective solution unless supported in this approach, and even then "students did not make a clear distinction between the bijection itself and the result it was justifying (i.e., the number of elements of the two sets corresponded are equal)" (p. 244).

One-to-one correspondences are a natural object of study that are central to young children's development of number and play an important role in comparing infinite sets. Furthermore, bijections are central to discussing equivalent mathematical objects because an isomorphism (of graphs, groups, rings, topological spaces, etc.) is a structure-preserving bijection. I hypothesize that studying bijections in combinatorics, where the sets are typically discrete and easily visualized or listed, may provide students a space to understand and reason with bijections, injections, and surjections that could be drawn on and leveraged in other mathematical domains.

Theoretical Perspective

In this theoretical paper, I draw on Harel's dual constructs *ways of understanding* and *ways of thinking* (Harel, 2008a, 2008b). According to Harel, "a person's statements and actions may signify cognitive products of a mental act carried out by the person. Such a product is the person's *way of understanding* associated with that mental act" (Harel, 2008b, p. 490, emphasis original). For example, a solution is a product of the problem-solving mental act, and a particular proof of an assertion is a product of the proving mental act. Thus, a particular solution or proof is a way of understanding with respect to the corresponding mental act. Instead of focusing on the product of a single mental act, one can also look across ways of understanding to identify a way of thinking: "Repeated observations of one's ways of understanding may reveal that they share a common cognitive characteristic. Such a characteristic is referred to as a *way of thinking* associated with that mental act" (Harel, 2008b, p.490, emphasis original). Sticking with the previous example, problem-solving strategies and proof schemes (Harel & Sowder, 1998) are examples of ways of thinking associated with the mental acts of problem solving and proving, respectively. These constructs are central to Harel's Duality-Necessity-Repeated Reasoning (DNR) instructional framework, and the Duality Principle notes that ways of understanding and ways of thinking are interdependent. As students engage in a mental act, they may use a way of understanding multiple times, which can contribute to the development of a way of thinking. Similarly, they may draw on a way of thinking to understand a particular idea or problem.

Researchers have used Harel's ways of thinking and ways of understanding to make sense of students' counting activity in enumerative combinatorics. Lockwood has repeatedly concluded that attending to sets of outcomes is an important way of thinking (Lockwood, 2014; Lockwood et al., 2017; Lockwood & Gibson, 2016). She calls this way of thinking a set-oriented perspective, which she has defined as "a way of thinking about counting that involves attending to sets of outcomes as an intrinsic component of solving counting problems" (p. 31). In her dissertation, Halani (2013) identified three broad categories of ways of thinking about combinatorial solution sets. Lockwood and Reed (2020) defined an equivalence way of thinking, which allows a student to frame "division as a way of accounting for duplicate outcomes, allowing a counter to identify such duplicates as belonging to the same equivalence class" (p. 4). This paper extends this work into bijective combinatorics.

Three Ways of Understanding Bijections in Combinatorics

Here, I will define and discuss three ways of understanding bijections in a combinatorial context: relabeling, representational, and relational. For each, I will present one or more combinatorial examples and discuss the potential affordances and constraints of thinking about a bijection from the perspective of each way of understanding. These three ways of understanding are associated with a bijective way of thinking, which is marked by a student conceptualizing two sets (possibly the same) and imagining how the elements of one set can be transformed or mapped to elements of the other set via a bijection.

Relabeling Bijections

Suppose two students are asked to solve a coin flipping problem such as the following: "If a coin is flipped five times in a row, what are the possible outcomes?". Student A solves the problem by denoting the possibilities of a single flip, using "H" for heads and "T" for tails. Student B, in contrast, decides to denote heads as "1" and tails as "0". Each student lists the 32 possible outcomes, and the question arises as to whether their answers are the same. The two solutions can be related to each other using a bijection that changes "H" to "1" and "T" to "0" and vice versa, and thus the students realize they have the same answer differing only by notation. This is an example of a *relabeling bijection*, which is a bijection that connects two sets by changing the surface features of those sets, typically by changing notation.

Relabeling bijections can serve as a starting point for students to recognize situations as similar, which can be leveraged to connect different representations. This way of understanding bijection may serve as a starting point into an intuitive understanding of injectivity, surjectivity, and invertibility, since the function is relatively simple. Additionally, relabeling bijections may be a way to begin to discuss permutations as a bijection from a set to itself. However, if a student only understands bijections as relabeling, it may difficult for them to construct a bijection between two sets whose elements differ in more substantive ways, such as subsets and lattice paths (discussed below).

Representational Bijections

In combinatorics, students often encounter or are introduced to a variety of different problems whose solutions are the same. As an example, let A be the set of k-element subsets of an n-element set, let B be the set of binary strings of length n with exactly k ones, and let C be the set of north-east lattice paths[1] from (0, 0) to (k, $n-k$) (see Figure 1). The cardinality of each set is $\binom{n}{k}$. This can be shown by starting with the standard combinatorial definition of $\binom{n}{k}$ as counting the number of k-element subsets of an n-element set. Thus, by definition, $|A| = \binom{n}{k}$. To also see that sets B and C have the same cardinality, I will construct two bijections.

The first bijection is between sets A and B. A k-element subset of A can be mapped to a binary string of B by labelling the n positions of the binary string 1 through n and placing a 1 in

[1] A north-east lattice path is a path on an integer lattice involving the steps (0, 1) and (1, 0).

the i^{th} position of the binary string if the i^{th} element is in the subset and a 0 otherwise. So, if n = 6 and k = 3, the subset $\{2, 4, 5\}$ will map to the binary string 010110 and the subset $\{1,2,3\}$ will map to 111000. Similarly, a given binary string can be uniquely mapped back to a subset by inverting the process, i.e., 110110 maps to $\{1, 2, 4, 5\}$ and 000100 maps to $\{4\}$. Since bijections preserve cardinality, $|B| = \binom{n}{k}$.

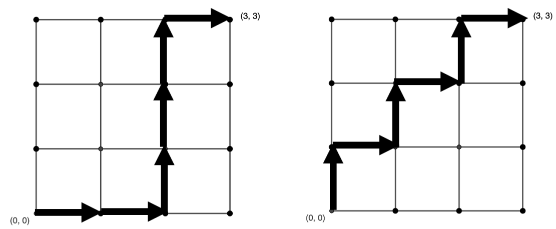

Figure 1. Two examples of a north-east lattice path from (0,0) to (3,3).

Finally, I will construct a bijection between sets *B* and *C*. Any binary string of *B* can be relabeled by changing each 1 to an "E" and each 0 to an "N," which can be turned into a lattice path by reading left to right and taking the step (0, 1) when there is an "E" and (1, 0) when there is an "N." For concreteness, I will continue to let n = 6 and k = 3. Consider the binary strings 110001 and 010101. These map to the binary words EENNNE and NENENE, which are exactly the two lattice paths shown in Figure 1. This mapping can be reversed by following the steps in reverse.

These two bijections are examples of what I call *representational bijections*. A representational bijection is a bijection between two sets represented in mathematically different ways that may afford different operations and ways of reasoning. In our example above, the elements of set *A* are subsets, which can be operated on naturally using intersections, unions, complements, and symmetric differences. In contrast, the elements of set *C* are lattice paths, which are geometric objects that can be reflected, rotated, and assigned an area (such as the area between the lattice path and the x-axis). It is not clear what the area of a subset would be, nor how to take the symmetric difference of a lattice path; however, it may be possible to interpret these through a representational bijection.

This way of understanding bijections enables students to connect different representations, which may allow them to better understand what a combinatorial expression such as $\binom{n}{k}$ counts. Additionally, having a range of contexts in which to interpret combinatorial expressions afford students choosing a representation with which they are comfortable working, which could support them in proving combinatorial identities (Lockwood et al., 2021). In the examples above, I have demonstrated bijections, and thus I know that every set can be counted by $\binom{n}{k}$. However, that does not answer the more fundamental question, which is, if I encounter a new context or representation, how do I recognize it as $\binom{n}{k}$? By examining the examples above, one can look for similarities and differences. In each case, there are n slots to be filled and two choices to be made:

1. **Set *A*:** To construct a subset of *A*, one decides whether to include the first element, the second element, and so forth. In order to get a subset with k elements, one must choose which k elements are included, at which point the $n - k$ excluded elements are determined.

2. **Set *B*:** To construct a binary string, one decides where to put a 0 or a 1. To ensure the binary string is an element of *B*, one has to choose *k* places to put a 1, which forces where a 0 can be put.
3. **Set *C*:** At each step of the lattice path, a choice to go east or north is made. The given constrains of the lattice (starting at (0, 0) and ending at (*k*, n – k)) imposes the restriction that *k* norths must be chosen, which will determine where the east steps must be.

In each of these cases, one decides between two choices (include or not include, 1 or 0, and east or north), and once *k* choices of one type have been made, the remaining *n* – *k* choices must be of the other type. This affords a student being able to look for similar reasoning in other problems and contexts, which they connect to this counting process (Lockwood, 2013), and by extension, to $\binom{n}{k}$.

When a combinatorial expression, such as $\binom{n}{k}$, is examined across the multiple contexts and representations, one can gain insight into the underlying counting process. However, this does not immediately afford an understanding of how a set counted by $\binom{n}{k}$ can be structured: Is there some recursion that determines the set? Does the set exhibit some symmetry? Can the set be restructured and counted according to some property? Being able to understand how a set can be structured, partitioned, refined, and counted is important for proving combinatorial identities, a student with a representational way of understanding bijections may overlook these finer processes.

Relational bijections

One goal of combinatorics is to understand the structure of the sets counted by a combinatorial sequence. As mentioned above, $\binom{n}{k}$ counts subsets, binary strings, and lattice paths; however, what properties do these objects have and how are they related to the binomial coefficients that count them? To be more concrete, I will discuss two binomial identities and highlight how each identity captures some information about the structure of sets counted by $\binom{n}{k}$.

The first identity is $\binom{n}{k} = \binom{n}{n-k}$. If I take the left-hand and right-hand side to be the cardinality of two sets, then this identity suggests a symmetry among the sets. To illustrate this, let us interpret these coefficients as counting the *k*-elements subsets of an *n*-element set and as counting the (*n* – *k*)-element subsets of the same *n*-element set. Taking the set complement (with respect to the *n*-element set) defines a bijection between the two sets, because the complement of *k*-element subset is an (*n* – *k*)-element subset and vice versa. What is this bijection really saying about objects counted by $\binom{n}{k}$? It indicates that if any *k* elements are chosen, then the other *n* – *k* element are determined. Thus, I could either count which *k* elements are included in a subset or count which *n* – *k* elements are excluded from the subset, which indicates a type of symmetry of $\binom{n}{k}$.

As a second example, consider the identity $\binom{n}{k} = \binom{n-1}{k} + \binom{n-1}{k-1}$. Once again, I interpret these in the contexts of subsets in order to describe a bijection. The left-hand side counts the number of *k*-element subsets of an *n*-element set while the right-hand side counts the number of subsets with either *k* or *k* – 1 elements chosen from an *n* – 1 element set. Given a *k*-element subset of *n*-elements, it either contains the n^{th} element, or it does not. If it does not contain the n^{th} element, then it is already a *k*-element subset of an (*n* – 1)-element set and can be mapped to itself. Otherwise, it contains the n^{th} element and can be mapped to a set counted by $\binom{n-1}{k-1}$ by removing the n^{th} element. This process is reversible and thus defines a bijection. In this case, this bijection illustrates a recursive structure of the sets counted by $\binom{n}{k}$, since each element of this set can be built from an element of the set counted by $\binom{n-1}{k}$ or by $\binom{n-1}{k-1}$ as described in the bijection.

Each of these examples illustrate a *relational bijection*. Understanding a relational bijection entails thinking not only about the sets being counted but also about a property of the sets being counted, which can be related to some other property of the sets. This provides additional information about how sets counted by combinatorial expressions, such as sets counted by $\binom{n}{k}$, are structured. In the first example, the bijection provided information about the symmetry between the subsets of an *n*-element set, i.e., one can either focus on which elements the set contains or which elements the set does not contain. In the second example, the bijection describes a systematic process for building new subsets out of old subsets; thereby, it defines a two-variable recurrence for binomial coefficients.

Conceiving of bijections in this way pushes students to go beyond pairing two sets and arguing they are equinumerous. It pushes students to examine what properties the bijection may be preserving or what structure the bijection is hinting at, e.g., a partitioned structure, a refinement, or a recursive structure. All of these properties are related to size and cardinality, since that is what a bijection is guaranteed to preserve. However, this way of understanding may provide a chance for students to build intuition about preserving structure and connecting (counting) processes, which could be leveraged in future discussions about isomorphisms of rings, fields, and groups, homeomorphisms of topological spaces, and isometries in geometry.

One constraint with this way of understanding relates to the difficulty of constructing these types of bijections. A priori, it is not clear what property of the sets one should be exploring and trying to connect, and thus it takes time to explore and understand the sets.

Discussion

These three ways of understanding bijection are not mutually exclusive; it is possible for a student to simultaneously understand a bijection in two or more of these ways. To illustrate, I return to the identity $\binom{n}{k} = \binom{n}{n-k}$. Instead of interpreting the binomial coefficients as counting subsets, I could interpret them as counting binary strings. Then, $\binom{n}{k}$ counts the number of binary strings of length *n* with *k* ones, and $\binom{n}{n-k}$ counts the number of binary strings of length *n* with $n - k$ ones. One can form a bijection between these two sets by interchanging zeros and ones. Certainly, this bijection can still be understood as relational for the reasons noted above; however, a student may not attend to a counting process and instead see this bijection as relabeling. Alternatively, a student could interpret $\binom{n}{k}$ as counting binary strings and $\binom{n}{n-k}$ as counting *k*-element subsets. In this case, a bijection between the two sets may be interpreted as (1) relational if the student understands how the bijection is relating the structuring of the two sets; (2) representational if the student sees subsets and binary strings as affording different mathematical ideas and approaches; and (3) relabeling if the student has internalized the relationship between binary strings and subsets and views the bijection as changing notation from binary strings to a more familiar context of subsets (or vice versa). Thus, it is important to attend to how the student is reasoning about the bijection in order to understand what way of understanding the student may have.

I see these ways of understanding as hierarchical in the sense that there is a natural progression from relabeling to representational to relational. Relabeling bijections are conceptually easier for students to construct and reason about since they usually involve notational changes, which can be written down explicitly and properties like injectivity and surjectivity are easier to check. Representational bijections can be more challenging because different sets of objects have different properties, and it is not immediately obvious what the relationship between two sets of objects is, if any. Thus, an instructor may leverage relabeling bijections to begin a discussion of representational bijection. For example, a bijection between lattice paths and binary strings can be thought of as a relabeling bijection where each east step is relabeled as 1 and each north step is relabeled as 0. However, a discussion can be focused around how the lattice paths and binary strings are mathematically different by focusing on, for example, the geometric properties of lattice paths and whether there are corresponding properties in the binary strings. Discussing properties and operations of a set can progress to relational bijections. For example, a student may wonder what happens to a lattice path that is reflected across the line $y = x$. Using the representational bijection, a student could convert each lattice path and its reflection to binary strings and recognize that the two binary strings have their zeros and ones swapped, i.e., the ones in the first binary string are precisely the zeros in the second binary string and vice versa. With some further exploration or guidance, this could lead to a justification of the identity $\binom{n}{k} = \binom{n}{n-k}$ using binary strings and using lattice paths.

In this paper, I have provided a theoretical account of three ways of understanding bijections in combinatorics: relabeling, representational, and relational. I provided combinatorial examples to exemplify each way of understanding, and I discussed some potential affordances and constraints of reasoning with each type of bijection. My hope is that these ways of understanding can serve as a foundation for future empirical research and conceptual analyses, both to provide evidence and to suggest refinements and additions to these three categories. Moreover, conceiving of combinatorial bijections in terms of relabeling, representational, and relational provides one avenue for designing tasks to target a bijective way of thinking in combinatorics. By elaborating ways of understanding bijections in combinatorics, I hope to inspire thought and research into bijections and how this research can be connected to other areas of mathematics education research, such as research in combinatorics education, functions, equivalence and sameness, and topics such as isomorphism, homeomorphism, and isometry.

Ways of Reasoning About Inverse Functions

Erin Wood
University of Georgia

Prior research on student understanding of inverse function has primarily focused on deficits in these understandings without explicitly addressing the mental actions and operations that researchers or instructors would like students to engage in. In this report, I present three ways of reasoning about inverse functions: a covariational approach, a mapping approach, and a set theoretic approach. I argue that all three entail productive ways of thinking about inverse functions, and that the coordination of the three can support students in reasoning about inverse functions in a variety of contexts.

Keywords. Conceptual Analysis, Inverse Functions, Precalculus

To intentionally design curriculum and plan instruction that targets the development of strong mathematical meanings on a particular topic, mathematics educators must first decide what specific mathematical meanings are most beneficial for students to construct (Steffe, 2007; Thompson, 2013). This includes a need to understand the mental operations and ways of thinking that are entailed in these desired ways of reasoning (Thompson, 2008; Thompson, 2013). Previous literature has primarily focused on student difficulty with inverse functions instead of providing a coherent description of how someone might reason productively about them. There is ample evidence that students often do not have coherent meanings for inverse function across contexts, but there are few detailed descriptions of what coherent meanings might entail. In this paper, I propose three ways of reasoning about inverse function and argue that all three are compatible with each other and useful for students, and that they should be targeted in teaching.

Literature Review

Although many researchers have studied student learning and understanding of function (e.g., Breidenbach et al., 1992; Carlson, 1998; Monk, 1992; Doorman et al., 2012) there has been less of a focus on inverse function in particular. Early work by Even (1990; 1992) examined the use of the metaphor of "undoing" to understand inverse function and several research groups have used characterizations of students' conception of function developed by Breidenbach et al. (1992) to extend to the context on inverse functions. Breidenbach and colleagues defined an action versus process conceptualization of function, where an action level of function involves the manipulation of objects (either physical or mental) and might allow a student to plug numbers into an algebraic expression to calculate a result but would limit the student to consider the result of such a calculation separately. A student with a process conception of function thinks about functions as processes that transform objects into other objects via some repeatable transformation but does not need to calculate any particular values to be able to conceptualize this process (Breidenbach et al., 1992). Vidakovic (1996) claimed that students with a process or object concept of function can develop concepts for inverse function. She argued that coordinating inverse function as the reverse of a function process, as the coordination of two function processes to get identity, and as an action of switching x and y and solving for y, is necessary for a deep conceptual understanding of inverse function but did not detail how a student might coordinate these different ways of thinking about inverse. Engelke and colleagues (2005) used the action versus process distinction and argued students who have developed a process view of function understand that this process can be reversed to obtain an inverse which would allow them to make sense of inverse function notation such as $f^{-1}(f(x)) = x$.

Oehrtman and colleagues (2008) discussed the implications of an action versus process conception of functions, and noted that an action view of functions makes it impossible to reason about functions dynamically because each input and output must be considered separately. Oehrtman et al. (2008) identified three distinct conceptions of the inverse of a function: as an algebra problem, as a geometry problem, and as the reversal of a process. They argued that students with an action view of function can understand inverse functions in the context of algebra (as a procedure to find the inverse of a given function) and the context of geometry (as a procedure to reflect a given graph over the line $y = x$), but do not understand why these procedures work or their connection to the ideas of composing or reversing functions. In contrast, students with a process conception of function can understand the inverse of a function to be the reversal of a process, which maps a set of outputs of the original function back to the associated inputs (Oehrtman et al., 2008). This way of reasoning requires students to be able to consider a function as a general process without having to coordinate individual input and output values as would be necessary for students with an action concept of function.

Paoletti and colleagues (2018) conducted task-based interviews that included contextualized and decontextualized inverse function tasks in analytic and graphical representations. Many participants tried to use the "switch and solve" procedure in contextualized contexts, which proved problematic because switching the variables led to a non-normative relationship between the two quantities. For example, when finding the inverse of a function that converts degrees Fahrenheit (F) to degrees Celsius (C), interchanging the variables F and C leads to a function that does not maintain the standard relationship between Fahrenheit and Celsius. Many of these participants concluded that their inverse was not meant to represent the same relationship as the original function or were unsure of how to interpret the inverse function that they found. Only one student demonstrated what the researchers inferred to be well connected meanings between analytic and graphical tasks in decontextualized and contextualized settings. This participant used "switching" techniques for all of the tasks, but she identified that she would need to change which quantity her variables referred to when switching in the tasks with quantitative context.

While most research on students' understanding of inverse functions has focused on the deficits and disconnected nature of this knowledge rather than on explicating potential ways that students might reason productively, Paoletti (2020) presented an example of a student successfully reorganizing her previously disconnected meanings for inverse function. The participant originally used switching techniques to solve tasks that did not support her in making sense of contextualized inverse function tasks. Throughout the course of the teaching experiment, the participant came to understand that a function and its inverse represent the same relationship in a contextualized situation, and that the switching and solving technique is used to maintain the convention that the quantity seen as the independent variable is represented on the x axis. Based on the student's actions, along with an analysis of research on covariational reasoning, Paoletti (2020) provided a detailed conceptual analysis of inverse functions that emphasized the invariance of the relationship between the two quantities related by a function and its inverse. This conceptual analysis will be discussed in more detail below.

More recently, Cook et al. (2023) conducted a conceptual analysis on the construct of inverse more generally (rather than specific to inverse functions), and proposed three ways of reasoning about inverse that can support students' understandings in a variety of algebraic contexts. Their first characterization is "inverse as undoing", where "inverse is viewed as a relationship between operations" and where "the purpose of the operation (or sequence of operations) in question is to undo the effect of the original operation(s)" (Cook et al., 2023, p. 757). They also argued that inverse can be thought of as "inverse as a manipulated element" in which students conceptualize an inverse as an element rather than an operation, and where this inverse element is "associated with a procedure by which a given element is manipulated into its inverse element")" (Cook et al., 2023, p. 757). Lastly, they proposed "inverse as a coordination of the binary operation, identity, and set" (Cook et al., 2023, p. 757) where students view inverse as a relationship between a pair of elements such that their interaction yields the identity, with whatever binary operation is relevant in the given context. This conceptual analysis provides potential ways for students to see commonalities in the broader construct of inverse across mathematical contexts but does not provide explicit ways that students might reason about particular inverse functions.

Three Ways of Reasoning About Inverse Function

To develop the ways of understanding inverse functions presented here, I conducted a conceptual analysis. Conceptual analysis is a method grounded in a radical constructivist epistemology that involves a fine-grained examination of the concepts surrounding a particular topic (Thompson, 2008). Importantly, the analysis is not situated in the abstract but instead the researcher considers how an individual might think about the concepts. Conducting a conceptual analysis can be a way to develop answers to the question "What mental operations must be carried out to see the presented situation in the particular way one is seeing it?" (von Glasersfeld, 1995, p. 78). Thompson (2008) identified conceptual analysis as a fruitful technique for describing productive understandings for students to develop, and for examining the coherence of different ways of understanding a collection of ideas. To this end, I conducted a conceptual analysis on inverse functions to describe potential productive ways for students to reason about inverse functions, and to examine the coherence (or lack thereof) of these ways of reasoning. Based on my own mathematical understanding and my review of the literature on inverse functions, I have identified three distinct approaches to thinking about inverse function: a covariational approach, a mapping approach, and a set theoretic approach.

A Covariational Approach to Inverse Function

Covariational reasoning, as defined by Carlson et al. (2002), involves "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354). This way of reasoning has been shown to be powerful for helping students reason about dynamic situations (Moore & Carlson, 2012), exponential growth (Ellis et al., 2012), calculus (Thompson et al., 2013) and trigonometry (Moore, 2014). Thompson and Carlson (2017) proposed a covariational meaning for the concept of function:

> A function, covariationally, is a conception of two quantities varying simultaneously such that there is an invariant relationship between their values that has the property that, in the person's conception, every value of one quantity determines exactly one value of the other. (p. 444).

This construct was extended to define the idea of a "covariational relation" (Paoletti, 2020), in which a student has conceptualized two quantities varying together where one quantity varies first and the other quantity changes along with the first. This can then become a covariational function once the student constructs the property that each value of the first quantity corresponds to exactly one value of the second (Paoletti, 2020). A student who reasons about functions from a covariational perspective can imagine the first quantity changing and knows that the second quantity will also change correspondingly, without having to think about or calculate actual values of either quantity. For example, a student might construct a covariational relation between height and volume when considering water being poured into a pool, where they consider the height of the water first and then the associated volume at that moment. If the student realizes that for any height value, there is a unique corresponding volume, they have then constructed a covariational function of volume with respect to the height of the water.

If a student then were to consider the volume changing first instead of the height, they would have constructed an inverse covariational relation (Paoletti, 2020). If they realized that for each value of the volume there is exactly one associated value of the height of the water, they would have constructed an inverse covariational function (Paoletti, 2020). Once a student has constructed both a covariational function and an inverse covariational function to describe the same two quantities varying, they can see that both the original function and its inverse represent the same relationship between the quantities, and the only aspect that changes is which quantity is considered to be varying first, with variation in the second dependent on the variation of the first. This does not imply an actual causal relationship between the two covarying quantities, but instead refers to the fact that the amount of variation in one quantity that is considered is dependent on the amount of variation considered in the other. From this perspective, there is no need to consider the inverse relationship as a separate entity from the original relationship, it is simply the same relationship viewed from a different perspective.

In a quantitative context in which one quantity is not uniquely determined by the other, a student can still conceive of an inverse covariational relation. For example, imagine that the student had instead considered the volume of the water in the pool as time varied, with the pool first being drained and then refilled. In this case, each value of the volume of water in the pool would correspond to (at least) two different times, one as the pool is emptied and one as it is filled. The student can still consider volume varying first with the associated time values varying with it, despite the lack of uniqueness. For example, the student can imagine that as the volume of water in the pool increases, one of the corresponding time values also increases (becoming closer to the time when the pool is completely refilled) while the other decreases (becoming closer to the time when the pool started to drain). The mental actions that a student engages in when constructing an inverse relation and an inverse function are the same from this perspective, and an inverse function can be seen as just a type of relation that happens to fulfill the uniqueness property. This flexibility in imagining inverse covariational relations that are not necessarily functions is in direct contrast to the way that inverse functions are typically taught, in which students learn that functions are not invertible if they are not injective. This may lead students to believe that it is impossible to construct an inverse relation in these situations, or that these inverse relations would have no use.

A Mapping Approach to Inverse Function

Traditionally, functions are defined as mappings that take each element of a function's domain to exactly one element of the function's range. To construct the idea of function from a mapping perspective, a student must conceptualize two arbitrary sets with some sort of rule that takes elements from one set as inputs and gives elements of the other set as outputs, and where each possible input maps only to one output. To construct the idea of an inverse function, a student must then imagine another function that maps in the opposite direction, taking the original function's output values to the associated input values. To be able to define this map that reliably takes an output value to its associated input, the original function must satisfy the property that each input maps to a unique output value. A student must see that if this were not the case, there would be no way to determine which input value the inverse function should map the output value back to, and thus the injectivity of the original function becomes a requirement to define an inverse function. The student can then imagine elements from the function's domain being mapped to elements in the range by the function, and then these elements of the range being mapped back to the original elements in the domain when the inverse function is applied. The opposite order of applying these mappings will yield the same result, where elements of the range of the original function are mapped to elements of its domain by the inverse function, and then applying the original function will map these elements back to their "starting point".

With a covariation approach to function, the student imagines changes in each quantity occurring simultaneously and attends to these changes in relation to each other (e.g., as quantity A increases, quantity B decreases). With a mapping approach to function, the student instead imagines change from one set to the other (e.g., an element, *x,* being "transformed" by the function to an element, *y*). Both approaches have an imagined dynamic element, but the types of change that are emphasized are fundamentally different. In contexts where students are reasoning with actual quantities, often a transformation approach to understanding function is incompatible (at least from the perspective of the researcher) because one quantity cannot "transform" into the other. Recall the example above where the volume of water in a filling pool is seen as a function of time elapsed. This function cannot transform time into volume, but instead simply provides a relationship between the values of the two quantities. Additionally, in contrast to the covariation approach where the inverse is seen as maintaining the same relationship as the original function but from a different perspective, the mapping perspective instead views the inverse as a separate function in its own right. Instead of the emphasis being on the sameness of the relationship defined by the function, the emphasis is instead on the relationship between the function and its inverse, namely that the inverse undoes the action of the original function.

A Set Theoretic Approach to Inverse Function

Relations can also be defined from a set theoretic perspective, as a set of ordered pairs (a, b) where the first element in the pairs are elements of a set A and the second element in the pairs are elements of a set B. The set A is defined to be the relation's domain, and the set B is the relation's range. In contrast to the covariation and mapping approaches, there is no mental imagery of change or variation, only of static ordered pairs being elements of a relation. From this perspective, in order for a relation to be a function, the property must hold that if (a, b) and (a, c) are elements of the relation then b and c are the same element of the range. The inverse relation would then be the set of ordered pairs (b, a) obtained from reversing the order of the pairs in the original relation and thus interchanging the domain and range. This inverse relation would be a function if it satisfies the above property. Using this definition to think about functions and inverse functions leads to an understanding of inverse as a switching of coordinate points. This is useful for mathematical settings that do not involve continuity or that are in contexts outside of the real numbers but does not support the use of quantitative reasoning to imagine "real life" situations, particularly those in which images of (co)variation are critical. If functions are thought of solely as sets of ordered pairs, then there is not a natural way to envision how one quantity might change in relation to another.

Despite these limitations of a solely set-theoretic approach, this approach is in no way incompatible with a covariation or mapping perspective. All three perspectives foreground pairs of values, but the set theoretic approach does not necessitate the consideration of variation between the pairs of values or a transformation from one value to another. From a covariation perspective in which two quantities are varying simultaneously, one must keep in mind that for any given value of one quantity there is an associated value of the other quantity, and these pairs of values can be seen as the ordered pairs considered from the set theoretic perspective. Similarly, the mapping perspective emphasizes that values from the domain are mapped to values in the range of a function, and each input/output pair can be seen as the ordered pairs from the set theoretic perspective. The set theoretic approach assumes the existence of these pairs of values but does not support someone in producing the pairs. In order to produce the pairs, one must use either a covariation or mapping approach to function to determine the value of one quantity for a given value of another quantity.

Examples

Each of the three ways of reasoning described above provide useful ways for students to reason about inverse functions, and it is the goal-oriented activity that a student engages in that dictates which way of thinking is best suited for the situation. For example, consider a quantitative context where two quantities covary and in which it can be useful to think of either quantity as varying first. A covariation perspective can allow a student to reason flexibly about either quantity varying first, with the persistent realization that both ways of thinking about the context maintain the same relationship between the quantities. A student reasoning in this way can view the graph of a function as also representing the graph of the inverse by considering the quantity on the vertical axis as varying first instead of the standard view of values on the horizontal axis representing the independent variable. This can allow them to reason about the inverse relationship using only a graph of the original function without needing to construct a separate graph of the inverse. In this context, a mapping perspective is somewhat less natural, and in order to reason about the inverse of a given function a student would be more likely to have to construct an equation or graph for the inverse first.

However, in contexts involving composition of functions, thinking of inverse from the mapping perspective is more productive. From a covariation perspective there is usually no motivation to consider the inverse relationship as a separate function from the original, and so composition is not obvious. From the mapping perspective the fact that a function composed with its inverse should yield the identity function becomes clear. If the inverse of a function is a function that maps the outputs of a function back to the original inputs, then performing one mapping and then the other must always result in whatever the original input was. When students are asked to produce a graph of the inverse function based on the graph of a given function, set theoretic reasoning is often most efficient. The original graph of the function consists of the ordered pairs of that function, and thus a graph of the inverse function must consist of these same pairs but in the opposite order. This reasoning can allow a student to bypass the cognitive effort of the analogous reasoning from a mapping perspective, where a student might reason that if a point on the original graph (x, y) means that the function maps x to y, then the inverse function must map y back to x and thus the point (y, x) will be on the graph of the inverse.

Despite the varying degrees of utility of each way of reasoning in different contexts, the three ways of understanding inverse function are in no way incompatible. Consider the example of the relationship between temperature measured in degrees Fahrenheit (F) and Celsius (C): $C=5/9(F-32)$. From a covariation perspective, a student can reason that this equation gives a relationship between the measures of temperature in both units and can see a graph of this relationship as providing information about the relationship viewed with either quantity varying first. At the same time, that same student can know that, as written, the function takes values of temperature measured in Fahrenheit and maps them to the appropriate value measured in Celsius, but that they can also find a function that takes values of temperature in Celsius and maps the opposite way back to the appropriate value in Fahrenheit. Along with these ways of reasoning about the situation, the student can also understand that the original function can be thought of as ordered pairs (*F,C*) that are solutions to the equation above, and that the inverse relationship can be seen as the pairs in the reverse order (*C, F*). Depending on the student's goal when reasoning about this context, any of these three meanings could be drawn on productively.

Conclusion

The ways of reasoning described above provide a finer grained description of the mental actions involved in reasoning about inverse functions. Previous work has provided hierarchical frameworks for the development of an understanding of inverse functions (e.g., the action vs. process conceptions of inverse functions), but the details of what an understanding of inverse functions entails were underdeveloped. The action versus process dichotomy does not capture differences between a student reasoning from a set theoretic, mapping, or covariational perspective. While the description of the covariation perspective on inverse functions is not new (Paoletti, 2020), the juxtaposition of this perspective with the mapping and set theoretic perspectives offers a broader view of productive meanings for inverse function. In addition, the conceptions of inverse functions identified by Oehrtman et al. (2008) separated conceptions of inverse mostly by the procedures or products of reasoning associated with them (i.e., reflecting over a line to graph, switching variables and solving, or understanding inverse as the reversal of a process), without specifying the associated mental operations behind the three conceptions. This categorization gives us three ways that students must be able to engage with inverse functions but is of limited use in specifying how we would like students to think about inverse functions. The conceptual analysis conducted by Cook et al. (2023) also identified three ways of reasoning about inverse, but in the more general context of inverse not specific to inverse functions. I argue that, while there is overlap between the characterization presented in this paper and that provided by Cook et al. (2023), there are ways of reasoning that are important for productive engagement with inverse functions that are not captured in broader reasoning about inverse. For example, a covariational approach to inverse function relies on continuity, and while it is a useful way of reasoning for students in these contexts, there is not necessarily an analogous form of reasoning when considering inverse elsewhere in mathematics. In turn, the characterization of inverse function meanings provided here does not capture meanings about inverse functions as an instantiation of the larger idea of inverse, and I have not attended to how students understand functions and their inverses as elements of a set.

A significant limitation of the characterization of inverse function reasoning presented here is that it is a first order model (Thompson, 2000) that it is based on my own mathematical meanings. It is informed by the extant literature base on student understanding of inverse functions and by my interactions with students but has yet to be studied empirically. Future research should examine how these ways of reasoning emerge in practice and explore ways in which the coordination of these different ways of reasoning might support engagement with inverse function tasks. If these proposed ways of reasoning about inverse function maintain their viability after empirical research with students, then further research could begin to explore the development of these ways of reasoning. Reflected abstraction (Piaget, 2001) can help to connect previously disjoint mathematical meanings into one coherent scheme and brings these connections to the level of conscious awareness. Therefore, I hypothesize that reflected abstraction is a potential way for students to integrate these distinct ways of understanding inverse function, and that supporting students in engaging in reflected abstraction may encourage coherence in their meanings.

In this paper, we motivate the need for a definition of mathematical autonomy that does not imply that autonomy is a trait of an individual. Rather, we demonstrate the usefulness of a lens on autonomy that captures the characteristics of actions taken in contexts that shape the space of sensible action. Shifting from trait to quality of action in context further allows us to analyze how actions of groups of individuals doing mathematical work can have qualities associated with mathematical autonomy. We ground our theoretical work in data from a longitudinal case study of an undergraduate student, Kaleb, whose orientation to mathematical sense-making changed sharply across multiple contexts of activity.

Keywords: Intellectual Autonomy, Mathematical Experience, Introduction to Proof, Upper-Division

Introduction

It has long been documented that U.S. students experience challenges of many sorts in moving from lower division courses to upper division courses (Moore, 1994). A challenge of particular interest is the movement from math coursework that is typically more algorithm and procedure oriented to upper division coursework that includes more focus on construction and validation of arguments and proofs (Selden, 2012). In light of the centrality of this challenge, a subset of the authors conducted a small-scale longitudinal study to investigate students' experiences as they navigated this challenge in the context of a large public U.S. university (Bae et al. 2018; Smith et al, 2017). This study focused on student experience and development of agency and autonomy through this transition to proof-intensive coursework in contrast to more traditional focus on mastery of proof methods and mathematical notation.

One way to capture an important facet of productive disciplinary engagement at the undergraduate level, and that is related in a key way to the transition from computationally-focused to proof-intensive work mentioned above, is that when students encounter a challenge in their mathematical work, they are able to consult perceived sources of mathematical authority (self, teachers, texts, internet resources) as appropriate and needed. This goal has been articulated in various ways in the literature discussing the need for students to be able to move away from appeals to external authority in determining validity of arguments (Harel & Sowder, 1998; Stylianides, 2007; Yackel & Cobb, 1996). Inglis & Mejia-Ramos (2009) caution that looking to authority figures, per se, is not a problem, but concur that students should be empowered to establish the validity of arguments through their own sense-making processes. That is, collegiate mathematics educators want students to come to see themselves as local disciplinary authorities that view the correctness of a proof as something they can assess via mathematical reasoning and mathematical logic, not something that they are dependent upon external sources of authority such as teachers or texts in determining.

In describing these goals for students and instruction, sometimes the term “autonomy” is invoked (NCTM, 2000) with the expectation that a goal for mathematics instruction is that students become increasingly autonomous as they move through their mathematics coursework and beyond. However, there are multiple perspectives on autonomy in the literature. Two prevalent perspectives relevant to students’ educational experiences include psychological and intellectual autonomy. Psychological autonomy (Deci & Ryan, 1980) is linked with self-determination, free-will, and independence (self-reliance). Intellectual autonomy, with roots in the work of Piaget, casts autonomy as a trait which individuals develop over time, in which individuals become increasingly independent in sense-making in the context of the ideas of others (Piaget, 1973). Later, Wood reformulated the notion of intellectual autonomy through a communicational lens, building upon Sfard, to focus more upon the individual in relation to sources of authority and whether individuals see themselves as sources of authority, capable of deciding whether a given mathematical inference is right or wrong (Wood, 2016).

In this paper, we broaden the original focus on individuals making determinations of right or wrong inferences to students remaining personally involved in processes of sense-making (e.g., making determinations of whether actions taken in response to mathematical challenges make personal sense or not). We further expand from individual sense-making to sense-making in group contexts and also consciously expand from other people as trusted external authorities to include other kinds of external sources of authority such as internet-based resources, including AI systems.

Research Focus and Question

The data for our study was collected at a large public U.S. university where students, both mathematics majors and minors, first encounter mathematical proof formally in a semester-long, problem-based ITP course. In the ITP course, project data collection involves a baseline interview, a task-based interview, and a series of homework reflection logs from each of the 15 participants in the first cohort. Both the mathematics majors and minors in our study subsequently enroll in two or more advanced, proof-based mathematics courses to satisfy their major or minor requirements. Our longitudinal study involves following students into these subsequent courses as well as collecting data from a second cohort of students. Participants were selected to represent a broad spectrum of gender, ethnicity, major/minor, and mathematical beliefs as measured by the Mathematics Attitudes and Perceptions Survey (Code, Merchant, Maciejewski, Thomas & Lo, 2016). In addition to the interview and reflection log data mentioned above, roughly a third of the ITP classes were observed by members of the project team to provide context for the research team in interpreting the experiences reported by students in the interviews.

The specific question that guided this inquiry in this paper is “Which view of mathematical autonomy [trait or quality of action] is more useful in understanding collegiate students’ progression through their upper-division mathematical coursework?”

Reconceptualizing Mathematical Autonomy: A New Definition

Our initial framing of mathematical autonomy followed Yackel and Cobb’s (1996) analysis in seeing intellectual autonomy as both a *state of awareness of one’s intellectual capabilities* and a *willingness to act on them in engaging in challenging mathematical work*. Where Yackel and

Cobb conceptualized intellectual autonomy solely within the social practices of mathematics classrooms, we needed our constructs to apply also to in–class and out–of–class mathematical activity, as college students have great freedom to act (or not) in ways they see as productive. Indeed, one key developmental task for college students is deciding how and why to deploy out–of–class time and activity productively.

Through our initial attempts to characterize the mathematical autonomy students were displaying at different points in time in their undergraduate experience, we became more attuned to the relationship between students and perceived sources of mathematical authority. That is, we came to appreciate how students' views of themselves as sources of mathematical authority was context-dependent, as well as students' views of themselves in relation to other sources of mathematical authority (instructors, other students, family members, or sources on the internet). In developing our definition, we previously analyzed students' shifting relationships to mathematical authorities such as family members (Castle et al., 2022) and students' usage and reflections on the usage of internet sources of authority (Levin et al., 2020). The working definition for mathematical autonomy that we settled upon is:

> *Mathematical Autonomy:* A quality of action that reflects the actor's active resistance to endorsing, following, or replicating the reasoning of mathematical authorities (e.g., texts, internet sources, instructors, peers) while engaging in a process of sense-making. The quality of action reflects the actor's judgment of using only the external resources necessary to continue a sense-making process when they meet a local obstacle and/or engaging in sufficient sense-making to transform the reasoning of others/other resources to their own.

Illustrating Features of Mathematical Autonomy: The Case of Kaleb

In this paper, we have chosen to illustrate the affordances of the new definition of mathematical autonomy using the data from a single case, Kaleb. Kaleb was a mathematics major, considering adding computer science as a second major or minor at the time of his Introduction to Proof course, when we began interviewing him. He had aspirations of graduate school in mathematics, and was possibly interested in teaching. By following Kaleb for multiple semesters, we found Kaleb displayed autonomy in different ways depending on mathematical context.

Kaleb's individual sense-making actions as autonomous in the ITP course

Early on in Kaleb's Introduction to Proof course, he showed more autonomous actions by actively engaging in sense-making and rejecting passively accepting others' mathematical authority. For example, in the ITP course, Kaleb thought the course was teaching them how students could think mathematically, and this aligned strongly with what he thought he needed to learn. Kaleb faced some challenges in doing homework, and his actions dealing with those challenges showed that Kaleb valued his work and tried to give him some time to think before he used other resources:

> Certain ones [tasks] took longer than others, but I found if I got stuck, I could get up, go get a drink, come back, play on my phone for a little bit, get my mind off of it. And then, looking at it with a fresh start, it would pop out.

He reported that if he had given enough thinking time for himself, he would reach out to other resources, such as peers or the course-provided online platform Piazza. In one instance, Kaleb reported in his homework log that he felt the instructor included more of a hint than what he thought necessary on Piazza. This led him to use only the first half of the hint and create his own outline for what he needed to do. After the whole process, he still spent another 40 minutes to an hour to write a proof. This excerpt shows Kaleb's autonomous action in this context in not accepting an authority figure's work when he was stuck, but rather trying to understand, evaluate, and use only the part he felt he needed to get unstuck. At this time, he expressed a strong view against copying solutions from other sources:

> If you are simply copying the answers down to get answers and submitting them as your own, then yes, that is cheating. However, looking for an answer and using it to get your own answer is fine… From what I can tell, one of the main themes about the class is teaching us how to think more mathematically. If you only copy someone, you let them do the thinking for you. You never learn anything and are wasting everyone's time.

Kaleb's joint work actions in ITP and Abstract Algebra as autonomous

When Kaleb could not solve problems, even though he gave himself some time to think about the problem, he consulted external resources. In the ITP course, the most used resource was a friend, Steven (pseudonym), whom he met in the ITP course and a statistics course. Kaleb and Steven regularly spoke on the phone and on Sunday night, and one explained to the other person as well as sometimes sending photos of their work when one of them was struggling.

Similarly, in Abstract Algebra, Kaleb worked with another friend who was also taking the same course in a different section but with the same instructor. Kaleb and the friend bounced off ideas with each other, and he described their contributions as 50-50. They sometimes had different ways of solving the same problem, and they examined each other's solutions and were content to submit their final work in different ways. We view this excerpt as showing that they did not just follow each other's work, but rather Kaleb's joint work with his friends in these contexts had features of mathematical autonomy.

Kaleb's use of internet resources as more and less autonomous, depending on context

In addition to human resources, Kaleb used internet resources, and his quality of actions shifted, depending on mathematical context. Above, we described how Kaleb resisted the reasoning of authorities when consulting internet-resources when stuck. However, Kaleb's actions towards internet resources changed in the following semesters. In the Linear Algebra course that Kaleb took concurrently with Abstract Algebra, he did not have a peer who could work together. He found himself consulting internet sources faster than in the ITP or the Abstract Algebra courses. He reported that once he spent 10-20 mins per question, he went to the internet to find some solutions. When he found a solution, he reported that 60% of the time he would try to make sense of what the found solution said and rewrite it in his own words. However, for the other 40% of cases, he reported that he copied the solution as he found it. Kaleb attributed the reasons for this action was that there were too many questions, each with little worth of his time because they were not a big part of his grade. In this course, homework was 8% of the final grade, and only some of the questions were graded in the course:

> I've definitely had it where I don't completely understand what's going on. […] It feels like cheating, or it feels…it doesn't feel good, but I know I'll get points and I'll get an okay grade.

Although there were external situations (i.e. having too many questions), it is important to note that in this context he started copying solutions from online sources. In the previous semester (in the ITP course), he viewed copying down others' solutions as relinquishing one's opportunity for sense-making. However, a less autonomous pattern of action emerged in Linear Algebra. His larger frame guiding action appeared to have shifted from understanding to earning points.

Later, in Spring 2020, when the COVID-19 pandemic erupted, Kaleb was taking Analysis I. Before COVID-19 changed the modality of the course, to do the homework in his analysis course, Kaleb said he spent 10 minutes thinking by himself and then left the problem to come back later. He said he usually repeated the cycle three times, then he tried to search online if he could still not solve the problem. Because the majority of the homework problems were from the textbook, Kaleb said it was very easy to find solutions on the internet. Also, he could find the solutions from other college courses or other professors. Even though he was using others' solutions, Kaleb reported that before COVID-19, he still valued understanding and sense-making because he knew that he would need them for the exams in the short term and for his career in the long term.

When COVID-19 happened, Kaleb had to go back to his home and had to go back to his parents' house, disrupting his sense of space and place (Küchle et al, 2023). His motivation for doing homework dropped significantly, which in turn influenced his actions, becoming less autonomous. Kaleb admitted that the quality of his actions before and after COVID-19 was different. Kaleb did not view his parents' house as a conducive workplace, and during this time he also suffered the loss of family. These changes made him focus on his personal life rather than schoolwork, which led him not to submit a few homework assignments, and to use the internet more on assignments he did complete.

Discussion

The data from the case of Kaleb illustrates how trait-based views of autonomy are insufficient for capturing the context-dependency of college students' actions in proof-based courses. As opposed to having a trait or characteristic of "being autonomous," Kaleb instead showed the actions he took could be cast as more or less autonomous depending on different contexts, such as his work with peers in his ITP and Abstract Algebra courses or the differences in his ways of using internet-based mathematics resources across his coursework. Further, as opposed to being a trait that increased in amount over time, we uncovered the way that circumstances and the constraints of his experience in different courses (e.g., different working conditions and course modality due to COVID-19) went hand in hand with him exhibiting less autonomous actions.

Thus, the data we present push the field to reconsider "autonomy" in a way that is not synonymous with a trait such as "individual independence." As opposed to framing autonomy as a trait that an individual may/may not possess, we are able to focus on qualities of actions taken during mathematical work. Our expanded way of framing autonomy focuses on qualities of action that align with being able to use resources (including social resources such as peers, and material resources such as the internet-based sources) appropriately. What is considered appropriate can align with current norms around collaboration and use of internet-based resources, both of which are features of modern work. Especially in the case of internet-based resources, the use of AI systems such as ChatGPT to assist in creative work, will only become a larger issue.

Methodologically, instead of assessing the amount of "autonomy" that an individual possesses, or even a Likert-based ranking, we can focus on records of specific interactions in specific contexts around mathematics. In conducting a case study of an individual over time, the focus shifts from differing amounts of "autonomy" across time to differences in the qualities of actions individuals take over time. One thing that complicates the tracing of qualities of action of individuals, is that the context in which actions are taken needs to be accounted for. The norms and practices in different course contexts can help one to explain how/why individuals take particular actions. For this reason, it is important for us to understand more about the constraints that participants perceive relative to their actions. We view this system of constraints as what constitutes the mathematical agency - the felt capacity for action - that students perceive (Levin, et al. 2020).

In terms of implications for instruction, our conceptualization of mathematical autonomy does not imply a restriction on the material and social resources available to students during their reasoning processes. In building the capacity to act with mathematical autonomy when faced with mathematical challenges, students need opportunities to engage deeply before abdicating their involvement in the resolution by, for example, calling over an instructor or other mathematical authority to direct them, or to search on the internet for the task they were working on and copying the argument. In undergraduate education, students' ability to navigate "stuck points" is linked with their ability to continue their engagement in mathematical challenges (Lu, 2021). Strategies for supporting productive struggle support the ability to act with mathematical autonomy (SanGiovanni et al, 2020; Warshauer, 2015).

A Conceptual Analysis of Expressing Distances Algebraically within the Cartesian Plane

Erika David Parr
Rhodes College

Samuel Lippe
Rhodes College

This theoretical report offers a conceptual analysis of expressing distances on graphs of functions in the Cartesian plane algebraically. We frame this mental activity as a connection between the algebraic and graphical registers, and describe three key connections it comprises: (1) differences express distances between two positions, (2) points are ordered pairs of distances from the axes in the Cartesian plane, and (3) equations give the relation between x and y for every ordered pair on a graph. We detail the conceptual components of each connection, which involve a component from each of the graphical and algebraic registers and an underlying interpretation that forges the connection between the two. This conceptual analysis makes explicit the complex cognitive steps involved in algebraically expressing distances on graphs of functions, with implications for researchers and practitioners using algebraic and graphical representations together.

Keywords: Graphical representations, algebraic expressions, conceptual analysis, Cartesian plane

The central goal of this theoretical report is to offer a conceptual analysis (Thompson, 2008) of the mental activity involved in representing distances between functions graphed in the Cartesian plane using algebraic expressions. Many mathematical objects involved in key results of undergraduate mathematics are often represented graphically and expressed algebraically in textbooks and curricular materials, such as the difference quotient in the limit definition of the derivative. Specifically, students' ability to use algebraic expressions to represent distances within graphs may support them in making sense of such representations that are paired together. Further, this ability may also assist students in conceptualizing other key results, such as how integrals find area under and between curves, and volumes of solids of revolution. In this paper, we consider the mental activity involved in expressing distances algebraically by centering our discussion around the following task and asking: what are the conceptions involved in algebraically expressing the horizontal distance between any point on $y = \sqrt{x-1}$ and a point on $x = 2$ (for all x such that $1 < x < 2$) in terms of x and in terms of y? (Figure 1).

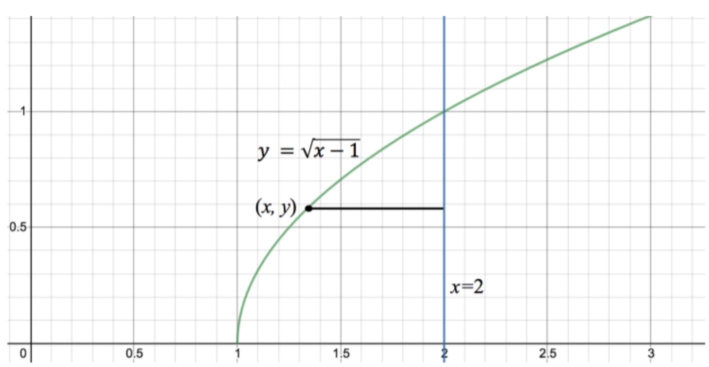

Figure 1. Graph showing a horizontal segment from a generic point (x, y) marked on $y = \sqrt{x-1}$ *to* $x = 2$*. The length of this segment may be expressed as* $2 - x$ *or equivalently as* $2 - (y^2 + 1)$*.*

Conceptual Analysis of Expressing Graphical Distances Algebraically

We engage in the process of conceptual analysis consistent with Thompson (2008) as describing "what students might understand when they know a particular idea in various ways" (p. 42) to detail the mental steps involved for students to conceptualize an algebraic difference expression as representing a horizontal (or vertical) distance within a graph in the Cartesian plane. Based on previous research and work with students on such tasks (e.g., Parr et al., 2021), we theorize that there are three main connections between the graphical register and algebraic register that underly this conception: (1) differences express distances between two positions, (2) points are ordered pairs of distances from the axes in the Cartesian plane and (3) equations give the relation between x and y for every ordered pair represented at a point on a graph. These three connections build upon each other to comprise the connection among *distances between functions in graphs* and *(algebraic) difference expressions*. We describe each of these connections between the graphical and algebraic register, as well as the underlying mechanism for how the connection is forged. We see potential obstacles for students within conceptualizing each component of the graphical register, algebraic register, as well as the mechanism of the connection. We will describe each of the three steps and previous research highlighting potential obstacles for students within each.

Connection 1: A difference represents a distance between two positions

From our perspective, the first main cognitive step to expressing distances on graphs of functions involves using a difference expression to represent a distance between two positions in a single dimension. Within the graphical register, this connection involves conceptualizing distance as a quantity, that is, a measurable attribute (Thompson, 1990, 2011) of the spatial arrangement of two positions within a number line or graph. Within the algebraic register, this connection involves operating from a "*determine the difference*," (Selter et al., 2012) also referred to as a "*comparison*" (Usiskin, 2008) model of subtraction, rather than a *takeaway* model. Connecting these conceptualized distances with difference operations relies on a magnitude interpretation of symbols (Parr, 2021). We summarize these components that result in this connection between differences and distances between two positions in Figure 2.

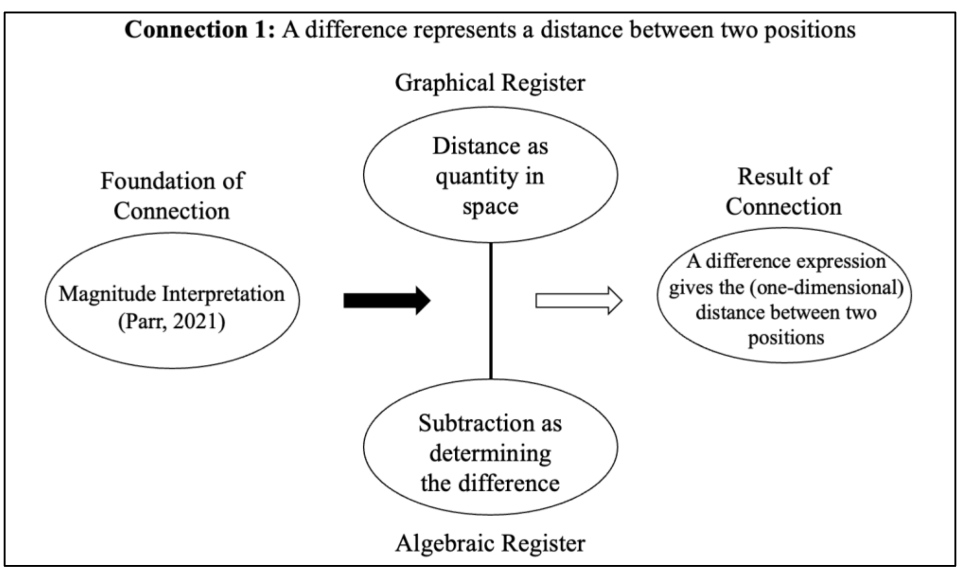

Figure 2. The components of connecting distances in graphs with difference expressions.

Previous research suggests that students may not use these ways of reasoning underlying the connection involved in representing distances with differences. Within the graphical register, conceptualizing a distance as a quantity in space is a non-trivial component of this connection. The Cartesian coordinate system relies on distances to relate points, yet students may not conceive of distance between points as relevant when viewing positions on a number line or graph. Alternatively, they may conceive of positions as labeled at arbitrary locations, or use some other comparison, such as relative location, without explicitly attending to or conceptualizing measurable distance between positions (Parr, 2021). At the elementary level, students may not necessarily place non-consecutive numerical values at appropriate distances apart from one another on a linear-scaled number line (Saxe et al., 2013). Instead of using a number line as a measurement model, some students may use it as a counting model (Diezmann & Lowrie, 2006), counting the number of tick marks or intervals (Mitchell & Horne, 2008). Within the algebraic register, conceiving of subtraction as an operation that determines the difference between two amounts that are compared is not a given for students. Previous research has found that the comparison operations are those that pose the most difficulty for students among types of subtraction problems in early grades (Stern, 1993). When asked to interpret an expression involving a difference, students may think exclusively of a counting down or takeaway model, rather than a comparison one (Figure 3).

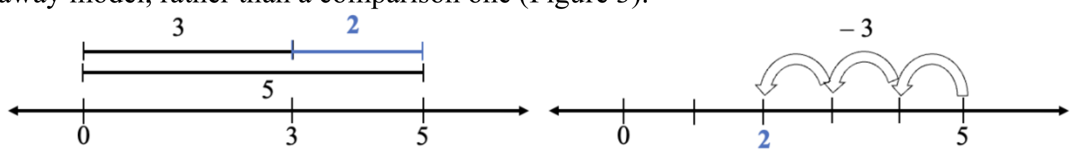

Figure 3. A determine the difference (comparison) model of 5-3 (left) vs. a takeaway model of 5-3 (right).

Students may also default to using the takeaway model for subtraction on a number line, and may not as readily use a determine the difference model, perhaps because the former is more commonly encountered in school mathematics and everyday situations (e.g., Selter et al., 2012). Even at the undergraduate level, students may default to using a takeaway model of subtraction. This was the case with a student, Peter who was at first unable to reconcile a difference expression in $|x–1| < \delta$ with a graph of a function showing a shaded vertical strip centered at $x = 1$ to represent all values of x within a given distance (δ) of 1. (David, 2018).

We view the magnitude interpretation (Parr, 2021) of a symbol (either a number or variable) or expression as the foundation of the connection between the graphical representation of distance and the algebraic operation of subtraction to determine the difference. A magnitude interpretation of a symbol recognizes that a symbol refers to both a position as well as a measure of a distance from 0 (Parr, 2021). To represent the "determining the difference" model of subtraction on a number line, one employs what Parr et al. (2021) refer to as a *composed* magnitude interpretation. For example, to understand conceptually why the difference expression $x_2 - x_1$ yields the distance between two positions, x_1 and x_2, in one-dimensional Cartesian space, one must first understand the positions x_1 and x_2 as distances from the origin themselves. Then, one can apply the operation of subtraction to find the difference between the length of x_2 and the length of x_1 to express the distance between position x_1 and x_2 as $x_2 - x_1$, as shown in Figure 4. Students may not readily use a composed magnitude interpretation of difference expressions, even in situations where it would support further mathematical activity. At the undergraduate level, students may still use a cardinal interpretation, counting tick marks or spaces to interpret a difference expression on an axis, rather than as a distance between two points, as in the case of Annie and Kate reported in Parr (2021).

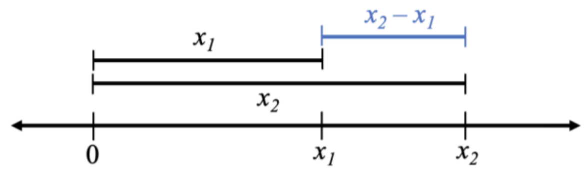

Figure 4. Composed magnitude interpretation of the expression $x_2 - x_1$ involves conceiving of x_1 and x_2 themselves as magnitudes, or distances measured from 0.

Connection 2: A point given by (x, y) represents an ordered pair of distances from axes in the Cartesian plane

The next connection involved in expressing distances in the Cartesian plane is the connection that an ordered pair of values, (x, y), that locate a point in the Cartesian plane represents an ordered pair of distances measured from the point to each axis. This connection builds on the prior one, such that x is a magnitude from the origin horizontally and y is a magnitude from the origin vertically. What is new in this step is the combination of the two magnitudes into two-dimensional space, so that a single entity given by an ordered pair is connected to the pair of distances. The foundation of this connection is value-thinking (David et al., 2019), in which one envisions a point as a multiplicative object (Saldanha & Thompson, 1998), at once a single entity that is comprised of two components conceived of simultaneously. When combined with a magnitude interpretation from the previous connection, one envisions a point as a multiplicative object of a pair of distances to the axes (Figure 5).

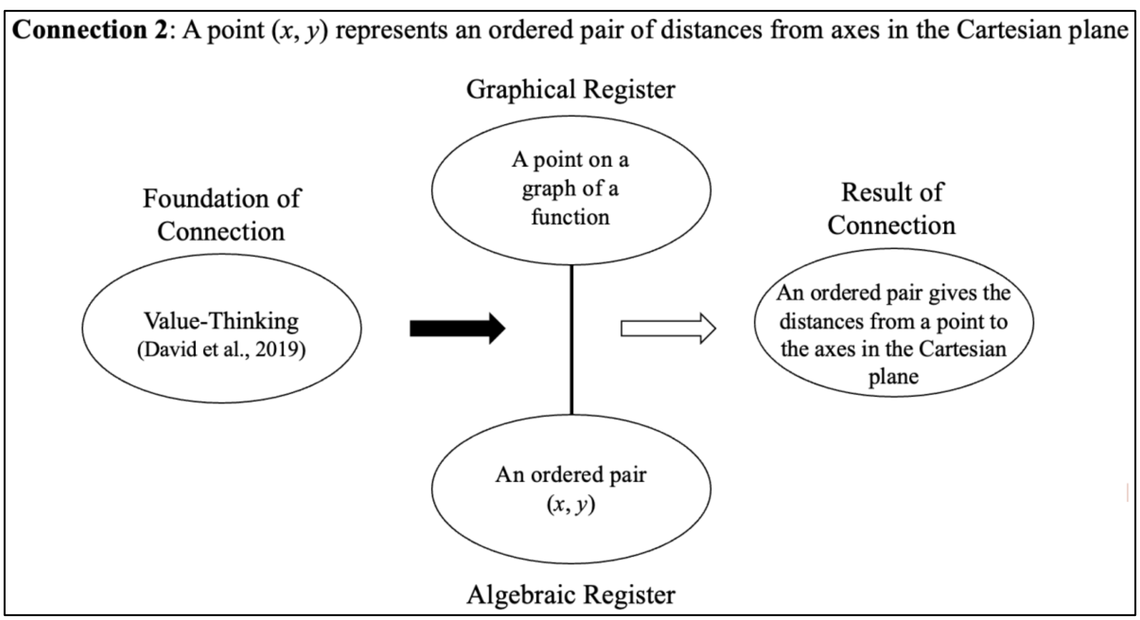

Figure 5. The components of connecting points on graphs with ordered pairs of variables.

Prior research suggests that students, both at the secondary and undergraduate level, may not connect a point on a graph of a function with an ordered pair of input and output values of the function via value-thinking. Students may instead associate a point solely with a single value- often the output of a function, rather than a pair of values, as in the case of location-thinking

(David et al., 2019). When students do connect a point with an ordered pair, they may conceive of the ordered pair purely as a directive for how to locate a point (Thompson et al., 2017)- right (or left) some amount *x* and then up (or down) some other amount *y*. Students who view ordered pairs this way may not be able to unite pairs of magnitudes represented on axes in a single point, even after appropriately plotting points themselves using the over and up technique (Frank, 2016). Thus, we view building the connection between ordered pairs and pairs of distances from axes as an essential part of supporting students in expressing distances between points on functions of graphs.

Connection 3: An algebraic relationship of *x* and *y* can be used to find equivalent expressions of distances

The third connection between the algebraic and graphical register that we view as essential to expressing distances is the Cartesian connection (Moschkovich et al., 1993). The Cartesian connection states that the set of all ordered pairs of points on a graph of an equation correspond to the complete set of pairs of values satisfying the equation. Using this connection with the prior two, in which ordered pairs for points give pairs of distances to the axes, allows one to conceive of the algebraic equation relating *x* and *y* as a way to express distances in the graph flexibly in terms of *x* or *y* as needed (Figure 6).

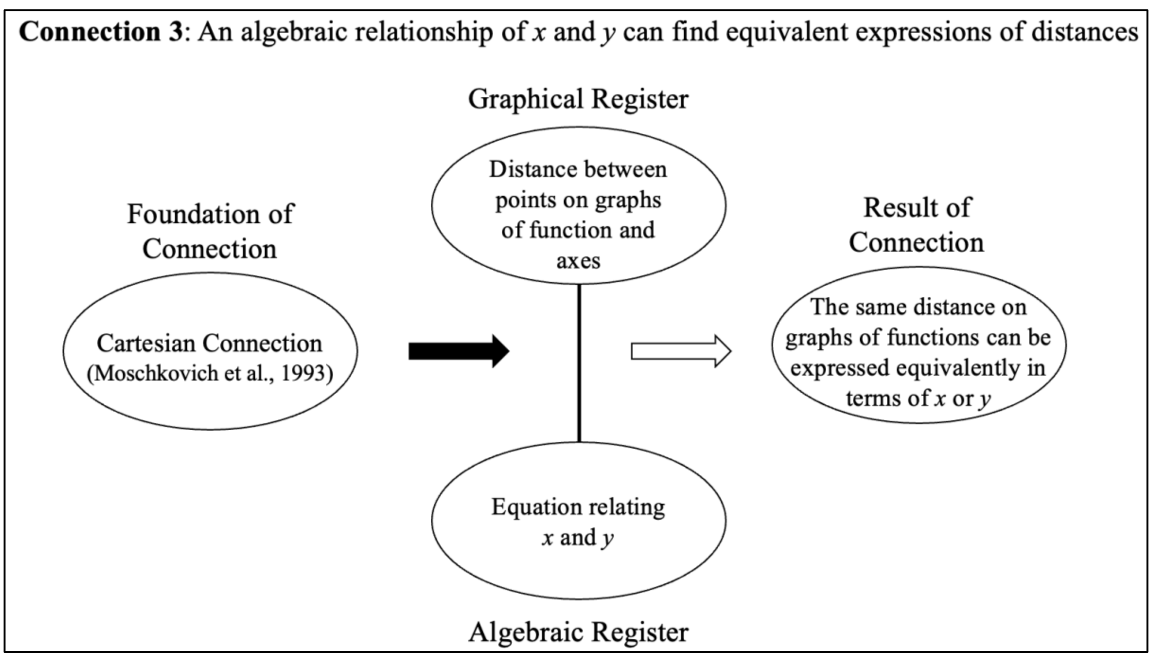

Figure 6. The components of connecting distances on graphs with equations of x and y.

Previous studies have shown that students may not recognize the Cartesian connection when working with graphs of functions and their algebraic relationships (Dufour-Janvier et al., 1987; Glen & Zazkis, 2021; Knuth, 2000; Moon, et al., 2013). Instead of viewing an equation for a linear function as comprising the set of all ordered pairs of values satisfying the equation, which can be plotted as points comprising the graph of the line, students may see a linear equation as a directive for how to draw a graph of a line using slope and intercept information (Parr et al., 2021). In the words of Todd, a Calculus student, "$y = 2x+1$… tells you how it's [the graph is] going to look, so the slope would be 2, the y-intercept would be 1" (Parr et al., 2021, p. 219).

Representing distances on two-dimensional graphs of functions using algebraic expressions is a complex cognitive activity. In order to conceptualize why expressions such as $2–x$ and $2–(y^2+1)$ in Figure 1 represent the distance depicted, students must connect the graphical and algebraic register in the three ways described in this section: 1) a distance between can be modeled using a difference, 2) an ordered pair of values gives the distances the associated point is located from the axes in the Cartesian plane, and 3) an algebraic relationship between x and y can be used to flexibly express distances within the graph of the relationship in terms of x or y.

In Figure 7, we show how these connections combine to connect difference expressions with distances between two points on functions in the Cartesian plane. Connection 1 supports students in expressing a straight-line distance between two positions x_1 and x_2 as $x_2–x_1$. Connection 2 supports students in expressing a straight-line distance from an axis in the Cartesian plane using the coordinates of the point, in this case, the horizontal distances as x_1. Combining these two connections supports students in describing the horizontal distance between two points in the Cartesian plane as $x_2–x_1$. Assuming the two points shown are located on functions f and g, respectively, Connection 3, the Cartesian connection, would support a student in expressing this same horizontal distance in terms of y, as $g^{-1}(y_2) – f^{-1}(y_1)$.

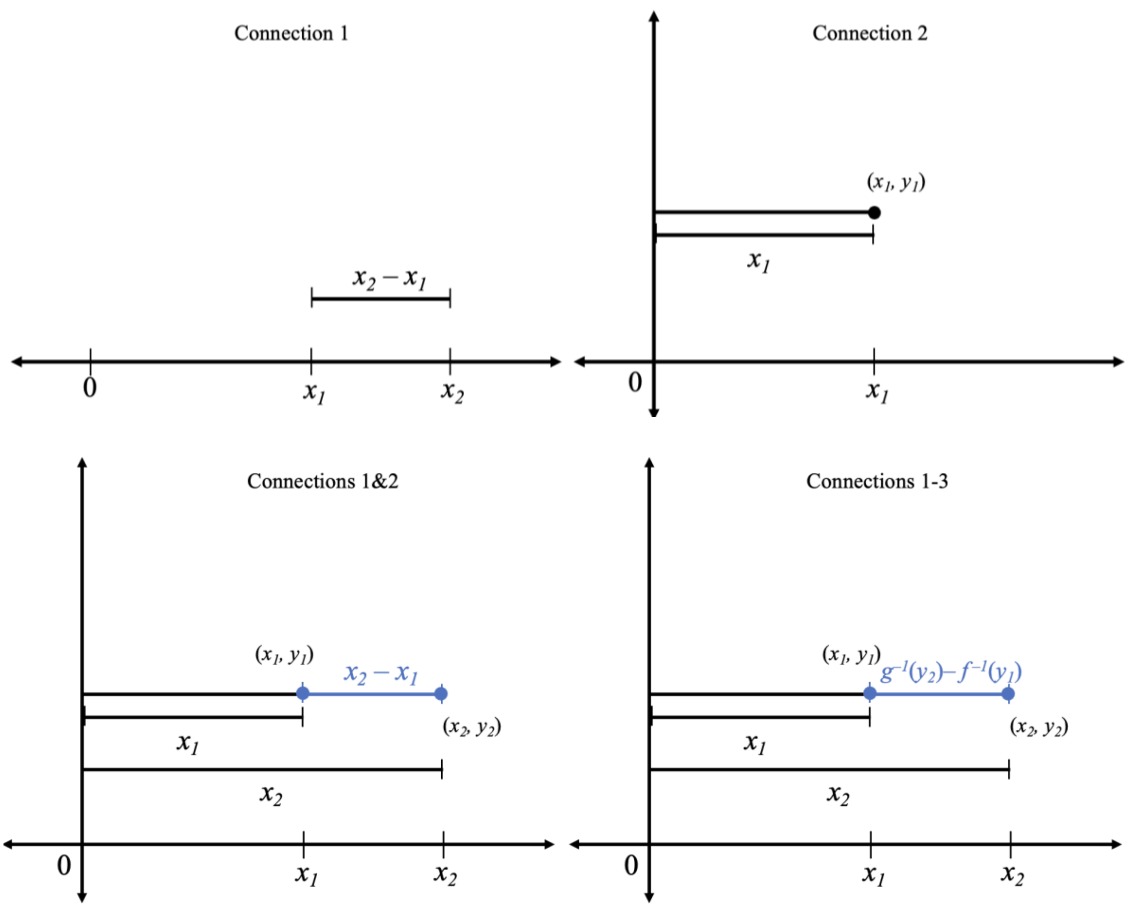

Figure 7. How Connections 1-3 combine to express horizontal distance between two points in the Cartesian plane.

Discussion

The conceptual analysis we present in this paper offers a detailed account of the cognitive connections need for students to meaningfully use an algebraic difference expression to represent distances between functions in graphs. This conceptual analysis has implications for both research and practice. First, the three connections we highlight between the algebraic and graphical register uncover the complex nature of the cognitive steps involved expressing distances algebraically. At the undergraduate level, researchers and instructors may take for granted students' fluency in moving between two representations. In fact, this connection is not included in typical calculus curricular materials and instruction. Yet, our research and this analysis suggest that students may benefit from more explicit instruction as to how these representations may be used together. In addition to drawing attention to its underlying complexity, this analysis may serve to support the development of learning trajectories and tasks to assist students in connecting graphs with algebraic expressions meaningfully. Further, this conceptual analysis may alert researchers and practitioners to potential issues in students' reasoning that they may anticipate when using subject matter represented both algebraically and graphically. These issues may arise in either conceptualizing the objects in the graphical register, the objects in the algebraic register, or the way in which these objects are connected.

More broadly, the structure of the conceptual analysis we offer here may serve as a model for others related to connections among registers. Many prior examples of conceptual analysis in the literature attend to students' understanding of mathematical ideas, but may not explicitly attend to representational structures involved in conceiving of or communicating these ideas. We add to the example of Lee et al.'s (2018) conceptual analysis of coordinate systems by attending to the representational structures involved in connecting graphical distances with algebraic expressions. We decompose the larger connection in question into sub-connections, which each include components in the algebraic register, graphical register, and an underlying interpretation. This structure may serve as a model for future conceptual analyses on other connections between the graphical and algebraic registers, or any other combinations among mathematical registers.

Inclusive and Equitable Mathematics Education: Active Learning is Necessary, but not Sufficient

Nancy E. Kress
University of Colorado Boulder

Numerous studies have demonstrated that active learning can increase student learning and reduce achievement gaps; research has also shown that active learning in undergraduate mathematics is not consistently equitable. These findings highlight a gap in what we know about active learning and indicate the need for a deeper understanding of the relationship between equity, inclusion, and active learning. Drawing on research about inclusive and equitable mathematics learning environments across secondary and postsecondary contexts, in concert with what is known about active learning in undergraduate mathematics classrooms, I present a theoretical argument that active learning is a necessary but insufficient condition for mathematics learning communities to be inclusive and equitable. I close by suggesting potential strategies for ensuring active learning is implemented in ways that are inclusive and equitable.

Keywords: active learning, inquiry, equitable, inclusive, critical

The use of active learning and inquiry-based mathematics education (IBME, a form of active learning) is becoming increasingly common in undergraduate mathematics courses (Stains, 2018). Active learning has been shown to result in improved student learning outcomes (Deslauriers et al., 2019; Freeman et al., 2014, Laursen et al. 2014) as well as significantly reduced achievement gaps between women and men (Laursen et al, 2014) and between students who are members of underrepresented and overrepresented identity groups (Theobald et al., 2019). Freeman et al. (2014) suggest that research supports "active learning as the preferred, empirically validated teaching practice in regular classrooms" (p. 8410), and Theobald et al. (2019) calls for evidence-based active-learning course designs to replace traditional lecturing across the STEM disciplines" (p. 6476). Active learning was found to be one of the common characteristics in a study of successful calculus programs at five doctoral degree-granting mathematics departments deemed to be exemplary based on persistence rates and students' reported enjoyment and confidence in mathematics (Rasmussen, Ellis, Zazkis & Bressoud, 2014; Rasmussen, Ellis & Zazkis, 2014). Abundant evidence of student-centered instruction supporting increased student success in mathematics at the primary and secondary levels (e.g., Boaler, 2006; Matthews et al., 2021) further reinforces the claim that active learning is a better way to teach mathematics than traditional lecture.

And yet, performance (Reinholz et al., 2022; Johnson et al., 2020) and participation (Reinholz et al., 2022) gaps between majority identity groups and those who are underrepresented in mathematics persist in some active learning classrooms. Johnson et al. (2020) showed that achievement gaps between women and men increased in a set of linear algebra classrooms using IBME. Reinholz et al. (2022) found performance differences and differences in participation rates between women and men in undergraduate mathematics classes taught using inquiry-oriented instruction and suggested that "simply implementing active learning is insufficient… for improving gender equity in mathematics" (p. 204). Research has shown that mathematics classrooms using active learning can be inclusive and equitable, while also demonstrating that not all active learning mathematics classrooms achieve this standard.

The relationship between equity, inclusion, active learning and IBME is under-researched, and scholars have not yet explained the distinctions between inclusive and equitable and exclusive and/or inequitable active learning. In this theoretical report I draw on research about inclusive and equitable mathematics learning environments in secondary and tertiary contexts, along with what is known about active learning and IBME in undergraduate mathematics classrooms, to answer the question: *What will it take to cultivate undergraduate mathematics learning environments that are reliably equitable and inclusive?* I present the argument that instructors' use of active learning in general, and IBME specifically, is a necessary but insufficient condition for mathematics learning to be inclusive and equitable. Then I propose additional criteria that may, when used in addition to IBME, contribute to creating reliably inclusive and equitable undergraduate mathematics classrooms.

Theoretical Perspectives: What is Inclusive and Equitable Mathematics?

Research showing the positive effects for students of learning mathematics through active learning or IBME is abundant and convincing. The strength of the case in favor of active learning can make it seem confusing or implausible when evidence is presented showing some settings exhibiting persistent inequity and/or exclusion. To explain how the extensive body of research supporting active learning can be correct while also failing to explain why some active learning settings are exclusive and/or inequitable, I leverage theoretical perspectives. A clear theoretical perspective names the researchers' commitments and perspectives; it provides a context that helps explain why certain decisions are made in conducting research, including the questions that are asked, the data that is collected and how that data is analyzed and interpreted. This section describes the dominant perspective that has shaped most of the existing research on active learning in undergraduate mathematics and the critical perspective that may help to usher in a new chapter focused on inclusion and equity in mathematics education. This is followed by a commitment to intersectionality and attending to the interplay of lived experiences across identity group memberships, and a description of the inclusive and equitable teaching practices that shape my thinking about the nature of inclusive and equitable undergraduate mathematics.

Critical Perspective

Gutiérrez (2007) and Martin (2003) called for mathematics education researchers to adopt a critical perspective, and yet much of the research on active learning in undergraduate mathematics continues to reflect a strongly dominant perspective. Gutiérrez's (2009) framework for understanding equity in mathematics provides a useful way to understand and interpret the body of research on active learning. This framework includes two axes. The dominant axis consists of the dimensions of access and achievement, and the critical axis consists of the dimensions of identity and power. The majority of the existing research on the effect of active learning in undergraduate STEM settings addresses questions about achievement – either learning outcomes or achievement gaps – or about access to learning opportunities that arise from engaging actively with course content.

Numerous mathematics education researchers across secondary and tertiary settings have called for paying greater attention to the role and impact of identity and power (Adiredja, 2015; Gutiérrez, 2009, 2013) – the critical axis of equity in mathematics – in mathematics learning spaces. Attending to the role of identity and power in mathematics classrooms means adopting a different vision if what it means for mathematics education, in this case specifically active learning, to be successful. Mathematics instruction that supports the "mathematical identities, excellence and literacies of marginalized students" (Gutiérrez, 2008, p. 357) may differ from that which leads to increased test scores and reduced participation gaps. Gutiérrez's framework helps to illuminate that the existing research on active learning has demonstrated active learning's success along the dominant axis. Active learning has been shown to increase *achievement* and *access* to learning opportunities. Gutiérrez's framework also highlights what remains to be investigated: by attending closely to *identity* and *power* in mathematics classrooms we may learn what helps students who are members of marginalized identity groups to succeed and thrive.

Framework for Understanding the Social Space of Mathematics

Leyva et al.'s (2022) proposed framework for understanding mathematics as a white cisheteropatriarchal space explains how sociomathematical (Yackel & Cobb, 1996; Leyva, 2017) and sociohistorical (Leyva, 2021) norms are at play in mathematics classrooms in ways that relate to identity including but not limited to gender, race and class. Leyva (2017) calls for researchers to "carefully attend to mathematics learning contexts and the interplay of students' multiple identities (including race or ethnicity, culture, class, gender, and sexuality)" (p. 406). Crenshaw (1991) suggests that intersectionality could provide the means for understanding and addressing experiences of marginalization that are shared across identity groups (p. 1299).

Inclusive and Equitable Instruction

Examples of instructional practices that have been shown to contribute to inclusive learning environments and equitable outcomes for students who are members of underrepresented or marginalized groups in mathematics include equitable teaching practices (Boaler, 2006) and belonging centered instruction (Matthews et al., 2021). Additionally, culturally relevant (LadsonBillings, 1995) and sustaining (Alim, Paris & Wong, 2020; Ladson-Billings, 2014; Paris, 2012; Paris & Alim, 2014) pedagogy supports inclusive and equitable learning environments that are not specific to mathematics. Describing each of these approaches to inclusive and equitable instruction in detail is beyond the scope of this paper. I will, instead, describe cross-cutting themes, since teaching strategies that appear in multiple of these instructional approaches are especially likely to be impactful across settings.

Teaching strategies that emerge as common across these instructional approaches include holding high expectations (Boaler, 2006; Ladson-Billings, 1995; Matthews et al., 2021), assigning competence (Boaler, 2006; Ladson-Billings, 1997) and decentering teacher authority (Matthews et al., 2021). Just as importantly, additional themes are present across these approaches that relate to interpersonal interactions, social dynamics, and community. Boaler (2006) described relational equity as a teaching approach that "valued different insights, methods, and perspectives in the collective solving of particular problems" (p. 45), an approach that supported students learning to "appreciate the contributions of different students, from many different cultural groups and with many different characteristics, and perspectives" (p. 45). Belonging centered instruction includes an interpersonal domain that attends to community, empathy, and social and emotional aspects of students' classroom experience (Matthews et al., 2021). Ladson-Billings (1997) emphasizes the "need to develop caring and compassionate relationships with students" (p. 707).

Review of the Literature: Three Plus Decades of Inquiry and Active Learning

The dominant perspective is evident in active learning and IBME in how researchers have sought to understand their impacts, and in the origins of these instructional practices. Active learning, inquiry-oriented instruction and inquiry-based learning all developed as strategies for increasing student engagement and student learning in undergraduate science, technology, engineering, and mathematics (STEM). While they each differ somewhat in their commitments and orientations, curriculum development and classroom instruction that adheres to principles of inquiry and/or active learning is consistently oriented toward a common goal of supporting students to understand STEM course content more deeply and to succeed in their undergraduate STEM courses. Over time there has been a trend toward coalescing around common definitions and principles, as described below.

Active Learning

Definitions and conceptions of active learning have consistently centered around the idea that students benefit from being actively involved and engaged in learning instead of passively listening to lecture. Prince (2004) defined "the core elements of active learning to be introducing activities into the traditional lecture and promoting student engagement" (p. 225). Bonwell and Eison (1991) suggested that students should be engaged "in such higher-order thinking tasks as analysis, synthesis, and evaluation" (p. *iii*), and they proposed defining active learning as "instructional activities involving students in doing things and thinking about what they are doing" (p. *iii*). In 2016, the Active Learning in Mathematics Research Action Cluster of the Mathematics Teacher Education Partnership synthesized the research on active and inquiry based learning available at that time and developed a set of five design principles for active learning that included 1) mathematical coherence, 2) instructional activities that promote "active construction of meaning" and "sense-making," 3) norms for classroom discourse that encourage students to share "reasoning in process," 4) an instructional environment that includes multiple modes of instruction, and 5) instructional decision-making in which "the choices made in lesson design and adaptation should favor the perspective of the learners." (Webb, 2016, p. 2).

Inquiry Based Mathematics Education

Laursen and Rasmussen (2019) named four pillars of Inquiry Based Mathematics Education (IBME), the term they proposed to unify inquiry-oriented instruction and inquiry-based learning, and to situate it as a specific form of active learning. The four pillars are as follows:

1. Students engage deeply with coherent and meaningful mathematical tasks.
2. Students collaboratively process mathematical ideas.
3. Instructors inquire into student thinking.
4. Instructors foster equity in their design and facilitation choices. (p. 138)

There is significant overlap between the four pillars of IBME as explicated by Laursen and Rasmussen (2019) and the design principles for active learning. One result has been that the four pillars have increasingly been taken up as a definition of active learning. A team of researchers from the Student Engagement in Mathematics through an Institutional Network for Active Learning (SEMINAL) project analyzed data from interviews with 115 stakeholders (administrators, members of client disciplines, coordinators, leaders, instructors and learning assistants) who were asked about their conceptualizations of active learning. The research team compared stakeholders' responses to the four pillars of IBME and found that instructors' conceptualizations of active learning aligned closely with the first three of the four pillars (Williams et al., 2022). I conjecture that the inquiry and active learning instructional contexts for which research has shown increased student learning outcomes and reduced achievement gaps (Deslauriers et al., 2019; Freeman et al., 2014; Laursen et al., 2014; Theobald et al., 2020), particularly "high-intensity" (Theobold et al., 2020) forms of active learning, are closely aligned with the first three pillars of IBME.

Inclusive and Equitable Undergraduate Mathematics Education: What does it take?

The call for mathematics education researchers to investigate the nature and effect of inclusive and equitable instruction in undergraduate mathematics is becoming increasingly powerful. Hagman (2019) called for an eighth characteristic of successful calculus programs – diversity, equity, and inclusion practices. Laursen and Rasmussen (2019) included an aspirational fourth pillar specifying the need to foster equity in the design and facilitation of IBME and noted that it is not yet entirely clear how to accomplish this in inquiry-based classrooms. Theobald et al., (2020) posited that the large variation in efficacy observed across studies in their data set might result, in part, from variations in the culture of inclusion (p. 6479). Reinholz et al., (2022) suggested that implementing active learning alone is insufficient to improve gender equity in mathematics. And Leyva et al. (2022) analyzed thirty-four undergraduate Black and Latin* students' perceptions of "supportive-for-all practices" which include such active learning aligned practices as creating "space for questions and mistakes" (p. 339), discourse, discussion, and student-thinking centered instruction. They found that "supportive-for-all practices" were perceived by students of color to be "necessary yet insufficient to cultivate equitable opportunities for classroom participation and access to content" (p. 339).

Next I will describe the existing relationship between active learning and equity and argue that IBME is a necessary part of implementing inclusive and equitable instruction in undergraduate mathematics. I will propose instructional practices that are compatible with IBME, and which have potential for resulting in reliably inclusive and equitable IBME learning environments. Finally, I will close by calling for research that adopts a critical perspective to study the nature and effectiveness of inclusive and equitable active learning in mathematics.

Active Learning and Equity: An Under-Investigated Relationship

When researchers shared the seven characteristics of successful calculus programs (Rasmussen, Ellis, Zazkis & Bressoud, 2014; Rasmussen, Ellis & Zazkis, 2014), their definition of "successful" attended to students' experiences by considering reported levels of "enjoyment" and "confidence," but they did not consider how students who were members of underrepresented identity groups fared in the mathematics departments they described. Hagman (2019) identified this failure and called for the addition of an eighth characteristic – diversity, equity, and inclusion practices – not because it was found to have been present, but rather because that study had not been conducted with attention to the ways students' identities impacted their experiences of their calculus programs. The dominant perspective guiding that research project left the dimensions of identity and power uninvestigated.

The fourth pillar of IBME, "instructors foster equity in their design and facilitation choices" (Laursen & Rasmussen, 2019, p. 138), demonstrates commitment to currently under-investigated practices for supporting equity and inclusion. But it is presented with a caveat: "the research base in undergraduate mathematics education does not reveal just how to accomplish this in inquirybased college classrooms" (p. 138). The authors observe that, while research has shown the potential for inquiry classrooms to be equitable, "this is not automatic" (p. 138). They also point out that research on secondary contexts (e.g., Boaler 2006) provides potentially useful direction. In essence, Laursen and Rasmussen are not suggesting that IBME is equitable as it is typically enacted, but rather that IBME can and should be equitable when ideally implemented. Williams et al.'s (2022) findings show that instructors' conceptualizations of active learning align with the first three pillars of IBME but engage minimally, if at all, with the fourth pillar of fostering equity. These findings align with the aspirational nature of the fourth pillar of IBME. Active learning, as described by undergraduate mathematics faculty and instructors, appears to be accurately described by the first three pillars of IBME. For naming the critical goal of achieving equity and inclusion I appreciate Laursen and Rasmussen's inclusion of the fourth pillar that should motivate and inspire further research to describe exactly what is necessary to achieve inclusive and equitable undergraduate mathematics education. The remainder of this paper proposes what inclusive and equitable undergraduate mathematics education might require.

What Are Equitable Teaching Practices in Active Learning Classrooms?

First and foremost, I address the necessity of recognizing and including IBME as a central component, or perhaps a foundational building block, of inclusive and equitable mathematics education. I will then propose instructional practices that research across secondary and tertiary mathematics contexts suggests might be missing components of inclusive and equitable mathematics education. Finally, I call for research grounded in a critical perspective that increases our collective knowledge in the field related to creating the conditions necessary for students to succeed, thrive and to experience full membership in the mathematics community.

IBME: Is it necessary? Let's imagine mathematics instruction that *does not* meet any one of the first three pillars of IBME. What would this imply regarding equity and/or inclusion in such a classroom? I will take up each of the first three pillars individually.

1. A mathematics classroom in which students *do not* engage deeply with coherent and meaningful mathematical tasks denies students the experience of high expectations (Boaler, 2006, p. 44; Ladson-Billings, 1995; Matthews et al., 2021) and access to the rich learning experiences necessary to achieve high levels of learning. Mathematics instruction that fails to incorporate the first pillar of IBME fails to support the dominant axis dimensions of access and achievement and is not equitable.
2. A mathematics classroom in which students *do not* collaboratively process mathematical ideas misses crucial opportunities for students to experience equitable teaching practices of "assigning competence" (Boaler, 2006, p. 43) and decentering teacher authority (Matthews et al., 2021), and fails to support equitable access to learning opportunities.
3. A mathematics classroom in which instructors *do not* inquire into student thinking fails to exhibit equitable teaching practices of "assigning competence" (Boaler, 2006, p. 43), "student responsibility" (Boaler, 2006, p. 43-44) and decentering teacher authority (Matthews et al., 2021). Mathematics instruction that fails to incorporate the third pillar of IBME fails to provide access to learning opportunities. Failure to inquire into student thinking firmly upholds traditional power dynamics in which the instructor's ideas and thinking override other ways of thinking about or understanding mathematical content.

Such instruction fails to address the critical axis dimension of power.

This suggests that active learning that omits any of the first three pillars of IBME is inconsistent with inclusive and/or equitable mathematics instruction, demonstrating the necessity of including these practices in order to achieve inclusive and equitable mathematics classrooms. In fact, Mathematics instruction that results in students engaging deeply with coherent and meaningful mathematical tasks, collaboratively processing mathematical ideas, and in which instructors consistently inquire in student thinking is not only necessary, but it is an excellent place to start. Next, I will suggest what inclusive and equitable instructional practices could potentially be missing in an IBME classroom.

What else will it take? To consider what might need to be added to the first three pillars of IBME to cultivate reliably inclusive and equitable mathematics classrooms I return to the teaching strategies that I shared earlier in this paper. These included holding high expectations, assigning competence, and decentering teacher authority, all of which are somewhat aligned with the first three pillars of IBME. I also noted that inclusive and equitable teaching includes attention to interpersonal interactions, social dynamics, and community. In the socially interactive environments of active learning classrooms these social and community aspects of inclusive and equitable teaching are especially salient. Furthermore, the first three pillars of IBME do not explicitly call for attention to the community nature of active learning classrooms. The second pillar – students collaboratively process mathematical ideas – may imply the need for instructors to attend to social interactions; however, without careful and explicit attention to establishing norms of interaction, the group tasks that are often intended to foster collaboration are equally likely to reinforce preexisting and deeply established sociohistorical and socio-mathematical norms that are often marginalizing for students who are members of under-represented identity groups in mathematics. With a focus on the critical axis dimensions of identity and power as they are relevant in active learning mathematics classrooms, I suggest the following as potential strategies to support inclusive and equitable mathematics instruction:

1) co-development and ongoing revision of class norms of participation
2) opportunities for students to provide feedback about their experiences at regular intervals throughout the course
3) normalizing the experience of not knowing, particularly as it applies to “prerequisite” knowledge
4) flexible course structures that provide students multiple opportunities to demonstrate their learning.

Ultimately, applying a critical perspective and attaining the goal of supporting students to consistently develop positive mathematics identities that include a sense of belonging in mathematics and a sense of being a capable and skilled doer of mathematics should be central to achieving the aspirational fourth pillar of IBME: Instructors foster equity in their design and facilitation choices (Laursen & Rasmussen, 2019, p. 138).

Developing Personal Representations to Access a Set-Oriented Perspective on Counting

Adaline De Chenne
New Mexico State University

In some classical semiotic perspectives, signs and sign systems can be viewed as either institutional or personal. This dichotomy can place personal representations as antecedent to institutional ones, sometimes with the explicit goal of transitioning away from the personal ones entirely. In this paper I draw from qualitative data to argue that personal representations are legitimate and sometimes necessary components of developing combinatorial facility, and they play an ongoing role in understanding that is not replaced by institutional representations. I frame this theoretical argument around a discussion of common institutional semiotic systems for combinatorics, which can insufficiently support a set-oriented perspective on counting. I discuss how to incorporate personal representations into analysis that uses a classical semiotic lens. Doing so includes attending to the motivations for creating (or refining) a sign system, the connections between those systems and others, and how the form and nature of the sign systems seem to impact or reflect student reasoning. I also discuss how some differences between combinatorics and other areas of mathematics might affect the personal/institutional dichotomy in semiotic analysis.

Keywords: combinatorics, semiotics, student reasoning, personal representations

Consider the counting problem *how many ways are there to flip a coin three times in a row?* This problem is an appropriate introduction to combinatorics because it invites solutions that draw from multiple modalities, including and certainly not limited to: flipping physical coins to exhaust outcomes (systematically or not), listing entire or partial sets of written outcomes such as HHT or 001, reasoning structurally about enumeration processes or representations of those processes such as H/T H/T H/T, using embodied and/or gestural reasoning with or without iconic imagery, and applying abstract counting principles formally or informally. Each of the possibilities mentioned here, and countless others, can find the same numerical solution—there are 8 possible ways to flip a coin three times in a row. And yet the approach might impact how the solution is expressed. While one approach might yield 2^3, others might yield $1 + 3 + 3 + 1$ or simply the integer 8. Institutional combinatorial texts (such as textbooks or lecture notes) might only present solutions within limited modalities, often confined to a natural language (e.g., English), symbolic mathematics, and figures (if the text is generous). I consider the limit of modalities to be a byproduct of the textual medium and not necessarily an indication that the solutions are more sophisticated than those drawing from other (often non-institutional) semiotic systems. Moreover, the limited presentations of solutions can perpetuate negative attitudes towards combinatorics when the singular way combinatorial reasoning is presented does not align with what is natural for learners. This is especially unfortunate considering that the abundance of solution approaches enrichens combinatorics.

The purpose of this paper is to legitimize personal representations in combinatorics by discussing why they have an ongoing role in the production and justification of solutions, and why institutional representations seem insufficient in satisfying this role. I apply a fairly narrow view on semiotics which examines the inscribed signs and sign systems students create and use as they solve counting problems. Although this view does not incorporate other semiotic resources such as rhythm and gesture, it is consistent with prior undergraduate combinatorics education literature while still offering additional contributions. My core argument is as follows. Semiotic systems are ubiquitous in mathematics in part because they facilitate mathematical production. Yet, common combinatorial notation is more conducive to expressing solutions than producing them. Students develop personal representations for combinatorics in order to produce mathematics externally because there are limited institutional means of doing so. Institutional and personal representations can cohabitate in combinatorics because they are used for different purposes. One is not transitional or auxiliary to the other, and personal representations are not antecedent to institutional ones. However, personal representations are not neutral mediators of combinatorial activity. Two different personal representations might lead to two different arguments and two different mathematical expressions of the same integer value, numerically equal but indicative of different structural reasoning. A semiotic lens on combinatorics must account for such differences.

Combinatorics and a Set-Oriented Perspective

Combinatorics is a broad area of mathematics that includes enumeration and existence. Most introductions are through enumerative combinatorics, more commonly called counting problems. From an expert's perspective counting problems task the counter (i.e., the person solving the counting problem) with determining the cardinality of a set of objects or determining the number of ways an event can be carried out. Lockwood (2013) characterizes combinatorial activity as occurring between three components: sets of outcomes, counting processes, and formulas/expressions. The set of outcomes is the collection of objects being counted in a problem, and the solution to the problem is typically the cardinality of that set. Counting processes are the real or imagined enumerative processes the counter engages in as they solve a problem. Formulas/expressions are the mathematical expressions that yield some numerical value, and solutions to counting problems are typically given as some expression. Lockwood (2014) describes a set-oriented perspective on counting as "a way of thinking about counting that involves attending to sets of outcomes as an intrinsic component of solving counting problems" (p. 31). At the core of the set-oriented perspective is the connection between mathematical expressions and the structure in a set of outcomes. A mathematical formula can be applied because it reflects structural elements of the set of outcomes. The set-oriented perspective contrasts other approaches to counting which involve identifying problems types and applying formulas associated with those problem types.

Lockwood's characterization of a set-oriented perspective is sufficiently broad so as to incorporate the manyfold ways of reasoning combinatorially, which inevitably raises the question of how the one engages in such a perspective. Antonides and Battista (2022a, b) captured certain cognitive processes for spatial-temporal-enactive structuring involved with geometric objects, which included recursive reasoning that ultimately led to closed-form solutions for permutation problems. Some work with younger students (e.g., English 1993; Speiser, 2010; Tarlow, 2010; Tillema, 2013, 2018) has examined how material resources, iconic imagery, and emergent representations are key components in developing and communicating combinatorial reasoning. Literature examining undergraduate students has often examined student inscriptions, such as lists of outcomes (Lockwood & Gibson, 2016), and how encoding outcomes impacts solutions and justifications (Lockwood et al., 2018; Wasserman & Galarza, 2019). This literature has all reported on various semiotic resources as important to student reasoning, even if the analysis was not focused on the mechanisms through which the semiotic resources mediated solutions. A further step towards understanding how students engage in a set-oriented perspective is to examine the role of the semiotic resources in solutions that use a set-oriented perspective.

Connecting Classical Semiotics to Combinatorics

Student use and development of personal semiotic representations in combinatorics are not new phenomena. They appear in literature spanning from early elementary to graduate school (e.g., Tillema, 2013; Wasserman & Galarza, 2019), and they are reported as indicative of or contributing to combinatorial facility. By using a semiotic lens to investigate personal representations I seek to better understand the representations themselves, why students create them, and how they contribute to solutions. I begin discussing semiotics by discussing semiotic systems, and how common combinatorial notation fits within broader semiotic systems. This will include a discussion of semiotic systems as communicative mediums as well as ways for producing new mathematics. Then, I will briefly discuss some insufficiencies of institutional combinatorial notation and why students create personal representations. In the following section I will discuss some personal representations in combinatorics, and use the examples to illustrate how the personal representations demonstrated sophisticated sign systems that contributed to mathematical production.

Semiotic Systems and the Combinatorics Register

In broad strokes, semiotic systems in mathematics are the systems of signs and symbols used to communicate and carry out mathematics. Common semiotic systems are fractions, decimals, set-builder notation, and function notation. Semiotic systems exist in many modalities (e.g., speech, manipulatives, imagery, pictures) but for the purpose of this paper I will focus solely on written (inscribed) and spoken signs and sign systems. Ernest (2008b) characterizes a semiotic system as being composed of three components: i) a set of signs, ii) a set of rules for sign use and production, and iii) an underlying meaning structure that incorporates the relationships between the signs and the rules for their use. For fractions we may all be aware that '0', '3', '8', and '/' are included in the set of signs, and that the set of rules for sign use says that '30/8' is a permissible sign whereas '038/' is not. The rules for sign use are a consequence of using signs as a communication vehicle for an underlying meaning structure. The rules ensure that there is a way of interpreting the signs, and that the interpretations of the signs are consistent with what they represent. The fraction 30/8 is permissible because it is interpreted as the ratio between the integers 30 and 8. The sign 038/ does not have such an interpretation, and so it is not permissible.

Sign systems are also used to produce new mathematics through rules that state how some signs can be transformed into others (Duval, 2006). That is, beginning with the expressions $\frac{d}{dx}3x^2$ we can carry out the derivative purely symbolically to find $\frac{d}{dx}3x^2 = 2 \cdot 3x^{2-1} = 6x$. Although we can relate this transformation back to the underlying meaning structure, in practice doing so is rare. In this instance the set of rules in the semiotic system allow for more efficient mathematical production because they allow for a temporary foregoing of the underlying meaning structure. Duval (1995, 2006) distinguishes between two types of transformations. Treatments are transformations that occur within the same semiotic system (e.g., a fraction to a fraction), and conversions are transformations that occur between different semiotic systems (e.g., a fraction to a decimal). Duval calls semiotic systems that permit both treatments and conversions *registers*. With these theoretical constructs in mind, we can characterize some mathematical activity as reasoning within or between various semiotic systems (registers), and we can also characterize some difficulties as difficulty with types of transformations or semiotic systems.

One of the difficulties within combinatorics is that there are limited institutional semiotic systems students can access as they solve problems. Many counting problems are given in a natural language (e.g., English), and they task the counter to determine the cardinality of a set of outcomes, or the number of ways in which an event can occur. Solutions to counting problems are integers or parametric expressions that can be transformed into integers, which may include signs and symbols associated with combinatorics, including $P(8,3)$ and $\binom{n}{k}$. I refer to the semiotic system used for combinatorics as the *combinatorics register*. Seen purely as signs that can be transformed into integer values, the combinatorics register might be considered an extension of the fraction register or algebraic register. However, the underlying meaning structure of the combinatorics register is quite different, which leads to a duality of the notation (Wasserman, 2019). Wasserman claims that the combinatorics register (which he described as combinatorial notation) can be interpreted in two ways, first as integer-valued expressions, but also as representations of enumerative or structural processes. Underlying any combinatorial expression is the need for that expression to be tied to a set of outcomes. Not only does the expression need to permit a transformation into an integer, but the expression also needs to permit an interpretation as an enumerative expression for a set (Wasserman, 2019). This connection has repercussions for the set of rules for sign use. From a purely algebraic/arithmetic standpoint it is difficult to connect the two signs 2^n and $\sum_{k=0}^{n}\binom{n}{k}$, and substituting one for the other (although correct) might be considered lacking justification. Interpreted from a combinatorics standpoint this substitution is justified because the two expressions represent different enumerative/structural arguments for the power set of a set of n. The underlying meaning structure reorganizes and rewrites the rules for sign use and production because it focuses interpretation on cardinalities and enumeration of sets rather than abstract integers.

The combinatorics register provides a means of communicating cardinality and enumerative processes simultaneously, but it does not provide a means of producing the mathematics. The interpretations of the combinatorics register are purely internal. This contrasts with the prior calculus example where the semiotic system also permitted treatments that facilitated producing mathematics purely symbolically. The combinatorics register thus conflicts with a set-oriented perspective because it does not provide notation specifically for the objects being counted, requiring students to either form the connection mentally or develop entirely new notation for the objects being counted. In practice students do both, and in the following section I present some examples of personal representations to illustrate how personal representations inform and impact solutions to counting problems.

Examples of Personal Representations

In this section I discuss some examples of personal representations students created over the course of several interviews. These data come from a larger study that aimed to examine the roles of representations in solutions to counting problems. I have chosen these particular examples because they exemplify the potential symbiosis between personal and institutional representations. Although the students expressed a 'final answer' using an institutional representation, the bulk of their work was done using personal representations. Moreover, the students developed and refined the personal systems of representations over the course of multiple interviews, and the systems indicate sophisticated attention to structural aspects of the sets of outcomes which impacted the form of their solutions.

Lists and listing processes: Hallie and Leah

The students Hallie and Leah used lists and listing processes repeatedly over the course of six 90-minute interviews. During the first few interviews Hallie and Leah used the lists to completely enumerate a set of outcomes, solving a counting problem by tallying the total number of outcomes in their list. This use of lists became increasingly intractable as counting problems became more complex. Hallie and Leah observed symmetric properties in their lists, and their subsequent uses of lists exploited symmetry to decrease the number of outcomes they needed to write down. The exploitation of symmetry was accompanied by newly introduced signs (such as arrows) to indicate continuations of patterns. In early problems Hallie and Leah would list half of the total outcomes and indicate a continued pattern. In later problems the listing process was increasingly segmented, and symmetry was exploited throughout. Figure 1 provides an example of a listing process represented through segmentation of symmetric components of the list. This example solves a combination whose solution can be written as $\binom{13}{3}$.

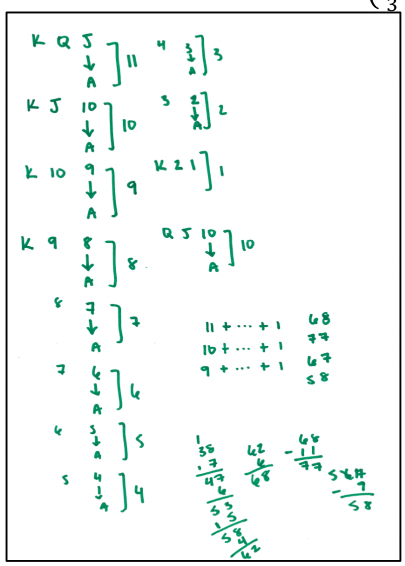

Figure 1: Representation of a listing process exploiting symmetry

In Figure 1 a listing process is represented using alpha-numerical characters, brackets, and arrows. The arrows are used to indicate a continuation of a pattern, and the brackets segment the list of outcomes into constituents. Hallie and Leah placed numbers next to the brackets to indicate the number of outcomes in each constituent piece. The list indicated in Figure 1 is only a partial list, but the sums in the middle of the figure illustrate how Hallie and Leah generalized the results of the partial listing to the remainder of the outcomes. The partial list in the example corresponds to the sum $11 + \cdots + 1$, and the remaining two sums $10 + \cdots + 1$ and $9 + \cdots + 1$ correspond to two other segments of the entire set of outcomes. Hallie and Leah used the partial sums to count the number of times each summand appeared in a partial sum. They found that 11 appears in one partial sum, 10 appears in two partial sums, and so forth, leading to their solution given in Figure 2. I present this example because it demonstrates that Hallie and Leah used personal representations (the lists and listing processes) to produce their solution, and their solution reflects the structure they observed in the outcomes.

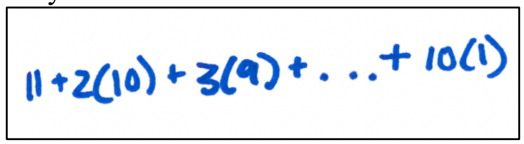

Figure 2: Solution to a combination problem

Sequences of characters: Pat and Damien

The students Pat and Damien repeatedly solved counting problems by representing outcomes as sequences of alphanumeric characters and leveraging know structural information about alphanumeric characters to solve their counting problems. This technique was challenged when they solved the road problem, which states “A certain map connecting locations A and B is given below. You are creating routes between A and B so that no roads are repeated. How many routes are there?”

Pat and Damien’s solution to this problem consisted of iteratively refining the method of encoding paths in the diagram as sequences of characters. The first method of encoding paths consisted of mapping the route of an imagined agent in terms of left and right path segments. This method of encoding was difficult to count because it resulted in paths of variable sizes with constraints that were challenging to characterize. Through several refinements consisting of reformulating how information was encoded or selectively choosing information to leave out of the outcomes, Pat and Damien found that each outcome could be encoded as a length-6 sequence of Ts and Bs. A T was used to indicate movement along the top of the diagram, a B was used to indicate movement along the bottom of the diagram, and vertical movement was omitted because it could be deduced by movement along the top or bottom of the diagram. After finding this method of encoding Pat and Damien concluded that there were 2^6 total paths along the diagram. I include this example because it illustrates that most of Pat’s and Damien’s solution consisted of using personal representations to characterize the outcomes in ways that were conducive to counting. Their final solution, which connected sequences of Ts and Bs to the expression 2^6, was merely one step in a larger process of iteratively refining representations of the outcomes, and the bulk of the mathematical production occurred in personal representational systems.

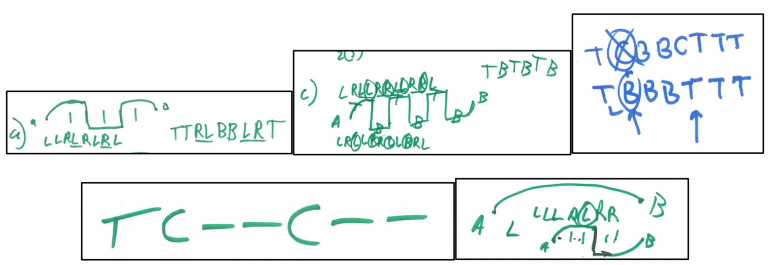

Figure 3: Multiple iterations of encoding paths as sequence of characters

Conclusions

In this paper I have argued that personal representations play a key role in developing combinatorial facility. In part, this role is necessitated by the combinatorial register (the common institutional semiotic system for combinatorics) insufficiently supporting mathematical production. Unlike semiotic systems common to calculus and algebra, the combinatorial register is most conducive to communication. The commonality of personal representations in combinatorics appears to be a result of this. Personal representations appear to facilitate mathematical production while reflecting student understanding.

Wasserman (2019) previously discussed the duality of combinatorial notation, and that the difficulty of learning to interpret combinatorial notation as representative of enumerative processes poses a pedagogical challenge. He proposed the development of institutional notation for sets of outcomes specifically in ways that align with the combinatorics register. In my view personal representations can fill the same role, and attending to personal representations can additionally increase student agency in solutions. This argument, of course, must weigh the possibility that students can still be challenged by creating personal representations, and that some personal representations might be more difficult to use in ways that are tractable. Further study is needed to determine how to leverage personal representations in a didactical setting, and potential tradeoffs between attending to personal representations and creating institutional representations that incorporate elements of observed personal representations.

Isomorphism across Courses: Students' Metaphors in Discrete Math, Linear Algebra, and Abstract Algebra

Cassandra Mohr
Northern Illinois University

Rachel Rupnow
Northern Illinois University

Isomorphism appears across many courses in mathematics, including discrete mathematics, linear algebra, and abstract algebra. However, examinations of student understandings of isomorphism have mostly focused on group isomorphism in abstract algebra. In this paper, we compare survey responses from 49 discrete math, 19 linear algebra, and 27 abstract algebra students who were prompted to explain the concept of isomorphism to a child. Results include a cross-course emphasis on types of sameness but variations in the types of language used to characterize isomorphism in each course. Implications include the need for care among instructors and researchers when referring the concept of "isomorphism" without a context as well as the need for further work in understandings of graph theory.

Keywords: isomorphism, abstract algebra, linear algebra, discrete math

Introduction and Background Literature

Isomorphism, especially group isomorphism, in abstract algebra has received extensive attention in the RUME community. Group isomorphism was among the first topics studied in RUME (e.g., Dubinsky et al., 1994; Leron et al., 1995), and has received sustained attention for its connections to proof construction (e.g., Weber, 2001; Weber & Alcock, 2004), curriculum design (e.g., Larsen, 2013), understanding functions (e.g., Melhuish et al., 2020; Rupnow, 2017), and conceptions of sameness (e.g., Rupnow et al., 2022; Rupnow & Sassman, 2022). This focus is understandable, given its centrality to the abstract algebra curriculum (Melhuish, 2015).

However, isomorphism has not received comparable emphasis in discrete math or linear algebra. Like in abstract algebra, graph isomorphism is central to understanding graph theory and, more broadly, discrete math (Ebert et al., 2004). However, most research on discrete math understandings have focused on other areas, such as number theory (e.g., Zazkis & Campbell, 1996; Zazkis & Liljedahl, 2004) and combinatorics (e.g., Lockwood, 2013; Lockwood & Gibson, 2016). Research in linear algebra has also focused on other areas, such as bases (Serbin et al., 2021; Stewart & Thomas, 2010; Wawro et al., 2012), eigentheory (e.g., Serbin et al., 2020; Thomas & Stewart, 2011), and linear transformations (e.g., Andrews-Larson et al., 2017), though change of basis and linear transformations are relevant to understanding isomorphism in linear algebra. Moreover, comparative examinations of concepts appearing in multiple areas have focused on broad topics like functions (e.g., Oehrtman et al., 2008) and sameness (e.g., Rupnow et al., 2022) rather than concepts using the same term but with subtly different meanings in different contexts like isomorphism. Thus, we address two research questions:

1. How are characterizations of isomorphism similar across discrete mathematics, linear algebra, and abstract algebra students?
2. How are characterizations of isomorphism different across discrete mathematics, linear algebra, and abstract algebra students?

Theoretical Perspective

Conceptual metaphors is a theoretical lens that illuminates how individuals' thinking is structured based on their language choices (e.g., Lakoff & Johnson, 1980; Lakoff & Núñez, 1997). Cross-domain conceptual mappings relate the cognitive structure of a target concept (e.g., isomorphism) to the more developed thoughts in source domains (e.g., same properties, transformation). For instance, “An isomorphism is a transformation” is a conceptual metaphor that gives information about a target domain (isomorphism) by relating it to a source domain that is already understood in some way (a transformation).

Previous work using conceptual metaphors include analyses of mathematicians’ views of isomorphism and homomorphism in abstract algebra (Rupnow, 2021; Rupnow & Randazzo, 2022; Rupnow & Sassman, 2022). Other work has examined undergraduate students’ understandings of various concepts, including bases and linear transformations in linear algebra (Zandieh et al., 2017; Adiredja & Zandieh, 2020) and isomorphism and homomorphism in abstract algebra (Melhuish et al., 2020; Rupnow, 2017). Here we extend the conceptual metaphors for isomorphism in abstract algebra identified in Rupnow (2021) and built upon in Rupnow and Randazzo (2022) to parallel uses in linear algebra and discrete mathematics.

Methods

Data was collected from surveys sent to six groups of students: two sections each of the first author’s discrete mathematics (DM) and linear algebra (LA) courses and two sections of other instructors’ abstract algebra (AA) courses. DM students were mostly computer science majors, LA students were STEM majors (including computer science, engineering, mathematics, and physics majors), and AA students were math majors or minors. The surveys were distributed after students had learned about isomorphism in all sections. Initial questions on the discrete math and linear algebra surveys asked about sameness in mathematics whereas initial questions on the abstract algebra survey assessed beliefs about learning (especially related to fixed or growth mindset). Here we analyze responses to one question from the middle of the survey: “How would you describe an “isomorphism” to a ten-year-old child?” (AA) or “How would you describe the concept of isomorphic/isomorphism to a ten-year-old?” (DM/LA). 21 and 28 students completed the DM survey in the two sections; 9 and 10 students completed the LA survey in the two sections; and 13 and 14 students completed the AA survey in the two sections. We did not observe major differences between the sections for each course and thus combine our reporting into a dataset of 49 DM responses, 19 LA responses, and 27 AA responses.

Data analysis was conducted by two researchers who coded independently, then discussed and came to consensus for each response. We recognize students were prompted to provide comparative explanations based on the task of explaining in a manner understandable by a child. Nevertheless, our goal was to classify the underlying meanings conveyed by these explanations according to our interpretations of the participants’ responses. As such, we used the metaphors for isomorphism in abstract algebra in Rupnow (2021) as an initial codebook, adding new metaphors as necessary. This process aligns with codebook thematic analysis (Braun et al., 2019), in which existing codes are used as a basis for coding but new codes are permitted to be added to adequately capture the nuances in data.

Results

We organize the results of our coding into three subsections, each corresponding to a different course. We also provide Table 1, which offers an initial overview of the frequencies of each metaphor by course. Metaphors are organized by cluster, with some belonging to sameness-based clusters such as sameness (*generic sameness*, *same properties*, *same but looks different*, *other branch analogues*), sameness/mapping (*renaming/relabeling*, *matching*), and sameness/formal definition (*structure-preservation, operation-preservation*) clusters. Other metaphors belong to the mapping cluster (*generic mapping/relation*, *morphing/transformation*, *invertible, journey*), the formal definition cluster (*literal formal definition*), or made *no attempt/unclear*.

Table 1. Frequencies of metaphors by course.

Metaphor Cluster	Metaphor Code	Discrete Math (n = 49)	Linear Algebra (n = 19)	Abstract Algebra (n = 27)
Sameness	Same but looks different	19	7	3
	Same properties	19	0	8
	Generic sameness	9	3	14
	Other branch analogues	0	0	1
Sameness/ mapping	Matching	4	4	3
	Renaming/relabeling	1	0	2
Sameness/formal definition	Structure-preservation	2	0	0
	Operation-preservation	0	1	0
Mapping	Morphing/transformation	2	9	2
	Invertible	4	2	0
	Generic mapping	1	0	5
	Journey	0	1	1
Formal definition	Literal formal definition	0	0	1
No attempt/ unclear	Unclear/no attempt	5	0	1

Discrete Math

We begin with metaphors used by Discrete Math (DM) students to describe isomorphism. The DM textbook defined isomorphism as: "A graph G_1 is isomorphic to a graph G_2 when there is a one-to-one correspondence f between the vertices of G_1 and G_2 such that the vertices U and W are adjacent in G_1 if and only if the vertices $f(U)$ and $f(W)$ are adjacent in G_2. The function f is called an isomorphism of G_1 with G_2" (Dossey et al., 2005, p. 159). Both *same properties* and *same but looks different* were commonly used metaphors, as was *generic sameness*.

Many of the metaphors discussed shared properties across groups of objects. As isomorphism in DM is centered on graphs, a large number of these metaphors identified the same properties across different graphs: "look and see if the two shapes of the graphs are identical, vertices, edges, weights." Other responses emphasized common properties across everyday objects, such as identifying similarities among houses or vehicles.

Another commonly used metaphor used to describe isomorphism was *same but looks different*. These types of instances place emphasis on the idea that while isomorphic objects have the same underlying structure or properties, they may appear different visually. The context of these metaphors varied; as with *same properties*, many discussed graphs: "we might have two different graphs…and even though they might look different, if we can rearrange the points and lines in one of the graphs to make it look exactly like the other graph, then we can say that the two graphs are isomorphic." Others emphasized the underlying action behind these surface differences through a variety of mediums, including sticks and puzzles, by demonstrating that physical manipulation does not change the inherent identity of the object being acted upon.

Still another metaphor characterizing isomorphism was *generic sameness.* The majority of metaphors in this category emphasized the underlying sameness of two graphs: "It's when something has a similar form or shape." In addition to more commonly utilized metaphors, *structure-preservation* was unique to DM in our data set. Two students chose to emphasize the *structure-preservation* property of isomorphism: "an isomorphism is a structure-preserving mapping between two structures of the same type that can be reversed by an inverse mapping."

Linear Algebra

We now move our focus to Linear Algebra (LA) students' depictions of isomorphism. The LA textbook's definition for isomorphism was: "Let V be a real vector space with operations $\oplus$ and $\odot$, and let W be a real vector space with operations $\boxplus$ and $\boxdot$. A one-to-one function L mapping V onto W is called an isomorphism (from the Greek *isos*, meaning "the same," and *morphos*, meaning "structure") of V onto W if (a) $L(\mathbf{v} \oplus \mathbf{w}) = L(\mathbf{v}) \boxplus L(\mathbf{w})$ for $\mathbf{v}$, $\mathbf{w}$ in V; (b) $L(c \odot \mathbf{v}) = c \boxdot L(\mathbf{v})$ for $\mathbf{v}$ in V, c a real number. In this case we say that V is isomorphic to W." (Kolman & Hill, 2007, p. 258). Among LA students, the most common metaphors were *morphing/transformation*, *same but looks different*, and *matching*.

Metaphors describing the act of *morphing* or *transformation* were the most common type used. Many such instances emphasized the ability of isomorphic objects to be physically manipulated into one another: "You can take one shape, move it, stretch it, or squish it into another shape, and be able to change it back to the original." This response also notes the *invertibility* of such transformations. Still others highlighted the underlying shared structure of isomorphic objects even under a transformation: "When you have a group of things and make the same change to everything in that group that is an isomorphism. So if I had a bucket of crayons and then shaved the tips off of all of them they would be isomorphic before and after."

Same but looks different instances emphasized that although an object or group of objects may look different, they still share core underlying properties: "I would describe isomorphism through the use of tiles or legos with numbers on it. The idea being that no matter how you rearrange the pieces, all of the numbers are still there, and you can trace the method used [to] mix up the shape."

Several students also discussed isomorphism in terms of *matching*. These examples often invoked non-mathematical objects such as dice or people, and emphasized an underlying correspondence or bijectivity:

> If we have 10 classmates on one side of a classroom, and 10 classmates on the other side of a classroom. If all 10 classmates went to the other side of the room, and found a friend. It is isomorphic if everyone has only one friend, and everyone has a friend.

In our data, Linear Algebra had the only use of *operation-preservation*: "if you were to change something in group one by adding or multiplying so there is more of it, there must be the same increase in the transformed group 2."

Abstract Algebra

Finally, we examine Abstract Algebra (AA) students' isomorphism descriptions. The two sections of AA used different textbooks. In one, the textbook's definition for isomorphism was: "Let G_1 and G_2 be groups. A bijective function f: $G_1 \to G_2$ with the property that for any two elements a and b in G_1, $f(ab) = f(a)f(b)$ is called an isomorphism from G_1 to G_2. If there exists an isomorphism from G_1 to G_2, we say that G_1 is isomorphic to G_2 (Pinter, 2010, p. 94)." In the other section, the definition given was: "Two groups $(G, \cdot)$ and $(H, \circ)$ are isomorphic if there exists a one-to-one and onto map ϕ: $G \to H$ such that the group operation is preserved; that is,

$\phi(a \cdot b) = \phi(a) \circ \phi(b)$ for all a, b in G. If G is isomorphic to H, we write $G \cong H$. The map ϕ is called an isomorphism (Judson 2019, p. 119)." Among these students, *generic sameness* and *same properties* were most frequently utilized, along with *generic mapping*.

Depictions invoking *generic sameness* were the most prominent among AA students, emphasizing some flavor of sameness that unites isomorphic objects: "It is when 2 things are similar in every way and act the same way when you do something to it." Also commonly utilized was *same properties*, which stresses specific shared properties across isomorphic objects: "Draw a group of triangles and a group of squares that have the same number of elements. The groups are similar because they are both shapes, or are of the same color, etc.". Several responses utilized both metaphors, such as the following which emphasizes both specific traits and generalized sameness: "With two bunches of objects, if they have the same number of things and each thing's traits are similar to one in the other bunch, they're probably isomorphic."

Generic mapping instances focused on the presence of some mapping between isomorphic objects: "It is a map that shows that two different things are the same." Unique to AA in our data were *other branch analogues* and *literal formal definition*, each used by a single student. *Other branch analogues* identified a parallel between isomorphism and equality: "It is similar to an equals sign except it can be between groups of numbers not just equations." An example of *literal formal definition* emphasized how elements are required to interact under isomorphism:

> When you have 2 groups A and B and all of the rules between the groups A and B are followed. There are also additional rules that A and B must follow. They must when given a number to plug in give you a number back, and if you put in the two numbers that are different they must give you different numbers back. For example if you put in the number 2 to A and put in the number 3 for A and get back 4 for both then it does not follow the rules. The same rules apply to group B.

Discussion

This study examined students' characterization of isomorphism in Discrete Math (DM), Linear Algebra (LA), and Abstract Algebra (AA) courses. Of note, each course had a different most-common metaphor. DM tied between *same properties* and *same but looks different*; LA's most common metaphor was *morphing/transformation*; and AA's most common was *generic sameness*. From this we note that while "isomorphism" is a shared name for concepts across courses, students still chose subtly different things to emphasize, indicating the need for care when referring to isomorphism and that isomorphism can mean different things in different contexts. This aligns with prior work with mathematicians, who carefully attended to the context-dependent nature of isomorphism (Rupnow & Sassman, 2022).

Despite these differences in emphasis, we note that metaphors from sameness-based clusters dominated the DM and AA students' descriptions of isomorphism and were a second emphasis behind the mapping cluster in LA. These differences do not appear to be related to the textbook's definition of the concepts given, as all definitions emphasized the function/mapping nature of isomorphism and the definition that directly used the word "same" was from LA, whose students had the least emphasis on sameness. However, the broader course contexts may have been impactful in terms of the objects to which isomorphism is applied, broader emphases of the course (i.e., proof), and whether isomorphism had been encountered in a previous course. Future research should compare the broader instructional contexts to better understand how students' perceptions of isomorphism were formed and what proved most impactful.

A "Different Vibe": The Effect of Discrete Mathematics on Undergraduate Students' Mathematics Beliefs

Christine M. Phelps-Gregory
Central Michigan University

Sandy Spitzer
Towson University

This paper presents emerging results from an investigation of undergraduate students' beliefs about mathematics (and themselves as learners) within the context of a discrete mathematics course. Our data sources include findings from a survey study with 11 participants and a follow-up interview study with 5 participants. Results suggest that students perceived discrete mathematics as being significantly different from their previous mathematics coursework, offering additional options for creativity and a shift in focus from computation to proof and logic. The impact of this shift on students' mathematical self-efficacy was mixed, with some students reporting unchanged self-efficacy but multiple students reporting decreased self-efficacy (either temporary or permanent). These results have implications for the teaching of discrete mathematics courses and shed additional light on our existing knowledge of students' belief change during the transition from K-12 school to undergraduate mathematics courses.

Keywords: Beliefs, Discrete mathematics, Mathematics self-efficacy

We present preliminary results of two studies examining undergraduate discrete mathematics students' beliefs about themselves as learners (their mathematics self-efficacy or confidence) and their beliefs about discrete mathematics. Discrete mathematics is a valuable site for study because it may allow for changes in students' beliefs. In particular, discrete mathematics courses typically include a variety of accessible topics that allow for deep mathematical thinking (Goldin, 2018; Sandefur et al., 2022). Particularly given recent increases in the number of undergraduate students majoring in the computer and information sciences, which typically require a course in discrete mathematics (Berg et al., 2023), it is timely to consider the impact of this course. However, little previous research has examined the effects of discrete mathematics on students' beliefs.

Conceptual Framework and Literature Review

In this study, we examine two types of beliefs held by undergraduate students enrolled in discrete mathematics courses. First, we examine students' mathematics self-efficacy (MSE), that is, their beliefs about their ability to do and learn mathematics (Bandura, 1986). The construct of MSE is related to mathematical confidence, although confidence is normally a broad measure whereas self-efficacy is task- or subject-specific (Morony et al., 2013). Self-efficacy beliefs are important because high MSE has been linked to higher achievement and improved learning, as well as non-academic skills such as perseverance and self-regulation (Hackett & Betz, 1989; Muenks et al., 2018; Usher et al., 2019). Generally, high MSE is seen as more beneficial than low MSE, though some researchers suggest that self-efficacy needs to align with actual ability (called calibration) to be fully beneficial (Russell & Phelps-Gregory, 2022). Thus, a goal of researchers and instructors should be, at the very least, to help students develop calibrated but confident self-efficacy.

Secondly, we examine students' beliefs about mathematics, including some of their generalized beliefs about the nature of mathematics (such as if math is creative) as well as specific beliefs about discrete mathematics. Unproductive beliefs (like the belief that mathematics is memorizing rules and is not creative) are commonplace among US students (Boaler, 1998; Kloosterman & Stage, 1992; Mann, 2006; Phelps-Gregory et al., 2020) and may harm students' learning because these beliefs correlate with higher anxiety and lower achievement (Geist, 2010; House, 2006).

We specifically examine students' beliefs (and possible beliefs changes) in discrete mathematics, a collegiate mathematics course typically taken by aspiring mathematicians, teachers, computer scientists and engineers, and information technology/information science majors. Discrete mathematics courses generally cover topics related to discrete objects and structures, though the exact topics covered are not always agreed upon. Sandefur and colleagues (2022) identified core topics and key themes of all discrete mathematics classes, including topics such as combinatorics and recursion. Previous research on discrete mathematics has examined student work (e.g., Greefrath et al., 2022) and teachers' pedagogical decisions and techniques in building student thinking (e.g., Alsardary & Blumberg, 2009; Love et al., 2006; Soto et al., 2022). However, one under-researched area is students' beliefs during and after discrete mathematics courses.

Discrete mathematics may be a good site to examine students' beliefs because researchers have argued that discrete students can engage in deep mathematical thinking regardless of their mathematical backgrounds and experiences (Colipan & Liendo, 2022; Goldin, 2018). This engagement might provide a site for changes in students' beliefs (Sandefur et al., 2022). In addition, discrete mathematics may also be a source of changes to MSE because mathematical transitions such as those required in discrete mathematics may be a site for disruption and change (Bandura, 1986; Gill, 2019). In particular, discrete mathematics courses often (but not always) include a focus on mathematical proof, thus prompting a transition to the so-called "axiomatic-formal" mode of mathematics (see Tall, 2008, for a fuller discussion of this transition). However, as noted by Stylianou and colleagues (2015), little research has examined undergraduate students' beliefs about proof, including their self-efficacy for learning proof. In general, few previous studies have examined students' beliefs in discrete mathematics. Our study sought to begin to address this. We examined the research questions:

1. How does discrete mathematics affect students' beliefs about their mathematics ability (their mathematics self-efficacy)?
2. What are students' beliefs about the nature of discrete mathematics?

Methods

We present here the related results of two studies of student beliefs. We first conducted a qualitative survey study examining undergraduate students enrolled in discrete mathematics at two regional universities. The survey used open-ended prompts to ask participants about their MSE and their beliefs about mathematics and discrete mathematics in particular. Eleven participants completed the survey, answering in their own words in sentences and phrases. We analyzed this data using an open coding procedure where codes were developed emergently from the data, following Campbell and colleagues (2013).

Once analysis of this data was complete, we conducted a second qualitative interview study to again examine undergraduate students' beliefs in discrete mathematics but with a new group of participants, enrolled in a different semester and with a different instructor. The goal of the interview was to explore the same questions as the survey, but in further depth and with the opportunity for follow-up questions. Questions included asking participants to describe their mathematics experiences before discrete mathematics, asking students to describe their discrete mathematics experiences, asking about the effect of discrete mathematics on their confidence, and asking belief questions (e.g., about the relevance and usefulness of mathematics). There were also questions asking participants to examine specific discrete mathematics questions and their confidence (MSE) in solving them. Five students completed interviews, lasting on average 29 minutes. Further interviews will be conducted in future semesters, but we present the results of the survey study and initial round of interviews here.

To analyze the interview data, we transcribed the interviews and then built cases for each participant by examining their data and highlighting important themes related to the research questions. Analysis then focused on categorizing participants by the effect of discrete mathematics on their MSE. We then compared and contrasted the groups of participants.

Results

Our preliminary results from both studies show that discrete mathematics may raise some students' MSE, temporarily or permanently, lower other students' MSE, and have no effect on the MSE of some students. This result is tied to students' beliefs about discrete mathematics, with multiple students mentioning their feeling that the course was qualitatively different compared to other mathematics classes. We will examine these findings in more detail below.

Findings of Survey Study

Of the eleven students who completed the survey, three participants reported that discrete mathematics did not affect their self-efficacy, three reported that it increased their self-efficacy and one reported that it temporarily lowered their MSE. Students' reasons for a change in self-efficacy included their course performance (i.e., grades), particularly given the reputation of the course as difficult and the nature of the mathematics in the course. For example, Noah[1] said, "I feel a little more confident because it isn't as scary as my dad made it out to be." Caleb reported that discrete mathematics temporarily lowered his MSE because the material was "different." When asked if discrete mathematics effected his confidence, Caleb said "Yes and no, it was harder for me to pick up the different topics because it's so different from, for example, a calculus class, but at the same time I just had to work harder to understand it and when I did my confidence was back."

Students' view of discrete mathematics as "different" could be seen in their other survey responses as well. Seven participants reported that discrete mathematics required more creativity than other mathematics subjects. Ava said, "The proofs in discrete math allow for slightly more creativity than in other math classes, because there is no one 'right' answer." However, not every participant agreed, with Noah saying, "Less creativity, [because] physics and calculus requires a lot of thinking outside of the box." Overall, the results of the survey study suggest that discrete mathematics could be a source of MSE change for some students due to the nature of the mathematics in the course.

Preliminary Findings of Interview Study

We are currently conducting an interview study to follow-up on the survey results. Based on preliminary analysis of data from five participants, one reported that their MSE was permanently lowered; one reported that, like Caleb, their MSE was temporarily lowered; and three reported no

[1] All names are pseudonyms to protect participants' identities.

change to their MSE. In contrast to the survey study, no students in the interview study reported that their MSE was raised as a result of discrete mathematics.

Jacob reported discrete mathematics permanently lowered his MSE, and Kaitlyn reported that discrete mathematics temporarily lowered her MSE. The major source of this lowered MSE for both students seemed to be their performance in discrete mathematics; both reported struggling some with the class material. Jacob said he was doing "not so hot [laughs]" in his discrete class. Kaitlyn said, "Usually math would come to me easy. Like I can pretty pick up pretty fast on it. But I just like for whatever reason cannot like wrap my head around some of the stuff that we're doing." Both attributed their performance and lowered confidence to the nature of the mathematics in the class being different from previous classes. Jacob said, "the material is like… logic based. So, it's really hard to like wrap your mind around sometimes." He also said:

> I guess there's not so many … like set formulas that I have to memorize. It's kind of just like applying all of the math that I've ever learned into one, without like formulas. And it's just kind of hard for me to … grasp my head around.

For Jacob, this lowered MSE seemed to be permanent; that is, he said overall now he believed he just was not as good at mathematics and would struggle in future classes. In contrast, for Kaitlyn, this change was temporary, and she assumed that she would be successful again in the future. The main difference between the two was that Jacob assumed that future classes would be like discrete mathematics. He said, "So I know a lot of like math from now on … basically builds off of discrete, like proofs and stuff like that." When asked to elaborate he said:

> Because I feel like the math before, … like calculus and stuff like that, it's all like here's the question and then there's an answer. But I feel like discrete and everything moving past this is more going to be like, why is this an answer? Or are there other answers? Or is there no answer? And like then explain why there isn't that and then prove it.

In contrast, Kaitlyn assumed that future mathematics classes would be similar to her previous classes and discrete mathematics was just an anomaly. She said, "I know it's just … one class. I know … it's like I'm good at math. I know I am, but it's just this one class. So, I guess short term [it affected my confidence], yes, but long term not really."

It is important to note that all five students reported that discrete mathematics was different from their previous classes, even students who reported that their MSE did not change. Four of the five said discrete mathematics required more creativity, with the fifth student reporting it was about the same. Makayla said:

> I would say it's more, more creative. I think there's definitely different ways you can go about getting the answer for some things. Which I know is true of like other math classes, but I think it's more, more true of this.

And Madison said it was more creative saying, "Probably more [strongly emphasized] because I would think the other classes are more just numbers and equations, whereas this one is thinking more outside the box with how they're related, I guess."

In addition, all participants implied that discrete mathematics had a "different vibe" from previous mathematics classes. Makayla said:

> I feel like it is just like a different overall like vibe, but I don't really know how to explain that. Like it just, it does kind of feel different in terms of math. It is more like logic and circuits and, and just kind of like… Um, I don't know. It's just … kind of like different.

Madison said, "How I described it to my friends is it's low-level math but use the most confusing words possible. [She laughs here.]" Tyler reported that discrete mathematics did not affect his MSE but did say the math was different and perhaps he was less confident in it. He said:

> I will say that I'm less confident about this class than most other math classes because with discrete math it's a bit different from other math. It's a lot less about computation and more about proofs and how the different concepts work together. And so I'm less confident in that than, say, solving equations. But … I would say it hasn't really affected my total confidence in math.

Overall, as with the survey study, the results of the interview study suggest that discrete mathematics could be a source of MSE change for some students due to the nature of the mathematics in the course.

Discussion

The results of this study add nuance to the field's understanding of how undergraduate mathematics courses such as discrete mathematics might influence students' beliefs. Previous research (e.g., Sandefur et al., 2022) suggests that the conceptual nature of discrete mathematics courses could be a source of increased MSE, because students might be able to engage more deeply with mathematical ideas compared with more computationally-focused undergraduate coursework which relies heavily on prerequisite knowledge and skills. In some ways, our results align with this result, in that nearly all our participants in both the interview and survey study described discrete math as being different from the math they have experienced in other coursework. Students described a "different vibe" including mathematics that seemed more creativity, had more options for completing problems, and had a focus on proof, logic, and concepts rather than computation. This aligns with existing research about students' perceptions of the transition to more formal mathematics at the undergraduate level (e.g., Tall, 2008).

However, in contrast with previous research and particularly within the interview study, we found that students reported that these perceived differences between their previous coursework and discrete math actually lowered their MSE (either permanently or temporarily). We might conjecture that this difference from previous research could be caused by the fact that the students in the interview study described themselves as having been successful in their prior mathematics coursework. Thus, rather than serving as a site where their insufficient prerequisite knowledge was not a barrier to achievement, for these students, discrete mathematics pushed them to think about math in unfamiliar and potentially uncomfortable ways. These results suggest that instructors of discrete mathematics courses should be aware that their students might be experiencing lowered self-efficacy, and this could cause students to disengage from the course. These students might need additional support to continue persevering despite the new challenges.

Questions for Further Discussion

We anticipate collecting further data for an additional two semesters, as well as finishing our analysis of existing data. Given this research is ongoing, we pose the following questions for the reader and the audience. First, the nature of interview work is that the questions you ask guide the interview. *What further questions should we ask during interviews to better explore students' beliefs?* In addition, as our analysis is ongoing, we are open to further interpretations of our data. *What analysis techniques and questions could help us better understand our data?* Finally, we pose a broader question to the field. *Given discrete mathematics, and possibly other advanced mathematics classes, may impact students' beliefs, what should be instructors' goals in these classes? How can instructors support students in positive belief change while also mitigating any effects of negative belief change (like permanently lowered self-efficacy)?*

Case Studies of Undergraduate Students' Agentive Participation in the Parallel Spaces of Calculus I Coursework and Peer-Led, Inquiry-Oriented, Complementary Instruction

Karmen Yu
Montclair State University

Steven Greenstein
Montclair State University

Calculus has long been known as a "gateway course" to STEM fields in postsecondary education. To address this issue, researchers in the Math Department at Montclair State University designed a model of complementary instruction that features peer-facilitated workshops where Calculus I students work in groups on inquiry-oriented, groupworthy tasks. The purpose of this multiple-case study is to seek answers to the question, "How do undergraduate Calculus I students experience and navigate their learning of calculus in the parallel spaces of coursework and inquiry-oriented complementary instruction?" The findings of one case study are presented here and include characterizations of the different forms of agentive participation afforded to students in each of the two spaces, as well as their complementary nature relative to learning calculus with understanding. Implications for dismantling the persistent barriers imposed by calculus on access to postsecondary STEM fields are also discussed.

Keywords: Calculus, Complementary Instruction, Agency, Participation

Calculus has historically operated as a "gateway course" to STEM fields in postsecondary education (Hagman et al., 2017). In the hopes of transforming calculus education to be "lean and lively," the calculus reform movement in the 1990s called for a change in calculus instruction to include fewer topics and utilize an active and engaging approaches to teaching and learning (Johnson et al., 2014). Two decades later, the President's Council of Advisors on Science and Technology (2012) proposed a similar suggestion in an effort to provide students with the time necessary to develop deep and conceptual understandings of calculus. Unfortunately, despite the ongoing efforts to reform calculus education, calculus maintains its gate-keeping role.

The Insights and Recommendations from the Mathematical Association of America (MAA) (Bressoud et al., 2015) suggested seven essential practices for establishing a successful calculus program: (1) attention to the effectiveness of course placement procedures; (2) proactive student support services, including the fostering of student academic and social integration; (3) construction of challenging and engaging courses; (4) the use of student-centered pedagogies and active-learning strategies; (5) coordination of instruction, including the formation of communities of practice for instructor learning; (6) effective training of graduate teaching assistants; and (7) regular use of local data to guide curricular and structural modifications. Informed by these recommendations, researchers at Montclair State University designed a peer-led (Roth et al., 2001), inquiry-oriented *complementary* workshop that runs parallel to students' learning in class in order to address this pressing issue. Calculus I students in these workshops (Yu & Seventko, 2015) work collaboratively on deliberately designed groupworthy tasks (Buell et al., 2016; Cohen & Lotan, 2014) that address calculus concepts.

A review of the literature on peer-led cooperative learning models in postsecondary education confirms their effectiveness in various undergraduate mathematics courses in relation to students' academic achievement and other outcomes (Altomare & Moreno-Gongora, 2018; Liou-Mark et al., 2015; Trenshaw et al., 2019). As this body of literature evaluates effectiveness using quantitative methods, little is known as to how and why peer-led cooperative learning models yield the outcomes found in these studies. The study reported here aims to fill this research gap as it seeks to answer to the question, *How do undergraduate students experience their calculus learning in the parallel spaces of coursework and inquiry-oriented complementary instruction?*

Perspectives and Methods

This multiple-case study (Merriam, 1998) is framed from a situated perspective (Lave & Wenger, 1991), and uses Holland et al.'s (1998) concept of *figured worlds* to analyze changes in agentive participation and in relation to identity formation (Vågan, 2011). The unit of analysis is forms of agentive participation enacted by students in class and in workshop. A grounded theory analytical approach (Corbin & Strauss, 2014) is used to characterize students' participation in order to answer the research question. With the agentive participation codes as clusters, a word cloud for each class and workshop space was created for each case study participant to depict a summary overview of their enacted participation in each of the two spaces.

Two cohorts of Calculus I students who attended the workshops as part of their course requirements participated in the study. Each cohort consists of four participants from the same class taught by the same instructor. The data corpus consists of video recordings of 24 classes, six workshops, and three focus group interviews (Creswell, 2012), all of which were transcribed and subject to analysis.

Findings

The table in Figure 1 lists the various forms of participation that emerged from the grounded theory analyses of the two cohorts. These participation actions were further sorted into three categories of interactivity: *high*, *moderate*, and *nominal* activity. *Interactivity* describes students' interaction with their peers, tasks, or material resources. The *high interactivity* category describes agentive actions involving a high level of interaction among students, such as inquiring, sharing, and explaining. Agentive actions in this category involve the conceptual practices of making associations and connections among mathematical concepts (Pickering, 1995), which are the kinds of high cognitive demand (Stein et al., 2000) practices that support learning with understanding (Hiebert & Grouws, 2007). The *moderate interactivity* category describes agentive actions that entail independent work on executing procedures, providing brief responses to dichotomous questions with binary answers (e.g., yes/no or right/wrong), and seeking confirmation of ideas or the correctness of a solution. Lastly, agentive actions in the *nominal interactivity* category involve limited interactions with others and material resources, such as *note-taking* and *launching tasks*. Agentive actions in these latter two categories are considered low cognitive demand because they entail memorizing or carrying out procedures without making connections to facts, procedures, and ideas (Stein et al., 2000).

In addition to yielding the emergence of these codes and categories, the analysis also revealed periods of "integration" (assimilating norms and expectations) and "expansion" (growth in participation) in the students' participation, which I was able to discern using sequences of Venn diagrams that show the trajectory of students' participation over time. Given the space constraints, this phenomenon will be presented in-depth in my presentation should this proposal be accepted. In order to illustrate how participation codes and interactivity categories are used to address the research question, my analysis of Boris's case is presented next. I chose to present Boris's case because it accentuates the unique opportunities to enact different forms of agentive participation in each of the two spaces.

Figure 1. A table of participation actions in class and workshop across both cohorts.

Boris's Participation Profile

The instructor of Boris's class tended to teach through lectures and demonstrations of solving problems on the board. It was rare for the instructor to engage students by asking questions or providing problems for individual, in-class practice. Occasionally, however, the instructor implemented what he called a "homework active learning activity," where he would guide the class in solving a selected homework problem by having students take turns responding to his guiding questions. During this homework activity, the instructor would pose an assortment of moderate and higher interactivity questions to lead students through the problem-solving process.

Across 22 in-person class observations, when the instructor offered students an explicit opportunity to participate, Boris *refrained* from participating 136 times, averaging around six times per observation. [Note: Words in italics are participation codes.] He only *responded* to the instructor when the instructor directly asked him questions during a homework activity. In general, Boris was an *independent* and *resourceful* student in class and an *explainer* and problem-solving leader in workshop. Even though a comparison of his class and workshop word clouds (Figure 2 and Figure 3) shows that Boris *worked independently* in both spaces, his characteristic *independent work* was magnified in class. The *independent work* cluster supports this observation as it is the largest cluster in his word cloud, taking up nearly half the space. On the other hand, the *independent work* cluster in Boris's workshop word cloud is only the fifth largest cluster, which depicts his tendency to initiate *independent work* moments in class by working on homework assignments or on the instructor's examples on the board. Along with *working independently* on problems in class, Boris often *accessed resources* (e.g., textbook, notes, and other online resources) to support his sense making and problem solving. Hence, the *accessing resources* cluster is the second largest cluster in his class word cloud. Considering his active participation in workshop and the limited opportunities to enact agency or work on practice problems in class, it can be inferred that Boris was inclined to agentively pursue learning on his own, even when these opportunities were not explicitly presented to him.

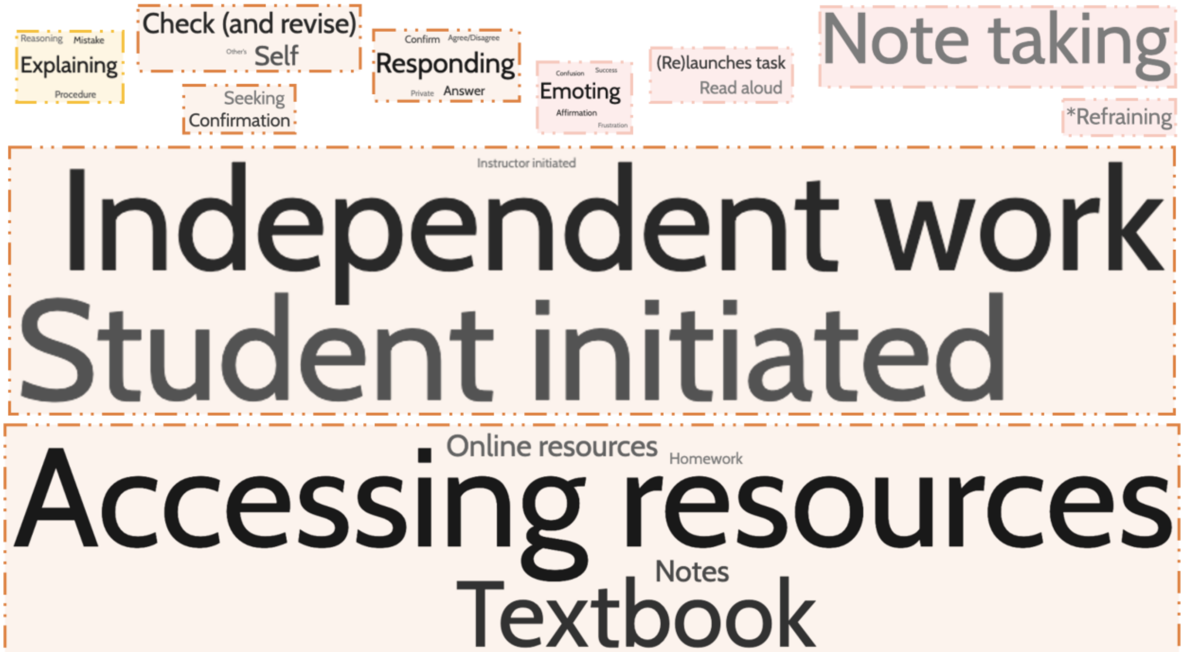

Figure 2. Boris's class word cloud.

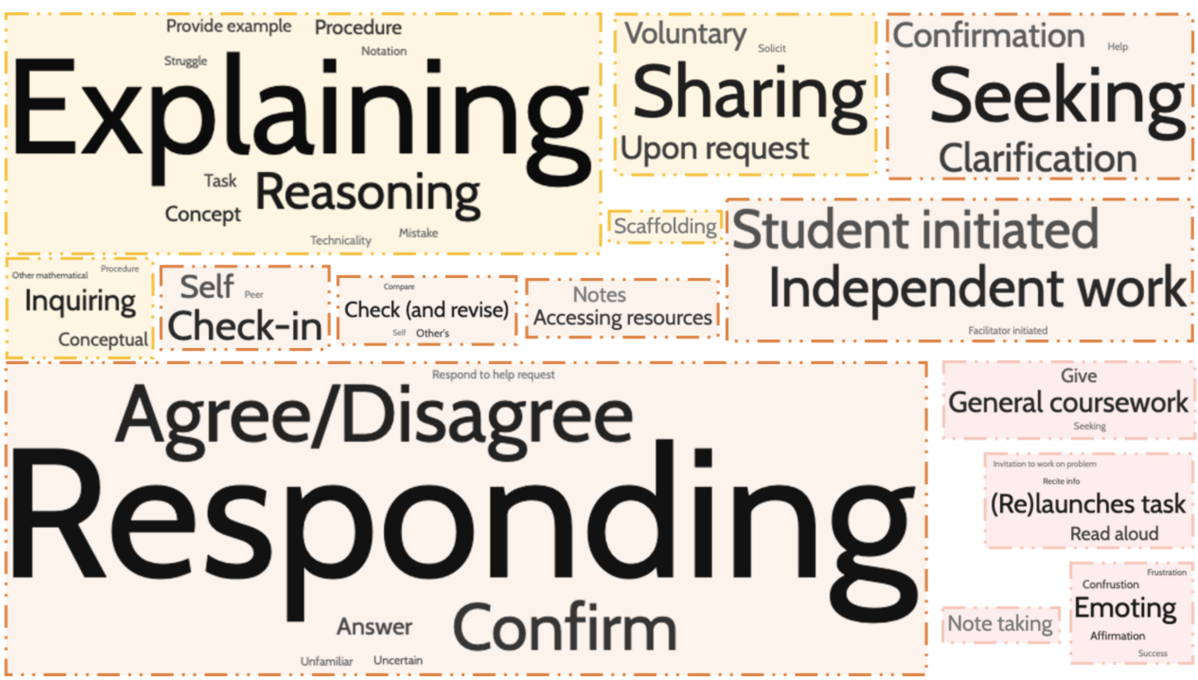

Figure 3. Boris's workshop word cloud.

Rather than choosing to *work independently*, as was his tendency in class, Boris tended to take on the highly interactive roles of a *responder*, *explainer*, and problem-solving leader in workshop. As a *responder*, his responses tended to articulate his *confirmation* and *agreement* with ideas shared by others. Compared to the rare occasions he enacted *explaining* in class, Boris had opportunities to enact *explaining* more frequently and extensively in workshop. This is evident from the *explaining* cluster as the second largest cluster in his workshop word cloud. Specifically, his workshop word cloud indicates his tendency to *explain concepts* and *procedures* and provide *reasonings* and *examples* in his explanations. Overall, Boris's role as a problem-solving leader in workshop was portrayed through his *explaining* actions and the occasional acts of *scaffolding* his cohort peer's problem solving.

Boris's case illustrates the differential forms of participation he enacted in class and in workshop. A review of his participation profile highlights these rather distinctive opportunities to enact agentive participation in each of the two spaces. In class, Boris tended to enact low-demand independent participation actions in moderate and nominal interactivity categories (i.e., *independent work*, *accessing resources*, and *note-taking*). In contrast, in workshop, Boris was more inclined to enact high demand participation actions in the high and moderate interactivity categories (i.e., *explaining*, *sharing*, and *seeking*).

As depicted in Figure 1, cohort A's participants had more opportunities to enact higher interactivity moves in class (i.e., explaining, inquiring, and sharing) than participants in cohort B, of which Boris was a member. Nonetheless, class and workshop were found to complement each other to offer all the participants a broad range of agentive actions. Given the value of highly interactive participation actions in particular, it is critical for students to have more of these in order to better support and enhance their learning.

Discussion and Conclusion

Reflecting on the MAA's seven recommendations for establishing a successful calculus program, the findings from this study can be used to inform calculus instruction by illustrating opportunities for high and moderate interactivity participation actions that can be enacted through student-centered pedagogies and active learning strategies (recommendation 4) in coursework or in complementary instructional workshop. Additionally, the participation codes observed in this study give a vision to calculus instructors of the kinds of interactive participation that are characteristic of challenging and engaging courses (recommendation 3). In turn, these findings can inform and guide the design and implementation of parallel spaces of coursework and complementary instruction, particularly when the realities of coursework alone impose constraints that do not allow for adequate opportunities for high and moderately interactive participation.

To summarize, this multiple-case study sought to address the research question, *How do undergraduate students experience their calculus learning in the parallel spaces of coursework and inquiry-oriented complementary instruction?* This study found a range of agentive participation actions that were further categorized into *high*, *moderate*, and *nominal interactivity* categories based on the quality of their interactions with others, tasks, or material resources. All in all, these findings would be of value to postsecondary calculus educators and program directors who are committed to offering students the kinds of participatory experiences that are productive for their learning of calculus. That way, they can be more mindful in planning, structuring, and designing their calculus programs so as to dismantle the persistent barriers imposed by calculus on access to postsecondary STEM fields.

Connecting Proof Comprehension with the Student Perspective: The Case of Christy

Lino Guajardo
Texas State University

Kristen Lew
Texas State University

The current state of proof comprehension research has focused on the instructor or researcher perspective. Either through assessing student proof comprehension (e.g., Mejia-Ramos, 2017) or developing interventions to improve student proof comprehension (e.g., Hodds et al., 2014). In this report, we discuss findings from one student from an exploratory study. We consider the influence of prior experiences on what it means to them to understand a proof and the reasoning behind the proof comprehension strategies used to understand a given proof.

Keywords: Proof comprehension strategies, student experiences, reading proof

Comprehending proof is one important task that a mathematician must do during their career. A goal for instructors of proof-based courses is to have their students develop the skills needed for mathematics research (Weber & Mejia-Ramos, 2011). One way of doing this is to have students participate in tasks done by mathematicians, such as comprehending proof. The existing literature has either focused on developing ways to assess student proof comprehension (e.g., Davies et al., 2020; Mejia-Ramos et al., 2017) or interventions to help improve student proof comprehension (e.g., Alcock et al., 2015; Hodds et al., 2014; Roy et al., 2010; Samkoff & Weber, 2015). Each of these studies take the perspective of researchers or instructors of proof-based courses and the student perspective is largely absent from the literature on proof comprehension (e.g., Weber, 2015). In this preliminary report, we begin to investigate the following research questions: (a) How do students' prior experiences inform their understanding of proof? (b) What reasons do students provide for using strategies to understand proof?

Relevant Literature

Proof Comprehension Assessment

Mejia-Ramos et al.'s model (2012) and tests (2017) have been used by multiple researchers to assess the impact of interventions. Alcock et al. (2015) used the model to create proof comprehension assessments to assess if workbooks given to students in an abstract algebra course improved their independent study of proofs. Zazkis and Zazkis (2016) used the model to identify what aspects (with respect to the seven question types) of a proof on the Pythagorean theorem preservice teachers focus on during a proof script task. As creating a valid and reliable proof comprehension test can be a daunting task (Mejia-Ramos et al., 2017), Davies et al. (2020) attempted to find another method to assess student proof comprehension by using student proof summaries. Investigating how student proof summaries could be used to assess student's comprehension of a given proof, the authors also hoped this would provide instructors with an alternative to the long process of creating a proof comprehension test. The authors found this method of comparative judgement to be reliable and valid, but the judgements from the experts correlated less with the final course grades in comparison to the comprehension test. The findings from Davies et al.'s study suggest that the proof comprehension tests created by Mejía-Ramos and colleagues may be more effective in assessing students' understanding with respect to course grades than the comparative judgements of student proof summaries.

Improving Student Proof Comprehension

Researchers have attempted to develop ways to present proofs to students so that the proofs can be easier for students to understand. Leron (1983) suggested an alternative to the linear presentation of proof by describing structuring mathematical proofs to highlight the overarching ideas of the argument. Rowland (2001) presented generic proofs for number theory, which used specific examples to highlight the general approach of the argument. Using the specific example sought to improve clarity and to remove abstractness for the reader.

More recently, researchers have also developed interventions to help with student proof understanding. These interventions attempted to help students in different ways, such as providing proofs that had visual and audio aspects to focus student attention (Roy et al., 2017), helping students learn how to productively study independently (Alcock et al., 2015), or providing students with self-explanation training (Hodds et al., 2014). These interventions attempted to support students in various aspects of reading proof. Either by providing students the chance to read the proof at their own pace and revisit instructor-provided explanations as many times as they would like (Roy et al., 2017), providing students opportunities to engage deeper with the concepts and proofs (Alcock et al., 2015), or by providing students with insight into how to productively summarize arguments (Hodds et al., 2014).

Weber (2015) and Samkoff and Weber (2015) offer seven strategies that successful students implement as they read proof for understanding. These authors implemented two instructional interventions, finding mixed results, to help students improve their proof comprehension skills.

Conceptual Framework

Since reading proof is an important part of a mathematician's career, it is equally an important task for students to take part in within their proof-based courses (Weber & Mejia-Ramos, 2011). Since students must read the proofs they encounter in class and textbooks, they are consumers of the presented proofs. As consumers, they are tasked (implicitly or explicitly) to understand a given proof. While we acknowledge Mejia-Ramos et al.'s (2012) model for assessing students' proof comprehension and the impact of this model on our own conceptions of proof comprehension, this study focuses on what it means to students to understand proof. When a student is given a proof with the goal of understanding, students may act to better understand particular points or aspects of the proof. That is, a student will employ a proof comprehension strategy.

Scholars have studied what students do when they are reading proof. For example, Weber (2015) investigated how successful mathematics majors attempt to understand a given proof through task-based interviews. Dawkins and Zazkis (2021) compared the reading behaviors between students who had little to no experience with reading proof to those who had experience. Additionally, Samkoff and Weber (2015) attempted to teach students seven productive strategies that can be employed to understand a given proof, such as dividing the given proof into independent sections.

Literacy education scholars have discussed student reading strategies and reading skills, with some scholars differentiating the constructs and others suggesting the two are the same. In both cases, scholars rarely (if at all) formally define them. Afflerbach et al. (2008) attempted to bring cohesion within the field by defining both constructs, offering the following definition of a reading strategy: "[r]eading strategies are deliberate, goal-directed attempts to control and modify the reader's efforts to decode text, understand words, and construct meanings of text" (pg. 368). With respect to reading proof, we define a strategy to be deliberate acts from the reader with the goal of understanding some subset of a given proof. To help in operationalizing this, we consider the ostensive strategies that a student enacts when attempting to understand a given proof. Thus, we define a proof comprehension strategy as any action of the reader that is done outside of the proof text with the goal to understand some portion of a given proof (inclusive of the whole proof). By outside of the proof, we mean the student engages in furthering their understanding through actions not done or recommended within the proof.

Meanwhile, the literature suggests that students' beliefs and prior experiences can have a significant impact on their actions within a classroom (Muis, 2004; Schoenfeld, 1989). Thus, as students are reading proofs to understand, they may rely on previous experiences with proofs or related topics. That is, they may reflect on past lived experiences, similar proofs they have seen, or on what proof comprehension strategies have previously been useful or productive. As such, we believe it is possible that students' beliefs and experiences may influence their own meanings of comprehension and the actions they take to understand a proof.

Theorem 1. *Suppose* $f : \mathbb{N} \to \mathbb{Z}$ *such that* $f(n) = \frac{(-1)^n(2n-1)+1}{4}$ *for* $n \in \mathbb{N}$. *Then* f *is a bijective function.*

Theorem 2. *Suppose* $f : A \to B$ *is a function. Then* f *is injective if and only if* $X = f^{-1}(f(X))$ *for all* $X \subseteq A$.

Theorem 3. *Suppose* A *is a set. Then,* $|A| < |\mathscr{P}(A)|$.

Figure 1: Three theorem statements

Methods

The data presented is from a basic qualitative study (Merriam & Tisdell, 2015) that investigated what students do as they attempt to understand given proofs on functions. Three participants were recruited from a large southern Hispanic-serving institution. Participants were interviewed during the winter break of 2022-2023 or during the Spring 2023 semester. Each participant had taken an introduction to proof course during the Fall 2023 semester. Participants were met with 1-3 times for hour-long clinical interviews (Ginsburg, 1997), based on their availability. For each interview, participants were given a theorem statement and its proof. Students were tasked to read the proof until they felt they understood the proof to the best of their ability. Each proof focused on functions, a topic covered in each of the participants' introduction to proof courses. Figure 1 shows the three theorem statements. Relevant definitions were available and provided if requested. After the participants indicated they understood the proof, interview protocol questions were asked. These questions focused on what it means to the participant to understand a proof, what the participants had done to understand the proof, and what they felt as they read the proof for understanding. All interviews were video and audio recorded. For this report, we focus on Christy[1], a computer science major at the time of the study (now a CS and mathematics double major). Christy successfully completed the course, continued in proof-based mathematics courses, and eventually engaged in undergraduate mathematics research. For the study, Christy met with the first author for three interviews. Data for this report was analyzed using open and axial coding by both authors (Corbin & Strauss, 2015). Both

[1] Pseudonym chosen by participant.

authors coded for student experiences and indications for how these experiences influenced what it meant for the student to understand a proof. Additionally, the authors coded for reasoning provided by the student for the use of identified proof comprehension strategies.

Preliminary Results

Christy's Definition of Understanding. In each interview, Christy was asked what it meant to them to understand a proof. Each time, Christy's response was similar: that understanding a proof means to understand the reasoning behind each action taken and decision made by the author throughout the proof. For instance, consider Christy's answer during the first interview:

> To understand, I think for me it's like understanding why people do things or like why certain actions we're taking. Like we are doing two parts cuz for proving it you need the onto and the one-[to]-one. ***But then like why do you have to assume - understanding why these assumptions are made. Because it's one thing to just do it and another thing to understand why it is*** […] ***[L]ike computer sciences, like CS. There's a difference between like having a program that works and actually knowing why it works. Because if you don't know why it works, then you could mess you up over later on when you're doing other things.*** […] Yeah, like why we make certain assumptions with things and like when we have to.

There are three key points to this quote. First, we note that Christy expressed the need to prove that a function is both one-to-one and onto to prove that it is a bijection – meaning that she is engaging in some proof comprehension strategies addressed by the literature, namely splitting the proof into various cases. Second, Christy emphasizes that simply identifying the modular structure (or cases) of the proof is insufficient. Rather, she states that it is also necessary to understand *why.* Why those two cases are made, why any assumptions can be made, and why the author is able to take different actions. Finally, Christy connects her need to consider both the cases of the proof and the reasoning behind these cases to her experiences in Computer Science. Throughout each of her interviews, Christy's focus on the "why" was consistent, as was her connection to computer science.

Christy's Comprehension Strategies. Christy was given a goal of understanding a given proof to the best of their ability. With their definition of what it means to understand a proof, Christy focused on various aspects of the proof to meet this goal. Christy used various proof comprehension strategies, some of which were previously identified by other researchers as strategies used by mathematicians. For example, for each of the given proofs, Christy segmented the proof into parts. Specifically, she marked each proof to indicate independent portions of the proof (such as differentiating the onto and one-to-one portions of the first proof). Christy also frequently used examples or drew diagrams to illustrate portions of a given proof. However, the reasons Christy used these strategies do not necessarily match the reasons the literature has indicated that mathematicians use and promote the use of these same strategies.

Consider partitioning a proof into independent portions. Samkoff and Weber (2015) state that identifying the modular structure of a given proof can be used to see overall structure of the proof. Additionally, Mejia-Ramos et al. (2012) discuss mathematicians views on the benefits of using this strategy as connections can be made between the portions identified. Yet, for Christy, this strategy held a different purpose, "I just need something there so I can see it. […] Like, yeah, block out what I don't need like sometimes I'll drive with the visor down even if it's there's no sun. Just so I can like focus on what's important." For Christy, portioning the proof was to allow them to focus on the independent pieces. Thus, we see Christy using productive comprehension strategies, but the personal reasons for implementing them differ from the motivation suggested by the literature.

Christy also used strategies not identified by Weber (2012). For example, one way Christy tried to understand certain portions of a given proof was to continue reading beyond the section she did not initially understand. In the second proof, Christy read the line "Since $f(x') = y$ and $f(x) = y$, then $f^{-1}(y) = \{x, x'\}$." Christy expressed she "didn't think functions could equal sets." When asked how she made sense of the line, Christy responded "mine was just read the next line." Similarly, while reading the third proof and attempting to make sense of the definition of a set (an element of the powerset and the mechanism by which the contradiction arises), Christy read over the definition multiple times before jumping forward in the proof saying "trying to see if the conclusion helps." In both of these instances, Christy continued to read further lines in the proof in an attempt to increase their understanding. This strategy was not identified by Weber in his 2015 study.

Connections to Computer Science. Christy made connections to their experiences with computer science in each of their interviews. Moreover, the connections varied in terms of scale. For instance, as discussed earlier, her experiences appear to strongly influence her personal definition of understanding a proof. Meanwhile, she also made connections between specific content in each field. For instance, during the first interview, Christy connected the concept of hash maps in computer science to the concept of a bijection:

> Computer science, there's like a hash map. So like to get values, you have to like, know the key for it […] There's just an infinite number of keys […] that's the definition of bijection is that you can get every single value. […] we just need to be able to get every single integer. Yeah, that makes sense in my head.

Discussion

Scholars have mainly focused on the instructor or researcher perspectives with proof comprehension research, though few have begun to investigate the student perspective. This study expands on Weber's (2015) findings that identified six strategies that successful students use to comprehend proof. Christy was a successful student in their introduction to proof course, yet her reasoning for using strategies previously identified by Weber are different than the motivation mathematicians might have for using these same strategies. Additionally, Christy was seen using strategies not reported by Weber. This study contributes to the field's knowledge about how students attempt to understand proofs in two ways. First, there may be additional strategies that successful students implement when reading proof. Additionally, we gain insight into the reasons students use different strategies. In this study, Christy did not necessarily use strategies for the same reasons a mathematician may, yet she productively used strategies that helped her understand the given proofs.

Investigating student perspectives on proof comprehension can inform continued and improved support to students. Additionally, investigating more students may provide deeper insight into ways to support students in comprehending proofs they see in their courses. Researchers can better identify which proof comprehension strategies are productive and when they are most productive to further support students in comprehending proofs they see in their courses. We aim to address this need in current and future work. We are investigating how more students attempt to make sense of given proofs. Further, we will be connecting student beliefs about proof and prior experiences with proof to what proof comprehension strategies they use with a given proof.

Student Understanding of the Direction of Vector Dot Products Across Contexts and Levels

Allison Molinari
University of Maine

Zeynep Topdemir
Johannes Kepler University Linz

John R. Thompson
University of Maine

As part of an effort to examine students' understanding of vector products, we present preliminary findings from student responses to survey questions asking whether the dot product has a direction in three different contexts and three different class levels. The contexts were two vectors with labels but no values, two vectors on a Cartesian grid with specified magnitudes and directions, and the flux of a uniform electric or magnetic field through a planar surface. The three courses were the second semester of an introductory calculus-based physics course, a sophomore-level mathematical methods in physics course, and a junior-level electricity and magnetism course. Depending on the context, between 25% and 30% of introductory students were successful at determining that the dot product has no direction. Performance increased with course level.

Keywords: Vector Products, Student Thinking, Pseudo-longitudinal

Introduction

Vectors are central to building a robust understanding of physics. Both conceptually and computationally, vectors play important roles through all levels of physics instruction. This has resulted in a significant body of literature addressing student understanding of vectors (e.g., Flores et al. (2004), Gire and Price (2014), and Nguyen and Meltzer (2003)). As is the case with the majority of physics education research, the majority of these studies are conducted in introductory calculus-based physics courses (Kanim & Cid, 2020). While some work has examined student understanding of vector fields (Bollen et al., 2017; Küchemann et al., 2021) and differential vector products (Topdemir et al., 2023; Walker & Dray, 2023) in the upper division, the evolution of students' ideas about vector products (dot and cross products) has not been thoroughly explored. This paper examines a preliminary study of the evolution of students' ability to identify properties of vector products at different levels and in different contexts. Data from a pseudo-longitudinal study is presented to demonstrate some aspects of how student performance is related to these factors.

Background

A significant amount of the work on student thinking about vectors has focused on student difficulties, with computational difficulties taking center stage. Mikula and Heckler (2013) examined students' ability to breakdown vectors into individual components by utilizing appropriate trigonometric operations. The decomposition of vectors into components has been shown to be challenging for students from a variety of introductory physics courses (algebra- and calculus-based, first and second semesters). Heckler and Scaife (2015) explored the effects of representation on student performance when adding and subtracting vectors, replicating previous findings on student difficulties adding vectors in the graphical (arrow) representation and identifying some novel difficulties. They also found that students performed significantly better using an algebraic representation than a graphical one. Bollen and colleagues (2017) examined student difficulties around the interpretation, construction, and translation between different representations of vector fields. They found that students' difficulties with addition and decomposition of vectors also impacted students' success transitioning between symbolic and graphical representations of vector fields and noted difficulties utilizing field line representations to appropriately represent field strength. A general lack of representational fluency was identified as a reason students may struggle with determining properties of fields such as the signs of the divergence and/or curl.

Zavala and Barniol (2013) investigated student understanding of the dot product in a graphical representation in introductory physics courses. This was done in three distinct contexts: mathematical (labeled "no context"), mechanical work, and electric flux. No significant difference was found between the two physical contexts, however there was lower performance on the no context problems than the others. Students also had significant difficulties connecting a conceptual understanding of the dot product to its formal representation. Barniol and Zavala (2014) subsequently produced the 20-item, multiple-choice Test of Understanding of Vectors (TUV), by considering difficulties reported by a large pool of previous studies and generating incorrect answers that tied directly to this literature. The TUV was found to track onto four primary factors for student difficulties: graphical properties, graphical procedures, geometric calculations, and unit vector notation calculations. However, the TUV did not include any physical contexts, and although the TUV did include some questions on the meaning of vector products, the majority of the items focused on procedures.

More recently, Carli and colleagues (2020) developed the Test of Calculus and Vectors in Mathematics and Physics (TCV-MP), examining differences in students' ability to answer questions in mathematical and physical contexts by asking 17 pairs of isomorphic questions. They found that students did not always use the same strategies to solve the isomorphic questions, implying that context influenced students' framing of the questions. Different difficulties were demonstrated by students between some question pairs. The researchers argue that differences in performance on some of the items suggest that success in physics is not solely dependent on mathematics preparation, but also necessitates students be able to appropriately blend the mathematical and physical reasoning in their problem solving. This is supported by other literature on student reasoning (e.g., Kuo et al. (2013) and Uhden et al. (2012)).

As part of a larger project to investigate student understanding of vector products at different levels and in different contexts, here we focus on recognition of features of the dot product. The research question we are pursuing here is: How, and in what ways, does student understanding of the direction of vector dot products differ between mathematics and physics contexts, and at different levels in the physics curriculum?

Methods

Data were collected via a four-item, online, multiple-choice survey, with three items focusing on dot products. While the result of the dot products are scalars and do not have a direction, it is not uncommon for physics students to ascribe directions to dot products and quantities described by dot products. Questions in the literature that ask students to calculate the dot product had both vector and scalars as part of the multiple-choice options (Carli et al., 2020). With common incorrect responses being vector options, it is unclear how students understand the nature of the operation of a dot product. Additionally, the selection of a calculated scalar response does not explicitly imply an understanding that the dot product has no direction. To address the vector versus scalar nature of vector products we asked about the magnitude and direction of the products in separate questions. Other questions from the literature include the words "vector" or "magnitude" in the answer (Barniol & Zavala, 2014). To avoid any cueing from specific vector-related vocabulary we asked, "Does the dot product $\vec{A} \cdot \vec{B}$ have a direction, and if so, what is it?"

Since the dot product results in a scalar quantity, the correct answer is, “It does not have a direction.” The answer choices were based on distractors from prior literature (Barniol & Zavala, 2014; Van Deventer, 2008). In all items students were presented with the appropriate formula for the dot product and asked whether it has a direction. A generalized list of the answer choices and abbreviated labels for presentation purposes can be found in Table 1. The same phrasing was used in all direction questions; only the vector labels were changed to reflect the specific context.

Table 1. Generalized multiple choice responses and abbreviated codes for the survey items.

Answer choices	Abbreviation
It does not have a direction	ND
In the direction of $\vec{A}$ (field vector $\vec{E}$ or $\vec{B}$ in the flux question)	A/FV
In the direction of $\vec{B}$ (area vector $\vec{A}$ in the flux question)	B/AV
In a direction between $\vec{A}$ and $\vec{B}$	BT
In the direction perpendicular to both $\vec{A}$ and $\vec{B}$ and into the page/screen	IP
In the direction perpendicular to both $\vec{A}$ and $\vec{B}$ and out of the page/screen	OP
Clockwise	CW
Counterclockwise	CCW
Not enough information to tell	NEI

The first two items used mathematical contexts. Students were provided with diagrams containing two vectors in space connected tail-to-tail, with labels $\vec{A}$ and $\vec{B}$. The vectors and labels were the only information provided in item 1 (Figure 1(a)); item 2 included a Cartesian coordinate grid and noted angles of each vector with respect to the positive *x* axis (Figure 1(b)). Item 1 asked about only the directions of the vector products $\vec{A} \cdot \vec{B}$ and $\vec{A} \times \vec{B}$, and subsequent items asked about the direction and magnitudes of the vector products.

Item 3 used the physical context of electric or magnetic flux through a surface area (Figures 1(c) and 1(d)); the choice of field was course dependent. In either case the flux due to a uniform field through a planar surface is given by a dot product of the field and surface area vectors (e.g., $\Phi_E = \vec{E} \cdot \vec{A}$). The potential for both positive and negative flux through a surface can sometimes be conflated for flux having a direction rather than being indicative of source or sink of field.

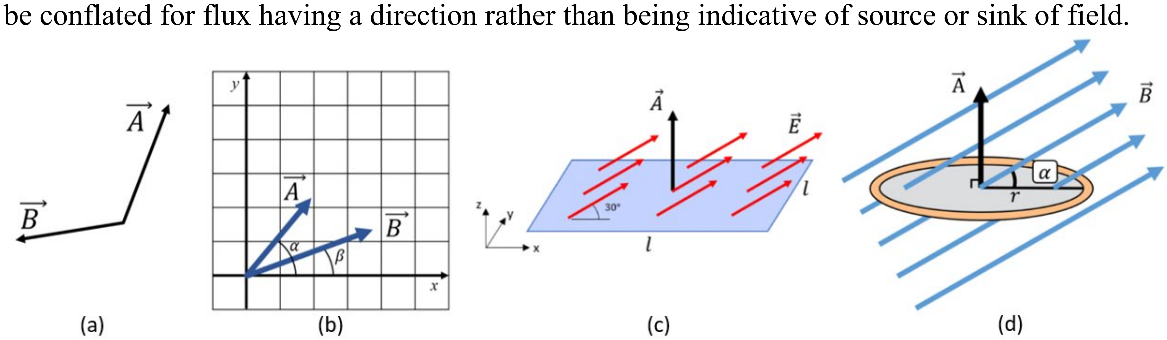

Figure 1. Diagrams provided in survey items asking about the direction of the dot product or the flux for the given situation. Diagrams for (a) item 1, (b) item 2, (c) item 3 for electric flux, and (d) item 3 for magnetic flux.

The survey was administered at a medium-sized public US university in three different physics courses: second-semester introductory calculus-based physics (N=153), sophomore-level mathematical methods in physics (math methods; N=14), and the second semester of junior-level electricity and magnetism (E&M; N=6). In each course, the survey was administered after instruction on the relevant mathematics or physics context(s). The context for item 3 for each course was most relevant to the context of instruction: magnetic flux in the introductory and E&M courses and electric flux in the math methods course.

To address the question of how student understanding of vector dot products differs at different levels of the physics curriculum we conducted a pseudo-longitudinal comparison between the three courses. For this comparison we limit the pool of introductory students to the physics and engineering physics majors who will go on to take the upper level courses (N=9).

Results

Performance across the three items related to dot products is presented for the introductory students before comparing the performance of students at different levels.

Introductory level

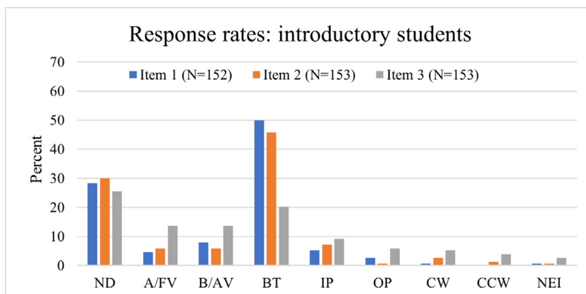

Figure 2. Introductory-level student performance on items 1, 2 and 3. See table 1 for answer choice descriptions.

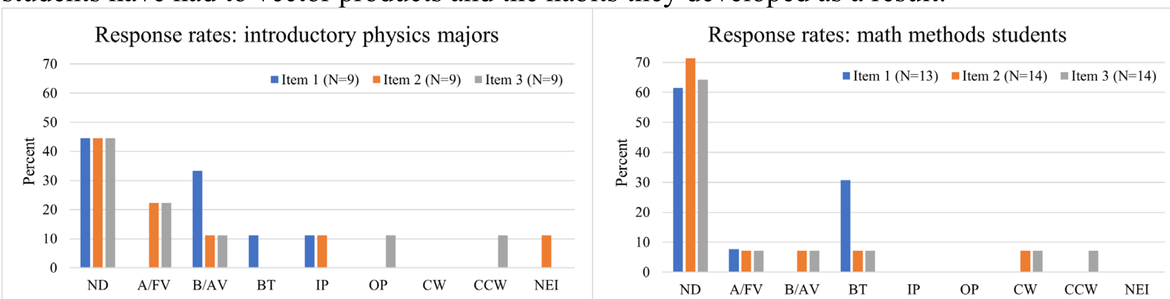
All three items had a similar percentage of introductory students selecting the correct response (Figure 2): 28% for item 1, 30% for item 2, and 25% for item 3. The most common choice for both items 1 and 2, 50% and 46% respectively, is that the direction of the dot product is between the two vectors (BT). This is consistent with the most common response seen by Van Deventer in a question asking which arrow, if any, describes the direction of the dot product of two given vectors (Van Deventer, 2008). Item 3, the flux question, had the most evenly distributed answer choices, suggesting less consistent understanding among students.

Similar percentages of introductory students selected the correct choice in each context, however only 16% of the introductory population selected the correct choice across all three items. Another 14% of students said the direction of the dot product is between the two vectors on all three items and 3% of students said that the direction of the dot product is in the direction of one of the two vectors (selecting either A/FV or B/AV) for all three questions. The remaining 67% of students did not answer consistently across all three contexts, which suggests that they do not have a coherent understanding of the dot product in multiple contexts.

Pseudo-longitudinal

The correct answer, "it does not have a direction," was the most common response on all questions through all three levels. At the introductory level, 44% of physics majors selected the correct answer on each item (Figure 3(a)). Between 62% and 71% of the math methods students chose the correct answer for each item (Figure 3(b)), and as expected, the junior E&M students had the highest performance of the three populations, with 100% correct in all three cases.

In all three levels, performance on the flux question, item 3, was similar to the performance on mathematics context questions, consistent with the similarities between isomorphic mathematics and physics questions in which mechanical work was used as the physics context conducted by Carli et al. (2020) and Van Deventer (2008). The most common incorrect answer in item 1 is different between the two lower courses: introductory students predominantly selected that the dot product is in the direction of $\vec{B}$, while math methods students selected that the dot product is between $\vec{A}$ and $\vec{B}$. The type of error may depend on how much exposure students have had to vector products and the habits they developed as a result.



(a) *(b)*

Figure 3. Performance by physics majors in (a) introductory and (b) math methods courses on items 1, 2 and 3. See Table 1 for answer choice descriptions.

Discussion and Conclusion

The performance of introductory students in this preliminary study (25-30%) is similar to end-of-semester introductory student performance on dot product direction questions in Van Deventer's study, with 25% of students in a mathematics context and 24% of students in a physics context selecting no direction (Van Deventer, 2008). The most common incorrect answer, a direction between $\vec{A}$ and $\vec{B}$, could be based on properties of vector addition. Some student explanations explicitly reference the tip-to-tail method, which is a strategy for vector addition not multiplication. For the introductory students, there seemed to be a wider variety of responses to the flux question than to the mathematics context questions. Asking these questions in other physics contexts (e.g., mechanical work) could document the relative difficulty of flux as a physics context for considering the dot product direction.

The trend of improved results as the course level increases is expected in the pseudo-longitudinal study, but the performance is not as good as one might expect, especially in the sophomore math methods course. Vectors and vector operations are introduced in the introductory sequence and proficiency in subsequent courses is almost assumed. A 100% correct response rate on all questions in junior E&M is a welcome result, but to promote student understanding of physics concepts in intermediate and upper division courses, vector operations need to be second nature as soon as possible, not after over half of the physics curriculum. While we see that student performance improves as we look at higher-level courses, a limitation of this study is the small sample size in each course.

Future work includes collecting more survey data, both internally and at other institutions, conducting interviews to elicit more detailed explanations of student reasoning, and connecting empirical data to existing frameworks.

Multivariational Reasoning in Linear Algebra:
How Mathematicians Reason about Linear Transformations

Wesley K. Martsching
University of Northern Colorado

Student difficulties in introductory linear algebra courses are often attributed to the novelty of the concepts in the course and the disconnectedness of these concepts to students' prior mathematical experiences. However, researchers have stated that a strong prerequisite understanding of the function concept is essential to students' understanding of linear transformations in linear algebra. In calculus and related courses, covariational and multivariational reasoning has been determined to be necessary for students to appropriately reason about functions in two or more variables. However, research on multivariational reasoning in linear algebra, especially with respect to linear transformations, is scarce. To contribute to the literature, we designed a study exploring a hypothetical model of how students might come to reason multivariationally about linear transformations. In this preliminary report, I discuss a part of the study – interviews with seven mathematicians who have either taught linear algebra or used linear algebra in their research.

Keywords: Linear Algebra, Linear Transformations, Multivariational Reasoning

Linear algebra is an important topic for many STEM students, including those studying computer science, data science, engineering, mathematics, and physics (Stewart et al., 2022). Recently, the second Linear Algebra Curriculum Study Group (LACSG 2.0) published recommendations for linear algebra instruction, taking into account advances in the field, industry, and technology over the last 30 years. Among the recommendations was the removal of calculus as a prerequisite for introductory linear algebra courses (Stewart et al., 2022).

In response to recommendations put forth by the first Linear Algebra Curriculum Study Group in 1993, Dubinsky (1997) claimed that students' struggles with mathematical concepts that are not necessarily part of linear algebra curricula but that are foundational to understanding linear algebra topics are one of the primary sources of students' difficulties in the course. In particular, Dubinsky noted that a strong prerequisite understanding of the function concept is essential to students' understandings of linear transformations. Additionally, Dorier et al. (2000) attributed students' conceptual difficulties in linear algebra to their difficulties with the "avalanche of new words, new symbols, new definitions, and new theorems" (p. 95) and the lack of connection to what students have already encountered in their mathematical experiences. Considering these views, it is important to connect students' learning of the linear transformation concept to students' prior experiences with the function concept, especially if linear algebra precedes calculus in the college curriculum.

There exist studies exploring the connection between students' understandings of the function concept and their learning and understanding of linear transformations (Andrews-Larson et al., 2017; Bagley et al., 2015; Zandieh et al., 2012; Zandieh et al., 2017). Much of this work has focused on a comparison of the concept images that students come to possess for functions and linear transformations. As part of a larger study, Zandieh et al. (2017) characterized student responses into three categories of mathematical structures (computations, properties, and clusters of metaphorical expressions) to compare their concept images of these concepts. In their work, the researchers found that "a reliance on properties appeared to impede students' development of a unified concept image of function while an ability to draw on metaphors facilitated such a development" (p. 36). That is, when students leveraged metaphorical linguistic expressions in their reasonings they were more successful in understanding various functions and transformations as examples of the same phenomenon.

In calculus and related coursework, covariational reasoning has been determined to be a vital way of thinking for understanding of functions (e.g., Castillo-Garsow, 2012; Oehrtman et al., 2008; Tallman et al., 2021; Thompson & Carlson, 2017; Thompson & Harel, 2021). Covariational reasoning encompasses the mental actions involved in reasoning about how two related quantities change in tandem with respect to perceptual time. When able to engage at the highest levels of covariational reasoning, a student can envision changes in one quantity's value as happening simultaneously with changes in another quantity's value and envision both quantities varying smoothly and continuously. Being able to coordinate the dynamic relationship between two quantities as they covary is crucial for students to be able to reason about concepts relating to functions, including derivative and accumulation (Silverman, 2017).

In linear algebra, Turgut (2019) utilized a dynamic geometry environment (DGE) to promote student understanding of matrix representations of geometric transformations as representing co-variation of inputs and outputs, consistent with a covariational view of functions. A review of the literature reveals that this study is the only one to-date that focuses on conceptualizing co-variation of two mathematical objects in linear algebra. However, the covariational reasoning framework was not utilized as a lens through which the author analyzed the data. That is, the study was not concerned with *how* or *to what extent* the students reasoned covariationally. Rather, Turgut (2019) employed the use of a semiotic mediation lens to investigate students' development of a conceptualization of matrices as representing geometric transformations, where treating a function as co-variation of independent and dependent variables was the byproduct of the use of the DGE.

More recently, there has been a greater focus on students' reasoning about the simultaneous change in more than two variables, excluding conceptual time as mediator, in calculus and other STEM subjects; this reasoning has aptly been referred to as *multivariational reasoning*. The development and evolution of multivariational reasoning as a framework of mental actions is rooted in the conceptual analyses reported on by Jones (2018). This theoretical report was "meant to form the basis of future empirical work" (Jones, 2018) centered around multivariational reasoning. Jones's first conceptual analysis was focused on analyzing a large set of functions and formulas derived from a collection of STEM textbooks. In particular, Jones considered how the variables in these functions and formulas "could be conceptualized as changing with respect to one another" (p. 1111) simultaneously and interdependently (Castillo-Garsow, 2012; Jones, 2018). The analysis included an identification of four potential types of multivariation inherent to mathematical functions and formulas: *independent multivariation*; *dependent multivariation*; *nested multivariation*; and *vector multivariation*.

To date, no studies have employed use of the multivariational reasoning frameworks to linear algebra concepts outside of vector field tasks presented in the context of differential equations (Jones & Kuster, 2021; Kuster & Jones, 2019). However, there are implications for the teaching and learning of linear algebra concepts when considering vector multivariational reasoning, even when viewed as the composition of parallel independent multivariations. Jones and Jeppson (2020), in particular, noted many similarities in the various types of reasoning within multivariation contexts. And "that it might not be necessary for students to learn about each type of multivariation separate from the others. By learning to reason about one type, they may simultaneously be developing reasoning abilities that transfers to other types" (p. 1146).

If it is indeed the case that the mental actions involved in multivariational reasoning are transferrable across the different types, then it may be that multivariational reasoning could serve as the catalyst for connecting students mathematical reasoning across courses and disciplines. In particular, the teaching of linear algebra concepts, such as linear transformations, from a multivariational reasoning lens might provide additional support and opportunities to make connections to prior mathematical experiences and concepts, such as reasoning covariationally about the function concept. In this study, I aim to explore this idea by addressing the research question: *What would be a hypothetical model of how students might come to reason multivariationally about linear transformations?*

Theoretical Underpinnings

Quantitative reasoning, "conceptualizing a situation in terms of quantities and relationships among quantities" (Carlson et al., 2002, p. 425), is an important component of students' mathematical learning. In this framework, a student has conceived of a quantity when they have conceived of a measurable attribute of some object; in this way, the quantity is idiosyncratic to the student conceiving of it (Thompson et al., 2017). When a student mentally unites the attributes of two or more quantities to make a new conceptual object that simultaneously represents both original quantities, this new object is referred to as a *multiplicative object*. When the variations of two quantities, coordinated to form a multiplicative object, are conceptualized in tandem, we call this *covariational reasoning*.

The idiosyncratic nature of quantity under these framings has allowed for the identification of mental actions pertaining to increasingly sophisticated levels of covariational reasoning. For example, the first identifiable mental action in the covariational reasoning framework is "coordinating the value of one variable with changes in another" (Carlson et al., 2002). Similarly, researchers have begun identifying the mental actions pertaining to increasingly sophisticated levels of multivariational reasoning (e.g., Jones, 2018). In working to identify potential types of multivariation and associated mental actions, Jones (2018) conducted two conceptual analyses.

Conceptual analysis is a tool that leverages the tenet of radical constructivism that knowledge persists because it has proven viable in the knower's experiences. Because, as mathematics education researchers, we seek to improve the learning attained by all who study mathematics, the purpose of a conceptual analysis is to develop a model of how a concept may be structured, ways of knowing the concept that may be favorable to learners, or to develop models of what learners actually know at a moment in time and understand in specific situations (Glasersfeld, 1995; Thompson, 2008). In discussing the role of conceptual analyses in developing hypothetical models of a concept and how students might come to reason about it, von Glasersfeld (1995) stated:

> [I]t is indispensable to have a fairly explicit model of what these concepts might be in the adult. Mathematics textbooks are not very illuminating in that regard and philosophers of mathematics rarely stoop to say anything about the conceptual raw material of their construction. (p. 161)

Accordingly, I designed a study to investigate a hypothetical model of how students might come to reason multivariationally about linear transformations by first performing an initial conceptual analysis leveraging several undergraduate linear algebra textbooks. This analysis guided my work on designing interview protocols to elicit multivariational mental actions of mathematicians.

Methods

In this report, I share a part of a larger study in which I investigate mathematicians and students' multivariational reasoning in linear algebra, with an aim of developing a hypothetical model for how students might come to reason about linear transformations. To achieve this goal, I first conducted interviews with mathematicians. The purpose of the interviews with mathematicians was to identify the mental actions that they call upon when reasoning multivariationally about linear transformations. Then, I plan to refine the interview protocols to conduct interviews with students to again identify the mental actions that students call upon when reasoning multivariationally about linear transformations. With the results of from these data sets, I aim to develop a hypothetical model for how students might come to reason about linear transformations.

At this stage in the project, seven mathematicians each participated in two 60-minute, one-on-one, semi-structured interviews centered around the concept of linear transformation. Mathematicians were considered suitable for participation in the study provided they had previously taught a course in linear algebra, or their research had leveraged linear algebra knowledge.

The first interview was used to familiarize the researcher with each mathematicians' background in linear algebra and determine how the mathematician participants reasoned multivariationally about linear transformations represented algebraically. These algebraically represented transformations were determined to be more similar in appearance to functions that a student might have prior exposure to before taking an introductory linear algebra course. For example, after being asked which given transformations could be linear, mathematicians were each asked to describe the relationship between x and $T(x)$ for the transformation $T(x) = (x, -3x)$. If there was no discussion of varying quantities, then a follow-up question at this point was "What would happen to $T(x)$ as you changed/varied the value of x?". This prompting was used to elicit multivariational reasoning, so that the mental actions of multivariational reasoning that mathematicians engaged in could be identified during data analysis and used to inform the hypothetical model for students' multivariational reasoning.

In the subsequent second interview for each mathematician, participants were similarly asked to reason about matrix transformations and geometric transformations; an example of each is shown in Figure 1. For each type of representation, mathematicians were first asked which given transformations could represent linear transformations and were then asked to reason about the relationships between inputs and outputs for particular transformations. During task design, it was hypothesized that reasoning about the images of the standard basis vectors and the domain and range of a linear transformation might help students reason more powerfully about the relationship between the inputs and outputs of the transformation. This led to development of sub-questions ii. and iii. for the matrix transformation tasks (Figure 1). These sub-questions were given iteratively to the mathematicians, provided the ideas had not been brought up authentically by the participant while engaging in previous parts of the task. Throughout both interviews, each mathematician was frequently asked to reflect on anticipated student difficulties with each task.

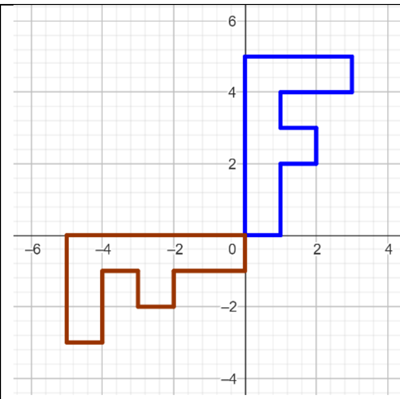
Given the matrix $A = \begin{pmatrix} 2 & -1 \\ 0 & 3 \end{pmatrix}$, determine whether the transformation given by $T(x) = Ax$ could be a linear transformation.

i. What happens to the output vector as you vary the input vector?

ii. What does A do to a vector?

   a. What does A do to the basis vector $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$? To $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$?

iii. What is the domain and range of the transformation?



What effect does the transformation have on an arbitrary vector?

Figure 1. An example of a matrix transformation task (left) and a geometric transformation task (right) given to mathematician participants during their second interviews.

During each interview, an over-the-shoulder camera was used to collect data relating to mathematicians' physical cues (e.g., hand gestures, motions, and written work). Mathematicians' written works were captured in real time using screen recording on the interviewer's iPad Pro®; data from the camera and screen recording for each interview was then superimposed for the proposed of data analysis.

In the initial coding of the data, I am identifying and categorizing mathematicians' reasonings (e.g., reasoned geometrically) and potential related mental actions (e.g., recognized one quantity's value as being dependent on another) from the overlayed video and transcribed audio. Next, I will identify properties of these categories (e.g., whether a mental action was task or representation specific). Following this initial analysis and coding of mathematicians' reasonings, I will perform a member check with each participant to ensure that their views and reasonings are accurately reflected. During axial coding, subcategories of mental actions will be related to categories of mental actions to which they are subordinate to or supporting. I will also examine subcategories of mathematicians' mental actions to determine whether any categories are repetitive and can be removed, condensed, or combined.

Mathematicians' responses to anticipated student difficulties for each task will also be coded thematically and compared to existing literature on students' difficulties. Insight from mathematician responses and results from data analysis will be used to modify interview tasks and protocols ahead of student interviews.

Discussion

I will present data analysis results from the interviews at the conference. In preliminary initial coding, I observed that some mathematicians focused on varying the input of a transformation component-wise by small arbitrary changes to determine the effect this had on the corresponding output vector. It seems that their reasonings included recognizing in/dependence and coordination mental actions. The audience will be asked to discuss some interview questions to elicit additional mental actions that I may have not observed in my data set.

Acknowledgments

I thank my mathematician participants for their time and input, and my thesis advisor Dr. Gulden Karakok for her guidance.

Learning to Teach Teachers: Community College Faculty Explore Fraction Tasks for Teaching

Anne Cawley

Cristina Runnalls
Cal Poly Pomona

Dulce Jimenez Maldonado
Cal Poly Pomona

Emily Perkins
Cal Poly Pomona

Teaching mathematics for future elementary teachers is fundamentally different from other forms of mathematics and thus requires different knowledge. As community colleges become increasingly involved in the process of training future teachers, it is essential to explore how instructors at these institutions develop as mathematics teacher educators. This paper reports on a preliminary exploration of how community college faculty grappled with teaching-oriented mathematical tasks involving fractions. Choices of mathematical representation, selection of answer before and after discussion, and overall themes are discussed, with a focus on development of mathematical content knowledge for teaching.

Keywords: Professional Development, Math Teacher Educators, Preservice Elementary Teachers

Mathematics teacher educators (MTEs) carefully consider the preparation and development of preservice elementary teachers (PTs). Though four-year institutions have predominantly prepared students for teaching and provide certification/licensure for elementary teachers through credential programs (Masingila et al., 2012), community colleges have begun to focus attention on widening the teacher preparation pipeline "as more students [turn] to them to take required mathematics and education courses" (Blair et al., 2018, p. 185). Masingila et al. (2012) found in a survey of 207 two-year college math departments that over 80% offered math content courses for PTs, implying that "two-year schools play a key role in the mathematical preparation of teachers" (p. 352).

Our study is framed by the perspective that teaching math for future teachers entails a fundamentally different approach than teaching other math courses, as learning to teach math requires different and complex ways of understanding (Ball et al., 2008). Just as teachers of math require a knowledge of math different than those *not* engaged in teaching, MTEs require knowledge of teaching mathematics that is developed and held in a way different than how teachers know it (Beswick & Goos, 2018). While the content being taught in elementary math content courses may appear simple, conceptual meaning underlying topics, addressed at both the level of the PT and the future elementary school student, is deceptively complex. Masingila et al. (2012) argue that "instructors teaching mathematics content courses designed for [PTs] may not be prepared to teach those courses in ways that will provide the type of mathematical support needed by [PTs]" (p. 355). While faculty may hold strong mathematical knowledge, many have not had extensive pedagogical training nor training for how to be a MTE. This paper focuses on the following question: How do community college math faculty reason through teaching-oriented mathematical tasks involving fractions?

Methods

This paper focuses on the mathematical work collected from a one-week professional development (PD) of 15 math faculty who are developing MTEs. None of the faculty had specific training as MTEs prior to the PD. Ten of the faculty were full-time math instructors from three community colleges, while six were part-time math instructors at a university and/or community college. Teaching experience ranged from two years to over 20 years, with over half of participants having some kind of K-12 teaching experience. Five instructors had taught a math course for PTs at least once before, while ten instructors had never taught a math course for PTs and therefore had never engaged with the ways that PTs think mathematically. All participants expressed a desire to develop their understanding of how to teach mathematics content in a first mathematics course for PTs.

Each morning, faculty engaged in a selected task from the Learning for Mathematics Teaching (LMT) Project from the University of Michigan (Hill et al., 2004). These LMT tasks were designed to be used in many different contexts. For purposes of the PD, we used tasks as "open-ended prompts which allow for the exploration of teachers' reasoning about mathematics and student thinking." (Hill et al., 2004, p. 2). We utilized a total of five tasks, each focusing on a mathematical topic related to the PD activities for that day. This paper highlights participants' responses for two of these tasks, shown in Figure 1. Task 1 targets the knowledge needed by a teacher to develop children's reasoning about comparing and ordering fractions. Task 2 demonstrates a task related to fractions, providing sequences of questions that may help a child determine how many 4s are in 3.

Task 1: Comparing and Ordering Fractions

Mr. Foster's class is learning to compare and order fractions. While his students know how to compare fractions using common denominators, Mr. Foster also wants them to develop a variety of other intuitive methods.

Which of the following lists of fractions would be best for helping students learn to develop <u>several</u> different strategies for comparing fractions?

a) $\frac{1}{4}$ $\frac{1}{20}$ $\frac{1}{19}$ $\frac{1}{2}$ $\frac{1}{10}$

b) $\frac{4}{13}$ $\frac{3}{11}$ $\frac{6}{20}$ $\frac{1}{3}$ $\frac{2}{5}$

c) $\frac{5}{6}$ $\frac{3}{8}$ $\frac{2}{3}$ $\frac{3}{7}$ $\frac{1}{12}$

d) Any of these would work equally well for this purpose

Task 2: How many 4s in 3?

Mrs. Brockton assigned the following problem to her students: How many 4s are there in 3?

When her students struggled to find a solution, she decided to use a sequence of examples to help them understand how to solve this problem. Which of the following sequences of examples would be <u>best</u> to use to help her students understand how to solve the original problem?

a) How many:
4s in 6?
4s in 5?
4s in 4?
4s in 3?

b) How many:
4s in 8?
4s in 6?
4s in 1?
4s in 3?

c) How many:
4s in 1?
4s in 2?
4s in 4?
4s in 3?

d) How many:
4s in 12?
4s in 8?
4s in 4?
4s in 3?

Figure 1: Task 1 and Task 2 from the LMT sample tasks.

Participants were first given five minutes individually to review the task, select a response, and explain their reasoning. In groups of four, participants were then given eight minutes to discuss the question with their peers before we discussed as a whole group. Finally, we asked the participants to reflect on their thinking after group discussion. Fifteen people responded to Task 1 and 13 responded to Task 2. This paper discusses the written reflections from participants. Data were analyzed through constant comparison analysis (Corbin & Strauss, 2008). All authors first read through each individual response, noting which choices were selected initially and after group discussion and notable themes from their reasoning. This guided our second read which focused on all participants' initial choice reasoning. Our third read focused on all participants' final choice reasoning. During the second and third read, we specifically focused on participants' use of language, inclusion of visual representations, and overarching themes in their reasoning.

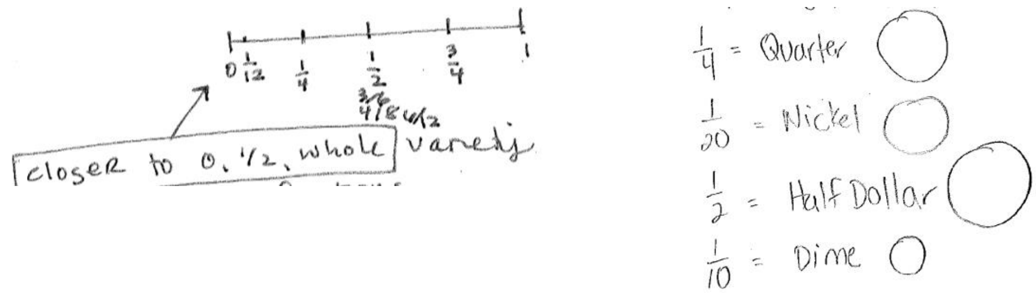
Findings

Findings are discussed for each task, with a focus on language/vocabulary participants used to explain their reasoning, types of visual mathematical representations provided in the response, and participants' initial and final answer selection.

We first discuss Task 1. Some language trends used by the participants were the words: *unit fraction*, *size*, *easiest*, and *variety*. Initially, option A was the most selected answer. Eight of the 15 participants identified (in some way) the list of fractions as unit fractions. Nine participants referred to the size of the fractions in option A, indicating that option A could help students focus on the value in the denominator and its meaning. One participant, Heidi, noted that "it is important for students to understand the 'size' of fractions first and also determine how the denominator affects the size of a fraction before comparing them." Across participants, there was significant overlap between thinking in terms of *unit fraction* and *size*, implying that the only difference in the fractions in option A was the denominator, which may help children determine the size of the fraction. Four participants labeled option A as *easy,* mentioning that the values were "easiest to compare." For example, Stephanie wrote, "Beginning by understanding fractions with 1 in the numerator makes comparing them easier to access," further sharing that most of the fractions "can be re-written with a common denominator of 20 fairly easily." The idea of *variety* was also something participants discussed, although it was not clear what they meant by the word. Four participants selected option C and one participant option B because of variety in the numerators and denominators. One participant initially liked option C because of the variety of prime and composite values in the denominators. The participant who initially chose option B changed to option C, this time mentioning variety to describe difficulty. Variety was also used to describe the many strategies that could be used to help students compare fractions.

Four participants drew diagrams in their response, while three provided real-life contexts related to the fractions in the options. The types of diagrams drawn included a tape diagram, fraction circles, a number line, and a coin model. For example, one participant drew a number line from 0 to 1, showing tick marks for 1/12, 1/4, 1/2, and 3/4 (see Figure 2a). Another bridged the idea of student knowledge and fractions in option C, stating that the denominator in 3/7 could represent days in a week or the denominator in 3/8 could represent the number of slices in a medium pizza. Courtney drew a diagram of coins to connect the denominators in option A (Figure 2b), which included different American coins in relation to a one dollar whole, drawing them to their relative size, noting that 1/19 caused a challenge for this model, but that students could compare it to a nickel.

There were substantial changes to the final selection in Task 1, with 12 participants changing their selection after group discussion. Initially, eight participants selected option A, three selected option B, two selected option C, three selected a combination of options, and one was unclear on their selection. After discussion, many participants selected a different option, and many struggled to select one option. Overall, 11 participants chose option C in some way, and *no* participants selected option A. Most participants' choices included some type of conditional statement, which indicated that they liked an option, but with some adjustments. One participant stated that she would pick options A, B, and C, sharing she would start with option A, move to option C, and then depending on class time, also use option B. It appeared that participants were highly open to hearing the perspective of others and multiple ways of thinking of the same problem. Participants noted that option C included many interesting values, could highlight the concept of benchmark fractions, and how the values could be organized in relation to closeness to 0, 1/2, and 1, as shown in Figure 2a.

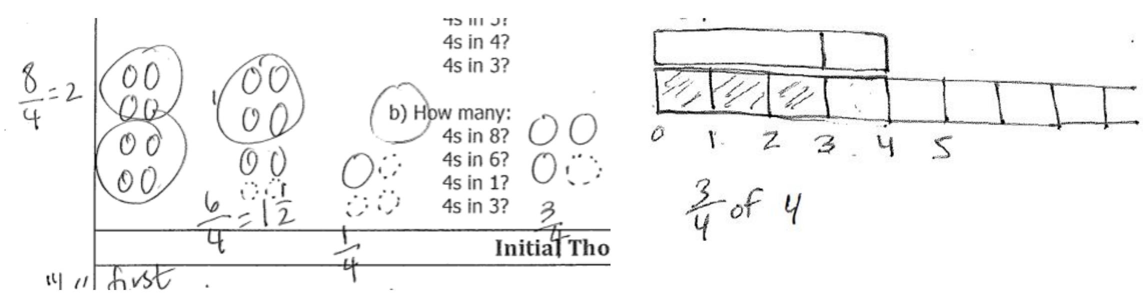


(a) (b)

Figure 2. (a) Diagram of Jane's number line. (b) Diagram of Courtney's thinking.

Next, we discuss Task 2, which asked for the best sequence to help students understand the concept of "4s in 3." Participants responding to Task 2 differed in how they conceptualized the problem, either as a division problem, fraction problem, or both. From the 13 participants, only one viewed the problem as solely a *division* problem, stating that option D led students "to recognize the use of division." Eight participants had writing indicating that they viewed this problem as a *fraction* problem, using language like whole, mixed number, or unit fraction, or by writing fractions. Four participants used language that indicated thinking of the problem as pertaining to both division and fractions.

Six participants utilized diagrams in Task 2, three of which had also drawn a diagram in the first task. One participant, Mara, had a visually distinct drawing for Task 2 involving a discrete model for her initial choice, option B, showing circles in groups of four with dotted lines to indicate fractional parts (see Figure 3a). The other four participants, in contrast, used number lines and tape diagrams. Figure 3b shows Patricia's use of a tape diagram to visually demonstrate that there should be less than one 4 in 3.



(a) (b)

Figure 3. (a) Mara's discrete drawing representing option B. (b) Patricia's tape diagram showing 4's in 3.

Task 2 also had a high number of people unable to choose one option after group discussion. Eight people had more than one answer listed, with six settling on options B and D. Reasoning included comments like "I think both explanations are valid" and "Perhaps I would use a combination of B and D," often showing slight preference for one or the other but not making a clear decision. Furthermore, one person had no answer listed but instead wrote, "context matters," with a list of the different factors that would affect a teacher's decision for which response to select, such as grade level and whether the teacher used discovery learning. Two more participants also did not choose an answer after group discussion, with one participant only including their ideal list of nine examples that would help students to understand the concept. In total, there were 11 participants who struggled to pick an answer in some way.

Due to the general indecisiveness of the group, participants were given the opportunity to create an ideal list of four example problems to lead up to the "4s in 3" question, creating a list of five examples. Twelve participants had a mixture of examples from options B and D, with six people from this group adding in the example "4s in 2" into the list. One person had a visually distinct list that was sourced from option C, using the same problems but instead listed as 4s in 4, 4s in 1, 4s in 2, then 4s in 3. Three people had lists that were longer than five examples, and after some large group discussion one participant remarked that in his classroom, he could give as many problems as he wanted. Rather than settling on a specific answer, the group felt relieved to create their own lists, agreeing that no option in Task 2 gave the "best" sequence of examples.

Discussion

The findings described above highlight both the challenges and affordances that may be leveraged in training community college faculty to become effective MTEs. Participants' work with two LMT tasks revealed differences in how they described and understood fractions and division, choices of visualization, and how they incorporated their experience into the work.

One of the most surprising features highlighted across both tasks was participants' limited use of visualizations. Very few participants provided number lines, tape diagrams, or other visuals in their work. Within their explanations and in discussions, many participants noted the importance of visualization when working with fraction ideas yet did not include a diagram themselves. It remains unclear whether this was due to a lack of need for diagrams personally or a perception that diagrams were not required when explaining to their peers. It has been shown that MTEs struggle to know when and how to incorporate visual fractional representations (Petit et al., 2016); without evidence of visualizations in the responses, it was not yet clear whether the MTEs had developed knowledge on how visualizations may support student thinking.

Across both tasks, it became clear that participants had a difficult time selecting a single answer after the whole group discussions. Many participants placed a strong emphasis on instructional context, providing qualifiers next to multiple choices. This indecisiveness and need for additional information were likely influenced by the background of the participants. As experienced teachers, they were acutely aware of the need to adapt materials to the specific class. They were also willing to engage in group discussions with colleagues and subsequently adapt or modify their choices - a necessary component of learning new ideas and building a community amongst their peers. These changes support the idea that participants were beginning to reshape their knowledge of teaching PTs, especially in the context of fractions and division, and were open to substantive change in their practice as future MTEs.

Questions for further discussion: (1) How have others transitioned from mathematicians to MTEs, specifically around elementary-school mathematics content? (2) How might lessons learned in this space transfer to teaching and learning in other mathematics courses?

Barriers and Drivers to Implementing GTA Professional Development focused on Active Learning, Equity, and Inclusivity

Hayley Milbourne
University of San Diego

Mary E. Pilgrim
San Diego State University

ELITE PD Research Group
EHR #2013590, 2013563, and 2013422

Mathematics Graduate Teaching Assistants (MGTAs) play a significant role in undergraduate mathematics education, as they are often in a teaching-related position for courses in the College Algebra through Calculus II sequence. Further, research shows that teaching practices that promote active learning, equity, and inclusion lead to improved student outcomes (e.g., Freeman et al., 2014; Laursen & Rasmussen, 2019; Mulnix, Vandegrift, and Chaudhury, 2016). However, MGTA PD that reflects these practices may be limited due to a variety of reasons. In this manuscript we discuss barriers and drivers to implementing PD that reflects active learning and equity-focused values. The goal is to understand ways that we can utilize institutional-specific drivers and navigate barriers to support the implementation of more PD programs like the one in this study.

Keywords: Mathematics Graduate Teaching Assistant, Professional Development, Active Learning, Equity, Barrier

Mathematics graduate student professional development for teaching has become increasingly important in the Mathematics Education community. However, what that professional development looks like depends on local institutional contexts. A department's culture can impact what classroom practices graduate students implement as well as whether equity and inclusion are identified as being an important element for instruction. Department leaders who work closely with graduate students who have teaching roles, such as department chairs, course coordinators, and professional development providers, have an understanding of that culture and recognize existing barriers and drivers to implementing professional development for mathematics graduate teaching assistants (MGTAs).

The work presented here is part of a larger NSF-funded project focused on creating, implementing, and studying a multi-term professional development program for MGTAs across three different mathematics departments. The program titled, ELITE PD, has two primary foci: 1) active learning and 2) equity and inclusivity. However, how departments think about and approach these ideas can vary. Thus, we sought to understand institutional-specific barriers and drivers for implementing a MGTA professional development program focused on active, equitable, and inclusive teaching practices. Specifically, we ask: What barriers and drivers do department leaders identify for implementing an MGTA PD program focused on active learning, equity, and inclusivity?

Theoretical Frameworks

We sought to identify analytical frameworks that reflected the ELITE PD program foci. In the work by Shadle et al. (2017), researchers sought to understand STEM faculty perspectives with regard to shifting teaching practices from instructor-centered approaches to more student-centered approaches. Additionally, Harris and Wood have done extensive work in understanding barriers to advancing equity in instruction in higher education (e.g., The Community College Equity Assessment Lab (CCEAL), 2017; Harris & Wood, 2018; Wood & Harris, 2015). Together, the work of Shadle and colleagues and Harris and Wood provide us with analytical frameworks that allow us to understand the barriers and drivers to implementing an MGTA PD program focused on active learning, equity, and inclusivity.

Shadle et al. (2017) examined STEM faculty response to a vision for teaching as proposed by university leadership. The vision proposed a shift towards student-centered instruction and leadership solicited input from faculty regarding the proposed vision, and faculty-perceived barriers and drivers toward this vision were then identified. Identifying barriers allowed leaders to better understand aspects and characteristics that might prevent change from occurring (e.g., university reward structures, individual beliefs) and drivers that could be leveraged to support change (e.g., collaboration in teaching, personal satisfaction). We drew upon Shadle et al.'s barriers and drivers as a starting point for our analytical framework for understanding barriers and drivers to implementing active learning in MGTAs' instruction.

While Shadle et al. (2017) address barriers and drivers associated with active learning and student-centered instruction, Harris and Wood (e.g., CCEAL, 2017; Harris & Wood, 2018; Wood & Harris, 2015) examine the barriers for doing equity-related work in higher education. Several of the barriers overlap with those identified by Shadle and colleagues. For example, both Shadel et al. and Harris and Wood highlight individual attitudes as playing a role in resistance to change efforts. Similarly, both groups of scholars emphasize institutional culture as potentially impacting change (e.g., institutional policies or processes). Harris and Wood additionally identify institutional "politics and power dynamics" as a potential barrier for equity-related work (2018, Barriers to Actually Achieving Equity section). Combined, both analytical frameworks provided us with a starting point for understanding department leadership perspectives on an MGTA PD program focused on active, equitable, and inclusive teaching practices.

Methods

A previous RUME paper with this project explored barriers and drivers tied to implementing an MGTA PD program focused on active learning, equity, and inclusivity (Fifty et al, 2022). That work examined a single institution through thematic analysis. Here we expand upon this work by looking across three institutions and implementing an a priori codebook built from the codes established by Shadle et al. (2017) and the work of Harris and Wood (e.g., CCEAL, 2017; Harris & Wood, 2018; Wood & Harris, 2015). We discuss our methods in the following sections. While we are building upon this work, this work is still preliminary, with only initial findings from coding being presented.

Data

ELITE PD is being implemented at three large, public universities: Beta University, Epsilon University, and Gamma University. Each university offers graduate programs in mathematics. Epsilon University primarily grants master's degrees in mathematics and Beta and Gamma Universities primarily grant PhD degrees in mathematics. At each institution there is a structure within the department around MGTA professional development and interviews were conducted with the leaders in these structures. Table 1 lists the titles of the leaders at each institution. In some cases, more than one person carried the same title, and those instances are documented by the number in parenthesis.

Table 1. MGTA Professional Development Leaders at each institution.

Epsilon University	Gamma University	Beta University
Incoming Dept Chair Outgoing Dept Chair Course Coordinators (3) PD Facilitators (1) Graduate Advisor	Dept Chair Associate Chair Graduate Program Chair PD Facilitator	Dept Chair PhD Director Course Coordinators (2) PD Facilitator

These interviews were semi-structured conversations around ELITE PD practices and implementation, which is described in more detail below. Interviews were conducted at the beginning of the study, before ELITE PD had been implemented at any of the institutions.

Coding

Analysis of these interviews was done through open coding. The initial codebook was taken from Shadle et al. (2017) and supplemented by the work done by Harris and Wood (e.g., CCEAL, 2017; Harris & Wood, 2018; Wood & Harris, 2015). As the interviews were coded, these codes were then refined, and other codes were added based on what was uncovered in the data. Codes were identified as being in one of three main categories: barrier, driver, or tension. Barriers were those codes that impeded ELITE PD practices, drivers supported ELITE PD practices, and tension codes were not necessarily barriers or drivers but emphasized local context or values that impacted ELITE PD practices. ELITE PD practices are:

- Active Engagement
- DEI practices in and out of the classroom
- Assessment (or feedback) of teaching practices aligned with active learning and/or DEI practices
- Faculty or peer MGTA mentoring practices
- Fostering MGTA autonomy/agency
- Awareness of and attending to power differentials (how MGTAs are treated, classroom practices, etc.)

Examples of barriers to ELITE PD practices include *Unclear Implementation* and *Student Resistance*, and *Improves Teaching and Assessment* is an example driver. Examples of tensions are *MGTA Workload* and *Student Preparedness*.

An utterance was coded only if it could be related to at least one of the ELITE PD practices listed above. If the utterance was not clearly related to one of those practices, it was not coded. For example, discussions around professional development for MGTAs were not coded unless it was clear that there was a connection to ELITE PD practices; general discussions about professional development were not coded.

Once a codebook had been formed, three researchers coded all of the interview. Each interview was coded by at least two researchers. For each interview, the researchers coded individually and then came together to discuss any differences in coding until there was 100% agreement.

Initial Findings

Some initial findings have included the most common barriers and drivers found across the three institutions. Each of these are described in more detail in the following sections.

Drivers

The three most common drivers were *Supportive Attitude*, *Current Practices*, and *Department Support*. A description of each of these codes is given in Table 2.

Table 2. Common drivers

Supportive Attitude	The interview participant expresses (personal) view in line with ELITE PD practices such as being supportive of efforts that align with ELITE PD values.
Current Practices	● Some MGTAs and/or faculty participate in PD that reflect ELITE PD practices ● MGTAs and/or faculty member(s) have already adopted ELITE PD practices
Department Support	In reference to the department as a collective (use of "we") in relation to efforts associated with ELITE PD practices. May be part of department-wide culture, expectations, vision statement, and/or department mission.

The drivers described in Table 2 were found to be the most common among the three institutions, with *Supportive Attitude* being the most common driver across all three institutions. These drivers did not vary much between the three institutions. For all three institutions, these were the most commonly discussed drivers, which was not the case for barriers as described below. Other drivers included *Institutional Support* and *Aligns With Existing Resources*.

One limitation with this finding is that all three of these drivers are quite broad and encompass many different beliefs and ideas. We are currently working on a secondary code system for each of these drivers, as well as for *Institutional Support*, so as to gain a better understanding of what the specific drivers are within each of these categories.

Barriers

The three most common barriers were *Unclear Implementation*, *Lack of Awareness*, and *Faculty Divisions*. Each of these codes is described in Table 3.

Table 3. Common barriers

Unclear Implementation	Don't know how to assess if doing ELITE PD practices, their appropriateness, or how to implement them effectively
Lack of Awareness	Participant indicates they are unaware of policies, structures, happenings/efforts in the department/institution related to or aligned with ELITE PD practices
Department Support	Disagreement and/or unwillingness among faculty/lecturer groups with regard to implementing ELITE PD practices. (e.g., tenured vs. un-tenured faculty; lecturers vs. faculty; etc.)

An interesting difference between the most common barriers and drivers was that the barriers varied across the institutions. For Beta University, the top three common barriers were Unclear Implementation, Lack of Awareness, and Faculty Divisions, which is consistent with the overall list described above. However, for Epsilon University, the top three common barriers were Unclear Implementation, Faculty Divisions, and Not-My-Job, and for Gamma University, the top three common barriers were Lack of Awareness, Focused on Metrics, and Misinformed/Theorizing, which includes codes not on the overall common barriers list above. It was important to delineate by institution, as the number of interviews were not the same for each institution. Further, examining barriers by institution allows us to better understand the role that local contexts can play when engaging in PD work focused on active learning, equity, and inclusive teaching strategies.

In addition, we found that the Not-My-Job code was used to note when the interviewee stated that something focused on ELITE PD practices was not part of their job. We found that this was not necessarily a strict barrier as we had originally thought it would be. Rather, it tended to mark instances the interviewee recognized that there were other people more qualified to address specific aspects or tasks in the department. In contrast, Focused on Metrics was a code used to note times the interviewee was more focused on the metrics of the department over the implementation of ELITE PD practices and Misinformed/Theorizing was used to note times the interviewee made a statement about ELITE PD practices that was not correct (e.g., active learning is not possible in large classes).

Conclusion

Understanding the barriers and drivers that can support or impede the implementation of an MGTA PD program focused on active learning, equity, and inclusion is important because they can be used to encourage the adoption of such a program. While drivers did not vary much across the three institutions, barriers did. As barriers can play an important role in hindering implementation of a PD program, understanding what those barriers are can help in knowing how to best leverage drivers in order to implement change. For example, the focus on metrics at Epsilon University could be leveraged in such a way that data collected for assessing impact of a PD program could include metrics that 'speak' to administrators and leaders. Lack of awareness and/or unclear implementation, on the other hand, may require a focus in communication and enhanced training to support PD efforts. Such a focus could also address the barrier of misinformed/theorizing. Moving forward, we aim to understand how institutional-specific barriers can be addressed through existing drivers.

Instructional Characterizations of Foundational Math Coordinators with Attention to Instructor-Student Interactions

Kimberly Cervello Rogers
Bowling Green State University

Camryn Grey
North Carolina State University

Nicholas Long
Bowling Green State University

We aimed to get a better understanding of participants' (eight foundational math course [FMC] coordinators') teaching approaches. In the first year of this grant project, we primarily gathered data (through surveys, self-reflections, and class observations) on these individuals as instructors. These data were compiled into narrative summaries for each participant and analyzed and compared. We discuss our findings from this analysis, using the instructional triangle as a framework, and particularly focusing on instructor-student interactions. This project aims to develop an understanding of what is needed to support instructional change in FMCs by evaluating how math-specific professional development (PD) cycles affect FMC coordinators' teaching practices and perspectives. We seek audience feedback on potential next steps towards fostering effective instructor-student interactions and future PD cycles.

Keywords: Foundational Math, Course Coordinators, Professional Development

Introduction

College math instructors typically work in isolation, negatively affecting quality of instruction and sustainability of evidence-based teaching practices in college math classrooms (Bressoud et al., 2015). Few instructors have access to or utilize explicit communities of support (Reinholz, 2017). This paper reports on data from the first year of a 3-year grant project (Rogers, 2022-2025) that ultimately aims to test and refine a community of practice (CoP; Wenger et al., 2002) among eight faculty members who coordinate and teach foundational math courses (FMCs, e.g., College Algebra, Precalculus, Quantitative Reasoning, Introductory Statistics, Math for Elementary Teachers, & Calculus). Course coordinators are a key population within college math education because they teach and supervise instruction of thousands of undergraduate students each semester. A CoP can provide a means for them to share and manage professional knowledge, in this case about math-specific professional development (PD) opportunities.

The overarching objectives of this grant project evaluate how math-specific PD cycles affect FMC coordinators' teaching practices and perspectives and contribute to theory about supporting meaningful instructional change in FMCs. The hypothesis is that by designing and implementing PD opportunities about teaching undergraduate math using active-learning (AL) strategies (Freeman et al., 2014; Laursen & Rasmussen, 2019) with FMC coordinators, they will develop their mathematical knowledge for teaching and become more effective instructors. Ultimately, this project will develop an understanding of what is needed to support instructional change in FMCs. Our first step toward these goals is to understand the current beliefs, practices, and competencies of the FMC coordinators in our study, use these findings to inform future PD decisions, and elicit feedback from the RUME community to consider moving forward. In this paper, we aim to answer, what are the prevailing characteristics (e.g., beliefs, competencies, classroom practices) of these FMC instructors?

Literature Review

Over a decade ago researchers (Speer et al., 2010) conducted a literature review on collegiate math teaching and concluded that instructors' practice (i.e., their pedagogical actions and reasoning related to those actions in the context of instructional activities) remains largely unexamined in the research literature. Research on PD in college math education is still sparse, especially when the focus is on instructors and tenure-track faculty (Florensa et al., 2017). Within the context of our larger research project, we first seek to better understand who these participants are as instructors and as a community of instructors. When we say community of instructors, we are examining this group of instructors as a CoP.

In a 97-paper meta-analysis of change theories in STEM higher education, the most prevalent change theory was CoPs (Reinholz et al., 2021). A CoP strives to create, expand, and exchange domain knowledge to develop individual capabilities and cohesion dependent upon passion, identity, and commitment (Wenger et al., 2002). These cohesive properties align with the model used in this study because all participants share the FMC instructor and coordinator identities, a commitment to teaching (per employment), and passion to support student learning outcomes.

To consider these CoP components, we note how the MAA Instructional Practices Guide (MAA, 2018) emphasizes student-centered teaching practices and pushes us to move away from direct instruction. This push is due to research findings that highlight how student-centered practices help increase access to learning opportunities for diverse learners (e.g., Laursen & Rasmussen, 2019). We specifically conceptualize student-centered instruction through the instructional triangle. Instead of solely emphasizing the teacher, Cohen et al. (2003) defined teaching as "what teachers do, say, and think with learners, concerning content, in particular organizations and other environments, in time" (p. 124). In their definition, four critical aspects of teaching become apparent- teachers, students, content, and environment- which are situated in a model that represents instruction as interaction where teacher, learners, and content create a triangle of interaction, existing within the environment (i.e., the instructional triangle). This framework for instruction is appropriate for our study because it allows us to look at participants' self-report data and classroom observation data and consider how their responses and practices emphasize components of the instructional triangle.

Method

Context: University and Course Coordinator Backgrounds

At a rural, public, liberal arts college in the Midwest, participants are eight FMC coordinators. Course coordination duties include (but are not limited to) deciding on, designing, and distributing course materials (i.e., syllabi, lecture notes, pacing calendars, example assessments, and activities) to maintain consistency across sections of the course that semester. They also include facilitating meetings with all course instructors, adjusting assessments so they align with learning outcomes, providing observation feedback for novice college math instructors (i.e., graduate student instructors and faculty), and addressing student concerns. Our campus has a main (4-year) location and secondary location less than an hour away. The secondary location focuses on the first 2-years of undergraduate course work, and providing explicit pathway supports for students. Table 1 lists participants' course names, years coordinating (self-reported), and campus location. For College Algebra, both campus locations utilize a math emporium instructional style[1], a computer-based opportunity to fill in gaps for content knowledge, while the other FMCs are taught in in-person lecture formats (pseudonyms are used throughout this paper).

[1] Math emporiums use adaptive learning systems to individualize student pathways (Cousins-Cooper et al., 2017).

Table 1. Participants' backgrounds and course coordination details.

Pseudonym	Course(s) Coordinating	Yrs Coordinating	Campus
Alaina	College Algebra	9	Main
Alexis	College Algebra	0	Main
Camille	(1) Calculus I, (2) Calculus II, & (3) Calculus III	15	Main
Madeline	(1-3) Math Ed Elementary Math Content Courses	4	Main
Patrick	(1) College Algebra & (2) Pre-Calculus	3	Secondary
Pricilla	Pre-Calculus	4	Main
Reema	(1) Math for Architectures & (2) Quantitative Reasoning	12-15	Main
Stella	Introduction to Statistics	4	Main

Community of Practice Context

Before this grant project began, Author 1 met with the FMC coordinators at least twice a month for course coordination meetings to address administrative and policy needs of the FMCs, department, and university. By utilizing these pre-existing meetings, we implement PD activities, learn about one another's teaching practices, and collect self-report and survey data without adding additional time commitments.

Data Collection and Analytical Approach

During project year 1, FMC coordinators completed surveys[2], answered reflection questions, completed an empathy map, and were observed teaching. These data points informed our understanding of their professional history, beliefs both as an individual instructor and as part of the FMC coordinator group, and typical classroom practices. We created narrative summaries of each participant's quantitative and qualitative responses. We analyzed the narratives to examine participants' beliefs and classroom practices, specifically regarding participants' teaching approaches. We conceptualize "teaching approaches as actions and strategies described and enacted by instructors when they talk about teaching mathematics or when they actually teach mathematics (Mesa et al., 2014, p. 122). We coded the data for student-, content-, or instructor-centered approaches, defined as instructor descriptions and strategies that are driven by…

1. …"instructors' interest in attending to students' cognitive, social, and emotional needs, seeking to give students a more prominent role in classroom activities" (Mesa et al., 2014, p. 122): Student-centered.
2. …"instructors' interest in emphasizing the content over students' cognitive, social, or emotional needs and involvement" (Mesa et al, 2014, p. 123): Content-centered.
3. …instructors' teaching or learning plans, goals, or decisions that do not explicitly attend to student- or content-centered aspects: Instructor-centered.

[2] The surveys included items from the Collective Teacher Efficacy Instrument by Goddard et. al. (2000), and the (self-) Efficacy Instrument by Enochs & Riggs (1990)

Findings: Characterization as Instructors

After analyzing each individual case study and comparing them across the group, we report on our initial findings of the identities of these FMC coordinators.

Beliefs

Based on their survey responses, we examined the participants' beliefs about self-efficacy and collective teacher efficacy. Each coordinator's response indicated a high level of self-efficacy in terms of their ability to teach mathematics. For most, this ability included self-assessed strength in terms of their content knowledge (content-centered). The self-efficacy instrument also highlighted the coordinators' beliefs on how influential instructors are to the learning and success of math students. Specifically, all but one coordinator said the instructor (instructor-centered) significantly impacts student learning. Only Alaina's survey responses indicated she believes classroom practices need to be organized to help students be the mechanism for their success in learning (student-centered).

Every participant also indicated a high level of collective teacher efficacy, with survey responses that suggest they believe the other individuals in their FMC CoP are effective in their teaching of mathematics (instructor-centered). Even so, the coordinators were not in consensus as to whether further training was needed for the group to "know how to deal with undergraduate students" (Enochs & Riggs, 1990). When responding to this Likert-scale question, Patrick, Madeline, and Stella all somewhat agreed more training was needed, Alexis somewhat disagreed, Alaina, Camille, and Reema disagreed, and Pricilla was not sure. Interestingly, those who somewhat agreed more training was needed have only been in their roles for 3-4 years, however those who disagreed with the statement have between 9-15 years of experience as a coordinator. We interpret that result to mean that individuals with more course coordination experience feel like they, along with their CoP, do not require further training.

Competencies

Self-reported data was collected during two different group meetings. In one meeting, participants reflected on their areas of strength and struggle as instructors. They described some strengths/struggles that were more instructor- or content-centered, however, most strengths/struggles described were student-centered. All but one participant explicitly discussed strengths related to their students and interactions with students (e.g., engaging students in discussion), and every coordinator described a student-centered area of struggle (e.g., difficulty motivating students to come to class). These student-centered aspects indicate that as a group, the coordinators place value on their students' role in the classroom and interactions with them.

We also asked the coordinators to reflect on what a typical day in their class is like. Alaina stated practices that are primarily content-centered but are implicitly student-centered by design of the emporium class she coordinated (e.g., creating problems for certain students based on their current content). We are gathering this data from the recently appointed emporium coordinator, Alexis, on her intended practices to compare with Alaina's (emporium director and former coordinator). Camille, Madeline, and Stella all described student-centered approaches including dedicating class time for students to engage in the content and interact with classmates. Stella, specifically, reports having a mostly student-centered class, while Camille and Madeline spoke to both instructor- and student-centered aspects of their class time. Patrick, Pricilla, and Reema all described a lecture-based environment (instructor-centered) and focused somewhat on the content aspect of their classes (content-centered). We therefore conducted observations to investigate how these reported practices aligned with what happens in their classrooms.

Classroom Practices and Observed Interactions

Each coordinator was observed twice in the same semester, except for Stella who was observed once (due to scheduling constraints). When comparing the coordinators' stated practices to what was observed, their reported practices mostly aligned with what they did during observations of their class. Instances where there were discrepancies between the stated and observed practices were mainly things that they articulated did not occur every class session. For example, Pricilla stated she occasionally gives students an exit slip or a quiz, however, neither of these were observed.

The observations also allowed us to analyze instructor-student interactions. For some coordinators, particularly those with a more student-centered classroom environment, students tended to give affirming body language (e.g., nodding their head, actively writing) during these interactions and appeared engaged in the math. However, in other coordinators' classrooms, students were observed having negative body language (e.g., turning away from the instructor, dissociating) and appeared to disengage with the conversation or content. These instructors did not react in a way that would indicate their acknowledgement of the students' negative body language. This observation shows a disconnect between the interpretation of these interactions by the instructors and the students we intend to investigate further.

Discussion and Questions for the RUME Audience

From their survey responses and self-reflections, it is clear this group of coordinators care about the quality of their interactions with students. During committee meetings, some of the coordinators discussed not being able to get through to some students, or not understanding why their interactions with students were not as fruitful as they wanted them to be. After considering their observations, however, we gained insight into the differences in reported perceptions between students and instructors.

With this finding, we are interested in hearing any ideas from the RUME audience about how to illuminate this discrepancy to the group as well as what interventions or PDs could be used to promote affirming instructor-student interactions. We attempted to make some initial headway in this area in year 1 when we guided the coordinators through developing *empathy maps* (Aldrup et al., 2022; Gibbons, 2018) about personas of students in the FMCs they teach. Given the student-centered approaches documented in this study, we were surprised to be met with an unwillingness to participate by a few participants who felt the empathy map was not appropriate in the educational setting. Discussing this pushback with the RUME audience and exploring factors underlying this pushback could provide avenues for future PD with this group.

Additional specific questions we plan to ask the audience during our presentation include:

- What research-based, but practitioner-focused papers or resources should we be aware of that could inform how we help instructors consider students' perceptions about instructor-student interactions?
- This paper focuses on the participants as *instructors* of FMCs. During this second year of the project, what suggestions do audience members have regarding data we should prioritize gathering about these participants' perspectives as coordinators? And why?

Invoking Conceptual Change in Adult Learners: "Seeing" Fractions Differently

Patrick Sullivan
Missouri State University

I was charged with developing and implementing a course redesign to improve low success rates in the lowest university-level developmental mathematics course (median ACT score = 17). As part of the initial implementation of the course redesign a diagnostic assessment was given to understand the nature of students' conceptions of foundational concepts. Student responses on several items indicated that over 25% of students had a dominant part-whole conception of fractions; not seeing fractions in terms of measures. This dominant part-whole conception of fractions also influenced how students reasoned about items involving other concepts (e.g., addition of fractions and ratio comparisons). In this preliminary report the results that led to our conclusions, the instructional intervention we used to move students' conceptions of fractions forward, and the impact of the intervention, based on the results of the post-assessment, on students' conceptions of fractions will be shared.

Keywords: developmental mathematics, conceptual change, fraction conceptions

Introduction

At the university in which I teach the five-year success rates in the lowest developmental mathematics (DM) course has consistently hovered between 50% and 60%. Despite these low success rates, not much has been known about the nature of these students' conceptions of foundational concepts besides their over reliance on procedures without knowing the mathematical "why" (Stigler et al., 2010). Charged with improving success rates in this course it was important to first understand the "roots" of their struggle with mathematics. A thirteen-item multiple-choice diagnostic assessment (n = 230) was given to assess students' current conception of place-value, fractions, area/perimeter, and proportional relationships. While the results suggested that students' faced challenges within each of these constructs the most striking and revealing were those related to their understanding of fraction.

Existing research with students at various levels of academic experience suggested that students' knowledge of fraction magnitude, or as a number, is highly associated with their computational skills (Schneider & Siegler, 2010), algebraic knowledge (Booth et al., 2014), and general mathematics achievement (Torbeyns et al., 2015). Seeing fractions as a magnitude requires students to engage in multiple levels of unit coordination that involve relationships between quantities and various size of units. We had previously conducted research with 4^{th} through 7^{th} graders and were curious as to whether DM students' conception of fractions was similar. We had previously found that elementary and middle school students often struggled with fraction magnitude concepts because their dominant conception of fractions was as a part-whole relationship between two quantities without regard for the size of the unit represented by the denominator of the fraction. An example of student reasoning reflecting this part-whole relationship is shown in figure 1. When asked to compare the fractions 5/6 and 7/8 the student partitioned the whole unit into a quantity of equally sized pieces represented by the denominator of the fraction (i.e., 6 and 8) and shaded the quantity of pieces represented by the numerator (i.e., 5 and 7). A student with a dominant part-whole conception of fractions will reason that the two fractions are equal because the quantity of missing pieces is the same (i.e., 1); not considering the size of the unit attached to each of those quantities, sixths and eighths, respectively. Students who do reason about the size of the units demonstrate elements of fraction-as-measure conception (Wilkins & Norton, 2018). We were curious as to whether DM students' conception of fractions was similar. We hypothesized that if DM students had a dominant part-whole conception of fractions it may also influence how these same students reason about operations involving fractions and proportional relationships.

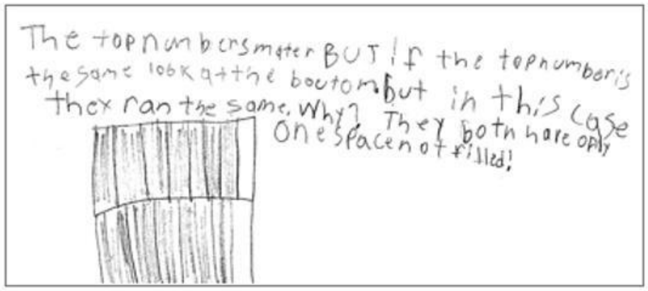

Figure 1. Student reasoning to compare 5/6 and 7/8.

To explore the nature of DM students' current conceptions a thirteen-question multiple-choice diagnostic assessment was given at the beginning of the DM course The results of three items from the diagnostic is shown in Table 1. Q4 is an item that was used to determine whether students had a dominant part-whole conception of fractions. Q9 and Q12 are also shared because it was hypothesized that student with a dominant part-whole conception of fractions would reason about these two tasks in a particular manner. The notation (C) in Table 1 represents the correct answer while the bolded response indicates the response in which a student with a dominant part-whole conception of fractions would most likely choose. It is important to note that given that Q4 was a multiple-choice we do not know whether the students who chose the correct answer had a meaningful conception of fractions or simply relied upon a whole-number relationship (e.g.,7 > 5). However, we believe we can infer that if a student chose "they ate the same amount" they were at best utilizing a part-whole relationship.

Table 1. Sample diagnostic questions (n = 230)

#	Questions			
Q4	Two pizzas are the same size. Carlos ate 5/6 of one of the pizzas and Terrell ate 7/8 of the other pizza. Who ate more?			
	Carlos	Terrell (C)	**They ate same amount**	Impossible to know
	30.43%	41.30%	**26.52%**	1.74%
Q9	Thomas ate 3/4 of a whole medium pizza and Lydia ate 5/8 of a whole medium pizza. Together they ate how much of a whole medium pizza?			
	8/12	11/8 (C)	8/8 (C)	Cannot determine
	40%	45.65%	9.13%	5.22%
Q12	Mix A: 3 cups of OJ to 4 cups of water Mix B: 6 cups of OJ to 8 cups of water Which mixture (A or B) will be juicier?			
	Mix A	Mix B	They will be the same (C)	Impossible to determine
	34.44%	14.50%	49.85%	1.21%

As part of our preliminary analysis of the diagnostic results a chi-square test for independence was conducted to examine our hypothesis that students answering Q4 in a way suggesting a dominant part-whole conception (i.e., two fractions are equal) would also answer Q9 (i.e., 8/12) and Q12 (i.e., Mix A) in a predictable manner. The results of this brief analysis confirmed our initial hypothesis.

Table 2. Chi-square analysis. X^2 *(230,1)* * $p<.05$

	Q9	Q12
Q4	6.6868	16.4698
	$p = 0.0097$*	$p = 0$*

Interventions

As the preliminary analysis of the diagnostic assessment revealed many of the DM students relied on a part-whole conception of fractions to reason about fraction comparisons. The first challenge of the course redesign was to develop learning experiences that confronted the limitations of a part-whole conception while also moving them towards fraction-as-measure conceptions. Guided by two frameworks, Conceptual Change (Vosniadou, 2013) and Progression of Fraction Schemes (Wilkins & Norton, 2018) a set of instructional activities were designed. One of the elements of the conceptual change framework is that "knowledge acquisition is not always a process of enriching conceptual structures. Sometimes the acquisition of new information requires the radical reorganization of what is already known" (Stafylidou & Vosniadou, 2004, p. 504).

A radical reorganization of DM students' fraction conceptions required explicit attention to the meaning and role of the unit. This was addressed in two ways. First, tasks were designed to engage students in mental activities that supported the development of fraction-as-measure conceptions (Wilkins & Norton, 2018). These tasks engaged students in the mental activities of partitioning, iterating, and disembedding. For example, as part of one the tasks we asked students to fold (partitioning) fraction strips representing the whole unit into equally-sized pieces such that only the unit fraction was showing. Then we asked them to iterate the unit fraction to determine the length of copies of the unit fraction. For example, as shown in figure 2, consider a paper strip representing 1 whole unit of length.

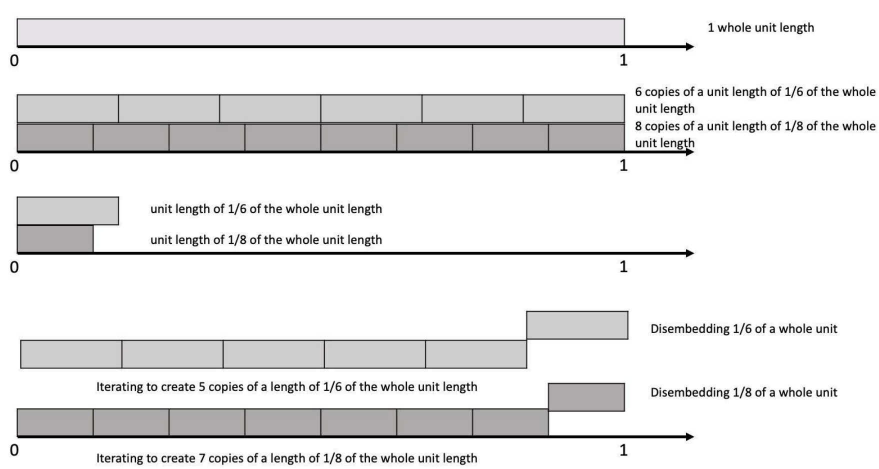

Figure 2. Coordination of units to engage in a measurement scheme for proper fractions.

The first action involves *partitioning* the whole into equally sized lengths and recognizing that each of those lengths represents a unit fraction (e.g., 1/8). *Iterating* the unit fraction, a given number of times represents a length that is multiple copies of the length of the unit fraction. For example, a length of 7/8 of a whole unit is 7 copies of the length of the unit fraction 1/8.The *disembedding* action happened to determine the "missing part" from the whole. For example, as shown in figure 2, the missing part of 7/8 of a whole unit is a unit fraction of 1/8 because 8 copies of the unit fraction 1/8 is the same length as the whole unit.

The second way in which the unit was made explicit is that fractions were represented using a novel notation, numeral-unit-name notation. For example, the fraction 7/8 was written as 7 eighths using the numeral to represent the quantity and the unit-name to represent the unit. This decision supported a learning acquisition goal and a connection goal. Students were introduced to the idea that the morpheme "ths" indicated that the whole unit is partitioned into a quantity of equally-sized lengths represented by the word preceding the morpheme (e.g., eighths). It also supported efforts to utilize overarching principles to connect operations across numerical and algebraic expressions. For example, instead of seeing an addition problem such as 3/4 and 5/8 in terms of "getting a common denominator" our goal was for students to see adding fractions as combining quantities of the same size of unit. Thus, 3 fourths and 5 eighths cannot be combined because the size of the units are not the same. However, utilizing an equal exchange of 6 eighths for 3 fourths the numbers 6 eighths and 5 eighths can be combined because the size of the units are the same (6 eighths + 5 eighths = 11 eighths).

While not a significant part of this preliminary report, it is important to note that making the units explicit was also an important aspect of the development of understandings related to equivalent ratios and proportional relationships in the DM class. For example, consider the ratios represented in Q12 of the diagnostic test. The ratio 6 cups of OJ to 8 cups of water is the same juiciness as 3 cups of OJ to 4 cups of water because it represents 2 copies of the ratio 3 cups of OJ to 4 cups of water [2 x (3:4) = (6:8)]. These multiplicative relationships between ratios were made explicit using ratio tables and double number lines.

Results

After one iteration of the course redesign the success rate in the DM course increased from 56% to 80%. Despite a significant shift of the DM content to more arithmetic concepts, as opposed to algebraic concepts, the failure rate in the ensuing general education mathematics course also decreased slightly, 31.40% to 28.74%.

A post-assessment involving the same questions as the diagnostic assessment was given ten weeks after the fraction concept module. Students were not given advanced notice that they would be re-taking the diagnostic assessment. The percentage of students that correctly answered each question on both the pre-assessment and same post-assessment was computed. Only the results of students ($n = 117$) who completed both the pre- and post-assessment are included to remove potential variation in percentage correct resulting from differences in pre- and post-assessment participants. A difference of proportions z-test was conducted to measure whether the change in percentage correct from pre- to post-assessment was statistically significant. Level of significance was set at $p < .05$. Results of this analysis are shown in Table 3.

Table 3. Comparing pre- and post-test results.

#	Question	% correct (pre)	% correct (post)	p
Q4	Two pizzas are the same size. Carlos ate 5/6 of one of the pizzas and Terrell ate 7/8 of the other pizza. Who ate more pizza?	47.86	61.54	.035*
Q9	Thomas ate 3/4 of a whole medium pizza and Lydia ate 5/8 of a whole medium pizza. Together they ate how much of a whole medium pizza.	52.14	76.92	.000*

The results suggest that there was growth in students' fraction-as-measure conceptions. We acknowledge, as discussed earlier, that comparing the fractions 5/6 and 7/8 requires a high degree of unit coordination sophistication (i.e., disembedding 1/8 and 1/6 to describe the measure of the "missing piece") and reasoning. We were specifically curious as to the change in percentage of students who indicated that the two fractions were equal. This percentage shifted from 26.5% on the pre-assessment to 13.68% on the post-assessment. We also conducted the same chi test of independence on the results of the post-assessment as we did on the pre-assessment and found the same relation between those who answered Q2 as equal and Q9 as 8/12, $X^2(1,117) = 7.87$, $p = .005$*.

Three other questions showed a statistically significant relation between indicating that 5/6 and 7/8 were equal and an incorrect response. These questions included Q8 (identifying measure on a tape measure), $X^2(1,117) = 24.159$, p = .0012* , Q11 (proportional reasoning involving distance traveled and a fraction quantity), $X^2(1,117) = 7.57$, $p = .006$*, and Q13 (proportional reasoning requiring unitizing), $X^2(1,117) = 5.258$, $p = .022$*.

Discussion

Consistent with what others have found (Pesek & Kirshner, 2000) as well as elements of Vosniadou's (2003) Conceptual Change Framework, it is challenging to move conceptions forward once students have procedures and conceptions already in place that interfere with the intended concept advancements. Even after the intervention 13.68% of DM students still indicated that the fractions 5/6 and 7/8 were equal and many still used this part-whole fraction relationship to add fractions.

This study gave us an opportunity to reflect on our teaching practices. We found that we need to spend more time engaging students in iterating unit fractions. From the analysis of the pre-and post-assessment we concluded that we need to begin these actions with whole numbers while also making more explicit the multiplicative relationship that exists between quantities and size of units of decimal numbers. Inherently numbers have an implied multiplicative relationship. For example, 0.5, is 5 x (1/10). Same is true with fractions, 4/8 or 4 eighth is also 4 x (1/8). Writing out the multiplicative relationship sheds light on the meaning of the unit fraction in relation to the whole unit and that 4/8 is 4 times greater than 1/8.

Dimensions of Mathematics Graduate Students' Professional Identities as Prospective Faculty

T. Royce Olarte
University of California, Santa Barbara

Graduate education in mathematics is instrumental to the socialization of prospective mathematics faculty, however, our understanding of how graduate students develop their professional identities is still limited. This preliminary study examines and compares how two doctoral students at different stages of their graduate programs reflect on and understand their professional identities. I highlight qualitative similarities and differences in how each participant identified as a teacher, as a researcher, and as a mathematician. The structure of the program and progression through degree milestones reflected how strongly participants were anchored onto dimensions of their professional identities. Both students strongly identified as teachers and both described how their gender identity as women negatively impacted dimensions of their professional identities, especially their mathematics identities.

Keywords: Graduate Students, Professional Identities, Socialization, Doctoral Education

Introduction

Many mathematics graduate students pursue faculty positions, however, our understanding of how they are socialized into the profession (Tierney & Rhoads, 1993) and develop their professional identities as faculty is still limited (Clarke et al., 2013), likely contributing to the minimal professional development opportunities that aim to develop strong professional identities (Austin & McDaniels, 2006; Jensen, 2011). I draw on Beijaard et al.'s (2000) conception of teachers' professional identity as "how they perceive themselves as teachers and what factors contribute to these perceptions" (p.751). Although there are similarities between K-12 teachers and higher education faculty, the differences in the preparation, institutional contexts, societal pressures, roles and expectations, and the discipline-specific cultures constitute a starkly different backdrop through which professional identities are developed (Nyquist, 1999; Van Lankveld et al. 2016). The experiences in graduate education are instrumental to students' professional identity development as future mathematics professors, and it is imperative that we understand how they make sense of their professional identities and identify the experiences that are formative or destructive to their sense of selves as faculty.

Additionally, it is important to examine the professional identities of prospective mathematics faculty as unique cases because the mathematics discipline has norms, beliefs, and values that set it apart from other disciplines. Clarke et al. (2013) noted:

> Discipline-based cultures are the primary source of faculty members' identity and expertise and include assumptions about what is to be known and how tasks [are] to be performed, standards for effective performance, patterns of publication, professional interaction and social and political status (p.7).

Examining the professional identity development of mathematics graduate students affords insight into the experiences and features of mathematics graduate education that prepare students for faculty positions. For this preliminary study, I examined the professional identities of two graduate students at different stages of their doctoral programs. The research questions that guided this study were: (1) How did mathematics graduate students reflect on their professional identity development as prospective faculty? (2) What experiences were formative to their professional identity development?

Framing

I drew on a sociocultural perspective of professional identity development (Solari & Ortega, 2020) to frame this study. Specifically, I consider the process of socialization into the profession (Tierney & Rhoads, 1993; Weidman et al., 2001) to be a mechanism of professional identity development. This view on identity development recognizes the weight and consequences of the context and the social interactions with others (Gee, 1996), and posits that the transmission of culture and the acquisition of the knowledge, dispositions, and skills necessary to perform in a profession are the product of the everyday social interactions that an individual has with others in a situated context (Clarke et al., 2013; Solari & Ortega, 2020). This can involve observing more expert others, learning by doing, interacting with others, and reconciling personal ideologies and beliefs about the profession with the everyday realities (Pillen et al., 2013; Tateo, 2012).

Within mathematics graduate education, I consider experiences such as serving as teaching assistants, engaging in research, attending conferences, receiving mentorship, and interacting with others can shape and inform graduate students' professional identities. Additionally, members of their profession and the mathematics community attach and attribute meanings to graduate students, prompting them to reconcile these various meanings and discourses (Gee, 1996; Sachs, 2001) to construct their professional identities. Lastly, I acknowledge that mathematics graduate students are embedded within institutional contexts, power structures, societal and political perspectives, and mathematics-specific cultures, values, beliefs, and norms. These factors, along with graduate students' individual social and cultural identities (Hayley et al., 2014; Trepte, 2013) interact to uniquely inform their professional identities as prospective faculty.

Method

This study is part of a larger dissertation project focused on the pathways to the mathematics professoriate and was conducted at a Minority-Serving Institution in California. Purposeful sampling (Miles et al., 2020) was used to recruit mathematics doctoral students pursuing faculty positions. They participated in 90-minute interviews over Zoom that included responding to a semi-structured interview protocol (Rubin & Rubin, 2011), writing a letter to the mathematics discipline, and graphing a visual representation of their graduate education experiences. For this preliminary study, I focus on two graduate students, Kayla and Morgan (pseudonyms), because they were revelatory (Yin, 2016) about the dimensions of their professional identities and the disparity in the time spent in graduate school afforded a comparison of the experiences that seemed to most impact their professional identity development. At the time of the data collection, Kayla had completed the first year of the doctoral program and Morgan had completed the fourth year (after being previously enrolled in a PhD program at another institution). Both graduate students self-identified as White/Caucasian, straight or heterosexual, female/feminine, and reported that they are actively pursuing careers as mathematics faculty.

The data for this study were the participants' responses to the semi-structured interview protocol centered around their experiences in graduate school and perceptions of the mathematics professoriate. I open coded (Miles et al., 2020) each response to make sense of how participants described themselves as future mathematics faculty, their understanding of the profession, and how they hope to be recognized as such by their prospective professional community. The initial codes that I conceptualized as dimensions of professional identity, included: (1) teacher identity, (2) researcher identity, and (3) mathematics identity. I analyzed themes across their responses and made sense of how these dimensions reflected similarities and differences in Kayla's and Morgan's identities and graduate education experiences.

Findings

I highlight the dimensions of participants' professional identities that most emerged when they reflected on their experiences and considered the ways they have seen themselves as faculty and how they hope to be recognized as such in the future. For this preliminary analysis, I focus on how Kayla's and Morgan's developing professional identities as faculty encompassed their teacher identities, researcher identities, and mathematics identities.

Teacher Identity

Kayla's and Morgan's professional identities as mathematics faculty were primarily anchored onto their identities as teachers (Berger & Lê Van, 2019; Mockler, 2011). They both described how an early passion for teaching, experiences with tutoring and helping others, and serving as teaching assistants or instructors of record during graduate school were formative and positively contributed to their professional identities. However, there were also differences in how each student recognized themselves as faculty or described what they would emphasize as a teacher or instructor.

Kayla said, "I've always known I wanted to teach." and mentioned that her decision to pursue a career as a mathematics faculty was primarily motivated by her desire to teach. She considers herself as an educator who is uniquely positioned to teach and support students in a variety of ways. As she reflected on her identity as a teacher, Kayla emphasized dimensions of teaching that went beyond subject matter expertise and the mathematics content. She expressed that getting to know students on a more personal level, connecting with them, and sharing about her own experiences are practices that she hopes to engage in. This was most influenced by her own experiences as a student when she learned the most from faculty who were more personable – explicitly articulating how she does not want to be like the professors she did not enjoy. An important aspect of Kayla's professional identity was that she saw herself as someone who can reframe dominant discourses and narratives around mathematics through teaching. She hopes to "reconfigure the narrative that mathematicians are these godlike people you can't talk to" and just make mathematics "more human" to the students. To Kayla, the experience that most formed her identity as a teacher was serving as an instructor of record, when she was afforded more ownership over the courses she was teaching, rather than just taking up a more supportive role as a teaching assistant to a faculty member.

Morgan shared a similar passion and early desire to teach students, however, given her more extensive experiences in graduate school, she recognized herself more jointly as a teacher and researcher in more evident ways than Kayla. To describe what being a mathematics faculty meant to her, she said "It means you get to teach students during the whole school year…You get to contribute to the field by research and publishing papers." Like Kayla, Morgan most recognized herself as a teacher when she was serving as an instructor of record during the summer terms – again emphasizing that employment positions that provide more ownership and agency of a course significantly contributes to professional socialization. Additionally, Morgan saw her identity as a teacher connected to her desire to mentor students and "foster collaborative environments" in mathematics. As she reflected on her future students and colleagues, she said, "I would like to be seen as someone that students want as a professor." We can see how Kayla and Morgan described their professional identities as teachers with direct consideration of how they would like to engage with and be perceived by students. Their teacher identities are consistent with literature on women faculty in STEM and how they tend to describe needing to be more caring and approachable (e.g., Guarino & Borden, 2017; Hart, 2016) and exhibit more student-centered pedagogies (e.g., McMinn et al., 2022).

Researcher Identity

Although both students acknowledged their identities as researchers (Castelló et al., 2020), Morgan identified more strongly as a researcher than Kayla, likely due to her more extensive research experiences, professional experiences (e.g., presenting conferences), mentorship from her advisor, and more time spent in graduate school. In the structure of the focal PhD program, students are not assigned an advisor until they pass their qualifying exams (i.e., advance to candidacy), and spend time reading scholarly works assigned by a potential research advisor. The mathematics department's norms with progressing through the degree milestones reflected the extent to which Kayla and Morgan disparately recognized themselves as researchers.

At the time of data collection, Kayla had not yet passed all her qualifying exams nor was in a position to complete readings and prepare for research with an advisor. Thus, Kayla seemed to identify less as a researcher when prompted to describe how she saw herself as a prospective mathematics faculty. She said, "I do think I'll probably end up doing research." which reveals an early understanding of what the profession may entail. Prior to graduate school, Kayla originally thought that mathematics faculty were solely focused on teaching. She said that the research aspect of the profession is something that she is still getting accustomed to.

On the other hand, Morgan explicitly said, "There's two aspects of being a math professor." – referring to her understanding of the mathematics professoriate as encompassing both teaching and researching responsibilities. She saw herself as someone who can contribute to the field by researching and publishing works, in addition to teaching mathematics to students. Morgan expressed that she wanted to be recognized as "someone who is known to be good at teaching but at the same time produces high quality mathematics." which reveals how her professional identity as a mathematics professor deeply intertwines her sense of self as a teacher and as a researcher. Morgan described that working with her advisor and completing her thesis were the most formative experiences to her identity and preparation as a researcher. Morgan more strongly identified as a researcher because she was in the latter stages of her program, whereas Kayla had only completed her first year. Within this particular institutional context, this revealed that graduate students are socialized as researchers later in the doctoral program.

Mathematics Identity

Lastly, Kayla and Morgan revealed that their mathematics identities (Cribbs et al., 2015; Voigt, 2020) were important dimensions of their professional identities as faculty. Despite recognizing themselves as math persons and being positioned as competent from an early age, graduate school marked a time when their mathematics identities were negatively affected. For Kayla and Morgan, adverse interactions and interpersonal relationships with members of the mathematics community damaged their self-concepts and identities. Kayla said, "I'm not *the* math person, I'm *a* math person." to describe how arriving in graduate school and seeing herself in relation to other students caused her to feel "less special" and made her question her place in mathematics. Additionally, Kayla articulated how her qualifying exams experience – particularly how she perceived the exams to be unnecessarily difficult and how she felt unsupported by faculty – caused her to doubt her career pursuits and sense of self as a mathematician.

It is important to note that Kayla and Morgan explicitly connected their mathematics identities with their gender identity and highlighted how navigating graduate school as women involved facing gender-based bias and microaggressions (Wilkins-Yel et al., 2019). Morgan was previously enrolled in another PhD program prior to her current program, and the experiences at that prior institution caused her to leave academia for a few years. She cited challenges such as the low salary to have contributed to her exiting this program, however, her identity as a mathematician and a prospective faculty was most negatively affected by how she was treated as a woman. She described the culture at the previous institution as "sexist" and said, "I felt like I had to work twice as hard to be taken seriously." To illustrate an instance of some of the microaggressions she experienced, she described an encounter with another graduate student:

> My first year, I won an award for best incoming, or best first year [student]. And then another grad student was like, "Oh, you just won that because you're a woman," or something like that. I felt like I wasn't really listened to as much and there, wasn't really supported.

Unfortunately, this is consistent with our contemporary understanding of the experiences of women-identifying graduate students or faculty in STEM (e.g., Herzig, 2004). The patriarchal and masculine discourses that have historically dominated the field (Leyva, 2021) fostered a climate where Morgan felt like her successes do not belong or are simply handed to her because of her gender identity, which in turn challenged her mathematics identity. After leaving that program, she spent a few years in industry before deciding to pursue a doctorate at the current institution. She has described feeling a sense of belonging in the current program and has more strongly identified as a mathematician because of the support she has received.

Discussion and Conclusion

The professional identity development of mathematics graduate students has been an often-overlooked dimension of the pathways to becoming mathematics faculty. The present work is aligned with scholars who have studied the socialization of graduate students (e.g., Clarke et al., 2013; Solari & Ortega, 2020), and have illustrated the complexity and multidimensionality of professional identities (e.g., Trede et al., 2011). I extend that work and highlight how dimensions of participants' professional identities (i.e., identities as teachers, as researchers, and as mathematicians) developed within higher education mathematics contexts. Kayla's and Morgan's professional identities reveal how formative the experiences of graduate education can be, and how students are more strongly anchored onto certain dimensions of their professional identities at different stages of their doctoral programs. Using professional identities as a lens also afforded insight into the experiences that seemed to drive or hinder professional identity development. For example, serving as instructors of record, where graduate students are given more agency and ownership, most developed their identities as teachers. Also, graduate students may identify more strongly as researchers later in their graduate education, which reflects the structure of the degree milestones. This suggests that mathematics departments can better support students' development as researchers at earlier stages of their graduate education or provide them more opportunities to serve as instructors of record.

Moreover, this preliminary study briefly illustrated how graduate students' professional identities, especially their mathematics identities, are influenced by their social and cultural identities. The tensions between participants' gender identities and their sense of selves as mathematics faculty demonstrates how mathematics can still be a patriarchal and masculine space (Herzig, 2004; Leyva, 2021). This suggests that for women-identifying graduate students, the self-recognition as mathematics faculty may be more difficult and challenging. Future research can more closely examine the gendered experiences of mathematics graduate students pursuing faculty positions and continue to make sense of how students' intersectional identities (e.g., race, sexual orientation, etc.) inform their professional identity development. In all, a more nuanced understanding of these dimensions of their identities allows higher education institutions and mathematics departments to broaden the access and reimagine systems of support that can better prepare graduate students to enter the mathematics professoriate.

Estrella Johnson
Virginia Tech

Feelings of inclusion in the classroom are one contributor to students' decisions to pursue a particular degree pathway, and students from marginalized groups are more likely to experience feelings of exclusion in these spaces. These feelings may be exacerbated by particular classroom actions and interactions, including microaggressions based on race and/or gender as well as being ignored or talked over; these actions are often compounded by instructor and student biases. Being able to observe such events is key to instructors' ability to disrupt those moments and develop more inclusive spaces, but many observation protocols are built from an external researcher perspective about practices that support equity. We report on a pilot study at an HSI, comparing what Hispanic and Latine students report makes them feel more or less included to what is typically captured by observation protocols.

Keywords: Estudiantes, Inclusion, Instructional Practice, Observation Protocols

Over the past decade, Estudiantes (students who identify as Hispanic, Latine/o/a/x, Chicane/o/a/x, Nuyorican, etc.) have experienced rapid growth (an increase of 53%) as a share of students enrolled in higher education (NCES, 2011; 2021). Likewise, the proportion of STEM degrees awarded to Estudiante undergraduates increased from 8.5% in 2008 to 15.1% in 2018 (NCSES, 2021). This growth has coincided with increased attention to STEM equity and inclusion, but Estudiantes in STEM fields continue to have negative experiences, such as encountering negative assumptions about their group, stereotype threat, and "scientific disidentification" during STEM coursework (Ong, Smith, & Ko, 2018; Woodcock et al., 2012). The knowledge base for creating equitable undergraduate classroom learning environments is growing yet remains underdeveloped. Scholars have called for postsecondary research to adopt a sociopolitical lens in ways that parallel the work done at the K-12 level (Adiredja & Andrews-Larson, 2017), supported by recent research illustrating that the links between active learning and equity (e.g., Tang et al., 2017; Laursen et al., 2014) are not consistent across contexts, and in fact, active learning has the potential to amplify or introduce new inequities (Johnson et al., 2020). Mathematical classrooms are not neutral spaces; they can, and often do, serve to perpetuate systemic inequities regardless of modality. Assessing the ways in which a class perpetuates or disrupts inequities is therefore valuable, however the majority of our field's instructional observation tools do not attend to equity, nor the perspectives of students in the classroom (Yee et al., 2022). We have both a moral and practical imperative to better understand inclusive instruction in partnership with students most affected by systematic racism. To further this goal, we report on a pilot study at an HSI, comparing what Estudiantes report makes them feel more or less included to what is typically captured by observation protocols.

Literature Review and Theoretical Perspective

This pilot project is part of a larger project aimed at developing new observation protocols for assessing the inclusivity of undergraduate mathematics classrooms for Estudiantes. We approach this broader work through a critical lens, drawing on tenets of LatCrit and QuantCrit. LatCrit is an extension and specification of Critical Race Theory (CRT) focused on the lived experiences of Hispanic and Latine people in the United States (Solorzano & Yosso, 2002). Consistent with CRT, LatCrit seeks to challenge the dominant ideologies of society that continue to propagate White patriarchal hegemony inside and outside the classroom (Battey & Leyva, 2016). A central tenet of QuantCrit is to bolster quantitative data with the experiential knowledge of people belonging to marginalized groups. This pilot is the start of an investigation of the lived experiences of Estudiantes in undergraduate mathematics classrooms that will be expanded and, in partnership with Estudiantes, inform the development of quantitative instruments that center their lived experiences.

In keeping with our critical lens, we incorporate the idea of *intersectionality*, which acknowledges and accounts for intersecting systems of oppression/marginalization and identities, highlighting the heterogeneity of experiences rather than homogenizing the lives of people sharing a particular identity characteristic (Collins & Bilge, 2016; Crenshaw, 1991). For example, the higher education experiences of Hispanic and Latine students vary significantly based on their economic class, gender, sexuality, and disabilities, among other factors (Byrd, Brunn-Bevel, & Ovink, 2019; Ovink, 2014). There is no singular "classroom experience" that is shared by all students in a classroom: students have multiple and differing experiences that are inflected by their identity and social location with reference to those of peers and instructors (Mohajeri et al., 2019). Applying an intersectional theoretical lens also focuses our attention on intragroup power dynamics: e.g., classroom experiences of Estudiantes will additionally vary because of power differentials between genders, upper- and lower-income status, other sources of social inequality, and histories of advantage and disadvantage, the legacies of which still reverberate in contemporary higher education environments (Collins, 1971; Karabel, 2005). We leverage intersectionality as we strive to develop local theories of how particular instructional approaches differentially affect students.

We see instructional practice—that is, what instructors actually do during instruction—as an essential element of promoting equitable classrooms, and an entry point where transformation can occur (Gutiérrez, 2012). Higher education literature also identifies the undergraduate classroom as critical to the experiences of minoritized students in terms of racial climates and the prevalence of microaggressions (Suárez-Orozco et al., 2015; Solorzano et al., 2000; Yosso et al., 2009). In the undergraduate mathematics education literature base, there are not many studies of classrooms and equity, and many of these focus on achievement or persistence outcomes (e.g., Laursen et al., 2014; Johnson et al., 2020) or instructor bias (e.g., Reinholz et al., 2019); these have primarily focused on inquiry-based learning (IBL) as the key to equitable instruction. We suggest two limitations of this: inquiry instruction is not a panacea for equity (e.g., Johnson et al., 2020) and most undergraduate instruction does not use inquiry (Larsen et al., 2015).

Recently, Leyva et al. (2020; 2021) have explored the ways that precalculus and calculus course instruction may reflect racialized and gendered mechanisms. Students' journaling revealed several mechanisms at play that reinforce broader discourses and stereotypes. For example, the "ignored student" event: students reported instructors more often ignored Black or Latinx students, potentially reinforcing "troublemaker" stereotypes about Black and Latinx students who spoke up and discouraging others of similar background from asking questions in class. A related finding is that the management of stereotype threat (particularly in relation to "who" is capable of doing mathematics) is significant to the STEM experience for undergraduates of color (e.g., McGee & Martin, 2011). Additional narrative, such as the myth of meritocracy, and advocacy for constructs like "grit" take a substantial toll on Latinx and Black students when societal racism is deemphasized, while individual perseverance is celebrated. These studies begin to unpack the experiences of minoritized students, but outside of a few cases and institutions, we still know little about these experiences in critical courses like precalculus and calculus (Leyva et al., 2021). We position our work as part of that which is needed "to document if, when, and how [inquiry] instructional approaches are equitable for all students" (Adiredja & Andrews-Larson, 2017, p. 459).

Methodology

Pilot data was collected in Summer 2023 at a large HSI in a state which shares a border with Mexico and has a high proportion of Estudiantes in their student body (40%); the proportion of bachelor's degrees awarded to Estudiantes is slightly lower (37%) and the proportion of STEM bachelor's degrees awarded to Estudiantes is slightly lower still (34%). Data comes from two courses taught in different modalities: Precalculus (flipped), Calculus 2 (in-person). Data collection for each class was conducted in the span of a single week. For each class, two sessions were video and audio-recorded on consecutive days, and interviews with students from that class were conducted on the following day. This will allow us to compare what is accessible to an observer with the moments that students found impactful. At the end of the second observation day, the observer/researcher (a Hispanic man) invited students who self-identify as Hispanic/Latine to participate in a group interview about their experiences. The two semi-structured interviews involved 2 men (Precalculus) and 1 woman (Calculus 2). Each lasted approximately one hour, and were also audio and video-recorded. Participants were asked to reflect on moments in which they felt included/welcome or excluded/unwelcome in the class, as well as specific actions that led them to believe that their teacher cared about them and other students (or did not); with an eye toward intersectionality, they were asked if they felt that their Estudiante and/or gender identities impacted their experience and/or treatment in the course.

Interviews were transcribed using Adobe Premiere Pro and manually checked for accuracy. Three members of the authorship team conducted the qualitative analysis of these transcripts, and that analysis was reviewed by the other authors. Analysis proceeded according to the stages of thematic analysis (Braun & Clarke, 2006). In the first phase, data familiarization, transcripts were developed and read independently by the researchers. In the second phase, the team independently made research memos (Maxwell, 2013) and generated initial codes of interest. We take a data-driven approach as part of our commitment to understanding what is salient to students themselves, while retaining a focus on students' feelings of inclusion/exclusion, perceptions of the impact of race/gender on their experiences, and aspects of classroom practice that students connect to those feelings. We then progressed to the interpretive phases, beginning with *thematizing*, in which individual codes are organized into broader umbrella themes and sub-themes. We are currently engaged in the fourth and fifth phases, in which the themes are reviewed in connection with the original data, edited, and finally named. In this report, we present the current state of our work, in which codes have been identified and themes have provisional names. Our next steps include analyzing the classroom data using three existing observation protocols and comparing those reports to the student interviews.

Preliminary Findings

All three students who were interviewed for this project report generally positive feelings about their current mathematics course, though they mention having negative experiences elsewhere. These were often brought up as a foil, in order to explain what *wasn't* wrong with their current class. As such, most themes emerged with both positive (inclusive, encouraging) and negative (exclusive, discouraging) codes; the exception being the *microaggression* theme. We present these themes and some of their constituent codes in Table 1.

Table 1. Themes and examples of codes within each theme from the interview analysis.

Theme	Positive Codes	Negative Codes
Involvement in daily classroom activities	Working in groups Going to the board Involved in in-class Q&A	Sitting and watching lecture
Personal relationship with instructor	Instructor shares personal information (e.g., hobbies) Instructor is fun / funny / personable	No insight into instructors' life Feeling like "a number"
Perception of inst. care [human]	Instructor knows name(s) Flexible deadlines / extensions	Instructor doesn't know name(s)
Perception of inst. care [math/learning]	Instructor's goal is everyone passes Instructor notices when Ss are confused Instructor tries to understand what Ss are thinking before helping Extra help sessions	Instructor states that many students will fail Instructor gives "how" solutions without "why"
Community [Class]	Knowing people in the class Having identity peers in class Small classes	Having trouble finding a group Large class / online class
Community [Uni]	Joining affinity groups Having identity peers on campus	Fewer Hispanic people than high school Seeing fewer Catholic people than home
Microaggressions	"How could you not understand this" Pretty girls aren't smart People assuming they're not smart	Being ignored in group projects Being told that engineering (STEM) is a "man's" major/field

From the themes that emerge, we note an emphasis on interpersonal relationships and community. These three students report that opportunities to connect on a quasi-personal level with an instructor who they believe cares about them and their learning, and enjoys being in the classroom with them, help them feel like they belong and are being included in a classroom community; similar things were reported regarding interactions with their peers and classmates. They also report experiences with distant instructors where they felt like "a number" and believed that the instructors were concerned only with doing the bare minimum with regards to interacting with them - those experiences left them feeling like they didn't belong or were unwanted in those academic spaces; again, there were similar comments regarding interactions with peers and classmates. These students also point to in-class instructional practices which made them feel more included and a part of the learning experience, such as working with other students (particularly when they were able to answer other students' questions), while large lectures felt impersonal and uninviting. All three students speak of a desire to be in community with others who shared identity markers, evincing clear awareness of the demographic makeup of their campus, majors, and classes. These ideas are evinced in the following exchange from the Precalculus interview:

Interviewer: If you could suggest any improvements or changes to this precalculus class to better support Hispanic/Latinx students, what would they be?

Student: Other than adding more Hispanic people? There's only like two or three in our class that are, like, Hispanic.
Interviewer: Well, how, what, how would that make it better?
Student: Um, because I think, like, because I'm going back to culture. Um, so like, where I'm from, like, everybody learns, you know, like the professor talks. And maybe that's why I'm so receptive to the professor, right, because he talks, like, on a personal level [...] And other professors here [...] were more impersonal, and maybe that's why the retention rate, like, for Hispanics is, like, lower, because they're just not, like, not relating to the professor. It's like a white, smart man who's like, you know, obviously he's worked hard for it, but maybe they just don't relate to it. I don't blame them, you know, but maybe it's just harder for them to understand or even want to be there, because they're uncomfortable [...] Nothing's familiar to them.

One theme did not fit in with the positive/negative coding, that of *microaggressions*, as they are inherently negative. We used this term to capture codes which referred to specific comments and interactions which negatively affected students' sense of inclusion. These include events that indicated others assumed they were not smart, although students could not always pinpoint *why* that assumption was being made. The two men in Precalculus were not specific about the root of the assumption, but they reported incidents which made them feel that way - including interactions with instructors and teaching assistants. The woman in Calculus 2 reported events which led her to wonder if people believed that she was "too pretty to be smart," compounded by others in her life making comments that "engineering is a man's major."

Discussion and Next Steps

All three students interviewed in this pilot study report feelings of inclusion in their current class, compared to prior experiences where they felt less sense of belonging. Common themes across the students included a recognition of the value of being in a community space and human interactions with peers and instructors. There were, of course, some differences in what they said. Only the woman noted gendered microaggressions and stereotypes, although the men recognized that women were a minority in their classes. The men emphasized the personal, humanized relationship they had with their instructor as valuable, while the woman did not mention this. Further work is needed to uncover the extent to which these distinctions are related to intersectional heterogeneity of identity, instructor, class modality, and/or course level. In this pilot, we inquired about students' ethnoracial and gender identity, and one student volunteered religious identity (Catholic) as a salient identity characteristic. Parsing heterogeneous intersectional experiences, while avoiding determinism, is one of the goals of this work.

The immediate next steps of this work are the application of three existing observation protocols to the class recordings, and comparison of the resulting reports to students' interviews. The three protocols are *Classroom Interpersonal MicroAggression* (CIMA; Suárez-Orozco et al., 2015), *Equity and Access Rubrics for Mathematics Instruction* (EAR-MI; Wilson, 2022), *Equity QUantified In Participation* (EQUIP; Reinholz & Shah, 2018). A cursory comparison of the themes and codes from the interview analysis with the constructs targeted by these protocols suggests the potential for considerable overlap with CIMA, some overlap with practices outlined in EAR-MI, but no overlap with the EQUIP constructs of participatory equity. Full analysis will reveal the extent to which these protocols capture these students' experiences in these particular classes. Future work will scale up this research to many more classrooms across multiple sites, building toward more generalizable findings.

What Mathematicians' Emotions Can Teach Us About Groupwork and Emotion Regulation

Fern Van Vliet
Arizona State University

Two mathematics professors at a large university were interviewed about how their emotions impact their research work. Joy and frustration were the emotions they reported experiencing most frequently. Both reported the benefits of collaboration and the importance of regulating both positive and negative emotions. Implications on collaborative learning in the classroom (e.g. groupwork, pair work) and implications for emotions in the classroom are discussed.

Keywords: emotions, collaborative learning, emotion regulation

This paper brings together research on emotions in mathematics education, collaborative learning, and the professional work of mathematicians.

Literature Review

Emotions and Mathematics

There has been an increased emphasis on research on emotions and affect in mathematics education (McLeod, 1992; Middleton et al., 2017). In recent years, there have been more publications in mathematics education journals focused on emotions and affect, and the number of publications appears to be continuing to increase (Schukajlow et al., 2023). Both negative emotions (D'Mello et al., 2014; Schukajlow et al., 2021) and positive emotions (Camacho-Morles et al., 2021) have been shown to be beneficial to student learning. However, both negative and positive emotions have been shown to be detrimental to student learning (Barenes, 2021; Villavicencio et al., 2016). Villavicencio et al. (2016) found that pride had a negative association with final course grades among engineering students in the Philippines. Barnes (2021) found that joy was associated with decreased focus and self regulation.

Collaborative Learning

Research on collaborative learning tends to focus on social components or the connections between collaborative learning and mathematical ideas (e.g. Langer-Osuna et al., 2020; Dekker et al., 2006; Fujita et al., 2019; Sjöblom et al., 2021).

Additionally, research on collaborative learning in classrooms includes work on collaboration promoting students building off of each other's ideas which in turn promotes individual learning (Francisco, 2013; Schindler & Bakker, 2020).

Some work has been done demonstrating emotional benefits of collaborative learning for students. Group work can have a positive impact on student problem posing (Schindler & Bakker, 2020). Students also report higher levels of perceived control (Pekrun, 2006) when working in pair or small groups which is associated with higher reported positive emotions (Bieg et al., 2017).

Mathematicians as Research Participants

Research on mathematicians has focused mainly on the cognitive aspects of their work. Researchers have explored mathematicians' thinking and problem solving abilities (Burton, 1998; Carlson & Bloom, 2005). Other work has shown that mathematicians enjoy collaboration with others, and that part of this enjoyment is through getting the intellectual input from colleagues on their work (Burton, 1998). Mathematicians' negative feelings of being stuck on solving a problem and potential implications on students' negative emotions towards mathematics have also been discussed in the literature with regards to choosing particular problems to do (Misfeldt & Johansen, 2015).

However, research focused specifically on mathematician's emotions appears to be a new area of study. The previously mentioned literature is focused on the cognitive side of mathematics rather than emotional components of doing and learning mathematics.

Theoretical Perspective

Two areas of psychological research provide a background for this study: the Broaden and Build Theory of Positive Emotions and The Cognitive Theory of Emotions. In relation to the mathematicians in this study, these theories imply that a) positive emotions provide two distinct benefits and b) emotions are the result of cognitive appraisals of events.

Broaden and Build Theory of Positive Emotions

The Broaden and Build Theory describes two distinct benefits of positive emotions beyond just feeling good (Fredrickson, 2001). First, positive emotions broaden awareness. When people experience positive emotions, they are more aware of "the bigger picture" and notice more than when they are feeling negative emotions. Second, this broadened state of awareness created by positive emotions allows individuals to build more resources for themselves. The explanatory power of this theory has been demonstrated by multiple authors (e.g. Fredrickson, 2004; Garland et al., 2010; Vacharkulksemsuk & Fredrickson, 2013).

For this study, this creates the perspective that positive emotions could give mathematicians benefits beyond just feeling good. Positive emotions could allow them to potentially work more creatively or be interested in solving new problems.

Cognitive Theory of Emotions

The Cognitive Theory of Emotions posits that cognitive appraisals of a situation are what triggers an emotional response to that situation (Ortony, Clore, & Collins, 2022). For example, a student taking a test realizes they do not know how to answer the questions. The student wants to do well on the test, but now knows that they will fail. Thus, the student feels anxious because of their appraisals that a) the test is important and b) they are unable to succeed. It is not the test itself which makes the student anxious. It is the student's interpretation of the situation that leads to the emotions.

Research Questions

The focus of this research was investigating the emotions experienced by mathematicians, and their interpretations of significance of these emotions. The guiding research questions were: (1) How can the emotions experienced by mathematicians be characterized?, (2) In what ways do mathematicians feel that emotions impact their work?, (3) In what ways does collaboration with other mathematicians relate to these emotions?

Methods and Analysis

Two active research mathematicians at a large research university in the Southwestern United States participated in interviews over Zoom. Professors were recruited via an email sent to all full time faculty members of the mathematics department. The participants will be referred to as Professor 1 and Professor 2.

Both participants were full research professors at the university, and they both described themselves as theoretical mathematicians and both were male.

The interviews lasted between 30 and 40 minutes. Participants were asked about their current mathematical research interests and the role that their emotions play in their work. They were asked to describe positive and negative emotions felt while doing their research. The interviews were loosely structured around the impact of the participants' emotions on their research, as well as emotions related to collaboration with other researchers. Interviews were recorded over Zoom then transcribed.

Due to the limited research on mathematicians' emotional experiences, the interviews were coded using open coding to identify common themes of mathematicians' emotions (Strauss & Corbin, 1990). After completing the interviews, field notes were taken by the researcher on any details from the interviews which felt relevant in the moment. Then, the interviews were transcribed. The transcribed interviews were read with the goal of identifying specific emotions experienced and how the participants felt the emotions impact their work. Preliminary categories of emotions were grouped together. Afterwards, the interviews were reread multiple times to compare the categories found with the interviews.

Results

Joy and frustration were the most common emotions reported. Without being prompted, both participants discussed the importance of emotion regulation of both joy and frustration in order to do their work effectively. Both participants also discussed the impact of collaboration on their emotions. These results are discussed in more detail below.

Joy: A Common Positive Emotion

Joy was the positive emotion that both participants described as feeling most often while doing their research work.

Collaboration Enhances Joy Both participants felt that working with others increased their joy in research. Professor 1 said, "I think it [collaboration] enhances the joy. So when you prove something, you're happy to prove it. But, you're even more happy if you could show it to someone." Being able to share their positive feelings with others amplifies the joy that these mathematicians feel from their work. Professor 2 said, "If I'm working with a co-author, then it's nice to have it [an idea] affirmed by the co-author. And then, when that happens, that feels really good."

Emotional Regulation of Joy However, these mathematicians did not feel that joy and positive emotions should be fully embraced. When discussing joy, both participants felt that joy should be treated with some caution and distrust while doing their work. After a probing question on Aha! moments of sudden realization (Liljedahl, 2005), Professor 2 said, "I always have to temper my enthusiasm… you get a stroke of brilliance…want to come back and write it down… Oh no, that's not gonna work. So I'm careful to not get too excited until I write it down, and see if it all works."

Professor 1 shared a story of another mathematician who would just lay down in bed and enjoy the feeling of believing he had figured something out because, in Professor 1's words, "9 times out of 10 - what you've done is wrong".

Frustration: A Common Negative Emotion

Both professors described frustration as their most commonly experienced negative emotion. Again, both spoke of the importance of regulating that frustration.

Collaboration Helps Regulate Frustration Both professors discussed collaboration as a method of dealing with the inevitable frustrations of research. Co-authors were mentioned by both participants as a useful tool to offset feelings of frustration.

Professor 1 said, “It [collaboration] may actually spread it [frustration] out so that it’s more tolerable. It’s more tolerable to be frustrated if you’re frustrated at the same thing that somebody else is frustrated at.” After a slight pause, he continued and said, “Isn’t that the reason for help groups?” in reference to group therapy. Professor 1 felt strongly that collaborative work helped him deal with the frustration of being stuck on a problem. Being able to share the load of frustration with another made the frustration easier to bear.

Regulation of Frustration in Other Ways - Taking Breaks Professor 2 spoke frequently of the importance of regulating frustration through taking breaks from research work. Specifically, he said “the other thing I've always done throughout my career is, I do a lot more than just research. Like, I teach classes. I get involved with some administrative work and I think for me that was always important. I didn't really like to have a job where 100% of the time is spent doing research”. He also discussed that stepping back from a problem and looking at examples is a “first way of relieving the frustration” for him.

Professor 2 actively works to keep frustration at bay and prevent burnout in his work.

Another Benefit to Collaboration: A New Perspective

Both professors described the benefits of being able to use a colleague’s perspective to benefit their work.The perspective of others helps them get through when they are stuck and having trouble making progress.

Professor 1 describes it as, “You try to prove things, and you know at least 9 tenths of the time. You can't do it. So yeah, you have to keep trying, and that's another reason why it's worthwhile to work with other people. Because you have to have lots of ideas to try it. I mean if you can't do something… You never know whether that’s because you're being stupid, or because it’s not true or really hard.”.

Professor 2 says, “ We can share what we're stuck on with the other. And you know, maybe the coauthor oftentimes sees something that you don't see And then that's a a way to make a forward progress”.

Discussion

Both collaboration and emotion regulation appear to play an important role in the work of mathematicians. Limitations and future directions will be discussed.

Limitations

Emotions are a vulnerable topic to discuss, thus the topic itself creates many limitations. Validity of self-reported data on emotions depends on many factors. First, participants may not be fully honest with their self-reported emotions (Rasinski et al., 2005). Also, social pressure exists against reporting negative emotions (Tourangeu & Yan, 2007). Social pressure may have presented itself in this study through participants focusing on overcoming and regulating the negative emotion of frustration while not discussing the actual experience of frustration in much detail. In other words, social pressure against negative emotions may have led the participants to focus the discussion on ending negative emotions rather than discussing the experience of negative emotions. An additional limitation is the possibility that participants may not have the emotional intelligence (Salovey & Mayer, 1990) to recall and name their emotions.

All of the limitations discussed above are out of the control of the researcher, but should be considered when interpreting the results.

Future Directions

Emotions and Collaboration in the Classroom As discussed in the literature review above, most research on collaborative learning focuses on cognitive rather than emotional factors in the classroom. Considering the results of this study, future research could examine how students can provide emotional support for each other while working through problems.

Collaboration is an important part of their work for these mathematicians. Yet group and pair work in the classroom is not frequently used, while lecture style direct instruction is likely the most common form of instruction (Bieg et al., 2017; Givvin et al., 2005). Both positive and negative emotions were shown to be an important part of mathematicians' work, and collaboration has a positive effect on both the positive and negative emotions. Confusion, an emotion similar to frustration, has been shown to be beneficial for learning in adults if the confusion is resolved (D'Mello et al., 2014). Thus, lecture style teaching in which confusion and frustration are avoided may be detrimental to student learning. Science education research has seen a push to engage students in ways that mimic the feelings of scientists (Jaber & Hammer, 2016). Perhaps, a similar movement can occur in mathematics education.

Emotion Regulation for Students With the discussed importance of emotion regulation of both positive and negative emotions, future research can examine ways of promoting this regulation among students. Some existing work provides promising results from an intervention on helping students cope with confusion in mathematics at the elementary level (Di Leo & Muis, 2020). This work can be extended to help students regulate other negative emotions. Students tend to report more negative emotions related to mathematics as they progress through the school system (Brown et al., 2008; Frenzel et al., 2009; Zazkis, 2015). Thus, it is crucial to help students to regulate these increasing levels of negative emotions at the undergraduate level. Other interventions can also be developed to help students regulate positive emotions. A study with elementary students has shown that positive emotions can be a barrier to perseverance in mathematical reasoning (Barnes, 2021), so similar interventions promoting regulation of positive emotions could also provide fruitful and beneficial results.

Where is Calculus in Chemistry? Determining Content Alignment Between Calculus and Chemistry

Slade C. McAfee
University of Wisconsin - Milwaukee

Jon-Marc G. Rodriguez
University of Wisconsin - Milwaukee

Previous research indicates that mathematics ability predicts student success in chemistry courses. Not surprisingly, chemistry students are required to take courses in mathematics as prerequisites and co-requisites, including calculus. In this work, we seek to identify the ways calculus skills and concepts appear in the undergraduate chemistry curriculum, focusing on the introductory general chemistry sequence. To this end, we combined relevant disciplinary frameworks and looked for alignment: the Calculus Content Framework (CCF) and the Anchoring Concepts Content Map (ACCM) for general chemistry. Preliminary results indicate explicit use of calculus is not common in introductory chemistry, although there are opportunities for instructors to use the general chemistry topic of chemical kinetics as a context for the application of differentiation and integration. Future work will involve mapping out the landscape of the remainder of the undergraduate chemistry curriculum and as an expected outcome of this work we seek to provide tangible resources to facilitate cross-disciplinary discussions between instructors in calculus and chemistry.

Keywords: Calculus, Chemistry, Curriculum Analysis, Interdisciplinary

Introduction

There is a large body of literature that indicates students' mathematical ability correlates with success in chemistry courses (Bain et al., 2014; Becker & Towns, 2012; Derrick & Derrick, 2002; Hahn & Polik, 2004; House, 1995; Nicoll & Francisco, 2001; Spencer, 1996; Tsaparlis, 2007; Wagner et al., 2002), which is not surprising given the large role mathematics plays in typical chemistry courses (Stowe et al., 2021). That said, student performance on standardized mathematics assessments (e.g., SAT) is often used to identify at-risk students and identify particularly challenging chemistry topics (Lewis & Lewis, 2007; Ralph & Lewis, 2018). Based on the emphasis placed on mathematics as a tool to explain and predict in chemistry, it is not uncommon to have prerequisite and co-requisite calculus courses for undergraduate students taking chemistry. For example, at the University of Wisconsin – Milwaukee, chemistry majors are required to take three semesters of calculus (covering topics including limits, derivatives, integrals, partial derivatives, and vectors), with the recommendation (not requirement) to take a course focusing on linear algebra and differential equations("Chemistry Major," 2024). However, there is a need to evaluate the alignment between the mathematics used in chemistry courses and the mathematics presented in calculus courses. To this end, we are interested in mapping the calculus concepts (Sofronas et al., 2011) on to chemistry concepts (Murphy et al., 2012).

In broad strokes, this project is the result of an interest in developing resources that further interdisciplinary connections and continue the on-going dialogue regarding how disciplines such as chemistry and mathematics can support one another to improve teaching and learning. Recently the authors attended *The Learning and Teaching of Calculus Across Disciplines* conference in Bergen, Norway (*Welcome*, 2023). The aim of this interdisciplinary conference was to bring researchers from multiple fields (biology, chemistry, economics, engineers, physicists) together to discuss how each discipline uses calculus concepts. The current preliminary report builds on a plenary talk given by Dr. Brian Faulkner at this conference that discussed prior work involving analyzing where calculus concepts are used in an engineering course (Faulkner et al., 2020), with Faulkner's work mirroring a study in mathematics that analyzed the role of calculus concepts in an advanced mathematics course (Czocher et al., 2013). Focusing on connections between chemistry and calculus communities, the intended outcome of this work is a practical tool for calculus instructors to see the contexts and extent calculus is used across the undergraduate chemistry curriculum to inform instructional choices. The guiding research question addressed in this report is, *Which concepts and skills learned in calculus are applied in general chemistry?*

Disciplinary Frameworks

The scope of this study is supported by readily accessible disciplinary-specific frameworks that outline the target content goals for chemistry (Murphy et al., 2012) and calculus (Sofronas et al., 2011). In the case of chemistry, the American Chemical Society Exams Institute developed the Anchoring Concepts Content Map (ACCM), which was developed through workshops with content experts (Murphy et al., 2012). There is currently an ACCM for the following chemistry course sequences in the undergraduate chemistry curriculum: general chemistry (Holme et al., 2015); organic chemistry (Raker et al., 2013); inorganic chemistry (Marek et al., 2018); physical chemistry (Holme et al., 2018); and analytical chemistry (Holme et al., 2020). The general multi-tiered structure for each ACCM involves a series of nested concepts that become increasingly more specific: big idea (also called anchoring concept), enduring understanding, subdisciplinary articulation, and content detail. For each ACCM, the big idea and enduring understanding levels reflect broad concepts that are relevant throughout the chemistry curriculum, whereas the subdisciplinary articulation and content detail levels are specific to individual courses (or course sequences), such as general chemistry or organic chemistry. Within the ACCM framework, there are ten big ideas, one of which is *Kinetics*. To illustrate the structure of the ACCM, the levels from the general chemistry ACCM are provided related to the *Kinetics* big idea (Holme et al., 2015):

1. Big Idea. Kinetics: Chemical changes have a time scale over which they occur.
2. Enduring Understanding. Chemical change can be measured as a function of time and occurs over a wide range of time scales.
3. Subdisciplinary Articulation. The rate of the reaction must be defined in a manner that is not dependent on which reactant or product is used to measure it.
4. Content Detail. The reaction rate should incorporate reaction stoichiometry when it is defined.

In the case of describing the calculus concepts, this study utilizes the Calculus Content Framework (CCF) (Sofronas et al., 2011). The CCF was developed through interviewing experts in the calculus field, including prominent textbook authors, experienced educators, and researchers. The focus of the interview questions was to elicit instructional goals for students in a first-year calculus sequence. To this end, the resulting CCF is organized based on four broad categories: (a) mastery of the fundamental concepts and/or skills of the first-year calculus; (b) construction of connections and relationships between and among concepts and skills; (c) the ability to use the ideas of the first-year calculus, and (d) a deep sense of the context and purpose of the calculus. Prior work has illustrated the utility of the CCF, with Czocher et al. (2013) applying the framework to investigate the necessary calculus content and skills in an advanced mathematics course and Faulkner et al. (2020) doing the same for an engineering course. In both cases, the researchers found a lack of alignment across courses, suggesting the need to consider not just whether calculus is used in future coursework, but also how calculus is used.

Methods

Data Collection & Analysis

To map calculus topics to chemistry, we focused on the *subdisciplinary articulation* level within the general chemistry ACCM, which typically represents a two-semester course sequence for first-year students. This was compared to the calculus concepts and skills developed in the CCF (*mastery of the fundamental concepts and/or skills of the first-year calculus*, discussed above). Our approach for this report is based on the methods described by (Czocher et al., 2013) and (Faulkner et al., 2020), which involved attending to mathematics-in-use to assess where and how the calculus appears in general chemistry. Using the mathematics-in-use technique requires analyzing the chemistry content (as described in the subdisciplinary articulation of the ACCM) and noting the ways calculus concepts and/or skills are involved by solving problems associated with the subdisciplinary articulation. As part of this, it is helpful to assess secondary routes that are available to solve the problem which often results in situations where calculus skills and concepts are an available route to successfully solve the problem, but another route is favored. To this end, the subdisciplinary articulations were evaluated based on whether: (0) there was no calculus associated with the related concepts and skills; (1) calculus was present, but it was not the preferred method to solve related problems and reason through and the concepts; (2) the application of calculus was the preferred approach toward solving problems and reasoning through the concepts. For this work, we report on our analysis related to the subdisciplinary articulations that fall nested under the ten big ideas in the general chemistry ACCM.

Preliminary Results

Our preliminary analysis, shown that the only calculus concept or skill present in general chemistry is derivatives. The subdisciplinary articulations that involve this concept are shown in Table 1. The only big idea from the ACCM that involved calculus concepts and skills (derivative) was chemical kinetics, which had three subdisciplinary articulations characterized as having calculus present, but not as the preferred approach. The remainder of the subdisciplinary articulations across the ten big ideas in the general chemistry ACCM did not involve calculus concepts and skills.

Table 1. ACCM subdisciplinary articulations involving derivatives.

The rate of the reaction must be defined in a manner that is not dependent on which reactant or product is used to measure it.
Rate is generally defined as the change in concentration of a reactant or product as a function of time.
When solids are included in reactions, surface area is an important factor in the rate of reaction.
Laboratory observation of reaction rates helps to establish the concept of reaction time scales empirically.

Chemical kinetics involves modeling the rate of a reaction to track changes in the concentration of reactants as a function of time. Thus, although chemical kinetics could readily be modeled using the derivative, this perspective is often circumvented in a first-year chemistry course. In the chemistry curriculum, topics are often explained with less rigorous mathematics detail, and subsequently revisited in upper-level courses. For example, one subdisciplinary articulation that was coded as having an alternative calculus explanation available was: “Rate is generally defined as the change in concentration of a reactant or product as a function of time.” In first-year general chemistry courses, the rate of a simple reaction ($A + B \rightarrow AB$) is typically defined as:

$$rate = k[A]^m[B]^n \quad (1)$$

Here, *rate* is the rate of the reaction, *k* is the rate constant, *m* and *n* are empirically determined reaction orders that describe the concentration dependence of rate, and the final equation is known as the *rate law*. This is the most common way to discuss chemical kinetics with introductory students, without associating the equation with derivatives. With this version of the rate law, students are expected to determine the reaction order, solve for the value of *k,* and generally, use algebra computational skills to manipulate variables and compute values.

In contrast, in upper-level courses such as physical chemistry, the rate law would be discussed using the differential form:

$$-\frac{d[AB]}{dt} = k[A]^m[B]^n \quad (2)$$

In the case, we make use of calculus to describe the rate of the reaction to afford a more complicated analysis of chemical systems. Often, the rate law for a reaction is integrated to further describe reactions (Table 2). The integrated rate law is helpful because the rearranged linear form of the integrated rate law can be used in laboratory contexts to determine reaction order by fitting kinetics data and assessing its agreement with the equations for each reaction order.

Table 2. Summary of equations corresponding to each reaction order.

	First-Order Reaction	**Second-Order Reaction**	**Zero-Order Reaction**
Chemical Reaction	$A \rightarrow B$	$2A \rightarrow B$	$A \xrightarrow{catalyst} B$
Rate Law	$rate = \frac{-d[A]}{dt} = k[A]^1$	$rate = \frac{-d[A]}{dt} = k[A]^2$	$rate = \frac{-d[A]}{dt} = k[A]^0 = k$
Integrated Rate Law	$-\int_{[A]_0}^{[A]} \frac{d[A]}{[A]} = k\int_0^t dt$	$-\int_{[A]_0}^{[A]} \frac{d[A]}{[A]^2} = k\int_0^t dt$	$-\int_{[A]_0}^{[A]} d[A] = k\int_0^t dt$
	$\ln\frac{[A]_0}{[A]} = kt$	$\frac{1}{[A]} - \frac{1}{[A]_0} = kt$	$[A] - [A]_0 = -kt$
Linear	$\ln[A] = -kt + \ln[A]_0$	$\frac{1}{[A]} = kt + \frac{1}{[A]_0}$	$[A] = -kt + [A]_0$

Conclusion and Questions

Within the first-year general chemistry course, calculus concepts and skills are not prominent, with the relevant mathematics required being related to other mathematics courses (e.g., algebra). This is not to suggest that calculus concepts and skills are not relevant for modeling phenomena in chemistry, but that calculus becomes more important in undergraduate chemistry courses as students advance to higher coursework. As an implication, we highlight that although calculus is often a prerequisite or corequisite for students in introductory chemistry courses, students struggling with the mathematics in chemistry need additional support and practice with mathematics at the pre-calculus level. Regarding future work, as part of the ongoing analysis, we are interested in expanding our focus toward the ways calculus concepts and skills are used across the rest of the undergraduate chemistry curriculum. Especially in upper-level chemistry courses such as physical chemistry in which calculus is heavily integrated through the curriculum. Moreover, our goal is for this work to be helpful to connect the mathematics and chemistry communities by discussing how we use the shared language of calculus. For the scope of this conference report, we have some general questions for the mathematics community:

1. What are some of the ways chemistry instructors and chemistry education researchers can support mathematics instructors and researchers interested in undergraduate mathematics education?
2. What suggestions do you have regarding the methodological approach and scope of this work?

Professional Obligations of Graduate Student Instructors and Undergraduate Learning Assistants in Partnership within Active Learning Mathematics Classrooms

Molly Williams[1]
Murray State University

Rachel Funk[1]
University of Nebraska-Lincoln

Learning Assistants (LAs) are undergraduate students who support active learning classrooms by acting as a second instructional figure in the classroom. Although research has shown a variety of benefits from the integration of LAs, little is known about the nature of the LA-instructor relationship and its impact on instruction. We present preliminary findings from a comparative case study of how graduate student instructors of record (GSIs) and undergraduate learning assistants (LAs) work together within an active learning classroom. Specifically, we focus on how the interactions between GSIs and LAs relate to the professional obligations felt by GSIs and LAs, both of whom are positioned as mathematics instructors, albeit in different ways. This preliminary report highlights initial findings and suggestions for further investigation.

Keywords: Learning Assistants, Graduate Student Instructors, Active Learning, Obligations

Research suggests that undergraduate students who are hired as near-peers can support students' academic, social, and emotional well-being (Barrasso & Spilios, 2021; Dawson et al., 2014; Whitman & Fife, 1988). There are many different near-peer models, including supplemental instruction, tutoring, peer-led team learning, and the learning assistant (LA) model. However, institutions are increasingly relying on the LA model, or variations of it, to support change efforts centered on the use of active learning pedagogies in STEM classrooms (Learning Assistant Alliance, 2023; Otero et al., 2006). Although there has been much research conducted about the LA model in other STEM disciplines, there is a dearth of research on the integration of LAs in mathematics classrooms (Barrasso & Spilios, 2021). Furthermore, existing literature suggests that implementation of the LA model varies considerably across different institutions and contexts, such as lectures, recitations, and online courses (Hill et al, 2023). Literature is also scant on the nature of the partnerships between LAs and instructors (Barrasso & Spilios, 2021). Although some researchers are investigating these relationships (Davenport et al., 2017; Jardine 2020; McHenry et al., 2010; Sabella et al., 2016), instructors are typically faculty. Some research has compared self-perceptions of the roles of graduate teaching assistants, learning assistants, and professors (Becker et al., 2016), but there is little known about LAs working with graduate students acting as instructors of record (GSIs). Given the increasing prevalence of LA programs and the large proportion of mathematics departments that hire GSIs to teach mathematics courses, it would benefit our community to investigate the nature of this relationship and its influence on instruction.

To that end, we investigated how GSIs and LAs described their interactions in and outside of an active learning mathematics classroom, focusing on the conditions (e.g., professional obligations) that influence those interactions. We asked the following research question:

> *RQ: To what extent did GSIs and LAs of an active learning mathematics classroom interact with each other in and outside of the classroom, and how does this relate to the professional obligations they felt in their roles?*

[1] Williams and Funk contributed equally to this work.

Theoretical Background

Instruction involves interactions between students, teacher(s), and content, but is also constrained by the environmental conditions in which these interactions take place (Cohen et al., 2003; Hawkins, 1974). These environments act as a source for the professional obligations felt by those positioned as mathematics teachers, which are in turn used to justify what teachers do in mathematics classrooms. Herbst & Chazan's (2011, 2012) theorize that four professional obligations influence the decision making by individuals who take on the position of mathematics teacher: disciplinary, individual, interpersonal, and institutional. See Figure 1 for definitions of these obligations.

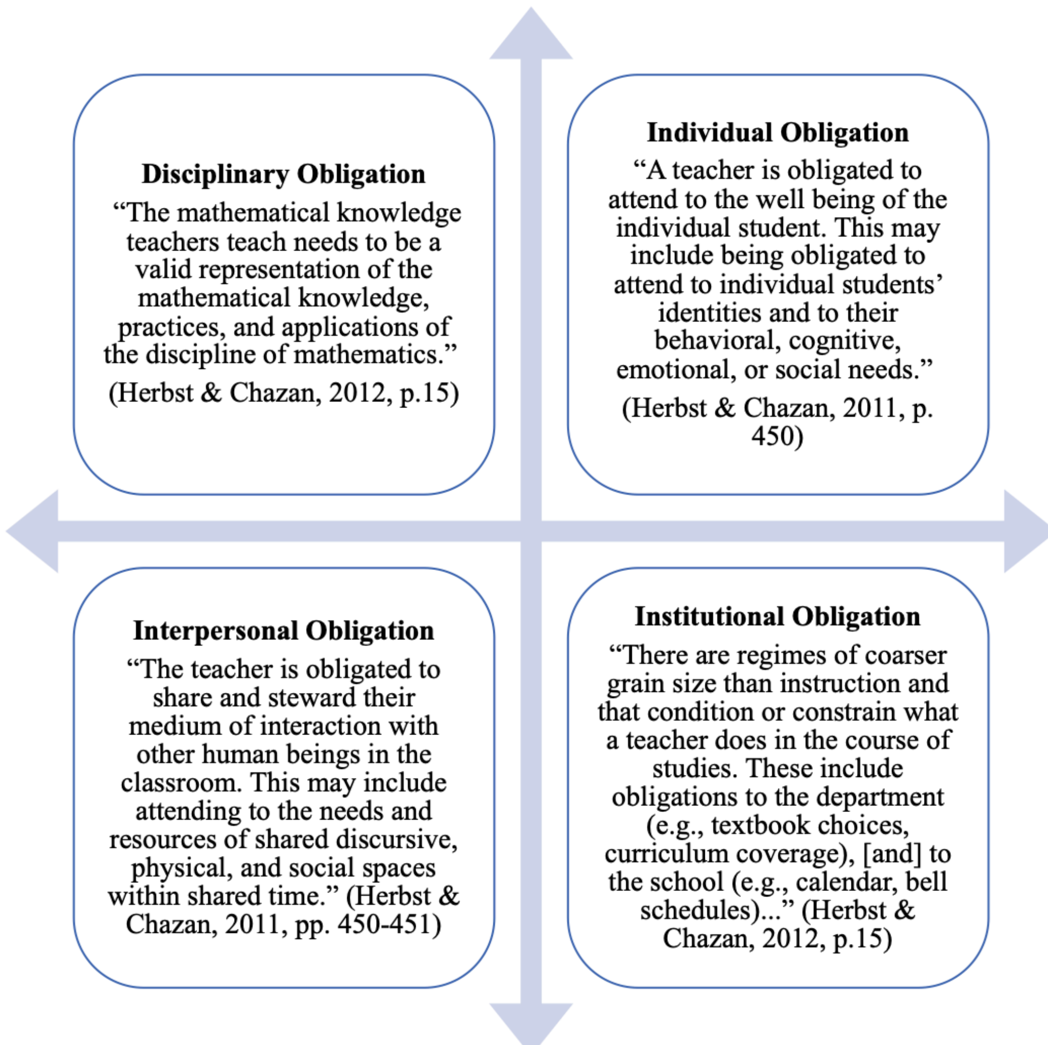

Figure 1. Herbst & Chazan's (2011, 2012) professional obligations

Instructors may feel these obligations acutely or be relatively unaware of them, nevertheless these obligations exist for every mathematics teacher. Furthermore, instructors who use active learning may become more aware of these obligations as obligations come into conflict. For example, instructors may feel an obligation to cover prescribed content (an institutional obligation) competing with an obligation to let students engage deeply with mathematics (a disciplinary obligation) (Mesa et al., 2020). Using the LA model could change what these obligations look like. Specifically, the obligations felt by GSIs and LAs may shift depending upon how GSIs and LAs are positioned in the classroom and in relation to one another. Although at times LAs may be positioned as mathematics teachers, and thus are subject to the same four professional obligations as that of an instructor, LAs take on additional positions in the classroom given their status as undergraduate students (Funk, 2023; Jardine, 2020). As such they may feel different obligations or feel these obligations differently. For example, LAs and GSIs may feel an individual obligation to students, but LAs might feel a stronger obligation to connect to individual students on a personal, friendly level, whereas the GSI may not feel that similar obligation because they are assigning grades.

These professional obligations are not the only obligations that teachers may feel in a classroom, however they provide a basis for understanding the decisions that teachers make in a classroom (Herbst & Chazan, 2012). We contend that integrating LAs into a classroom adds additional complexity related to the interpersonal obligation - how are LAs and GSIs sharing discursive, physical, and social spaces? Do instructors feel obligated to interact with one another? These are important questions to consider, as they influence how GSIs and LAs navigate their roles and relationship within an active learning environment, ultimately influencing the decisions they make as instructors.

Methods

This report draws from a larger multiple case study (Kaarbo & Beasley, 1999; Stake, 2006) to examine how the roles of GSIs and LAs may shift in a mathematics department involved in change efforts to improve their courses. The larger study includes data collected from two separate dissertation studies, both occurring within the same mathematics department but at different points in time. The first study occurred in Fall 2015, at the start of the mathematics department's efforts to transform their precalculus courses using an active learning, coordinated model. This study focused on the relationship and evolving beliefs of a GSI-LA pair across a semester, who had previously worked together in Spring 2015. The second study was conducted once the department's change efforts had been sustained for multiple years, but involved changes to instruction due to the COVID-19 pandemic. For this study, data were collected from Summer 2020-Fall 2021, and involved a total of 18 GSIs and 9 LAs, including 4 GSI-LA pairs.

Although multiple forms of data were collected in these dissertations, for this report we draw on interview data to examine how GSIs and LAs described their relationship. Despite being drawn from two separate studies, interview questions focused on similar concepts, including beliefs about the role of mathematics instructors and the GSI-LA relationship and changes to that relationship (e.g., "Did you notice any changes in [LA/GSI] over the course of the semester?" -Fall 2015 Interview Question; "What are the major roles and responsibilities for LAs that support your class? How do these roles and responsibilities differ from yours?" -Fall 2020 Interview Question).

We began analysis by reading the dissertations to identify specific instances of GSIs and LAs describing their interactions. Importantly, we operationalized interactions as encompassing direct conversations, as well as observations or noticings of each other's teaching. We then traced these pieces of evidence back to individual transcripts to examine the raw data. These instances were open coded (Miles et. al, 2014) by each author individually, then they were compared and discussed to generate preliminary themes. Through this analysis we identified variations in how participants interacted with one another in and outside of class, noting differences in the obligations felt by participants in these interactions. We use the findings sections of this proposal to elaborate on this theme. In future data analysis, we plan to analyze the entire corpus of interview data for evidence of professional obligations using Herbst and Chazan's framework as an a priori analytic framework.

Preliminary Findings

We found evidence of three different levels of obligation felt by the GSI and LA to interact: a definite sense of obligation, some obligation, and no obligation to interact. These different levels sometimes depended on whether interactions occurred inside or outside the classroom. In the following paragraphs we share evidence from each level of obligation.

Some GSIs felt a definite sense of obligation to interact with their LAs. This was evident from their insistence on the importance of communicating with or observing their LA in or outside of class. For many, this sense of obligation was tied to an obligation to ensure active learning methods were being used by LAs. GSI Jay said that for them to be an effective teacher, their LA's teaching "approach and philosophy" had to align with their own "at least in practice, if not necessarily in belief." Jay intentionally observed LA Jessie early in the semester to ensure that Jessie was using active learning. They said, "I know that my LA is not going into rooms and just giving students answers, right? That my LA is not undermining the structure [of the active learning course]." GSI Jay also hoped to treat LA Jessie as a "colleague" and a "peer" outside of class; they met frequently outside of class time to discuss student dynamics and approaches to teaching content. This related to their desire that during class the LA and themselves presented a "united front." Similarly, GSI Sally intentionally had "several quite long conversations about what it means to teach, what's the most effective way to teach, and what I want to happen in the classroom" with her LA. Sally admitted, "when we first started teaching together last semester, LA Cara stressed me out more than the students did" but Sally had come to trust her. Both GSI Jay and GSI Sally proactively interacted with their LAs to fulfill an obligation that the course be taught using active learning methods. Furthermore, their LAs sought-out interactions with the GSI to learn how to teach the course. For LA Jessie, this was in part inspired by an obligation to ensure they were presenting mathematics in a way that was aligned with the instructor. They described observing GSI Jay so that they were using "the same wording that [they do] in class." Further, they said it was important to communicate with the GSI to make sure "you're always on the same page, cause you don't want to split the class into two."

GSIs and LAs who had a less definite obligation to interact often described feeling constraints on their ability to interact, particularly in class. GSI River identified being a novice teacher as one such constraint, saying that "there is a cognitive overload" when one first starts teaching that prevents an instructor from paying attention to the LA. They elaborated by saying that "paying attention to what my LA was doing was a lower priority" for them, as they were trying to make sure they did "a good job" teaching. River believed that, as a more experienced instructor, they would now be able to "manage paying attention to what [their] LA is doing." However, other more experienced GSIs described feeling constrained by the dynamics of an active learning classroom. As GSI Aiden stated:

> I always had a really hard time knowing whether my LA was doing a good job because I was just very focused on teaching and trying to go to all of the groups and get a sense of how class is doing. So I just completely ignored my LA basically all the time until we reconvened at the end of class.

For GSI Aiden, the obligation to interact with each student group took precedence over an obligation to make sure the LA "was doing a good job." They did, however, reconvene with their

LA at the end of class, suggesting that they felt an obligation to interact with their LA beyond class time. Similarly, Instructor Blake felt an obligation to "hit every group so I don't miss anyone" and described not knowing what their LA was doing because they were "focused on the student." Unlike GSI Aiden, Blake interacted very minimally with their LA outside of class time, suggesting that Blake operated relatively autonomously from the LA.

Like Blake, GSI Poppy talked about ignoring their LA because they were busy "personally knowing the students." However, they also questioned the appropriateness of monitoring LAs during group work, suggesting that LAs are meant to "support us [GSIs] monitoring the [group] work." GSI Harper shared similar sentiments, but with a stronger statement. They felt no obligation to their LA during the class session and further felt this was in line with the views of the department. They said:

> I guess just sort of the general advice, or attitude I inherited from the department…they're [LAs] there to help you, they're there to help students. I don't know if this is advice or just a statement about how my classroom works, but don't focus on the LA. Assume that they're off doing good work on the other side of the classroom and instead just work with the students.

Thus, Harper did not feel the need to have any focus on the LA beyond assuming the LA was there to support the GSI and the active learning environment.

Discussion & Questions for Audience

Our findings highlight that participants felt different levels of obligation to interact with one another, and further that these differences can in part be accounted for by the context of the interaction (in or outside the classroom) and other professional obligations. For example, some GSIs prioritized having conversations with their LAs outside of class time to ensure that LAs explained content in ways faithful to the discipline (from their perspective) or to support LAs in using active learning methods. Likewise, one LA felt an interpersonal obligation to keep the classroom from splitting into two, and thus prioritized being on the "same page" as the GSI through conversations outside of class time. Some GSIs used in-class observations to ensure that LAs were using active learning strategies to engage students. However, one GSI felt no obligation to interact with their LA in the classroom, and furthermore described their view as being "inherited" from the department, suggesting that they felt an institutional obligation to not "focus on the LA" during class time. Several GSIs remarked on the difficulty of attending to students and observing the LA, suggesting that while they felt an interpersonal obligation to interact, this took less precedence than their obligation to interact with students. This brings up several questions: How do GSIs and LAs prioritize competing professional obligations? How does department culture influence this prioritization? Do GSIs and LAs prioritize competing obligations differently? Should GSIs feel an obligation to interact (or notice) LAs? Should LAs feel an obligation to interact (or notice) GSIs?

More work needs to be done to consider how Herbst and Chazan's (2011, 2012) framework supports understanding of the GSI-LA relationship, particularly in active learning classrooms. For example, White and Smith (2023) suggest that the interpersonal obligation should be magnified to support inclusion in active learning classrooms; they argue that instructors should explicitly be encouraged to support student-student interactions. In what ways does integrating LAs into a classroom add additional possibilities for magnification of the interpersonal obligation?

Exploring the Interplay Between Preservice Teachers' Mathematical Beliefs and EB Students' Mathematics Education

Luis M. Fernández
University of Texas Rio Grande Valley

Ursula Nguyen
University of Nebraska–Lincoln

We explored the intersections between two sets of pre-service teachers' beliefs, revealing potential relationships between beliefs about mathematics and beliefs about EB mathematics education. PSTs whose beliefs about mathematics were consistent with reform-oriented mathematics were identified as social constructivists, and they were more likely to express equitable beliefs about EB mathematics education. However, we find a more mixed pattern regarding beliefs about EB mathematics education among PSTs identified as moderately-traditionalists. Specifically, we find that the association between PSTs' demographic backgrounds and engagement with EB issues and their endorsement of more moderate beliefs may differ across different groups of PSTs. This research contributes to understanding the complex interplay of teacher beliefs in mathematics and EB education, offering insights that can inform more effective teacher-preparation programs to enhance PSTs' ability to teach EB students effectively.

Keywords: Emergent Bilinguals, Pre-Service Teachers, Beliefs about Mathematics

While teacher-preparation programs have made strides in adopting asset-oriented perspectives regarding what Emergent Bilinguals (EB) students can achieve, research reveals that many pre-service teachers (PSTs) still graduate underprepared to meet the mathematical needs of EB students, including prevalent deficit-oriented views about how EB students learn mathematics (e.g., Fernandes, 2007; National Center for Education Statistics, 2013; Pappamihiel et al., 2017). These beliefs strongly influence the instructional practices that PSTs enact in their mathematics classrooms (Akinsola, 2008; Beswick, 2005; De Araujo, 2017; Wilkins, 2008).

Recent research has started exploring the experiences shaping PSTs' beliefs about EB students' mathematics education, including PSTs' beliefs about mathematics, its teaching, and learning and how these appear to influence their views on how EB students should learn mathematics (e.g., De Araujo, 2017; Janzen, 2008; McLeman & Fernandes, 2012). For that reason, identifying relationships between PSTs' beliefs about mathematics and EB students can further inform the development of more effective teacher-preparation programs. By addressing PSTs' preconceived notions about mathematics learning and teaching, these programs can enhance PSTs' capabilities to teach EB students. The study aims to answer two research questions:

1. What beliefs do PSTs seem to hold about the nature of mathematics, its teaching and learning, and the mathematics education of EB students?
2. Are there any relationships between PSTs' beliefs about the nature of mathematics, its teaching and learning, and the mathematics education of EB students?

The study utilizes a quantitative approach to collect data and situates its work within the broader context of research on teacher beliefs, encompassing beliefs about mathematics and the education of EB students. The hypothesis is that PSTs who share beliefs about mathematics that are aligned with reform-oriented efforts of mathematics teaching and learning will also share equity-oriented beliefs towards EB learners and mathematics.

Literature Review and Theoretical Background

Teacher Beliefs about the Nature, Teaching, and Learning of Mathematics

According to Borg's theoretical framework (1997, 2003, 2005) on teacher cognition, teachers enter teaching with existing mathematics beliefs, knowledge, and attitudes categorized as either instrumentalist, Platonist, or problem-solving orientations (Ernest, 1991; Raymond, 1997). These orientations represent distinct views of mathematics: instrumentalists see it as facts and rules, Platonists as static interconnected knowledge, and problem-solvers as dynamic and inquiry-oriented. This has spurred extensive research into exploring such teachers' beliefs about mathematics through various survey instruments, including the Mathematics Belief Instrument (Hart, 2002), the Mathematics Beliefs Questionnaire (Adnan & Zakaria, 2010), and the Teachers Beliefs Survey (Beswick, 2005; Hughes, 2016). These studies consistently reveal a divide between teachers who view mathematics as interconnected knowledge best acquired through student-guided experiences and inquiry-based learning and those who see mathematics as a finite set of facts and procedures conveyed directly to students, with limited room for exploration.

More recently, Hughes (2016) adapted Ernest's framework, categorizing instrumentalist and problem-solving/Platonist beliefs as traditional and constructivist beliefs, respectively. Research finds that teachers tend to align with either traditional or constructivist beliefs (Hughes, 2016; Paolucci, 2015). However, recently among newer teachers, another group has emerged whose mixed beliefs combine elements of both traditions. However, the literature on teacher beliefs rarely delves into the factors influencing these beliefs about mathematics' nature, teaching, and learning. Limited studies suggest a positive link between teachers' mathematical backgrounds (including coursework and teaching knowledge) and constructivist beliefs about mathematics (Ogan-Bekiroglu & Akkoç, 2009; Kutaka et al., 2018). Yet, the evidence in this area is inconclusive regarding the role of other factors, such as experiences with linguistically or culturally diverse students, on teachers' beliefs about mathematics.

Teacher Beliefs about the Mathematics Education of EB Students

In recent decades, studies exploring teachers' broad beliefs regarding EB students, extending beyond mathematics education, have surged. This body of literature finds that teachers often exhibit deficit views, perceiving their role mainly as content instructors (e.g., Tan, 2011; Garmon, 2005; Mellom et al., 2018). De Araujo (2017) observed that secondary mathematics teachers often chose procedure-focused tasks for EB students, reflecting their deficit-oriented beliefs about EB students' ability to engage with mathematics. Additionally, McLeman and Fernandes (2012) noted that even PSTs with overall positive beliefs about EB students also endorsed the commonly held belief that lack of parental and family involvement, potentially contributed to EB students' mathematics underachievement.

An intriguing aspect of this research is the exploration of factors shaping teachers' beliefs about EB students' mathematics education. Training in EB instruction appears to lead to more positive beliefs about teaching EB students (Pettit, 2011b; Polat & Mahalingappa, 2013). Similarly, PSTs who engaged in multicultural courses during their teacher preparation, specifically addressing EB student issues, tended to hold more positive beliefs about EB students and their mathematics performance. These PSTs also had opportunities to interact with EB students during their student-teaching experiences (McLeman, Fernandes, & McNuttly, 2012; McLeman & Fernandes, 2012).

Methods

This study aims to investigate a diverse array of PSTs beliefs, encompassing perceptions, attitudes, conceptions, and beyond. Therefore, the study adopts Borg's (2003) comprehensive conceptualization of teacher cognitions as its main theoretical framework, integrating various facets of teacher beliefs, particularly those related to the nature of mathematics and the mathematics education of EB students. This framework aligns with the study's perspective of teachers as active agents who base their instructional decisions on their situated understanding and therefore, frames PSTs' beliefs as a flexible yet robust collection of "what teachers know, believe, and think" (Borg, 2003, p. 81), particularly in the context of mathematics and the education of EB students.

We collected survey data from 84 PSTs attending a southwestern US public research university. Specifically, we recruited PSTs enrolled in an elementary teacher preparation program and pursuing either an ESL Generalist Certification (*n* = 68) or a Bilingual Generalist Certification (*n* = 16). As our intent in this study is to focus on views held by PSTs about the mathematics education of EB students as well as their beliefs about the nature of mathematics, we selected Bilingual and ESL elementary PSTs who had either completed (*n* = 53) or were currently enrolled (*n* = 31) in the mathematics pedagogy course (i.e., Mathematics Methods) for the elementary teacher preparation program. Through this course, PSTs were exposed to research-based instructional strategies for teaching mathematics in elementary grades.

To capture beliefs held by PSTs regarding the nature of mathematics, teaching mathematics, learning mathematics, and the mathematics education of EB students, we utilized two different sets of survey items. The first set, or Survey A, (Cronbach's alpha=0.77) describes beliefs about mathematics and mathematics education and was comprised of 28 previously validated items (Hart, 2002). A sample item includes "A demonstration of good reasoning should be regarded even more than students' ability to find correct answers." Response categories were 5-point Likert-scales, ranging from 1=*Strongly Disagree* to 5=*Strongly Agree,* with higher scores indicating more alignment with reform-oriented efforts. The second set, or Survey B, consisted of 30 previously validated items (Cronbach's alpha=0.87) describing beliefs about the mathematics education of EB students. One item from this set is "The inclusion of EB students in classes of mathematics creates a positive educational atmosphere." Response categories followed the same 5-point Likert scale described earlier, with higher scores indicating more asset-oriented views towards the mathematics education of EB students. Survey data collected also included PSTs' demographic background information, including gender, race/ethnicity, and previous college course experience.

As this study seeks to explore the potential relationship between PSTs' beliefs about mathematics and the mathematics education of EB students, we utilized cluster analyses, which is a descriptive statistical method appropriate for this exploratory study about PSTs' beliefs (e.g., Beswick, 2005; Rodriguez-Muñiz et al., 2022). For each set of beliefs (Surveys A & B), we utilized hierarchical cluster analysis to identify and categorize latent types of common beliefs shared by PSTs. To analyze the intersection between beliefs about mathematics (Survey A) and mathematics education of EB students (Survey B), we used a cross-tabulation analysis and identified unique relationships between these two sets of beliefs.

Results

Teacher Beliefs about the Nature, Teaching, and Learning of Mathematics, and the Mathematics Education of EB Students

Results from the hierarchal cluster analysis on Survey A responses provided a solution of three clusters (i.e., CA1, CA2, & CA3). On the other hand, results from the hierarchal cluster analysis on the responses of Survey B yielded two clusters that reflected the PSTs' beliefs pertaining as it relates to EB students' mathematics education (i.e., CB1 & CB2). These results were further validated by splitting the data into two equal sets and confirming the persistence of the same solution for the split data, respectively (Garson, 2012; Hair & Black, 2000; Sarstedt & Mooi; 2014). Furthermore, given that significant differences are to be expected among clusters (Hair & Black, 2000), a comparison of means for all survey items incorporated ANOVA and post-hoc tests among CA1, CA2, CA3 and CB1, CB2. Survey items that presented significant differences (i.e., $p < 0.05$) among all the two groups of clusters were used to create cluster descriptions and labels.

Focusing on Survey A clusters, Traditionalist PSTs (CA1; n=29) shared more traditionalist orientations towards mathematics. This includes beliefs that mathematics is a collection of isolated strands of knowledge best taught through repetition and reinforcement. Moderately-Traditionalist PSTs (CA2; n=34) shared similar beliefs about mathematics, such as the view that there exists a right or wrong answer in math, strongly contradicting the beliefs expressed in mathematics reform efforts. However, these and other similar traditionalist beliefs are not as strongly believed as those from CA1, and therefore the "Moderately" in the label. Social Constructivist PSTs (CA3; n=21), on the other hand, shared beliefs about mathematics, including its teaching and its learning, that strongly aligned with those of reform-oriented efforts. This includes beliefs about mathematics being best taught through a student-centered approach that values peer discussions, guided explorations, and self-discovery.

Regarding the beliefs about the mathematics education of EBs, or Survey B, Moderately-Equitable PSTs (CB1; n=56) expressed beliefs that align well with recommendations found in the literature on the learning and instruction of mathematics to EBs. However, beliefs in CB1 are "weaker" than those believed in CB2 (n=28). That is, PSTs in CB1 were more moderate compared to CB2 PSTs in how much they agreed and disagreed with research-based recommendations for EBs' mathematics education, and therefore the "Moderately" in the label for CB1 and "Equitable PSTs" for CB2, respectively. Demographic and other background information were also considered when exploring the composition of each cluster. However, results from the Chi-square and ANOVA tests did not reveal any significant associations.

Relationships between PSTs' Beliefs about the Nature of Mathematics, its Teaching and Learning, and The Mathematics Education of EB Students

The percentages from the crosstabulation analysis between the two sets of clusters of PSTs are shown in Table 1. We focus on the interesting yet important intersections formed by Moderately-Traditionalists and Moderately-Equitable (i.e., CA2 $\times$ CB1) and Moderately-Traditionalists and Equitable (i.e., CA2 $\times$ CB2) while recognizing that we also observed other relationships, such as between PSTs labeled as Social Constructivists and Equitable (i.e., CA3 $\times$ CB2).

Table 1. Crosstabulation Between MBI Clusters and MEELBI Clusters

	Moderately-Equitable (CB1)	Equitable (CB2)
Traditionalists (CA1)	28 (49.6%)	1 (4.3%)
Moderately-Traditionalists (CA2)	23 (40.6%)	11 (40.2%)
Social Constructivists (CA3)	5 (9.8%)	16 (55.5%)
Total	56 (100%)	28 (100%)

Specifically, as seen in Table 1, both CB1 and CB2 shared a large proportion of PSTs that were labeled as Moderately-Traditionalists. This finding suggests the possibility that Moderately-Traditionalists' beliefs might be more susceptible to other factors, and these factors may contribute to these beliefs differently according to PSTs' beliefs about the mathematics education of EB students. In fact, looking closely at each proportion's composition revealed differences between Moderately-Traditionalists and Moderately-Equitable PSTs and Moderately-Traditionalists and Equitable PSTs, respectively. For example, PSTs within the Moderately-Traditionalists and Moderately-Equitable intersection were most likely to identify as White (72.7%) and be pursuing a Generalist/ESL certification (100%) whereas PSTs from Moderately-Traditionalists and Equitable intersection share more diversity in both ethnicity and degree plan. PSTs from the Moderately-Traditionalists and Equitable intersection were also more likely to be bilingual (52.6%) than those in the Moderately-Traditionalists and Moderately-Equitable intersection (37.35%). In terms of previous course enrollment, Moderately-Traditionalists and Moderately-Equitable PTSs reported the lowest average number of courses that focused on EB issues (M=2.55; SD=2.16) and the highest rate of interaction with EB students during their teacher education program (M=2.57; SD=.731). Moderately-Traditionalists and Equitable PSTs, on the other hand, reported a higher average number of EB-focused courses taken (M=5.75, SD=3.36) and the lowest rate of interaction with EB students during their teacher education program (M=1.42; SD=.729).

Discussion

As hypothesized, evidence suggests that PSTs who embrace progressive, reform-oriented approaches to mathematics education appear to be more inclined to endorse empirically-based strategies for effectively teaching EB students in mathematics. Conversely, PSTs with more traditional beliefs about mathematics seem to exhibit a degree of caution or reluctance when it comes to fully embracing research-based recommendations for the education of EB students in mathematics. However, there also existed a group of PSTs that, while adhering to traditional views on mathematics, paradoxically champion equitable practices when it comes to teaching mathematics to EB students. Several additional factors may also come into play, potentially shaping and influencing the beliefs of PSTs. Elements such as the ethnic and cultural backgrounds of PSTs, the extent of their exposure to EB-focused coursework during their educational journey, and the depth of their interactions with EB students during their student-teaching placements are all critical factors that warrant exploration. These variables suggest that the development of beliefs about mathematics education and equity for EB students is a nuanced process influenced by a multitude of contextual and experiential factors. Further exploring this holds the potential to better inform teacher preparation programs.

Beyond Correctness: Characterizing Authority to Assess in an Abstract Algebra Classroom

Michael D. Hicks
Virginia Tech

Corinne Mitchell

Rachel Rupnow
Northern Illinois University

Lindy Hearne
Virginia Tech

In what ways do students bear mathematical authority in advanced mathematics classrooms? What authority relations arise within inquiry-oriented classrooms? Answering these questions may give insight into the inequities that exist within undergraduate mathematics education. We share findings from our initial investigation of 7 lessons from one inquiry-oriented abstract algebra (IOAA) classroom to determine who gets to have authority to do certain activities. Taking an action-based approach to parsing authority relations, we attended to who bears authority for the activities of authorship, communication of ideas, and assessment of ideas. Our preliminary findings propose five categories of activities for assessment as well as several observations about the nature of authority relations within an IOAA classroom.

Keywords: Abstract algebra, authority, assessment

Increased attention on student-centered instruction eschewing traditional lecture formats in undergraduate mathematics demands better understanding of the complex dynamics by which students participate in mathematics discourse, especially when they are expected to engage in activities like conjecturing, proving and justifying mathematical ideas. Investigating the authority relations created in such courses is one avenue for interpreting both productive and unproductive mathematics discourse. For example, it has been argued that inequitable learning and participation outcomes (Johnson et al., 2020) in inquiry-oriented classrooms arise from students' differing experiences in leveraging their authority in small-group and whole-class discussions, especially in terms of whose ideas are taken up, and how (Hicks, Tucci, Koehne, Melhuish & Bishop, 2021). In this paper, we extend an existing framework for interpreting authority relations by further parsing another relevant activity found within classroom authority dynamics: assessment of mathematical ideas.

Authority is a multi-dimensional construct, and as such, there are multiple approaches to parsing authority structures. Weber's (1947) power-oriented perspectives on authority have been used extensively, often to make observations about the nature of inequitable classroom interactions (e.g., Langer-Osuna, 2017; Esmonde & Langer-Osuna, 2013), or discursive positioning moves (e.g., Wagner & Herbel-Eisenmann, 2009). Despite the prominence of Weber's power-oriented authority in sociological research, concerns have been raised over the negative attention attributed to authority as a necessary evil to be resisted rather than as a positive force for social change. In the context of educational philosophy, Benne (1970) espoused a perspective that characterized authority in education with greater optimism, one which treated *bearers* of authority as a source of assistance to *receivers* of authority who willfully seek help from an authority and may be provided opportunities to bear authority for themselves. This type of authority is known as *anthropogogical* authority. The reform-oriented nature of Benne's contributions established a natural dichotomy between the Weberian and anthropogogical perspectives wherein the first is treated as typical of traditional classrooms and persists in most situations, while the second is thought to be an ideal form of authority to be strived for (Amit & Fried, 2005).

In contrast to the mathematics education literature as a whole, authority relations in undergraduate mathematics education have been understudied. This research has largely focused on *sources* of authority. Gerson and Bateman (2010) conducted a grounded theory investigation of an inquiry-based calculus classroom and developed a framework for identifying the many types of authority that can exist in the university setting, including hierarchal, mathematical, and pedagogical authorities. Other research has focused on authority for specific activities relevant to undergraduate advanced mathematics classrooms. For example, Bleiler-Baxter, Kirby and Reed (2023) investigated ways in which authority manifested in situations related to proof and proving activity, finding that students attended to course syllabi, their peers, and logical structure as sources of authority. In this paper, we focus specifically on investigating *mathematical* authority in the context of an inquiry-oriented abstract algebra class. We pose the following questions:

RQ1. What are the authoritative activities associated with assessment in an inquiry-oriented abstract algebra classroom?

RQ2. What are the mathematical authority relations in this classroom?

Theoretical Framing

We define authority as a dynamic and negotiated relationship between people (or groups, or organizations) in which one party agrees to lead and another party agrees to follow in a given situation. Thus, authority is transient and can shift between parties from one moment to the next rather than remain as a permanent fixture within a single person.

In contrast to Weber's power-oriented and Benne's reform-oriented definitions of authority, we adopt an *action-oriented* approach to parsing mathematical authority (Bishop, Koehne & Hicks, 2022). In particular, we contend that within any given *field* (i.e., the specific context in which bearers and receivers negotiate relevant authority relations), a member of the field becomes a bearer of authority by actively participating in one or more activities. These activities are situated discursively within a community of practice, either by recognizing that the community at large views the activity as pertinent to the field (e.g., a medical doctor bears authority by providing a patient with a diagnosis), or through localized negotiation that might be exclusive to a subset of the community (e.g., students might become bearers of mathematical authority through public *validation* of proof in one class, but never have such an opportunity to publicly validate proof in another.)

Table 1. The AAA Authority Framework for Authority Relations

Authorship	Refers to the significant contribution to the mathematical ideas under consideration.	Who is the primary source, or author, of the mathematical ideas?
Animation	Refers to who is publicly communicating or extending mathematical ideas.	Who is communicating mathematical ideas in the classroom?
Assessment	Refers to judgements/evaluations made about an idea.	Who is assessing mathematical ideas in the classroom and who is being assessed?

While several researchers have investigated authority relations between individuals, we examine the relations between students (as a collective party) and their teacher in this study. Thus, when one student partakes in an activity and bears authority, they bear authority for the students as a whole. This allows for a broadscale analysis of authority relations across several days of class, a scale of analysis that is absent from current literature. To characterize mathematical authority, we attend to the activities of *authoring* ideas*, animating* (or communicating) ideas, and *assessing* ideas. See Table 1 for a description of these broad activities.

Methods

The preliminary data consist of seven 1.25-hour long recordings of whole class activity from an introductory abstract algebra class at a large, land-grant university in the eastern United States, taught using the Inquiry-Oriented Abstract Algebra (IOAA) curriculum materials (Larsen et al., 2013). The class was composed of 15-20 students and covered the group isomorphism units from the curriculum materials in the 7 classes that were analyzed. Analysis began with segmenting classroom video, which indicated a stretch of classroom activity associated with a focal mathematical idea or task, or consistent participation structure, ranging from 30 seconds to 5 minutes in length. Four types of segments were identified within each video: whole class (WC) activity, small group activity (SG), independent activity (i.e., students worked by themselves rather than in groups), and segments that were not considered mathematical in nature (i.e., task set-up or returning graded work). Each segment that was labelled as WC was assigned codes using a version of the AAA framework modified to capture assessment authority.

Because the AAA framework was originally developed to capture the authority of whole-class interactions, the authority of students (versus the authority of the teacher) was documented collectively, rather than attending to the authority of individual students. In other words, if a student authors an idea in a segment, then students are credited collectively for that authorship. Codes were assigned based on which group (teacher, students, or both) held authority for authorship, animate-speak, animate-represent, and several types of assessment. In our initial analysis, we viewed assessment as any explicit statement that indicates judgement or evaluation of a mathematical idea. That is, utterances that could be implicit assessments were not coded.

The first two classroom videos were coded as a team to establish an initial coding scheme. The third lesson was coded independently by the first two authors, and then disagreements were resolved as a group. After that, the first author coded the fourth and sixth lessons, and the second coded the fifth and seventh lessons, with each author bringing difficult segments to the group to get consensus. The codebook was then refined over the course of analysis resulting in five types of mathematical assessment. These types are exemplified below in our findings, along with some general trends in authority relations captured by preliminary counts of the current coding.

Findings

In order to parse the authoritative activity of assessing, we attended to five different categories related to how students or teachers assess mathematical ideas within public classroom discourse: (1) correctness focused assessments, (2) assessments focused on comparison of ideas, (3) assessments focused on a particular quality of an idea, (4) justification of assessments, and finally (5) reflective or metacognitive assessments. Below we share examples of a subset of these activities identified within two interactions.

We view correctness focused assessments as largely related to the traditional discursive structure of initiate-respond-evaluate (IRE) (Mehan, 1979), although correctness focused assessments can appear more productively as well. Consider the following excerpt from one lesson in which the instructor sets up the class for a new phase of investigation into subgroups, beginning first by establishing collective understanding of some possibly unfamiliar notation:

Teacher:	We're going to go into our next reinvention phase now. And to get there, we need to know what 5Z is. Do you guys know what 5Z is?
Student A:	Z like integers?
Teacher:	Yes, Z as in integers (*points and nods at student while speaking.)*

The above interaction showcases an example of a correctness-focused assessment where the teacher was a bearer of authority for assessing a mathematical contribution. To capture the wide range of productive assessment activity within an inquiry-oriented course, attention to other forms of assessment was required. Consider the following excerpt:

Teacher:	*(Revoices student's idea at the board proving an implication about abelian groups.)*
Student B:	Is it not simpler than that?
Teacher:	Can I make it even simpler than that?
Student B:	*(Describes a proposed alternative proof.)*

In this interaction, Student B claims to have a simpler alternative proof than the previous one, and thus bears authority for comparing two mathematical ideas. In the discussion that followed, the teacher commented, "I think they are equally slick," giving her authority for comparison in addition to the students. Because each of students and the teacher was a bearer of authority for comparing ideas, we assigned a code of Both to this segment. Such interactions are evidence that students are engaging in mathematical practices valued by the field as a whole. Here, the student is attending not only to the correctness of a given proof, but also to the comparison of multiple ideas in an effort to find a more efficient approach. This is just one of five types of assessment indicative of mathematical community practices that arose, the remainder of which are summarized in Table 2 below.

Table 2. Five Authoritative Activities for Assessment

Correctness Focused	Assessments that indicate correctness/incorrectness of a mathematical contribution.
Comparison Focused	Refers to the comparison of two or more mathematical contributions.
Quality Focused	Assessments that are focused on a particular quality of a contribution, such as efficiency or clarity.
Justification Focused	Providing evidence or rationale to support a previously made assessment. Often paired with another assessment type.
Reflective/Metacognitive Focused	Assessments that are reflective of one's own thinking, and typically appear as an assessment of one's own contributions.

General Trends and Observations on Authority Relations

Authority was shared by teacher and students across the activities of authoring, animating, and assessing. Out of 150 total segments, students had or shared authority to author ideas in 101 segments. This preliminary finding count may be an indicator of the increased attention to student thinking within the inquiry-oriented setting. Inquiry-oriented classrooms often leverage tasks designed for students to inquire into mathematical ideas with their peers in small group settings, but allowing students to work in small groups generates a certain level of risk. Pimm (2019) identified these risks as *gambits.* One trend we have observed within this IOAA classroom is that by allowing students to engage in group work, students may bear either more authority for themselves or share more authority with the teacher. Small group work was followed by student authorship in nearly all transitional segments across all seven lessons.

Furthermore, authority for speaking was nearly always shared between teacher and students, with speech coded as both in 131 segments. Taken together with the high level of student and shared authorship, we view this as an indicator that the class did not engage in teacher-driven lecture very often. However, students were also provided little opportunity to completely control the spoken public discourse without teacher intervention. In contrast to speaking, students rarely wrote on the board during whole class discussion, with examples of students bearing authority for written representations occurring in only 17 segments. Thus, the teacher had significantly more authority to animate ideas through representation.

Students bore authority to make assessments in all 7 classes, most often focused on correctness, justification, or metacognitive aspects. Strikingly, students engaged in justification assessment nearly as often as in correctness assessment, and they made assessments that reflected on their own thinking far more than the teacher (see Table 3). Furthermore, students also always had authority to assess when assessment was the focus of a segment. In terms of the teacher's authority for assessment, the teacher bore authority for corrective assessment most often, while authority for justification was the second highest. Note that due to varying segment lengths, these percentages are proportions of segments containing assessment activity, of which there were 143. Because segments could receive multiple codes, the totals do not add to 100%.

Table 3. Number of Segments Containing Assessment by Type

Type	**Student**	**Teacher**	**Both**
Correctness	11 (~8%)	69 (~48%)	7 (~5%)
Comparison	6 (~4%)	11 (~8%)	3 (~2%)
Quality	2 (~1%)	19 (~13%)	2 (~1%)
Justification	10 (~7%)	21 (~15%)	9 (~6%)
Reflective	8 (~5%)	2 (~1%)	0 (0%)

Discussion

As this work is preliminary, more analysis is needed to establish claims about trends throughout the course of the semester. In particular, as the content within abstract algebra increases in difficulty (e.g., quotient groups are commonly identified as a difficult topic), authority relations may shift more toward one of student, shared, or teacher. In particular, we wonder whether teachers are more likely to assess as content difficulty increases. In addition to the success of groupwork gambits at promoting student authority in whole class discussion, the very act of engaging in groupwork yields students some private authority to do mathematics, free of assessment from the teacher. While prior research indicates inequities in small group interactions due to social factors, such as influence (Engle et al. 2014), examining assessments on a small group level within an inquiry-oriented course could explore inequities related to mathematical authority, such as parsing whose ideas are assessed and how, as well as who bears authority to make such assessments. Future work may consider the following questions: Are marginalized students' ideas assessed only for correctness, as opposed to more mathematically demanding assessments for justification or quality? Do students of higher social status assess more often? More generally, what other activities can lead to students bearing authority?

Investigating the Resources Framework through the Lens of Analytic Autoethnography: Analyzing Research Questions and "Resource" Grain Size

Jon-Marc G. Rodriguez
University of Wisconsin - Milwaukee

There has been a recent trend in the application of fine-grained constructivist frameworks such as the resources framework; however, the resources framework has been operationalized in a variety of ways, particularly regarding analytic choices. In this work I seek to further discussions surrounding theory use and the ways frameworks may inform (1) research questions and (2) data analysis. Using an analytic autoethnographic approach, I characterize the variation in the application of the resources framework in my own work (n=10). This allows me to provide specific examples without evaluating the quality of colleagues' research, as well as contextualize the research within my experiences and within the broader norms of the chemistry education research community. To this end, I discuss alignment between the research questions and the resources framework and demonstrate variation in how "cognitive units" were operationalized. As an implication, suggestions are made regarding future work using the resources framework.

Keywords: theory; cross-disciplinary; research questions; methodologies

Background

Rationale and Scope

This work is part of a broader interest in furthering a dialogue related to methods and theory use in education research, which is of interest to the RUME community (Haas et al., 2022; Melhuish & Czocher, 2022). Last year at RUME I presented on a preliminary report that focused on the presence and use of frameworks across discipline-based education research (DBER) articles (Rodriguez & Nardo, 2023); this work was recently published as a systematic review in *Chemistry Education Research and Practice* (Rodriguez et al., 2023). As part of this review, we noted the potential for frameworks to connect DBER fields, "Therefore, it is more than shared disciplinary skills, language, and concepts that connect DBER communities. We are connected by theories and frameworks related to concerns such as how students learn and how to promote conceptual change." (Rodriguez et al., 2023). Illustrating the potential bridging connection afforded by theory, we noted research articles in the review sample across chemistry (Kelly et al., 2021; Parobek et al., 2021; Watts et al., 2021), mathematics (Abu-Ghalyoun, 2021), and physics (Barth-Cohen et al., 2021; Goodhew et al., 2021; Robertson et al., 2021) that used fine-grained constructivism as the theoretical framework. Nevertheless, although frameworks may be used across fields, there may be variation in their application. This work focuses on variation in theory use *within* a field (chemistry education research, CER), focusing specifically on analyzing my work that utilized the resources framework.

To this end, this work is guided by the research question: Across n=10 research articles involving the application of the resources framework to investigate undergraduate chemistry students' reasoning, what trends emerge related to the ways the resources framework informs: (1) the research question(s) and (2) analytic decisions?

Resources Framework

In brief, the resources framework is a constructivist-based theory used to model the nature and structure of knowledge, emphasizing the "fine-grained" and context-dependent nature of knowledge and describing the mechanism of conceptual change involving the gradual restructuring of a network of cognitive units ("resources") (diSessa & Wagner, 2005; Elby, 2000). For a theory of learning to be useful for education researchers it must: support prediction, possess explanatory power, be applicable to a broad range of phenomena, help organize thinking about phenomena, serve as a tool for analysis, and provide a language for communicating about learning (Dubinsky, 2001; Schoenfeld, 1998). I have found the resources framework to meet these criteria, using the framework to predict and explain patterns in student responses across contexts, informing how I think about students' reasoning, and influencing how I analyze data. Nevertheless, to improve teaching and learning we need to further refine the methods and theories that inform how we conduct research, employing an analytic agenda that emphasizes theory-building and the evaluation of theory.

Analytic autoethnography

Generally, ethnography is a field of study that emphasizes interpreting culture and its products, with autoethnography highlighting and leveraging the experiences of the researcher in this process (Adams et al., 2017). Acknowledging variation in the goals for studies within autoethnography, Anderson (2006) highlights a subgenre called analytic autoethnography. Here, the modifier *analytic* is used to draw attention to research aims focused on the analysis of empirical data that contributes toward theory development. To this end, the intended output of this work is a refined understanding of how to model cognition with a practical concern related to the ways it informs project scope and its application in data analysis. I view this as personally relevant in my application of theory but also seek to provide support for other researchers, particularly new and emerging researchers.

In the current study, the culture that serves as context for this work is the CER community of practice. The boundaries of a community of practice are defined through shared goals and norms, but these boundaries can often be fluid and complex (Wenger, 1998). This is especially true given the connections made between communities through boundary objects (e.g., journal articles) and brokers (e.g., researchers attending conferences), which could result in a "constellation" of interconnected communities of practice (p.127).

Data Collection & Analysis

For the purposes of this report, I narrowed the scope of the sample to include research articles involving the analysis of undergraduate chemistry students' reasoning where the resources framework was explicitly discussed as the theoretical framework (n=10) (Bain et al., 2018, 2019; Rodriguez et al., 2018; Rodriguez, Bain, Hux, et al., 2019; Rodriguez, Bain, & Towns, 2019; Rodriguez, Bain, Towns, et al., 2019; Rodriguez, Hux, et al., 2019; Rodriguez, Bain, et al., 2020; Rodriguez et al., 2021; Rodriguez & Towns, 2019). Analysis was guided by the research question presented above emphasizing the research question(s) and analytic decisions of the articles in the sample.

With regard to analyzing the research questions in the sample, I applied a framework that was developed in the context of ethnography (Spradley, 1980). The framework describes nine dimensions an ethnographer should attend to when collecting observational data: *space* (physical location), *object* (physical or cognitive entities), *actor* (individuals involved), *action* (behaviors and activities carried out by individuals), *time* (sequencing in a process), and *goal* (individuals' aims). Here, *object* has been adapted to include not just the physical entities but also cognitive or mental entities to afford a focus on students' knowledge and reasoning, as suggested by Melhuish and Czocher (2022); also, *act*, a*ctivity*, and e*vent* will be collectively described as *actions* for this work because the distinction between these types of observable behaviors is less relevant here. As discussed by Melhuish and Czocher (2022), this framework serves as a useful tool for discussing qualitative research questions, and in this work, analysis focused on the presence of different dimensions in the phrasing of the research questions, as well as the nature of the research question phrasing in relation to exploring relationships between dimensions and its connection to the resources framework. In terms of the analytic decisions expressed in the sample, analysis focused on the ways the framework was operationalized with an emphasis on the "size" of the identified resources. Additional analysis involved inductively grouping articles based on patterns related to the research questions and grain size. Throughout this process I engaged in reflexivity, which contributes to trustworthiness and validity of claims (Vagle, 2009, 2018). As a member of the CER community of practice, I'm familiar with expectations related to theory use in research. I implicitly interact with these norms as a producer (when publishing CER articles, presenting at CER conferences, etc.) and consumer (when reading CER articles, listening to presentations at CER conferences, etc.) but I also explicitly communicate these norms as an evaluator (when reviewing articles for a journal). The specific examples of articles discussed in the next section were selected to maximize variation, and I encourage interested readers to reference the articles if additional context is needed.

Preliminary Findings

Research Questions

Across the sample, the research questions tended to involve slight variations of the *actor-action-object* triad, where the stated goal was to elicit students' (*actor)* chemistry knowledge (*object*) using an interview task (*action*). References were not made to the other dimensions (*space*, *time*, *goal*). For example, in Rodriguez et al. (2021), our research question used problem-solving (*action)* as way to characterize students' (*actor*) understanding related to emergent properties and molecular behavior in a system (*object)*, *How do students use assumptions regarding system ontology to solve enzyme kinetics problems on an exam?* According to Melhuish and Czocher (2022), research questions that follow this pattern tend to have a singular focus and suggest a list as the research outcome. Although there was some variation with the research questions, this involved: an implicit reference to the *action* (the task is unspecified) – e.g., *How do students reason about rate constants in chemical kinetics?* (Bain et al., 2019); and multiple *objects* identified related to an interest in students' blending of chemistry and mathematics knowledge – e.g., *In what ways do students use mathematics in combination with their knowledge of chemistry and chemical kinetics to interpret concentration versus time graphs?* (Rodriguez, Bain, Towns, et al., 2019). The latter example moves closer to a relational focus that emphasizes connections between dimensions in the research question (Melhuish & Czocher, 2022).

Grain Size

As discussed by Wittmann (2006), resources can be described as fractal in nature: a cognitive unit described as a *resource* could be divided into a cluster of smaller resources. This is consistent with how I've observed the resources framework used in my work and others' broadly. Although this provides flexibility related to analytic decisions, this flexibility contributes to challenges with its application and defines the focus of this work. In the current work, thematic grouping resulted in the following grain sizes depicted in Figure 1: *p-prim*, *distributed element*, *concept projection*, and *frame*. Apart from *frame*, these terms are taken directly from the class of theoretical models outlined within knowledge-in-pieces (diSessa et al., 2016), the implications of which are discussed below.

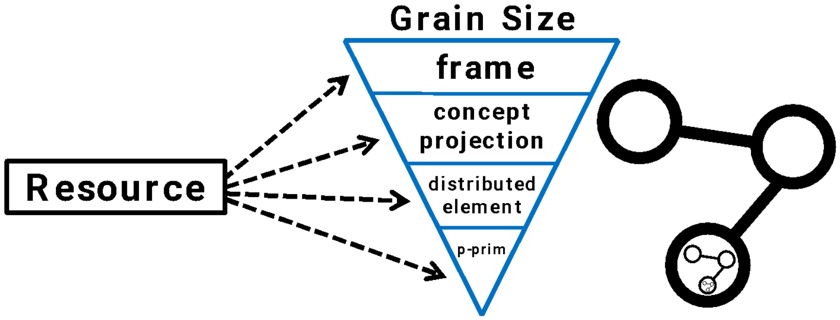

Figure 1. Variation in grain size observed in the articles.

Frames describe the expectations individuals have about a situation, which is important because of the ways epistemological frames may mediate the activation and use of knowledge (Redish, 2004). *Concept projection* is a reference to coordination class theory, which defines a *concept* and the mechanism of conceptual change within the knowledge-in-pieces perspective (diSessa et al., 2016; diSessa & Sherin, 1998; diSessa & Wagner, 2005). Here, *concept* (or *coordination class)* is defined as the combination of an inferential net (network of knowledge elements) and extractions (features attended to); it is the coordination of the knowledge component and perceptual component that allows students to “see” a *concept*. In practice, a *coordination class* would be a large cognitive structure and individuals use a subset of that knowledge when solving a task, a *concept projection*. Additionally, *distributed element* is a reference to specific knowledge elements within a *concept projection*. Lastly, *p-prims* (phenomenological primitives) are the smallest functional unit within a fine-grain constructivist view, reflecting intuitive knowledge that is self-explanatory and developed based on experiences (e.g., *dying away* is abstracted based on the observation that physical phenomena such as motion or sound tend to dissipate over time). In the next sections I will provide examples, focusing on distinguishing between *distributed element* and *concept projection*.

In Bain, Rodriguez, and Towns (2019) we analyzed students’ reasoning related to the rate constant (*k*, a parameter relevant when discussing equations related to chemical kinetics). Some examples of the resources identified are *rate and rate constant as directly proportional* and *k is defined by the Arrhenius equation*. What I would like to draw attention to here is that these cognitive units are all narrowly focused on the rate constant and are phrased as statements (inferential or propositional statements), which provide a certain level of specificity, negating the need for a formal code description. This focus and specificity make the resources too small to be a larger cognitive structure like a *concept projection,* but are larger than *p-prims*, thus, described here as *distributed elements*.

In Rodriguez and Towns (2019), we analyzed how students reason about competitive, non-competitive, and uncompetitive enzyme inhibition. In this case, the inductive codes reflect cognitive units that are broader and larger than the *distributed elements* discussed above: *competitive inhibition, mechanism*; *non-competitive inhibition, mechanism*; *uncompetitive inhibition, mechanism*. Each of these codes has a general description: “Student discusses what physically happens with this inhibitor in a general sense or at the molecular level". Here, the codes are not statements and phrases related to a topic, but rather terms referencing broad discussions. Other examples might be codes such as *equilibrium, acid-base reactions*, *chemical kinetics*, etc., where the code description emphasizes that students "discussed" this topic, as opposed to stating the specific details students articulated about the topic. In the study referenced here, each of the different inhibition types can be described as a different *concept projection.*

Discussion

Reflecting on the connection between the research questions in the sample and the resources framework, only listing resources does not leverage the potential power of fine-grained constructivist frameworks in making claims related to the nature and structure of students' knowledge and its dependence on context (i.e., span and alignment) and time (i.e., conceptual change) (diSessa et al., 2016). As part of this, for researchers interested in applying the resources framework, there is room for incorporating more considerations related to other dimensions and relational aims across these dimensions, such as emphasizing how students' knowledge structures change over time (e.g., *How do chemistry majors' knowledge structures related to reaction rate change as they move through the undergraduate chemistry curriculum?).*

Regarding resource grain size, my plan for this analysis was to provide theoretical clarity related to the resources framework. I initially planned on avoiding making claims related to discussing the relationship between the knowledge-in-pieces and resources frameworks, but I found the language from knowledge-in-pieces to be helpful for describing the variation within the resources framework. According to diSessa (2016), the resources framework builds on knowledge-in-pieces providing language to discuss general nodes with varying structure and function within a knowledge system, but "resources are not particular kinds of knowledge elements" (p.58). Aligned with this, I discussed above that a resource could be different types of knowledge elements: a *p-prim*, *distributed element*, *concept projection*, or *frame*. Given a resource can vary in, for clarity, it is important that researchers are very clear in describing the scale of the knowledge they are analyzing. This does not necessarily have to involve the use of the terms discussed above, but detailed descriptions are important, such as "We are identifying resources at the level of evaluating students' inferential and propositional statements". As a disclaimer, these discrete resource sizes are just a few observable sizes within the data analyzed, and although they have a specific rank order, these are not all the possible grain sizes and the scale or distance between these levels are not necessarily equal. Moreover, there could also be dynamic interplay as multiple scales are considered, such as analyzing *frames* of individuals and groups (Conlin & Hammer, 2016).

Lastly, as a practical consideration, depending on choices related to the grain size in analysis there may be some drawbacks. For example, the resolution provided by coding at the *concept projection* level is too coarse to allow discussions regarding the connections students' make within a concept, with additional analysis needed (e.g., constructing resource graphs from a line-by-line analysis of an interview since the coded resources are too broad to afford claims about the structure of students' knowledge). On the other hand, the challenge with analysis at the *distributed element* level is that coding individual students' responses may be too idiosyncratic, resulting in concerns related to saturation of themes and workload when looking at large samples related to student responses on open-ended surveys and exam questions. Nevertheless, narrative coding and smaller samples involving selected episodes and cases (Rodriguez, Stricker, et al., 2020) aligns more with the approach toward knowledge analysis described by diSessa et al. (2016). Balancing the analytic tensions with the scope reflects on area warranting further inquiry.

Student Interpretations of Conditional Statements in Probability: The Cases of Byron and Sophie

Megan Ryals
University of Virginia

Morgan Sellers
Colorado Mesa University

Students often have to interpret conditional statements in mathematics classes without prior training in logic. In a previous study, we investigated how students interpreted variants of the conditional statement: If two random variables are independent, their covariance is 0. The purpose of the current study is to explore surprising results and apparent inconsistencies in student interpretations using clinical interviews after a lecture introducing the conditional statement. In this paper we contrast the experiences of two students, Byron and Sophie. Preliminary results suggest that Byron relies both on his logic training and his domain knowledge to solve problems about independence and covariance. Sophie's incorrect domain knowledge led to her reversing the implication. Once this was resolved, she was not confident in assigning truth values to statement variants. We discuss teaching implications that arise from issues of both mathematical efficiency and accuracy in presenting this theorem.

Keywords: Probability, Conditional Statements, Logic, Covariance, Independence

Undergraduate math courses typically present multiple definitions and theorems in the form of conditional statements. We know students often do not interpret these statements in the mathematically normative manner, and learning how to interpret conditional statements is particularly challenging due to epistemic issues related to set-theoretic components of conditional statements (Case, 2015; Dawkins & Cook, 2017; Durst & Kaschner, 2020; Sellers, 2020). In a previous study (Ryals, et al., 2023), we analyzed Probability students' written work to determine how they interpreted and used the following theorem: "If X and Y are independent random variables, then $\text{Cov}(X, Y) = 0$" (Casella & Berger, 2002, p. 171). We also considered whether students' prior logic training, or lack thereof, would impact their interpretations. Approximately 1/3 of the participants incorrectly used covariance being 0 as justification for two random variables being independent, and 10% of students failed to use covariance being nonzero as justification for variables being dependent. The results did not significantly differ for students who had and had not previously received logic training in a prior course.

In Spring 2023, we began conducting clinical interviews (Clement, 2000) with students in the same course in an effort to investigate results from our prior study. Specifically, we address:

1. How do students view the relationship between covariance and independence?

2. How does their view of this relationship influence how they use the value of covariance to determine and justify whether two variables are independent?

In this report, we present preliminary findings from interviews with two students, Byron and Sophie. We discuss and compare their conceptions of covariance and independence and the relationship between the two as well as how and why they used covariance values to determine independence of two random variables.

Review of Literature

For multiple reasons, students often do not interpret conditional statements in conventional ways and the same student can interpret logically equivalent statements differently in different contexts (Dawkins & Cook, 2017; Durand-Guerrier, 2003). Students often interpret conditional statements as biconditionals (Hoyles & Küchemann, 2002; O'Brien et al., 1971; Wason, 1968) which is often *intended* in common language (Epp, 2003). Moreover, a statement indicating P implies Q, devoid of quantified variables, is an open sentence, which could be considered true for one case and false for another (Durand-Guerrier, 2003). Yet, mathematicians typically read these statements as generalized conditional statements. This means we interpret our theorem as saying "*For all pairs* of random variables, if X, Y are independent, then $\text{Cov}[X, Y] = 0$." However, the implicit "for all" quantifier is not typically stated explicitly, which understandably leads to non-normative evaluations for some students (Durst and Kaschner, 2020).

Efforts have been made to improve teaching students how to interpret conditional statements appropriately within the mathematics register (Dawkins & Norton, 2022; Dawkins, et al., 2023). Evidence suggests students have an easier time interpreting verbal and mathematical statements than abstract or symbolic ones. Consequently, one approach has been to use colloquial statements whose inverse, converse, and contrapositive are obviously true or false to students through context or familiarity as an introduction to the topic (Case, 2015; Epp, 2003, Stylianides et al., 2004). However, training students to generally place a label of "true" or "false" on specific variants such as the converse has not proven to transfer to using those variants appropriately in novel situations in mathematics (Sellers et al., 2017; Attridge et. al, 2016; Cheng et. al, 1986; Inglis & Simpson, 2008). This implies that many students have not fully abstracted logic rules with conditional statements across different mathematical domains. Thus, there is a need to study how students interpret conditional statements in different mathematical contexts and determine how mathematical content of a particular statement may impact students' logical inference.

Methods

Data Collection

This study was conducted in Spring 2023 in a semester-long Applied Probability course designed for engineering and computer science majors. The first author taught the lesson introducing the theorem to four sections of the course. After presenting the theorem, students were asked to individually determine whether each of the three variants listed below was true or false in a pre-class quiz. In this paper, we subsequently refer to these statements as the inverse, converse, and contrapositive, respectively, though we did not use this terminology with students.

1. *Theorem: If X and Y are independent random variables, then $Cov(X, Y) = 0$.*
2. *Inverse: If X and Y are not independent, then Cov (X,Y) ≠ 0.*
3. *Converse: If Cov (X,Y) = 0, then X and Y are independent.*
4. *Contrapositive: If Cov (X,Y) ≠ 0, then X and Y are not independent.*

After the quiz, the instructor clarified the fourth statement was true and the second and third statements were false and explained it is possible for two random variables to have a nonlinear relationship and have a covariance of 0. The instructor then worked through two examples related to the theorem. Each required first determining whether variables were independent and then finding the value of covariance. In one example, the variables were independent, so the theorem could be invoked to conclude the covariance was 0. In the other, the variables were not independent, so the covariance had to be calculated. These examples were chosen to demonstrate the theorem's utility in specific situations and limitations in others.

Following a brief discussion, students individually solved two similar problems. In each problem, they were given a joint probability mass function (Figure 1) and first asked to compute covariance and then determine whether X and Y were independent. In the first example, covariance was 0 so independence had to be determined using the definition of independence. In the second example, the covariance was not 0 so dependence was guaranteed. We will subsequently refer to these examples as the Converse problem and the Contrapositive problem, respectively.

X / Y	-1	0	1	$P_Y(y)$
-1	0.2	0	0.2	0.4
0	0	0.2	0	0.2
1	0.2	0	0.2	0.4
$P_X(x)$	0.4	0.2	0.4	

X / Y	0	1	2	$P_Y(y)$
0	0.1	0.2	0.2	0.5
2	0.1	0.25	0.15	0.5
$P_X(x)$	0.2	0.45	0.35	

Figure 1. Probability Distributions used in the Converse and Contrapositive Problems

We invited all students who had either used the converse on the Converse problem or neglected to use the contrapositive on the Contrapositive problem to participate in a 30-60 minute semi-structured interview. Three students agreed to be interviewed one week after instruction and prior to any formal assessments on the topic. The first author was the primary interviewer and the second author prompted the first with additional questions. We used a prepared protocol but allowed for both follow-up questions and probes (Rubin & Rubin, 2005). During the interview, students were asked to provide definitions of covariance and independence and justify their in-class work. We then presented several colloquial statements and asked the students to provide truth values for those statements and their variants to check for consistency or inconsistencies in logic across different mathematical domains.

Analytic Framework and Analysis

During the interviews and throughout analysis we attempted to construct second-order models of students' thinking about their domain knowledge and logic; "those the observer constructs of the subject's knowledge in order to explain their observations or experience of the [student's statements] and activities" (Steffe et al., 1983, p xvi). To achieve this goal, we asked multiple follow-up questions during the interview and the authors discussed multiple possible interpretations of student claims to come to consensus.

We developed several categories of codes related to specific interview questions. Our first group of codes described the participant's conceptions of independence and covariance. We paid particular attention to whether these were formalized or intuitive notions, whether they were normative, and whether linearity was part of the covariance description. We asked them to describe any mental images that they may have had in relation to covariance, in particular. Our second group of codes addressed their beliefs about the relationship between independence and covariance. Finally, a third group of codes attended primarily to responses to questions involving everyday statements to describe the participant's approach to determining truth values of conditional statements in various contexts. In the subsequent section, we present results for two participants, Byron and Sophie, which includes their conceptions of independence and covariance and the relationship between them as well as their level of comfort with logical equivalence. We then draw comparisons between the two and discuss implications for practice.

Results

Byron was invited to participate in the interviews because he did not use the fact that covariance was nonzero to conclude variables were dependent on the end-of-class exercise.

Instead, Byron correctly applied the definition of independence. Byron's approach was particularly interesting since he had identified the contrapositive as true on the pre-class quiz and he had previously taken Discrete Math.

The interview revealed that Byron held normative and robust mental images related to both independence and covariance. He provided both the formal definition of independence as well as an explanation, saying "I think that means the observed value of one of them will not affect what you'll observe for the other." Byron stated that covariance was a measure of a linear relationship and stated that variables could have a relationship that was not linear. He provided an example, saying "…if all of your data fell on a circle, [the two variables] would have a relationship. But I think…the covariance would come out to exactly 0 if it was exactly on a circle." Additionally, Byron was clear about the claims and limits of the theorem. He stated that independence guarantees a covariance of 0 but a covariance of 0 does not guarantee independence.

Byron had not made use of the theorem on the end-of-class Contrapositive problem, which seems surprising in light of the evidence above. However, when he was asked if there was an alternative way he could have justified X and Y being dependent, he immediately said, "Oh yeah, I do remember now. If two random variables are independent, their covariance is 0, is equivalent to saying if their covariance is not 0, they are not independent. So I guess you can tell from [the fact the covariance is not 0] that they're also not independent."

First, we hypothesize that Byron may have been influenced to use the definition of independence on the Contrapositive problem, rather than invoking the theorem, by the examples worked by the instructor just moments before. In the interview, when asked about these two approaches, Byron said they are equally valid, and that invoking the theorem would make more sense in the case where a nonzero covariance has already been established. Second, we note that Byron introduced the word "equivalent" to explain the relationship between the statement and its contrapositive. He made the same argument to justify his choice of truth value for a variant of a colloquial statement, this time introducing the word "contrapositive," which we had not used in the interview. With this example, he used logical equivalence of the contrapositive as his primary justification for his provided truth value.

Sophie, who had not previously taken Discrete Math, was invited for an interview because she stated that X and Y must be independent because $\mathrm{E}[XY] = \mathrm{E}[X]E[Y]$ on the Converse problem. We coded this response as Applying the Converse. Consistently, Sophie had classified the converse statement as true on the pre-class quiz.

Sophie demonstrated a conceptual understanding of independence by comparing selection with and without replacement. However, Sophie's concept of covariance was influenced and limited by a graphic presented in lecture. When asked what it means to say $\mathrm{Cov}[X, Y] = 0$, she replied, "it means that X and Y are not correlated, so the graph would be more like no pattern, a bunch of scattered dots everywhere." A graphical depiction of dependent variables with a covariance of 0 had not been presented. Additionally, when asked what it meant for two random variables to be independent, she responded, "When the expected value of both of them equals the expected value of each of them multiplied." That is, Sophie believed that two variables are independent *if and only if* $E[XY] = E[X]E[Y]$. This was further clarified when we presented Sophie with a situation where $\mathrm{Cov}[X, Y] = 0$ and she concluded X and Y must be independent. Sophie was not intentionally applying the converse. Rather, Sophie had believed she was checking independence *directly using the definition*. Accepting Sophie's definition of independence would also mean believing the theorem is a *biconditional* statement. Yet, Sophie was unsure about this claim because of what she remembered from class.

Interviewer: What is [covariance] comes out to 0; what will that tell you, if anything?
Participant: I think what I wanna say is that they're independent, but (*pause*)
Interviewer: How confident would you be on a scale of 1-10?
Participant: Probably like 5. I don't know. I remember you saying something in class, like there's a caveat.

At this point Sophie believed a covariance of 0 guarantees independence because of her definition of independence, but she did not believe independence guarantees a covariance of 0 because she remembered from lecture there was a "caveat." Sophie was then prompted to review the definition of independence as well as the theorem written in her notes. She quickly revised her claim about the relationship between independence and covariance.

> "Now I'm thinking if they're independent based on that equation, then covariance should equal 0, but then if they're not independent, covariance can still equal 0. But they're not related inextricably. It's like a weird relationship."

At this point Sophie believed independence guaranteed a covariance of 0 but not the reverse. However, when prompted, she could not produce an example of two dependent variables with a covariance of 0. Moreover, she was still hesitant to provide truth values of the statement variants. When Sophie was asked about her pre-class quiz response of false to the contrapositive, she first claimed that response was incorrect, but then hesitated and ultimately did not provide a definitive answer. She responded similarly to a prompt about the contrapositive of one of the everyday statements later in the interview and relied primarily on context rather than logical equivalence.

Discussion

Byron has two distinct advantages over Sophie. First, since his concept of covariance involves linearity, he can conceive of dependent pairs of random variables with a covariance of 0. He can reference his domain knowledge to determine truth values of variants of the theorem. Secondly, he can avoid referencing his domain knowledge when expedient because he is assured of which statements are logically equivalent. Our analysis of Byron suggests that Probability students may rely on their logic training to quickly assess the truth value of variants of conditional statements, regardless of whether they are focused on the mathematical content in the predicate of a conditional statement. On the other hand, a student who avoids using the contrapositive could simply be relying on their knowledge of the mathematics of the statement.

Sophie demonstrates how gaps in domain knowledge, and specifically lack of counterexamples, can prevent students from determining which conditions imply others and lead them to rely on memorization. The power of examples in justification has been noted already in the literature (Zazkis, et al., 2008). We strongly suspect that instructors including a graphical depiction of dependent variables with a covariance of 0 when introducing covariance would have established for Sophie that the theorem's converse was false. Even so, without a strong notion of logical equivalence, truth values of the inverse and contrapositive would still not be obvious. We do not know at this point whether prior logic training gives students an advantage in Probability courses, especially in light of our previous study (Ryals, et al., 2023). However, we certainly value the flexibility Byron had in using both his domain knowledge and logical inference to answer questions confidently. We need to conduct further interviews or larger-scale surveys with more students who have taken Discrete Math and those who have not to make appropriate conclusions regarding logic training. Also, absent from our participants thus far were students who stated the converse was false on the pre-class quiz but then used it during the exercises. We plan to repeat the in-class instruction and invite more interview participants.

While there is evidence that college students benefit from classroom activities that engage them, a shift in instruction from the lecture style of teaching to methods where students are actively involved in their learning is difficult to generate. This study focuses on providing structure and support for college algebra instructors to implement evidence-based instructional practices. We interviewed participants each semester they were involved with this project to gain insight into their perspectives on their teaching practices. We also video-recorded three lessons each semester when participants were implementing co-constructed in-class materials. Initial results showed how collaboration empowered instructors to implement evidence-based instructional practices in their class. Additionally, even though instructors collaborated to co-create in-class materials, results showed variation in their implementation styles as they moved towards more student-centered practices.

Key words: Professional Development, Active Learning, Instructional Change

College students' learning and conceptual understandings of mathematics benefit from instruction that actively engages students in their learning (e.g., Kogan & Laursen, 2014). Although there have been numerous calls to increase student engagement in college mathematics classrooms (CBMS, 2016; PCAST, 2012), lecture (where instructors present information and students receive it) remains the most prominent form of instruction (Stains et al., 2018). Notably, instructional change is difficult to catalyze, especially amongst college-level instructors (Fairweather, 2008; Henderson & Dancy, 2007). Shadle et al. (2017) identified several barriers to implementing practices that actively engage students and drivers that foster instructional change and support college instructors in adopting evidence based instructional practices (EBIPs). The project described in this report aims to better understand how a particular form of a professional learning community (PLC) can encourage the adoption of EBIPs by college mathematics instructors. We address the research question: In what ways does the structure and goals of the PLC support college algebra instructors in making changes in their teaching?

This study is part of a larger ongoing funded project of collaborative instructional improvement at the university level, aiming to support the implementation of EBIPs that actively engage students with the course content (NSF IUSE: HSI #2116187). The project supports the development of a PLC of instructors of all sections of a university-level college algebra course at a single large, southwestern, Hispanic-serving institution. Before the start of the project, the mathematics department had recently implemented a strong effort of course coordination, including a leadership structure with a coordinator for every multi-section course, weekly or bi-weekly meetings of all the instructors of the course, and aligned assessment procedures, instruments, and structures. Additionally, the college algebra team chose to implement innovative assessment techniques in the semester before this project began.

Theoretical Framework

The theoretical framing that guided the design of this project is the Ethic of Practicality (Doyle & Ponder, 1977), which describes the factors teachers consider when deciding whether innovative curricula is practical or realistic for implementation in the context of an actual classroom. Doyle and Ponder (1977) argue that in order for curriculum to be considered practical, it must: (a) Be compatible with the instructor's classroom, setting, and instructional goals (congruence); (b) Have potential benefits (e.g., student outcomes, student attitudes) that outweigh the effort and other costs of implementation (cost); and (c) Consist of clearly articulated procedures for ease of implementation in the instructor's classroom (instrumentality).

The Continuous Improvement (CI; Berk & Hiebert, 2009) framework began as a roadmap for instructional improvement within courses for preservice teachers, but its alignment with the backwards design principles for lessons are broadly applicable (Wiggins & McTighe, 2005). These principles advocate for planning lessons by first defining the student learning outcomes and the aligned assessment and then designing the in-class task. As part of this project, instructors worked as a group to implement CI cycles (Berk & Hiebert, 2009) to develop and facilitate lessons on particular course topics. In this model, each semester participants isolated specific lessons and implemented the following cycle: 1) *Design a task* that targets a particular student misconception or deepens understanding of a particular mathematical idea based on existing research on student learning about that concept. 2) Develop hypotheses about *anticipated student responses*. 3) *Collect data* in the form of student work and classroom recordings and *analyze the data* for evidence of the desired student learning outcomes. 4) *Record this information* and use it to revise the task for use in subsequent iterations of the course.

Instructors chose to create and use Desmos Classroom activities as a way to incorporate EBIPs in their teaching. Although instructors differed in how they used these activities (with some soliciting and leveraging student thinking more than others), they mostly gave students time to work individually or in small groups before discussing the activities in class. The CI model was a natural fit for a project guided by the Practicality Ethic. The model empowers instructors to make choices about curricular revisions and drive decisions about implementation and the CI framework leverages the knowledge, experience and priorities of instructors to guide these changes; thus, it maximizes congruence. Additionally, in order to maximize instrumentality and minimize cost, we used project funds to secure course releases for college algebra instructors so that they would have time and space to implement the CI cycles and participate in the PLC.

Methods

This report focuses on two participants who were full-time fixed-term faculty participating in the PLC instructional improvement project: Alex and Ivy. While Alex and Ivy were involved in the project, the course coordinators, Nicholas and Shay, also participated in the project. In the final semester of Alex's and Ivy's participation, two more instructors joined. Data were collected over the first three full academic semesters that these instructors were involved, which were also within the first two years they taught the course at this institution. Instructors were interviewed each semester. Interviews were semi-structured and included questions that prompted instructors to describe their teaching practices and participation in the project activities. We also collected class video data. In the first semester one lesson was filmed, and this recording served as a snapshot for what instruction looked like before implementing lessons co-created as part of the project. During the second semester, we filmed three lessons when the instructors taught lessons that were co-created by all the members of the instructional / PLC team.

Interviews were analyzed using thematic analysis (Braun & Clarke, 2006). We focused on coding segments that shed light on instructional practices in the context of the collaboration and coordination within the project. Multiple people from the research team reviewed the interview transcripts and identified representative quotes. Video from the filmed lessons were coded by at least two people from the research team using the College Observation Protocol for Undergraduate STEM (COPUS; Smith et al., 2013). Researchers coded the recordings individually and then met to discuss coding decisions and to reach consensus. After the filmed lessons were coded, we used the collapsed codes of Instructor Presenting, Instructor Guiding, Student Receiving, Student Working, and Students Talking in order to create radar plots of the percentage of class time where students and the instructor were engaged in these activities (Reisner et al., 2020). Collapsed codes grouped together codes that captured similar behaviors. For a detailed description of the codes grouped in these collapsed codes see Smith et al. (2014).

Results

It was clear from the interviews with instructors that the collaboration and support in the context of this project enabled them to try new things in their classes. For example, Alex described how watching other instructors implement different lessons gave him ideas of what to try in his class. He also highlighted how he was motivated to continue trying new things as the semester progressed instead of primarily lecturing. He said:

> Because of the grant I'm refreshing and recycling through different strategies much more than I think I would. I think normally I would just settle into what's easy, which might end up looking like semi-lecture style … But this time I randomly was pushing my students to do more group work. And I wouldn't have been doing that if it wasn't for the grant and seeing all the [other instructors use] group work.

This quote helps illustrate that there was a sense of accountability to keep implementing EBIPs amongst the instructors, as well as support. Alex emphasized, “I don’t have to worry if what I’m doing in the classroom is good enough because it’s what everyone else is doing and we’re all trying it together.”

Ivy also commented on how she tried new things because of the collaboration and coordination of the course. She said, “I've always wanted to do the flipped classroom, and I'm getting the benefit of seeing how it works right now.” In another part of the interview, Ivy said that “peer pressure” enabled her to try more EBIPs in her classes. She went on to emphasize how having access to the co-created resources was important in her decision to implement more student-centered activities. She said:

> I have … more freedom to - I can explore this stuff. So the fact that Shay and Alex are doing all these activities, and they're amazing, so I've got all these resources. My experience was lecture, and now I get to try the things I've always wanted to try. So I'm loving it. I love the activities, and I'll be honest, at the start of the semester, I was like, ‘Oh, we're going to do this now?’ because I didn't know how powerful it was. … And yeah, it's just cool to see everything that we can do with [Desmos], and it really helps the students understand.

In addition to instructors discussing how participating in this project enabled them to implement more EBIPs in their teaching, the analysis of what happened in class (as measured by the COPUS; Smith et al., 2013) indicated that there was some instructional change that occurred. Before being involved with this project, Ivy spent most of class time lecturing while students listened and took notes (Instructor Presenting and Student Receiving), see Fall 2021 semester in Figure 1. As Ivy participated in co-creating Desmos activities to use during class time, her instruction shifted to include more time where students were working and she was guiding them, see Spring 2022 and Fall 2022 radar plots for the Algebraic Properties, Fractions, and Factoring lessons in Figure 1. In the following quote Ivy describes how she used the Desmos activities in her class.

> I think Nicholas and I take a more laid-back approach to the Desmos and let the students fight through it and ask us questions. Whereas the other four instructors this semester seem to do the pacing a whole lot more. And especially Shay, Shay is … really talking through every slide … Whereas Nicholas and I, instead of pacing them, … we let them pace themselves. … we take the more passive approach and answer individual questions.

Alex also demonstrated a shift in how he spent class time before and during the project. Before the project, he tended to spend a large percentage of class time presenting material (Instructor Presenting), see Fall 2021 in Figure 2, but then as he taught the lessons with the co-created instructional materials, he spent less time presenting. In the interview, Alex shared how he started to create more space for students to work through problems themselves or share their answers with the class. He said:

> From the interactive style that we would do with … the Desmos [activities], and then talking about it, I think that's how I was able to tie in with my lectures. Like even just having those long pauses to let the students answer I think I got better at doing all of that with the Desmos. And that helps with breaking it up. ... Even though it's like a lecture, I try to have some moments where we just really stop and think about a question.

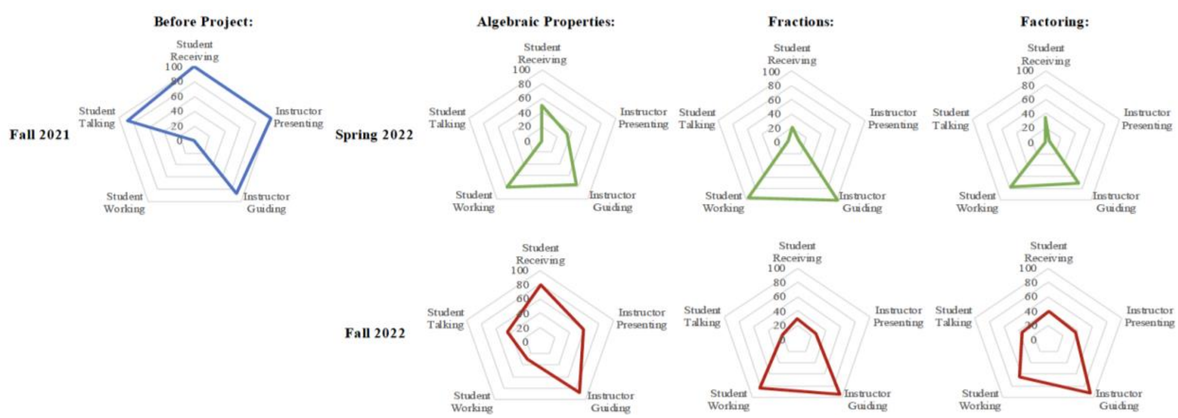

Figure 1. Radar plots by semester / lesson of the percentage of class time spent with Students Receiving, Talking, Working and the Instructor Presenting or Guiding for Ivy's recorded classes.

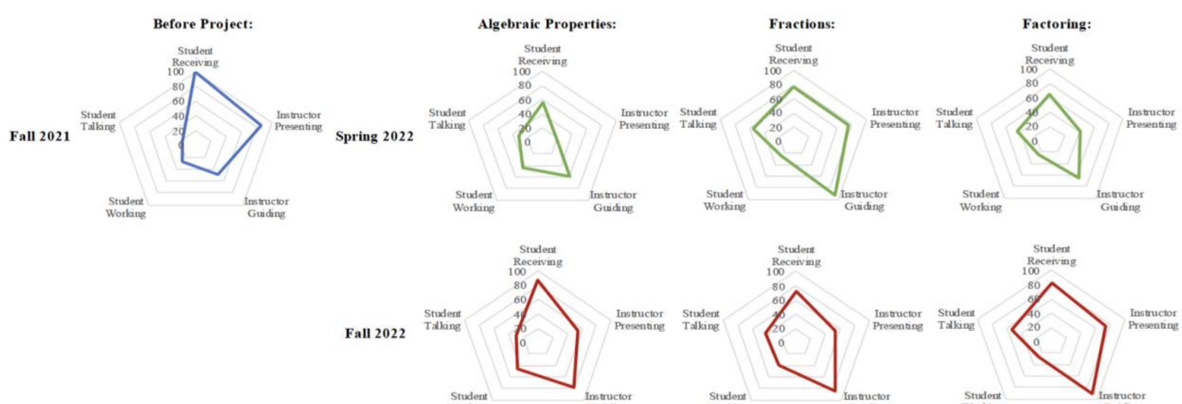

Figure 2. Radar plots by semester / lesson of the percentage of class time spent with Students Receiving, Talking, Working and the Instructor Presenting or Guiding for Alex's recorded classes.

Although the instructors co-created the Desmos materials as part of this project, it is important to notice that their implementation of the lessons varied (see Figures 1 and 2). That is, the analysis video data showed that the instructors (and their students) spent different amounts of class time with the instructor presenting or guiding and the students receiving, talking, or working. Each instructor had their own way of incorporating the materials into their instruction, retaining independence and control over what happened in their section(s). Ivy's quote above also points to these different approaches to implementing the co-created lessons, with her and Nicholas taking a more "passive approach" and Shay providing pacing and leading class discussions on nearly every slide of the Desmos activity.

Discussion

Instructors discussed how the project impacted the activities they did in class and their pedagogical decisions. The analysis of class video shows some differences in instructor and student activities over the course of three semesters. We hypothesize that the course coordination system in place allowed for "coordinated independence" (Rasmussen & Ellis, 2015), where instructors were encouraged to implement more evidence-based and student-centered activities while also retaining independence with their pedagogical and instructional decisions. In an interview that was conducted in the semester after her involvement with the project, Ivy said:

> For me the flipped classroom, it didn't work for my teaching style. … That was one of the reasons actually, that I asked to try to teach something else … so the flipped classroom was just... It just didn't work for me because I preferred to be more 'do it in the moment.'

This quote highlights that while participating in the project and teaching in this coordinated course, Ivy still used this style of teaching even though the "flipped classroom" did not align with her teaching preferences. The coordination and collaboration are also what empowered Alex to try different practices throughout the semester. Often, instructors may be isolated when attempting to adopt EBIPs, but the experiences of Alex and Ivy show how institutionally supported collaboration structures (such as course coordination) can be a powerful force in changing instruction.

Proof and proving are critical to the work of mathematicians, and in turn research on the teaching and learning of proof has historically been one of the larger strands of research presented at annual RUME conferences. In this project we systematically reviewed the RUME conference papers on mathematical proof from 2018-2023 to provide a picture of (a) the most prevalent topics of proof research in RUME, and (b) the data sources drawn upon in proof research methodologies in RUME. This review revealed the most frequent primary topics of RUME proof research to be proof instruction, assessment and feedback, and proof conceptions. We also noticed an overwhelming proportion of RUME proof research papers rely on qualitative data sources. Our continued work on this project will allow us to examine the impact research RUME has on the larger body of knowledge of undergraduate proof research.

Keywords: proof, research, literature review, methodology

Within the past six years, two major reviews of research on the teaching and learning of proof have been published (i.e., Stylianides et al., 2017; Stylianides et al., 2023), both casting a wide net and synthesizing research across K-16 mathematical contexts. In the first review, a contributed chapter in the Compendium for Research in Mathematics Education, Stylianides et al. (2017) examined the field of research on the teaching and learning of proof across K-16 mathematics education and classified the proof literature into three research perspectives: proof as problem solving, proof as convincing, and proof as a socially-embedded activity. In the second review, in a recent issue of ZDM-Mathematics Education, Stylianides et al. (2023) again examined the field of research on teaching and learning of proof across K-16 mathematics education, but this time classified the research according to the various didactic relationships emphasized between student, teacher, and mathematical content. We aim to add to the literature review work of these authors by (a) focusing exclusively on recent research accepted and published in the RUME proceedings, (b) taking a more emergent approach to identifying topics studied by proof researchers, and (c) attending to the methods utilized by proof researchers.

The reasons for isolating our literature search to RUME conference proceedings are threefold. First, by focusing on the RUME conference proceedings, we can better understand how this community of scholars is approaching proof research and empower the community to recognize its strengths and areas for growth. Second, we argue the RUME conference proceedings can indicate the most up-to-date trends in research, as the conference accepts contributed, preliminary, and theoretical proposals, providing a space for researchers to share early ideas and research-in-progress. Third, confining our literature search to RUME conference papers will enable us to later observe patterns in how proof research presented at the RUME conference evolves (or fails to evolve) into eventual journal publication, providing greater insight into the impact of the community's work.

Our goals in this review are to, in RUME, (1) identify trends in topics of proof research and (2) identify trends in methods of proof research. Specifically, our research questions are:

1. When RUME researchers study proof, what topics are they investigating? (In other words, what are they studying as it relates to proof?)
2. When RUME researchers study proof, what data sources are they drawing upon? (In other words, through what mechanism(s) are they telling the story of their research?)

Theoretical Framing: Advocating for Variability of Topics and Methods

In this research, we come from a pragmatic perspective, which assumes "knowledge guides method while method also guides knowledge" (Paul, 2005, p. 46). In this way, we seek to understand both the topics proof researchers are attending to in their research and the methods they are using to do so. We believe that variability in both the topics of investigation and methods of investigation can lead to a field of research that is more robust and has greater impact on practice. We draw from Stoecker and Avila (2021), who describe the benefits of addressing complexity of topics through variability of methods:

> From [a mixed-methods research] perspective, quantitative and qualitative methods are complementary, each compensating for the other's weaknesses in studying complexity. […] Greene (2007) and Clark and Ivankova (2016) believe that different methods can produce different kinds of information, such that one method can initiate research questions for another method, or expand a research project and lead to broader conceptual development [… and] even advocate that mixed methods research can promote social justice. (Stoecker & Avila, 2021, pp. 627-628)

In particular, we recognize different data sources have a different ability to tell a story. If we, as RUME researchers, have a preference toward certain data sources we use to make conclusions, we may be getting a limited perspective on a given proof topic. For example, consider video data from a classroom setting versus in a task-based interview setting. The classroom video data can help us better understand the proof learning contexts we are most interested in influencing, while the interview data provides a potentially cleaner and more focused picture of proof topics. Similarly, survey data has a potentially wide (but not deep) reach while interview data offers a potentially deep (but not wide) reach. Variety of methods is critical to the impact, robustness, and balanced perspective of a field of study (Stoecker & Avila, 2021).

Moreover, exploring the topics of study within a field (i.e., proof research), and in this case within a professional community (i.e., RUME), will allow us to identify areas of proof research that are over- or under-represented. Given the recent reviews of research on proof and proving we summarized above, we believe it will benefit the RUME community to compare the results of this literature review to those of other reviews. Previous proof reviews (Stylianides et al., 2017; Stylianides et al., 2023) were focused on proving literature related to teaching and learning in K-16 broadly, or on the teaching proof in undergraduate settings (Melhuish et al., 2022) and thus future research could benefit from comparing the RUME-specific topics of study from this review to the findings from previous broader reviews.

Methods

In this study examined proof research published in the RUME conference proceedings during 2018-2023. After collecting all contributed, preliminary, and theoretical reports from these years, we identified reports related to proof by a word search for "proof" or "proving" in both the paper titles and abstracts. The four authors sorted these reports into three categories: Proof Inquiries, Proof Settings, and Unrelated. Proof Inquiries include research about the teaching, learning, or professional practices of proof or research regarding proof-related concepts/topics conducted in a proof-based course context. Proof Settings refers to research that occurs in a proof course but was not investigating topics specific to proof. Finally, reports classified as Unrelated are those reports with the words "proof" or "proving" in the text of the title or abstract, yet these words were not used in the sense of mathematical proof. All reports were sorted by at least two authors who met to reach consensus on any disagreements. We excluded the 2021 RUME Reports due to the difference in that year's call for research to be conducted primarily by early career scholars. Moreover, our analysis of the 2023 proceedings is ongoing. We describe the methodological approach used to answer each research question below.

RQ1 Methods: Topics in RUME Proof Research

To identify the topics of RUME Proof research, we took an emergent approach to analysis. First, all four authors independently described the study focus of each report in their own words. We collapsed our individual descriptions into a list of topic codes through a card sort activity. We then each independently coded reports using these topic codes by assigning weights to the most relevant topics (3: Most Relevant Topic; 2: Very Relevant Topic; 1: Relevant Topic). Although each researcher was required to assign a most relevant (3) code to each study, topics weighted with a (2) or (1) were optional. Each proceedings year was coded by two authors, and although we did not seek to reach exact agreement, we discussed our codes in pairs and sought to understand each other's rankings and potentially altered our codes following further discussion.

We analyzed our topic codes by first summing the weighted topic codes of both coders on each article, so the topic code for each report ranged from 0 to 6. Our analysis proceeded in two ways: (1) we considered the topic codes with maximum sum value as the "primary topic" for each report, and (2) we observed trends in overall topic prevalence, regardless of weight, by considering the frequency of topics by code sum greater than or equal to one.

RQ2 Methods: Data Sources in RUME Proof Research

We first developed a list of data source codes by consulting textbooks and publications regarding educational research methods (e.g., Creswell, 2013; Ottinger, 2019; Merriam & Tisdell, 2016). Although our research team originally set out to classify research reports according to a set list of categories, after many efforts to precisely define our data sources, we determined this goal was much more complicated than expected. Upon further reading, we learned we are not the first mathematics education researchers who have encountered such difficulties. Schoenfeld (2010) described his efforts to create a taxonomy of research methods,

> My original intention […] was to provide a selective overview of some relevant categories of research methods, and to raise some issues about their use. This is by no means a straightforward task. (p. 495).

After reaching a conclusion that, like Schoenfeld (2010), we could not create a list of well-defined, mutually exclusive sources of data, we decided to proceed with our list of codes, treating each code as independent despite potential overlap. The categories for analysis were theoretical reports, literature reviews, qualitative data sources in the form of interviews, observations, artifacts, and surveys, and quantitative data sources in the form of surveys and assessments. The four researchers met in teams of two to discuss and resolve any disagreements.

Preliminary Findings

Across the RUME conference proceedings in the last five years (2018-2023), there have been 736 preliminary, contributed, and theoretical reports. Our search for reports regarding proof yielded 88 total reports: 18 reports from 2018, 15 reports from 2019, 20 reports from 2020, 18 reports from 2022, and 18 reports from 2023. Broadly, proof papers have composed about 12.3% of preliminary, contributed, and theoretical reports published in the RUME proceedings in the last five years (excluding 2021). We report preliminary findings from the 70 proof-focused reports from 2018-2022, as analysis of the 2023 proceedings is ongoing.

RQ1 Findings: Topics in RUME Proof Research

Across the RUME proceedings for which our research team has completed analysis, the most frequent primary topic in the RUME proof reports was proof instruction and feedback (12/70, 17.1%), followed closely by proof conceptions (views/beliefs about proof; 11/70, 15.7%). In contrast, the topic least prevalent as a primary focus was the transition to proof (2/70, 2.9%). Analysis of the primary topics of each report also revealed the, unsurprising, emergence of investigations of proof and online learning and technology in 2022, likely due to the transition to online instruction of many university courses during the COVID-19 pandemic. Figure 1 illustrates the prevalence of the primary topics of RUME proof research across 2018-2022.

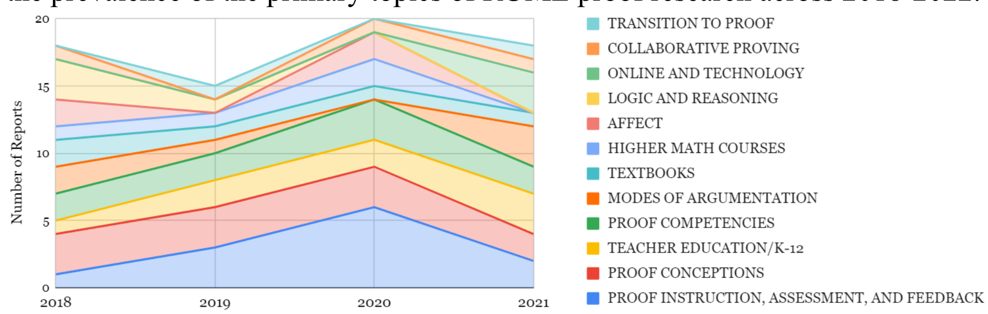

Figure 1: Primary Topics of RUME Conference Proof Research 2018-2022

By viewing the data, instead, with respect to the topics labeled any level of relevancy for each report rather than only the primary topic, we also observe trends in potential secondary topics and/or contexts of the RUME proof research. For example, although the transition to proof was least frequently the primary topic of investigation for the proof reports 2018-2022, it was the topic most frequently marked as relevant to the study in some capacity (i.e., at least one of the coders marked Transition to Proof as a 3, 2, or 1). Meanwhile, the investigation of textbooks appeared less frequently as a topic across all codes, yet when it was labeled as relevant this was often the primary topic for a report, so we can deduce textbooks are rarely a secondary or tertiary topic focus for proof research in RUME.

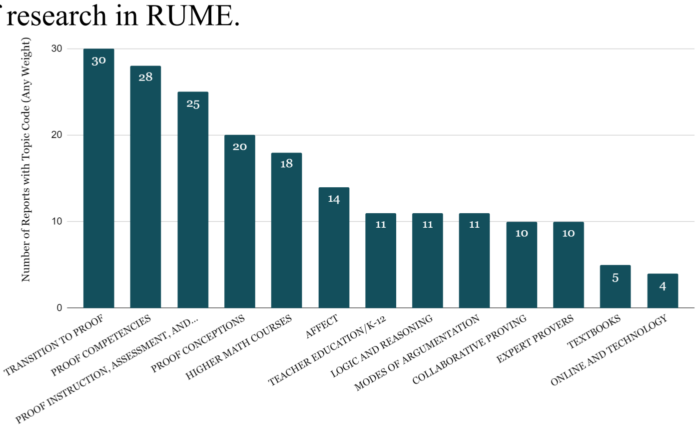

Figure 2: All Topics Marked Relevant (Any Weight) in RUME Proof Research 2018-2022

RQ2 Findings: Data Sources in RUME Proof Research

Because we encountered difficulties developing precise code definitions for data sources, we took suggestions from Schoenfeld (2010) in conjunction with methodological precedence from DiMartino and colleagues (2022) and classified RUME reports on proof as having drawn upon qualitative data, quantitative data, or both. This simple classification of reports revealed a drastic disparity between qualitative and quantitative data in RUME proof research. Two relevant theoretical reports did not employ any empirical data, so leaving 68 reports to consider data sources. Of these reports, 67 (98.5%) used some source of qualitative data, whereas only 7 (10.3%) used some form of quantitative data. Six reports used both qualitative and quantitative data, and therefore there was only one report which drew upon quantitative data alone. A final notable finding is the prevalence of interview research. Thirty-four (50%) of the proof reports using empirical data included interview data.

Discussion and Conclusion

After analyzing the 736 preliminary, contributed, and theoretical reports published in RUME conference proceedings in 2018-2023, we identified some of the most common topics of and data sources used in proof research within the RUME community. These preliminary findings indicate there is a strong presence of research regarding proof instruction, assessment, and feedback as well as proof conceptions, but there is much less research regarding collaborative proving, online learning and technology, and logic and reasoning. Much of the proof research (n=30, 42.8%) concerned the transition to proof, yet only two of these reports (2.8%) had the transition to proof as its primary topic. This finding indicates that there are many researchers conducting research within transition-to-proof courses but are not as frequently foregrounding students' transition to proof-based mathematics as their research focus.

With respect to methodologies and data used in RUME proof research, it is clear an overwhelming majority of reports used some form of qualitative data, and only one report used purely quantitative data. We speculate this absence of quantitative data may be due to the lack of reliable measurement tools relevant to the research of mathematical proof. Although we have not yet explored the reports in each topic in depth, we are interested to discover if RUME research regarding proof instruction, assessment, and feedback might be working toward developing measures which would allow for the collection of quantitative data.

In conclusion, we see several areas in which the RUME proof community could grow to assure there is a diverse presentation of topics and methodologies used to investigate proof at our conferences. In particular, there is room for more research on the transition to proof as a moment of mathematical development, and research on collaborative proving and proof learning and instruction through online mediums and technology. We also recognize the need for more quantitative data in order to complement the depth of qualitative data with widespread, generalizable claims. In moving this work forward, we intend to complete analysis on the 2023 proceedings, and then shift our focus to research journal publications on proof at the undergraduate level. This shift to journal publications will allow us to compare the distribution of research topics at RUME to the larger body of work in undergraduate proof research as well as track how research presented at RUME conferences evolves (or fails to evolve) into eventual journal publication. We pose the following questions for discussion with our audience:

1. What strategies for classifying proof research by methodology could best inform the field?
2. What research journals does our audience either seek publication in for proof research or look to for research on proving at the undergraduate level?

Supporting Instructors in Implementing Team-Based Inquiry Learning

University of South Alabama

Julie M. Estis
University of South Alabama

S. Raj Chaudhury
University of South Alabama

Team-Based Inquiry Learning (TBIL) is a novel active learning pedagogy designed to facilitate the use of inquiry-based learning in lower division courses. This preliminary report examines supports provided by the TBIL project to instructors, as well as the fidelity of implementation of TBIL by participants of the project. Initial findings suggest that classroom-ready materials and ongoing support, both synchronous and asynchronous, were most helpful to faculty in their TBIL implementations.

Keywords: inquiry-based learning, team-based learning, professional development

Introduction

Inquiry-Based Learning (IBL) is a well-established collection of pedagogies with many documented benefits for students (Laursen et al., 2011; Laursen & Rasmussen, 2019). Despite its benefits, IBL is more likely to be implemented in upper level courses, smaller courses, and courses for mathematics majors (Ernst et al., 2017). Team-Based Inquiry Learning (TBIL) is a novel active learning pedagogy implementing Team-Based Learning in an effort to facilitate the use of IBL in lower division courses (Lewis et al., 2021). TBIL was initially studied by the authors in the context of a linear algebra course at a single institution, where it was shown to improve students' content mastery, grades, and procedural flexibility (Lewis & Estis, 2020).

This paper reports preliminary findings from ongoing work to study the effectiveness of TBIL across varied instructional contexts. The authors conducted faculty development workshops (described below) to train interested instructors, who then implemented TBIL in their Calculus I, Calculus II, or Linear Algebra course. These instructors were invited to participate in the present study aimed at addressing the following research questions.

RQ1: (A) Which of the supports provided to faculty led to a successful implementation of TBIL in various instructional contexts? (B) Which additional supports would aid faculty in their implementation of TBIL in various instructional contexts?

RQ2: How faithfully do faculty implement TBIL after participating in the training workshops?

Team-Based Inquiry Learning

Team-Based Learning (TBL) is a highly structured active learning pedagogy that focuses on application of course content through collaborative problem-solving. Each module, or unit of instruction, consists of three phases: Preparation, Readiness Assurance, and Application of Course Concepts (Michaelsen & Sweet, 2008). TBL balances individual preparation and responsibility with the benefits gained from working together as a team to solve problems. Students receive frequent and timely feedback, and assignments are designed to promote team development, as well as learning. This is typically operationalized through the usage of four practical components: permanent teams; a readiness assurance process; so-called '4-S' application activities (in which students work on the **S**ame problem, which is to be a **S**ignificant problem, and make a **S**pecific choice that is **S**imultaneously reported); and peer evaluations (Michaelsen et al., 2004).

Team-Based Inquiry Learning (TBIL) utilizes the structure, flow, and principles of TBL to implement IBL in lower division mathematics courses. The 4-S application activities are designed to allow students to engage deeply with coherent and meaningful mathematical tasks, while the simultaneous reporting structure helps the instructor to inquire into students' thinking. The readiness assurance process is designed to remind students of prerequisite knowledge needed to fully engage with the challenging 4-S inquiry tasks by reducing extraneous cognitive load. A further explanation of how TBIL fulfills the four pillars of IBL is found in (Lewis et al., 2021).

The TBIL project, led by the authors, began in 2021 with goals to (1) Determine the extent to which TBIL is effective across differing instructional contexts; (2) Create and publish a library of accessible, classroom-ready, open-source TBIL materials for lower division courses; and (3) Train and support faculty as they implement TBIL at a diverse group of institutions and instructional contexts.

Supporting TBIL Instructors

The TBIL project provided a number of supports to instructors, beginning with an intensive faculty development workshop. Two cohorts of 13 instructors each participated in these workshops in the summers of 2021 and 2022, respectively. The first workshop was held in a hybrid format to maximize participation (5 faculty participated in person, with 8 connecting remotely), while the second workshop was entirely in person. The first workshop was five days in duration, while the second was three days; this was done to allow time for the first cohort to contribute to development of the curricular materials (described below). Both trainings included sessions on the fundamentals of team-based learning, integrating IBL into team-based learning, and mock teaching activities.

Instructors were also provided with a set of curricular materials prior to implementing TBIL. The linear algebra materials were initially written by the authors, and then revised by participants in the first cohort; while the single variable calculus materials (both Calculus I and Calculus II) were developed by participants in the first cohort, building on existing open-source calculus active learning materials such as *Active Calculus* (Boelkins et al., 2018). These materials included a full set of classroom-ready, student-facing activities, in addition to other support materials such as banks of exercises for practice and assessment, readiness assurance resources and quizzes, and videos.

In addition to initial training, previous work on adoption of IBL has shown that ongoing support during implementation is crucial (Hayward et al., 2016). Thus, the project team provided instructors with Online Working Groups (Fortune & Keene, 2021; Wawro et al., 2023), which were synchronous meetings of the instructors and a project team leader to have informal conversations about challenges and success in their TBIL implementations. Additionally, the project team created and maintained a Slack community devoted to TBIL. This ongoing resource serves to provide instructors with asynchronous support, again both from peers and from the project leaders.

Methods

We employed a survey methodology with the 26 instructors who completed the provided TBIL training. These instructors were located at 23 different institutions, 17 classified as predominantly white institutions and six classified as minority-serving institutions. Of the 23 institutions, 21 were four-year colleges and two were two-year colleges. To answer the first research question, this paper reports on a single survey administered at mid- and end-of-semester for each semester in which participants implemented TBIL. This survey contained three open-ended questions about instructor supports ("Of all the provided support, which has been most useful and why?", "Are there additional supports that have aided in your implementation of TBIL?", and "What additional supports would aid you in your implementation of TBIL?"), as well as four Likert-scale questions asking the frequency at which the instructor implemented the four practical components of TBIL (Permanent Teams, Readiness Assurance Process, 4-S Application Activities, and Peer Evaluations). Twenty-five of the 26 participants completed the faculty support survey at least once, with a total of 54 responses across all participants and semesters of data collection--Fall 2021 through Spring 2023.The three open-ended questions about supports were coded by the first author using open coding to identify the kind(s) of support described in each response.

In addition to the surveys, the 26 instructors were also invited to submit a syllabus from their TBIL course. 12 responses were received, which were coded by the first author for the presence or absence of the same four practical components of TBIL (Permanent Teams, Readiness Assurance Process, 4-S Application Activities, and Peer Evaluations).

Results

When determining which supports faculty identified as either leading to a successful implementation of TBIL, or which additional supports would be helpful in implementing TBIL, five codes emerged, with their frequencies presented in Figure 1. The most frequently mentioned support was 'Materials' in reference to the curricular materials provided. In discussing materials as a helpful support, one participant said, "Ready-made materials for the obvious reasons: I've really been able to focus my time on my students and facilitation, rather than higher level course design work." In contrast, when materials were described as a needed support, instructors desired either additional ancillary student resources (such as videos), or a desire to customize the materials to meet their unique needs. It should also be noted that 13 of the 14 respondents who identified materials as a needed support also identified elements of the materials as a helpful support. The next most frequent codes were 'Online Working Groups' and 'Slack,' referring to the synchronous and asynchronous informal support from the project team and their peers that extended through the academic semesters. The code 'Training' was unique in that there were more codes specific to additional supports needed (n=8) versus the training being helpful in implementation (n=7). Those instructors with a desire for additional support related to training either wanted a more nuanced understanding of creating TBIL activities, "how-to-guides" related to generating additional fluency-building or assessment questions, or desired to have additional training specific to TBIL implementation, possibly a refresher on in-class implementation or facilitation strategies. The last code was 'Peer', which referred to support from peer instructors, either through the project or at their institution.

To address the second research question, we first considered the frequency with which participants reported they implemented various components of TBIL in two ways. Since instructors were invited to respond to the survey in several semesters, we considered their initial response (n=25), as well as the most recent response from those who responded multiple times (n=19). We see a high implementation rate of permanent teams and the readiness assurance process in the initial response, with the latter waning somewhat in the final response. Implementation of the 4-S application activities was somewhat lower; only 72% of initial responses indicated that they were implemented 'Most of the time' or 'Always,' though this rose to 95% in the final response. Peer evaluations were the least used component; notably 47% of the final responses indicated that they were never used.

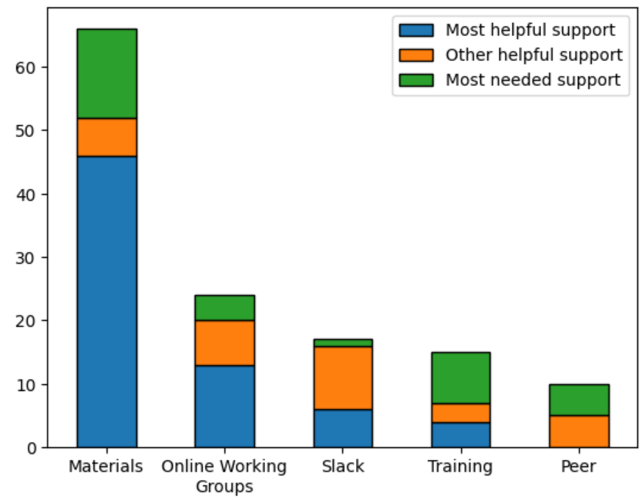

Figure 1. Supports identified as the "Most helpful support" provided, "Other helpful support" provided, or an "Additional needed support".

As noted above, 12 participants provided a syllabus for analysis. All of them indicated the use of 4-S application activities, with 92% indicating a Readiness Assurance Process and 83% indicating the usage of permanent teams. Only 67% of syllabi indicated that peer evaluations would be used.

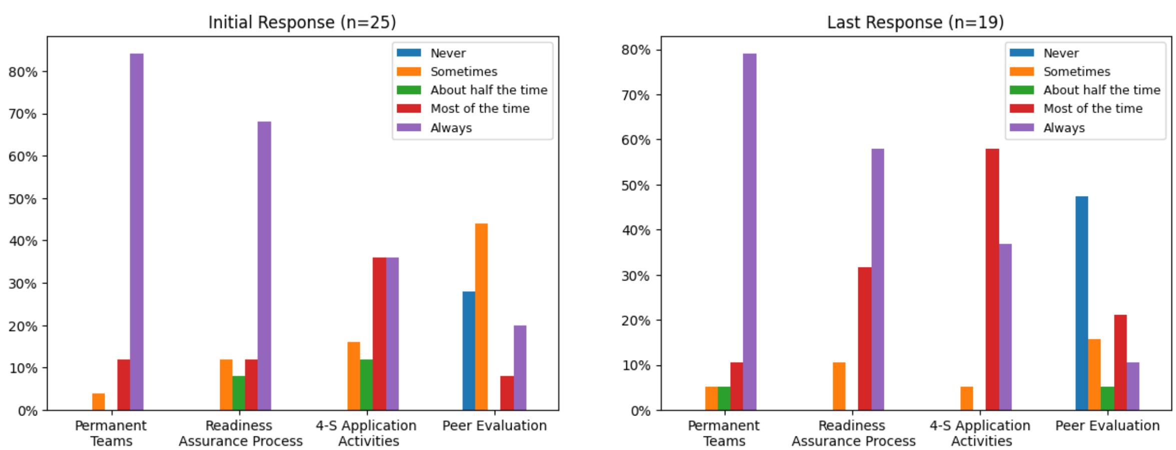

Figure 2. Initial and final responses of the frequency at which participants reported implementing components of TBIL

Discussion

Overall, we found participants identified two key supports in their implementation, namely the provided curricular materials, and ongoing support from peers and project leaders. Several participants specifically noted that having the provided curricular materials reduced the planning time necessary for the course, allowing them to focus on the novel aspects of the TBIL pedagogy such as classroom facilitation. We interpret this as the provided materials serving to reduce the cognitive load on participants as they learned to implement the other aspects of TBIL. We also note that one participant observed that the choice of the project to distribute the materials without requiring a login made it easier to share the materials directly with students.

We note this latter ongoing support was described by participants and coded separately as referring to either the synchronous online working groups or the asynchronous Slack community. The prevalence of both suggests that each communication modality offers something valuable to instructors that the other does not. The implications of these results are that leaders of similar pedagogical and curricular reform projects need to design ongoing faculty development efforts that accommodate these support preferences. While some aspects like the Slack channel almost maintain themselves after the initial setup, the synchronous online working groups are resource-intensive in terms of investigator time, which needs to be taken into consideration in the project design. An additional observation: the project's financial investment was greatest in materials development and initial training workshops. While the curricular materials were viewed as very valuable by our participants, the training was not. In fact, the online working groups and the Slack are both mentioned as more important than the initial training. However, we expect the community-building aspects of the intensive workshops, which led to participants' participation in the online working groups and Slack, were quite important second order benefits that do not appear in participants' responses.

Regarding the second research question on fidelity of implementation, we observed very high usage of permanent teams and the Readiness Assurance Process across both the self-report and syllabi. Usage of 4-S application activities was also quite high on both measures, but the self-report showed many instructors only used them most of the time. Usage of peer evaluations was much lower. We suspect one aspect contributing to this is the growing movement in mathematics (and other disciplines) to use alternative assessment and grading practices. Indeed, we (Lewis et al., 2021) specifically advocate for the use of Standards-Based Grading (e.g. Elsinger & Lewis, 2020) in our paper describing the TBIL pedagogy. We assume this stance implicitly permeated our trainings and support structure. We also note that Lewis and Estis (2020) reported that peer evaluations had no correlation with content mastery. It seems likely that participants may similarly have not found value in the evaluative nature of the peer evaluations, and instead opted for other peer feedback and team-building pedagogical moves.

Future Work

While this preliminary report represents partial progress towards addressing the research questions, we believe additional qualitative work is needed to fully answer these questions. In particular, we have collected (but not yet analyzed) video recordings of classroom sessions to further address the second research question regarding fidelity of implementation, particularly with a view toward facilitation moves and the usage of the 4-S application activities. We intend to conduct follow-up interviews with some of the participants at the end of the academic year to try to paint a fuller picture of the utility of various supports (in regards to the first research question), as well as to try to understand why various aspects of TBIL (such as peer evaluations) were implemented less frequently.

A Preliminary Investigation of the Language of Proof in Mathematical Textbooks

Kathleen Melhuish
Texas State University

Elizabeth Wrightsman
Texas State University

Keith Weber
Rutgers University

Lino Guajardo
Texas State University

Mathematical proof writing is known to follow various norms and conventions set by the mathematical community. Yet, recent scholars have questioned if these norms and conventions hinder the progression of the field to be inclusive in proof courses. In this report, we discuss preliminary findings of a linguistic analysis on the degree of gendered language used in eight undergraduate textbook proofs ranging in content. We report a mixture of gendered language use in mathematical proof writing.

Keywords: proof, language, gendered communication

It is largely accepted that the language of mathematical proof is genre-specific and follows particular norms and conventions (e.g., Burton & Morgan, 2000; Dawkins & Weber, 2017; Lew & Mejia-Ramos, 2020). A small body of research has attempted to empirically investigate these norms such as Burton and Morgan's work exploring mathematical texts and interviewing mathematicians related to elements of proof related to authority or Lew and Mejia-Ramos's investigation of a set of conventional breaches and mathematicians' evaluations of them. Such work points to the fact that there are observable linguistic features of mathematical proofs that can be studied. Further, these features do not only involve the structure and nature of argumentation; they primarily concern language in which proof is conveyed.

Recently, Weber and Melhuish (2022) argued that the adherence to language conventions may be in tension with critical and inclusive aims in mathematical proof courses. Indeed, scholars such as Brown (2018) have illustrated the ways that students who are first generation and urban may use more "varied and at times colorful dialects" (p. 7), losing advanced mathematical contributions because they are not communicated in a standard way. It is possible that the conventions of proof writing are not due to epistemic aims entirely and might systematically exclude certain individuals. To make this point, Keith (1998) argued that proof characteristics (such as being impersonal and directive) may align with typical ways men communicate rather than women. However, to our knowledge, there has been little empirical work on how proof texts may be masculine or genderized. With this background in mind, the aim of this preliminary report is to build on the work identifying language features of mathematical proof and to begin an exploration related to Keith's (1998) observation. We focus on two research questions: (1) What are the language features of proof found in undergraduate textbooks? (2) To what degree do these features reflect types of communication associated with gendered communication?

The Norms and Language of Proof

A number of scholars have pointed to the language and norms of proofs being distinct from other types of language. Selden and Selden (2014) refer to the distinct stylistic and linguistic features as part of the genre of proof. Recently, Dawkins and Weber (2017) reflected on the values and norms of proofs both held by professional mathematicians and in mathematics classrooms. Of particular relevance to our examination of proofs, they identified, "Mathematical knowledge is justified by a priori arguments" and "Mathematical knowledge and justifications should be a-contextual and specifically be independent of time and author." Upholding these values is then reflected in linguistic choices in proofs. For example, they identified that proofs are written in such a way to reference the author or reader's agency. So, a proof would not contain an "I" statement, but rather impersonal "we." Such choices reflect the value of a priori arguments and that mathematical proof is meant to be universal and dependent on a particular author.

Perhaps in contrast, other scholars, such as Burton and Morgan (2000) argue that, "Conventions of mathematical writing are neither necessary nor natural consequences of the nature of the subject matter" (p. 450). In fact, in Burton and Morgan's analysis of published proofs and mathematician interviews, they identified similar conventions as Dawkins and Weber (2017), but also noted that authority can be found in proofs. For example, "terms such as clearly and obvious are relative to the individuals using them" and Burton and Morgan further suggest, "the extent or absence of such words is one of the interpersonal aspects of the writing that will influence the ways in which the readers of the text will construct an image of the author and will consequently judge the worth of the text itself."

The fact that there are some conventions that are not necessary to the subject matter is unlikely to be contested. For example, Lew and Mejía-Ramos's (2019) norm breaching study identified a number of breaches that mathematicians found unacceptable, especially in the context of textbooks. These include, "using non-statements, overusing variable names, lacking punctuation and capitalization, mixing mathematical notation and text, lacking verbal connectives, using formal propositional language, using unclear referents, and using an unspecified variable with an existential quantifier" (p. 55). While some of these breaches may hamper interpretability or validity of a proof, others are merely stylistic.

The imposition of linguistic and stylistic features that are not necessary to the validity of mathematical arguments has led several researchers to wonder about this impact for students (e.g., Brown, 2018; Tanswell & Rittberg, 2020; Weber & Melhuish, 2022). In Tanswell and Rittberg's reflection, they explain the concern with the particularities of mathematical language in proof (e.g., the interweaving of symbols and words, avoiding the first-person "I", the unusual "Let n be a number" style constructions, specialized use of imperatives and instructions, and being devoid of many features of natural language):

> This has the effect of elevating the regimented mathematical language that has grown up over the centuries to the level of being the sole vessel of objective mathematics. ... Once we realise that learners do not come from uniform linguistic backgrounds it quickly becomes apparent that the allegedly impartial language of mathematics is easier to access for some students than others (p.1202).

Brown (2018) illustrated this point sharing data from an inquiry class where majority of students were first generation and urban. She pointed to the "colorful dialects" they used and the ways they stand in contrast to standard ways of communicating math in proofs. Students' rich mathematical arguments may not been seen as important contributions if they are not structured in a way to align with conventional preferences. Overall, the literature base points to the fact that there are strong conventions in how proofs are written and that this is an important element to study because they have the potential to disenfranchise some students more than others.

Theoretical Framing

We take on the perspective that language reflects culture, and more broadly that language can be treated as a cultural artifact itself (Maltz & Borker, 1982). The culture in which one develops their language shapes their communication choices and how they interpret others. As noted by Maltz and Borker, these communication differences are salient across different ethnic backgrounds. Furthermore, the culture of language is not just developed at a global level (such as American English), but within gender, class, and other subgroups. For the scope of this paper, we provide particular attention to gender, and adopt Mulac et al.'s (2001) view of gender-as-culture. They suggest that, "much of what people know about interpersonal communication is learned from same-sex peers during the ages of 5 to 15 years." This then leads to communication differences across gender-lines. We note that this sociological interpretation does not mean that power dynamics are not at play for how and why there are communication differences, rather that it provides a mechanism for their existence.

This allows for identifying distinct language and communication aspects that may reflect different subcultures. For example, women may be associated with communicating in ways that involve more uncertainty and hedging while men may be associated in communicating in more direct ways. We further make the assumption that the language of proof reflects a distinct culture that may or may not align with communication elements salient in how different genders communication. While there are some that conjecture proof is more masculine in communication features, this remains an empirically open question.

Methods

In order to begin to analyze language features of proof, we began with the framework developed by Mulac et al. (2001). This framework stemmed from the synthesis of a number of studies identifying differences in how men/boys and women/girls communicate in both written and orally. The features can be found in Table 1. We note they align with four verbal communication style dimensions: direct versus indirect, elaborate versus succinct, personal versus contextual, and instrumental versus affective (Gudykunst & Ting-Toomey, 1998). The direct-indirect style captures the degree to which one explicates their intention through verbal communication. Elaborate-succinct style describes the richness and expressiveness of the language used, ranging from the most expressive (i.e., elaborate) to the most understated (i.e., succinct). Along the dimension of personal-contextual, a personal verbal style heavily rests on the use of personal pronouns (e.g., we, us) and locatives (e.g., then, there) whereas a contextual style deemphasizes the use of these language features. Instrumental communication style is goal-oriented and relies on the speaker (sender-oriented) to make the message clear. Alternatively, an affective communication style is process-oriented and the responsibility falls on the listener (receiver-oriented) to read contextual cues to decipher the message.

Table 1. Features of Language Found in Empirical Studies (Mulac et al., 2001) where M: male features, F: female features; X: mixed results from empirical studies.

Language Variable	Definition
Elliptical sentences (M)	A unit beginning with a capital letter and ending with a period in which either the subject or predicate is understood
Questions (X)	But not including directives in question form
Tag questions (F)	An assertion that is followed by a question asking for support
Directives (M)	Telling another person what to do

Negations (F)	A statement of what something is not
Sentence initial adverbials (F)	Answers the questions: how, when, or where? regarding the main clause [why and how long]
Dependent clauses (F)	A clause that serves to specify or qualify the words that convey primary meaning
Oppositions (F)	Retracting a statement and posing one with an opposite meaning
Judgmental adjectives (M)	Indicating personal evaluations rather than merely description
Uncertainty verbs (F)	Verb phrases indicating lack of certainty or assuredness
Progressive verbs (X)	Verbs presented in the "-ing" form
Intensive adverbs (F)	Adverbs such as "really" or "so"
Hedges (F)	Modifiers that indicate lack of confidence in, or diminished assuredness of, the statement
Justifiers (X)	A reason is given for a previous statement
References to emotion (F)	Any mention of an emotion or feeling
References to quantity (M)	References to an amount or quantity
Locatives (M)	Usually indicating the location or position of objects
Personal pronouns (X)	Words that stand for beings
"I" references (M)	First person singular pronoun in the subjective case
Fillers (X)	Words or phrases used without apparent semantic intent

We selected four common undergraduate textbooks across different subject areas: Smith et al.'s (2004) *A Transition to Advanced Mathematics*, Gallian's (2012) *Contemporary Abstract Algebra*, Fitzpatrick's (2009) *Advanced Calculus*, and Munkres' (2000) *Topology*. We then randomly selected a number between 1 and 10 (4), and selected the fourth proof in each text and the fourth proof after the halfway point in each text. Each of the four members of the research team applied the framework from Table 1. We met to reach consensus on the meanings of codes, discuss borderline cases, and ultimately arrive at finalized coded versions of the textbook proofs.

Results

We begin by providing some of the expected results in terms of features of proof language. None of the proofs contained: *elliptical sentences* (M), *questions* (F), *tag questions* (F), *uncertainty verbs* (F), *reference to emotion* (F), *"I" references* (M), *fillers* (X), *intensive adverbs* (F), or *hedges* (F). We note that this evidence points to a particular way of communicating in proof that does not contain many features of communication in other contexts. We also note that proofs do not contain some common masculine ways of speaking (elliptical sentences and I statements) nor contain many feminine ways of speaking such as reflecting questions and uncertainty or references to emotions.

We now consider the language codes that did appear in proofs beginning with the most universally found. All proofs had initial adverbials (F). These are sentences beginning with words or phrases serving the function of adverbs. "Thus" or "Therefore" are initial adverbials, as are clauses such as, "By Theorem 16.1," or "If I = {0}." On average, each proof had 6 initial adverbials (ranging from 4 to 10). Thus, we suggest that the use of initial adverbials is standard feature of proof and seems to serve the purpose of chaining one logical claim to the next. We contrast these with *justifiers* (X). Justifiers, as defined in the literature, provide a reason for something *after* it is stated. Only one of the eight proofs had any justifiers with the first of the topology statements having two sentences containing "for" statements. The first was, "The case which B=∅ is trivial, for there cannot exist a bijection of the empty set B with the nonempty set {1, ...,n}." Otherwise, any explicit warrants were found before the inference being warranted. That is, they were found in initial adverbials with language such as, "Since X is normal,..." or "Because the theorem..." So, while justification is common in proofs, it is not provided as a justifier after a statement, but rather anticipates the statement that will be justified.

Other features found across all proofs were *dependent clauses* (F) (average of 3) and the *personal pronoun* (X) "we." Dependent clauses are more frequently found in the communication of women than men, but it is unclear whether the average of 3 is more or less than a baseline. The existence of "we" across all the proofs is hardly surprising as the literature has pointed to the commonality of the royal or impersonal we. We do know that "we" and one instance of "us" were the only personal pronouns in the proofs. We found no uses of the pronoun "I".

We also found that all, but one proof (7 of 8) contained *directives* (M). These directives begin with, "Let," "Suppose," "Assume," "Show," "Define," "Note," and "Choose." We note 23 such instances indicating that the commonality of directives mentioned in literature seems to bear out our analysis of the undergraduate proofs.

We quickly note the remaining features' prevalence. *Quantity* (M) was found in all eight proofs (usually references counts for abstract quantities such as "infinite"), but this seems like a contextual feature rather than a convention feature. *Location* (M) was not found in the proofs (although reference set membership was common). Again, we hesitate to say this is anything but a context feature. We also did not observe any *oppositions* (F) occurring within sentences as described in the framework, but we note there existence as complete new sentences in proofs by contradiction. We found that half of the proofs we analyzed had *negations* (F), that is defining something by what it is not such as "b-1/2 is not an upper bound." Three of the eight proofs contained progressive verbs (e.g., "consisting", "covering") reflecting a use, but not frequent use of these. Finally, we note the use of *judgmental adjectives.* One proof contained "trivial" while another contained "it is clear" reflecting at least the existence of these authority-driven language even within undergraduate texts.

Discussion

Our preliminary analysis explores the extent that language features from the linguistic literature are present in proofs. In the eight proofs we explored, we found that the impersonal "we" and directives were common in these proofs. We did not find any instances of uncertainty, including hedges, qualifiers, and leaving questions, nor did we find any references to emotion, oppositions, or the personal pronoun "I". While justification was common, *justifiers* (i.e., phrases used to justify prior statements) were rare. It is interesting that some features of proof align with masculine ways of communicating, such as the giving of directives, the lack of references to emotions, and the lack of hedges and oppositions. However, other features, such as the absence of "I" statements, are associated with the literature as feminine ways of speaking. At this point, it would be premature to make any claims about the degree to which mathematical proofs reflect masculine ways of speaking. Future research may involve a corpus linguistics analysis to document more accurate prevalence of these features, a convention breach analysis to see which of these features are considered salient to mathematicians, and comparisons to other texts both academic and non-academic. This is especially important when documenting prevalence of features such as dependent clauses. Dependent clauses are found more often in communication by women, but that is a comparison and not a claim that men do not use dependent clauses. It would be useful to consider how these features in proof compare to some baseline texts that are not proofs.

Using CAS to Promote Students' Ways of Thinking Through Observation and Conjectures: The Case of Eigenvalues and Eigenvectors

Ryan Peffer, Washington State University
Judi McDonald, Washington State University
Sepideh Stewart, University of Oklahoma

Linear algebra is an important topic in mathematics and many other disciplines. In this paper, we consider a set of digital interactive figures (I-figs) using Mathematica created for linear algebra students in an introductory course. The figures were designed to facilitate students' ability to visualize and work with eigenvalues and eigenvectors while minimizing computation for the benefit of conceptual focus while looking at an unlimited number of examples. The worksheets provide a foundation for motivating students to participate in a system of observation, conjecture, proof, and theorem. Based on our preliminary analysis of students' reflections on the I-figs, we found that students were confident in making and believing example-based conjectures.

Keywords: eigenvalues and eigenvectors, technology, observation, and conjecture

Literature Review

Already an important topic in mathematics, science, and engineering, the relevance of linear algebra has expanded into other areas as it provides the foundation for a wide range of data-driven and AI-related techniques. Linear algebra plays a central role in almost any area that uses quantitative information and methods to process data, hence the way linear algebra is taught is of paramount importance.

In the early 1990s, the Linear Algebra Curriculum Study Group (LACSG) recommended that "faculty should be encouraged to utilize technology in the first linear algebra course" (Carlson et al., 1993). As a part of this initiative, David Lay implemented the use of computer algebra systems (CAS) educational support such as MATLAB, Maple, and Mathematica in his book *Linear Algebra and its Application* (Lay, 1994). For example, in working with matrices and vectors, solving systems, matrix multiplications, finding inverses, and reducing a matrix to a reduced echelon form, technology can help with accurate and fast calculations as well as allow one to concentrate on the deeper conceptual aspects of the discipline that are often difficult for students to grasp. In addition, technology can be employed to build a visual image of the details, as well as the big picture, and allows for predictions, investigations, and producing conjectures.

Despite national initiatives in the US on teaching linear algebra with MATLAB, for example, the ATLAST project initiated by Steven Leon and his colleagues (Leon, Herman, & Faulkenberry, 2002) in the early 90s, systematic studies of linear algebra instructors' thought processes and their students' feedback on the effect of technology on their understanding are lacking. In a survey paper by Stewart, Andrews-Larson, and Zandieh (2019), the authors looked at linear algebra education papers from 2008-2017 in mathematics education journals and found almost no systematic classroom studies on the effectiveness of the use of Mathematica, Maple, Python, or MATLAB in the classroom, with the exception of a study of using MATLAB in mathematical modeling (Dominiques-Garcia, Garcia-Plana, & Taberna, 2016). However, the survey paper found studies on eigentheory using Geometer's Sketchpad (e.g., Gol Tabaghi, 2014; Caglayan, 2015), and Geogebra (Beltran-Meneu, Murillo-Arcila, & Albarracin, 2016) focused on the geometric aspects of the topic. The linear algebra recommendations by LACSG

2.0 also emphasized the importance of technology in teaching linear algebra (Stewart et al., 2022).

The second author has developed a series of digital interactive figures (I-figs) that aim to provide students with an opportunity to play with linear algebraic objects in an embodied format meant to be easy-to-access and requiring minimal time investment. Linear algebra students' conceptual understanding of eigenvalues and eigenvectors have been a topic of study in some studies (e.g., Thomas & Stewart, 2011; Salgada & Trigueros, 2015; Wawro, Watson, & Zandieh, 2019), largely focused on student thought processes. We also wish to study student ways of thinking, with the added structure of a series of I-figs targeting properties of eigenvalues and eigenvectors.

Theoretical Perspective

The theoretical framework for this study will utilize Harel's (2008) ways of thinking and Tall's three worlds of mathematical thinking (2010). Harel (2008) introduced the notion of a mental act as actions such as interpreting, conjecturing, justifying, and problem solving, which are not necessarily unique to mathematics. These several types of mental acts are the foundation of ways of thinking defined as "a cognitive characteristic of a mental act" (p. 269). These ways of thinking have the characteristics of being able to abstract, generalize, structure, visualize, and reason logically. Tall (2010) describes the embodied world as "our operation as biological creatures, with gestures that convey meaning, perception of objects that recognize properties and patterns… and other forms of figures and diagrams" (2010, p. 22). In his view, "The world of operational symbolism involves practicing sequences of actions until we can perform them accurately with little conscious effort. It develops beyond the learning of procedures to carry out a given process (such as counting) to the concept created by that process (such as a number)" (2010, p. 22). The formal world "builds from lists of axioms expressed formally through sequences of theorems proved deductively with the intention of building a coherent formal knowledge structure" (2010, p. 22).

Our research questions are: What are the effects of the use of these I-figs on students' ways of thinking involving a system of observation and conjecture and how does that influence their understanding of proof and theorem? How did the use of the I-figs influence learning of eigentheory?

Methods

In this case study, 16 participating students were enrolled in an honors section of introductory linear algebra at a large public land-grant R1 university in the USA. These students were first and second-year students, with most declared or interested in degrees in mathematics, science and engineering, or medicine.

Five I-figs related to properties of eigenvalues were collected as one digital worksheet for students to explore. The worksheet was given to the students over a weekend's time to complete, immediately following the first class on eigenvalues and eigenvectors. In this lesson, students were shown the definition of eigenvalue and eigenvector with necessary conditions such as non-zero eigenvectors and uniqueness of eigenvalues for an eigenvector. By the time of worksheet participation, students had not practiced or discussed in class how to compute eigenvalues or eigenvectors, nor had any of the eigenvalue properties displayed in the worksheet been demonstrated. Students were instructed to spend approximately 15 minutes manipulating the digital figures and look for any observable patterns or trends.

Three forms of written data were collected at different times following the students' participation. Immediately after their time with the worksheet, students were asked to write a few paragraphs describing anything that they found interesting or noteworthy while working in the digital worksheet. Second, a few days later in the following in-person class time, students completed a short quiz asking if they could recall the definition of eigenvalue and eigenvector, and again to recall anything that stood out to them about the worksheet. Lastly, two weeks after the worksheet was administered when the class had concluded their study of eigenvalues and eigenvectors, students were asked to complete a final exit survey consisting of seven short answer response questions: (1) In what ways, if any, did you find the digital worksheet useful in understanding the concept of eigenvalues and eigenvectors? (2) What pros/cons do you see with this activity being a digital worksheet versus a pen-and-paper worksheet? (3) Describe, if any, the connections you see between the digital worksheet and the following week's content on eigenvalues and eigenvectors. (4) Do you like the idea of these exploratory activities before the content is introduced in class? (5) Would you have preferred a different sequencing? Please share your reasoning. (6) In our modern data-driven society, how do you see the relationship between linear algebra (matrices as data) and technology? (7) What part of the digital worksheet stood out to you as most important? Why?

As another data perspective, the instructor of the course (the first author) logged teaching reflections after each class meeting. These reflections included a summary of the day's class content, delivery, and notes about what did and did not go well, especially including important (from the instructor's perspective) student interactions. The instructor had weekly meetings with the rest of the research team and discussed their perspectives about the class further. The research team helped to design the study and research tools. Open coding by Strauss and Corbin (1998) was performed to analyze the data. In this paper, we will only analyze students' responses to their immediate post-worksheet reflection.

Preliminary Analysis

Some of the common themes in students' data so far have been as follows: play and exploration, pattern/non-pattern seeking, desire for relevance, and mathematical (formal) conjecture. These reflections ranged from one to three paragraphs, typically no more than half a page of writing.

We will begin by analyzing student responses relevant to each I-fig. The first I-fig (Figure 1) treats eigenvectors geometrically. Students may adjust the second component of v manually or use presets to snap to two eigenvector relations. Only four of the thirteen respondents addressed this geometric figure in their reflection. Those that did unilaterally employed physically embodied language surrounding their work, such as "It was interesting to scale the vector with my hand and check the gradual change of the values on my own" (S09). However, only one student explicitly named those special vector equations as demonstrating an eigenpair relationship.

For the second and third I-figs (Figures 2), eight students were able to correctly comment on the intended patterns in these I-figs (the same students for each). From this activity, these students make assertive statements (conjectures) such as "when you scale a matrix, the eigenvalues are scaled the same amount" (S03) or "When the matrices were put to a specific power, the eigenvalues were also just put to that power" (S05). From these notes we observe that those eight students all communicated a confidence that their perceived relationship is true (without supplying or referencing any justification), and also were able to supply a productive phrasing of the appropriate eigenvalue property, without having seen or otherwise been exposed to those properties in the class. As mathematics instructors, we can capture this as students' displaying an emergent way of thinking of the form (way of thinking: I can build a conjecture with a finite set of examples) and (way of thinking: I feel strongly that my conjecture is true). Notably, in the second way of thinking, students are unbothered by the absence of any supporting proof and have yet to become skeptical that a small set of examples can be used to identify a general trend.

Only one student who addressed these two I-figs proposed related though fundamentally incorrect statements such as "when scaling a eigenvalue, it affects the matrix" (S07). Nevertheless, we see the fundamental idea (of matrices and their eigenvalues sharing a scalar relationship) communicated, though this student's implication is reversed.

Next, Figure 3 shows an I-fig meant to display eigenvalue properties (or lack thereof) in relation to matrix operations on two matrices A and B. Seven students remarked upon this I-fig. Of those, five students were able to either state that the eigenvalues of A and B do not simply determine the eigenvalues of AB or A+B ("adding two matrices together does not necessarily add the matrices' eigenvalues, nor does multiplying two matrices together multiply the eigenvalues" (S06)), or stated that they were not able to find those patterns ("I wasn't sure how there is a correlation between eigenvalues of matrixes and their sums and products" (S12)). We note that these students leave open the possibility of there existing some pattern or rule that they simply were unable to find.

The final I-fig (Figure 4) concerns the relationship between eigenvalues, trace, and determinant of a matrix. Six of the thirteen respondents were able to conjecture a relationship, with five of those being correct ("I realized that adding the eigenvalues gives you the trace, while multiplying the eigenvalues gives you the determinant" (S07)). The final student observed "With the matrix provided, if I took the sum of all the eigenvalues, I received the trace of the matrix. Then, if I took that sum and multiplied by negative two, I got the determinant of the matrix" (S12). We see this student extending a previously identified way of thinking (I can build a conjecture with a finite set of examples) to now creating an incorrect conjecture apparently from a single viewed example. Again, showing no hesitation in endorsing this conjecture, indicating a lack of a way of thinking such as a mathematical conjecture requires a proof to be accepted.

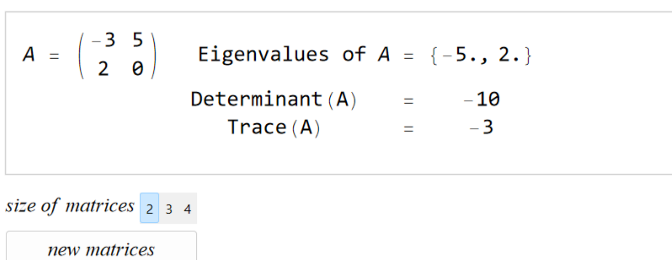

Figure 4. Relationship between eigenvalues, determinant, and trace.

Concluding Remarks

As we continue working on this research study, we plan to develop the theoretical framework further, complete the coding, and analyze the data by employing our theoretical framework hybridizing ideas of Tall's (2010) three worlds of mathematics and Harel's (2008) ways of thinking and understanding. Our analysis will also include some recommendations for teaching linear algebra using and developing CAS worksheets, and to target future iterations and additional worksheets.

Academic Resources and Precalculus Students: Knowledge and Use of Tutoring Services, Skill Sessions, and Academic Coaching

Katie McKeown
The University of Alabama

Discussion of a study that examines data from a single large, public university to determine how and when precalculus students elect to use learning center resources and their experiences using these resources. Data collected and to be analyzed includes survey and interview data from the precalculus students, interview data from instructors, class and learning center artifacts, and interview data from learning center leaders.

Keywords: learning centers; mathematics; precalculus

Colleges and universities provide many supplementary academic resources to support students outside of the classroom in their learning. Designated spaces that provide many of these supplementary resources in one space are often referred to as learning centers and can be found at the majority of colleges and universities (Bhaird et al., 2009; Byerley et al., 2019; Gilbert et al., 2021; Grove et al., 2020; Lawson et al., 2020; Matthews et al., 2013; Rickard & Mills, 2018). However, a large number of factors may influence a student's decision to use these resources, including the difficulty of finding new sources of help when first entering college, their desire to learn the course material, and their prior knowledge (Giblin et al., 2021). While a variety of research on learning centers has examined the impact of learning centers on students' success (e.g., Wurtz, 2015) or the various roles of learning centers on a campus (e.g., Solomon et al, 2010), one of the gaps in learning center research is how students make the decision to seek out help and their experiences of the provided resources. This study intends to approach that gap using a multiphase mixed methods design study to explore what precalculus students experience concerning the phenomenon of using free supplemental learning resources. Data from the students, instructors, and learning centers at a single university will be analyzed to look at how and when students elect to use learning center resources and their experiences using them once there.

Given the importance of learning centers to postsecondary institutions and of knowing more about how students decide to use these sites, this study will look at how, in past, present, and future, precalculus students learn about, decide to use, and experience using academic resources external to their introductory mathematics course at a large, southern, public research university, following the proposed theory of source selection by Giblin and colleagues (2021). The resources focused on in the study will be the mathematics content tutoring offered by the campus learning center (LC), mathematics content tutoring offered by the campus student success center (SSC), academic coaching offered by the SSC, and skill sessions offered by the SSC. In particular, I ask:

1. What opportunities do precalculus students at a large, southern, public research university have to learn about each of the four resources being studied, and to what extent do students identify as being aware of each resource?
2. What factors relate to patterns or changes in use by students over time?

I will answer these questions using a variety of data sources, including site observations, student surveys and interviews, instructors and center coordinators interviews, and center and course artifacts. These data and research questions are part of a larger study that also incorporates learning center usage and demographic data from students in the precalculus course.

Literature Review and Theoretical Framework

Postsecondary institutions provide a variety of resources to support students in their learning of course material outside of classroom and lab time. However, in order to take full advantage of these resources, students must learn that the resources are available, decide to use those resources, and then, decide whether to continue or discontinue use for the duration of the academic term. Access to these resources is often found in central locations on campus, called learning centers, but places that provide academic supports also often go by the name of tutoring centers or subject specific centers.

Postsecondary Academic Support

In his glossary of developmental education and learning assistance terms, Arendale (2007) defines support areas as, "Institutional services, other than regularly scheduled classes and labs, designed to assess and improve the academic and emotional well-being of students" (p. 29). These services include a number of common support areas, including tutoring and advising services (Parker, 2020; Truschel & Reedy, 2009). Institutions also frequently offer academic skill sessions, which are usually defined to have the purpose of supporting students in developing skills that will transfer to future courses, such as how to study or manage time (Munley, 2010; Parkinson, 2009; Wurtz, 2015).

Learning Centers

When an institution creates a central location where multiple of the previously discussed supports are located, they are usually referred to in the literature as either learning assistance centers or learning centers (Arendale, 2007). As previously discussed, learning centers often are called by a variety of names, including tutoring centers and mathematics support centers.

Mathematics course support. Students seeking success in their mathematics courses frequently find their way to learning centers. In fact, in a study surveying 61 learning centers, the only service that every center reported offering was mathematics assistance/tutoring (Franklin & Blankenberger, 2016). Learning centers can provide a variety of services, but the courses a student is enrolled in determine which of the previously discussed resources are available to them at their institution. As this study explores student resource use in relation to a mathematics course, special attention is on the relationships that the learning center structure and resources have with mathematics content and coursework.

Learning center structure. The structure of learning centers varies widely across institutions (Byerley et al., 2019; Johnson & Hanson, 2015; Perin, 2004; Truschel & Reedy, 2009). Three of the most common services offered in learning centers are tutoring, academic coaching, and skill workshops (Truschel & Reedy, 2009). Structural differences include drop-in versus appointment only assistance, online versus in-person support, the qualifications of center staff, and the relationship, or lack thereof, between mathematics departments and learning centers.

Student decisions surrounding learning center use. This study explores precalculus students' experiences concerning the phenomena of using free supplemental learning resources. I look at this phenomena using Giblin and colleagues' proposed theory of source selection of (a) narrowing of sources, (b) evaluation, (c) solicitation, (d) evaluation of presented help, and (e) use of source as a theoretical framework (2021). In other words, students must find the resource, decide to try the resource, and then, after using the resource, decide whether or not to continue use.

Methods

Seven main types of data will be used to answer the presented research questions: class artifacts, interviews of course instructors, center artifacts, interviews of learning center supervisors, center observations, student surveys, and student interviews.

Class Artifacts

The course syllabus and information shared on the Blackboard home page were gathered. Information from these sources have been reviewed and will be coded for any evidence of information of any of the four free academic resources being considered in this study.

Interviews of Course Instructors

Once during the semester, I interviewed the course instructors. Questions focused on the nature and frequency of instructor-classroom communication concerning academic resources available to students as well as the instructors' knowledge of these resources. Interviews of course instructors used a semi-structured format, meaning that the interview protocol is used as a guide and questions and probes may or may not be used as well as may be presented in a different order than written (Roulston, 2013).

Center Artifacts

Center artifacts in the form of data presented on resource webpages and distributed advertisements for services sent to students were collected. These data were collected because direct contact from the centers may be a way that students learn about these available academic resources outside of the classroom. Center artifacts will be reviewed for any information that may support student survey and interview responses.

Interviews of Learning Center Supervisors

Once during the semester, I interviewed the learning center supervisors. The questions asked during the interview focused on the center's communications with students concerning available academic resources, including any intrusive messaging, and what they perceived as the typical experiences of students when using each of the resources being studied. Interviews of learning center supervisors used a semi-structured format described previously (Roulston, 2013). The questions and guidelines provided in the initial protocol were framed by the six significant dimensions of undergraduate mathematics tutoring centers described by Byerley and colleagues (2019): "(1) Specialist versus Generalist Math Tutor Models, (2) Strength of Relationship between Center and Math Instructors, (3) Type and Extent of Tutor Training, (4) Types of Tutoring Services, (5) Physical Layout and Location, and (6) Tutoring Capacity." The SSC leader interviews also contained questions about the skill sessions and academic coaching appointments available.

Center Observations

Twice during the semester, I observed both the campus LC and SSC. The observation protocol focused on gathering the nature of student-computer, student-student, and student-staff interactions in the centers. The questions in the observation protocol were framed by the six significant dimensions of undergraduate mathematics tutoring centers described by Byerley and colleagues (2019), described previously, as both centers provide tutoring services.

Student Surveys

Twice during the semester, I surveyed students about their use or plans to use the four resources being considered across the two centers. The first survey took place immediately following the end of the drop/add period at the university, in the second week of classes. The second survey was given near the end of the semester. Both surveys asked about each of the four resources being studied, with students reporting (1) the extent to which they have heard about or seen advertisements for that resource, (2) how much they have used the resource in the past, and (3) how much they intend to use the resource in the future. Questions concerning knowledge of, past use, and intended future use of resources were asked using scales increasing in frequency (e.g., never; happens on occasion, happens at least once a month, happens at least once a week, happens daily) along with clear layout and other recommendations for survey creation (Walston et al., 2017). The second survey also included questions about help-seeking behaviors and attitudes towards mathematics.

Student recruitment. Students were recruited into the study during a classroom visit that occurred immediately following the drop/add period of classes. During this classroom visit, I described the survey including risks and benefits and then provide a link to the first survey using an electronic QR code that was projected during class. In addition to asking about students' knowledge and use of the academic resources, the linked survey also contained a question asking students if they have interest in participating in the interviews.

Student Interviews

During the semester, I interviewed five different student participants, with three student participants completing two interviews. The first interview took place within the first month of the course, and the second interview took place following the second survey distribution. Interview questions focused on students' decisions to seek help, what informed their decisions to use any combination (including none) of resources offered by the two centers, and their experiences while using the resources.

Student interviews were conducted using semi-structured format as described previously (Roulston, 2013). The first interview focused on collecting information about the student, their course history, and other prior experiences related to seeking help in a mathematics course followed by the tailored questions concerning resource use experiences. The second interview followed a similar format. However, there were data points from two surveys as well as the first interview to guide questions. For example, if a student in the second survey indicated that they were using a resource after indicating they did not intend to use that resource during the first survey, I asked a question that aimed to dive into how that decision was made.

Planned Analysis

As I have just begun my analysis, the following descriptions of planned analysis are in future tense. However, all data have been collected at the time of this proposal submission.

Research Question 1

What opportunities do precalculus students at a large, southern, public research university have to learn about each of the four resources being studied, and to what extent do students identify as being aware of each resource? Using appropriate psychometric analysis on the student survey data, the frequency that precalculus students hear about resources available to them will be determined. Class artifacts, interviews of course instructors, center artifacts, interviews of center supervisors, center observations, and student interviews will first be reviewed for mention of different ways that resource availability may be advertised or discussed. The analysis of these data sources will flag any mention of these services, which could come from a variety of sources, including verbal or written communications, posted information in course Blackboard, or physical flyers. Finally, this information on the different methods of exposure to the resource availability will then be used to explain the student survey results related to whether students report being aware of those resources. These all point to the first step of Giblin and colleagues' theory of source selection, narrowing of sources (2021).

Research Question 2

What factors relate to patterns or changes in use by students over time? Using appropriate psychometric analysis on the student survey data, separately, the changes over time in survey responses will be analyzed. Analysis of student interviews, center supervisor interviews, and instructor interviews using a phenomenological line-by-line approach will point towards factors related to certain combinations of resources being used. The analysis of these data sources will flag any mention of decision to use or stop use of a resource, which could present in a variety of forms. Possibilities regarding decision of use include mentions of failing a test, struggling with homework, being referred to the resource by their instructor, or being referred to the resource by a friend. Possibilities regarding the decision to stop the use of a resource include expectations of using resources were not met, description of services by source they heard about resource from turned out not to be accurate, by their perception, or mention of not having time. Any mention of deciding to use no resources, a single resource, multiple resources, or all resources will be coded and considered. These data will point toward the other steps of Giblin and colleagues' theory of source selection including evaluation, solicitation, evaluation of presented help, and use of source (2021).

Next Steps and Questions

Next steps include completing the analysis; although all data have been collected, analysis has just begun at the time of submitting this proposal. Thus, there are not yet any results or conclusions to share. The analysis will continue until the conference in February, at which time I expect to provide results and conclusions.

Audience Questions

1. Can you think of any other frameworks that I should look at this data with?
2. Any experiences at your institutions/in your learning centers that might shed light on this study that you would like to share?

Student Perceptions of Individual and Group Creativity in Proving

Amanda Lake Heath
Middle Tennessee State University

Student described experiences in creativity can provide insight into instruction to foster creativity. In this report, I describe the emergent themes among student narratives describing when and why they felt creative during a collaborative proving activity. Continued work to refine these themes and their prevalence in student reflections can provide implications for how to best structure collaborative work to foster creativity in proof-based courses.

Keywords: Creativity, proof, collaboration

Both collaboration and creativity are central to the work of mathematicians (Karakok et al., 2015; Sriraman, 2004). Professional mathematicians have indicated collaboration is an important feature of their work (Sriraman, 2004), and the Conference Board of Mathematical Sciences (2016) has called for university mathematics classrooms to incorporate more active, collaborative learning. Therefore, there is a substantial need for K-16 education to focus on developing creative mathematicians and problem solvers with strong communication and collaboration abilities. In mathematics, students follow a journey in which there is an eventual transition from computational to proof-based mathematics (Civian & Schley, 1996). During this transition to proof, point students are often expected to become producers of mathematical ideas on their own for perhaps the first time (Boyle et al., 2015). For this reason, it is critical to study mathematical creativity and collaboration within the context of undergraduate mathematics courses and proof in order to cultivate the expertise needed by future mathematicians.

The purpose of this study is to investigate the creativity at work within an individual during creative collaborative proving. Although this study is being conducted in the larger context of a dissertation study, for this report I focus on the following research question: What actions or moments of the collaborative proving process do individuals report fostered their creativity? In this report, I first provide background literature on undergraduate mathematical creativity. I then describe the definitions and theoretical framings adopted in this study, outline the context and methods of the study, describe some preliminary results, and discuss the potential implications and future directions of this research.

Definitions and Theoretical Framing

Mathematical Creativity

Creativity has been notoriously difficult to define. Mann (2005) claimed there are over 100 existing definitions of creativity in the mathematics education literature, and this number has only grown with the volume of research on creativity published in the last 17 years (Savic et al., 2022). In this study, I adopt a perspective on mathematical creativity that describes creativity as *domain-specific*, meaning specific to the context of mathematics and mathematical proof, *a process*, meaning I will consider the motivation, perception, learning, thinking, and communicating involved in creativity, and *relative*, meaning considered within the context of the knowledge, abilities, and experiences of an individual. Put succinctly, ***mathematical creativity*** is defined to be the processes of creating, constructing, or implementing mathematical ideas, strategies, or processes, which are perceived as non-routine by the individual.

In this study I use the terms ***collaborative creativity in proving**,* or creative collaborative proving, to describe the process of approaching a shared goal in proving with significant contributions from two or more people, in which the proving task is either (a) assumed to be non-routine for all group members based on context or (b) established to be non-routine for all group members by asking them for their perspective.

Proof

In this study, situated within a university Introduction-to-Proof course, I adopt the definition of ***proof*** given by A. J. Stylianides, (2007):

> Proof is a *mathematical argument*, a connected sequence of assertions for or against a mathematical claim with the following characteristics:
> 1. It uses statements accepted by the classroom community (*set of accepted statements*) that are true and available without further justification.
> 2. It employs forms of reasoning (*modes of argumentation*) that are valid and known to, or within the conceptual reach of, the classroom community; and
> 3. It is communicated with forms of expression (*modes of argument representation*) that are appropriate and known to, or within the conceptual reach of, the classroom community. (p. 291, emphasis in original)

This definition allows for flexibility in the growth of a classroom community and the tools (both accepted statements and modes of argumentation) valid within this community.

Collaboration

One way to highlight the inner workings of students' approaches to proof initiation, proof construction, and proof validation is to engage students in collaborative proving. Collaboration is a tool for revealing the deeper processes behind proving and reflects the work of mathematicians (Grossman, 2002). To define collaboration beyond social interaction (Sriraman, 2004), I emphasize two elements of collaboration as a process: (1) contribution from two or more parties and (2) a common goal. This definition of collaboration can be applied to a classroom setting to describe collaborative learning, wherein typically student groups of two or more gain mutual understanding or create a product (Smith & MacGregor, 1992)**.**

Residue

Taking mathematical creativity as a relative construct requires asking students what they recall as fostering creativity for them, and these recollections will describe "what actually comes to the fore of [students'] attention" (Marton et al., 2004) regarding their creativity during collaborative proving as well as other activities in the Introduction-to-Proof course. Hiebert et al. (1996) described the importance of remembered experiences and influences as residue. Residue provides a way for thinking about what students take with them from classroom experiences. Therefore, residue for students with respect to creativity can give insight into the experiences, activities, and interactions that were meaningful for the student and inform how instructors can best shape classroom environments and activities to foster collaborative creativity in proving.

Background

It is undisputed that mathematical creativity has grown immensely as a research domain in the last ten years (Savic et al., 2022; Sriraman, 2017), yet research on mathematical creativity has been slow to extend to the tertiary setting (Savic et al., 2022). In this report, I aim to describe the actions or moments students experienced during in-class collaborative proving that fostered creativity for either themselves or their group. It is generally accepted that mathematical creativity can be developed and enhanced in students (Sriraman & Haavold, 2017; Zazkis & Holton, 2009), and mathematicians believe that mathematical creativity can and should be fostered in undergraduate mathematics courses (Karakok et al., 2015). Despite this consensus, there is little empirical research on what teaching strategies develop mathematical creativity among undergraduate students (Savic et al., 2022). No extant research has explicitly considered the impact collaborative work or collaborative proving may have on creativity. Investigating student perceptions of how collaborating with their peers on proving tasks fosters (or does not foster) creativity for them can inform how to best facilitate collaborative activities to promote creativity in proving.

In extant literature, the teacher actions most supported as effectively promoting mathematical creativity are choosing appropriate tasks (Satyam et al., 2022; Savic, El Turkey, et al., 2017a; Tang et al., 2022), allowing time for incubation (e.g., Savic, El Turkey, et al., 2017b), demonstrating different ways to solve problems and illustrating the mathematical process for students (Satyam et al., 2022; Tang et al., 2022), making the classroom a safe place to take risks (Satyam et al., 2022; Savic, El Turkey, et al., 2017b; Tang et al., 2022), attending to the emotions of students (Satyam et al., 2022; Tang et al., 2022), and providing space for discussion and disagreement (Satyam et al., 2022; Savic, El Turkey, et al., 2017a, 2017b; Tang et al., 2022).

Both Cilli-Turner et al. (2023) and Satyam et al. (2022) investigated how to foster creativity in undergraduate settings by considering student perceptions of creativity. Both of these studies, conducted in the context of Calculus I, reported six themes of student views of creativity: Actions and Attitudes, Application, Different Ways, Originality, Against Authority, and Understanding. Although these themes can help describe the ways in which students in an Introduction-to-Proof setting may view creativity, I seek to understand the specific ways in which students perceive themselves (or their group) as creative in a collaborative proving setting.

Methods

Context and Participants

Data were collected from an undergraduate Introduction-to-Proof course at a large public southeastern university in the United States. This course was facilitated in a collaborative, inquiry-based learning environment in which small groups of 3-4 students worked together to prove instructor-provided mathematical conjectures. The study discussed in this report is a small portion of a dissertation study on collaboration and creativity in mathematical proving. This report focuses on undergraduate students' impressions of their individual and group creativity after working in groups in class to collaboratively prove the statement: The product of consecutive twin primes is one less than a perfect square. In this report, I draw upon available written narrative data from eight participants.

Data Collection and Analysis

Students were instructed to remain seated at their group tables for five minutes of individual think time and then move to a whiteboard space to share their ideas with their peers and construct a proof. Students were each given a different color whiteboard marker to track their ideas on the collective dry erase board space. After the class session, students completed a retrospective writing assignment in which they were tasked with reflecting upon their experience working collaboratively in class and describing the times in which they felt (or did not feel) creative during the activity. These assignments were due at 11:59pm the day of the collaborative proving activity to mitigate delayed recall (Gass & Macky, 2000), in which a person creates a new mental process instead of recalling their original ideas (Lyle, 2003). Students were asked to (I) provide a sequential narrative of their group proving experience and (II) answer the question "When during the collaboration did you feel like you or your group were creative? If you did not feel creative, explain why not. Include as many details as you can."

To determine the actions or moments students perceived as influential on their individual and group creativity during the in-class activity, I narrowed my data source to only include written responses to task (II) of the writing prompt. First, I conducted an inductive, in-vivo coding strategy (Saldaña, 2016). The in-vivo codes were grouped into themes, and I conducted a second round of coding using this list of themes to identify the most frequently cited moments and incidents that initiated creativity for students. All sentences of responses to (II) containing reasons for feeling (or not feeling) creative were given at least one thematic code.

Preliminary Results

The inductive analysis of participant retrospective writing assignment submissions revealed 11 themes in their reflection on their individual creativity: Brainstorming, mistakes, noticing patterns/making conjectures, task novelty, suspense/pressure, teamwork, trying different ways/seeing things in different ways, writing an equation/formula, connecting mathematics and words, uncreative, and other. The most common themes were teamwork/collaboration, noticing patterns/making conjectures, uncreative, and writing an equation. Table 1 provides the frequency of sentences, proportion of participant responses, and a participant quotation illustrating the code theme for the themes reported by at least three participants, excluding the "other" category.

Table 1. Themes to Answer RQ1: What actions or moments of the collaborative proving process do individuals report stimulated creativity for them?

Theme	Frequency	Proportion of Students	Participant Quotation
Teamwork	13	5/8	"I believe that my group was even more creative than we could have been individually."
Noticing Patterns/ Conjectures	10	6/8	"We also felt creative in noticing the pattern with every pair of numbers we used to verify the proof."
Uncreative	10	5/8	"I did not feel very creative at the beginning of the group exercise, as I was sure that every group was thinking about writing out examples for the first step."
Writing an Equation/ Formula	9	6/8	"In our group work I felt that we were able to be the most creative when we were figuring out our initial equation."

Trying Different Ways/ Seeing Things in Different Ways	7	5/8	"Thinking outside of the box and using a variety of methods to solve a proof is what creativity in mathematics is all about."
Brainstorming	4	3/8	"We all began throwing out ideas on how we could solve this problem."

Discussion and Conclusion

In this report, I have characterized the types of actions or moments students reported as causing them to feel creative during an in-class collaborative proving exercise. A first observation is that students rarely emphasized themselves as feeling individually creative in their narratives (e.g., "I felt creative when…"), but rather emphasized the creative actions of the group as a whole (e.g., "my group was creative when…"). This distinction, in part, may be attributed to feeling as though the group's capacity for acting creatively was greater than capacity of the sum of the constituent members, as one participant indicated, "I believe that my group was even more creative than we could have been individually." Further, students may feel uncomfortable taking individual ownership in their narrative writing reflecting upon a collaborative task.

Regarding the themes present in student narratives, many align with the teacher actions previously indicated to foster creativity in different undergraduate mathematical contexts (e.g., Tang et al., 2022). For example, five students recognized themselves or their groups as creative when they tried to approach the proof using a different strategy or look at the problem in a new way, which corresponds to Tang et al.'s "encourage mathematical behavior" (p. 541) teaching action to foster creativity. Moreover, the most frequently mentioned moment, engaging in teamwork (13 mentions), corresponds to "allow for discussions" (Tang et al., 2022, p. 541), yet participants in this study attributed their feeling creative to positive teamwork, rather than simply the opportunity to engage with their peers. One student said,

> I think a vital part of collaboration is the group's overall willingness to actively collaborate. In this way uncooperative group members stifle the creativity of the group. I really appreciated that no one in my group ignored the ideas of others.

These preliminary findings indicate students may recognize opportunities to be creative in mathematical proving by collaborating with their peers in specific ways. Data used in this report is limited to eight student narratives following a single in-class collaborative proving activity; however, data collection and analysis will continue throughout the Fall 2023 semester to provide a more holistic image of the ways in which students perceive themselves and their teams to be creative in proving. The results of this study may be able to both verify the results from previous research on student perceptions of creativity in Calculus I (Satyam et al., 2022; Cilli-Turner et al., 2023) as applicable also to an Introduction-to-Proof setting, but also provide a guide for facilitating creativity-fostering collaborative work in undergraduate proof-based mathematics courses.

Acknowledgments

I would like to thank Dr. Sarah K. Bleiler-Baxter for graciously welcoming me into her classroom for this study and assisting me with data collection.

Motivations for Grading Among Math and Physics Faculty

Brianna Huynh
Pomona College

Warren Christensen
North Dakota State University

A student's course grade is typically an overall representation of multiple graded categories chosen by faculty. This study uses interviews with math and physics faculty to determine their rationale for selecting grading and assessment systems. We hope by identifying common faculty motivations, we can provide a baseline for future discussions on the implementation of alternative grading practices. Semi-structured interviews were conducted to present math and physics faculty with questions regarding enrollment size, length of implementation, and feedback processes. Preliminary analysis of faculty interviews demonstrates significant similarities in rationale across departments. All faculty considered enrollment size and course content when selecting systems. Findings indicated two central student learning goals and the emergence of four dominant motivations.

Keywords: Faculty Rationale, Goals for Student Learning, Teaching Practice, Grading Practice

Background

Teaching practices are at the heart of transforming STEM education in U.S. colleges and universities. More specifically, students' experiences in introductory mathematics courses play a crucial role in their overall retention in STEM fields. Both high and low-performing students have frequently cited teaching in their introductory courses as a factor in their choice to switch majors (PCAST, 2012). Members of groups underrepresented in STEM fields have also experienced significantly lower retention rates (Brainard & Carlin, 1998; Bressoud, 2011; NASEM, 2016). Recent calls for improving mathematics education have focused on the implementation of instructional activities that engage students in active learning and promote higher order thinking (CBMS, 2016; Freeman, 2014; Saxe and Braddy, 2015). This study seeks to expand upon prior research by focusing on teaching practices, specifically grading practices, rather than instructional activities.

To distinguish between instructional activities and teaching/grading practices, we employ the definitions provided by Speer, Smith, & Horvath (2010). Instructional activities refer to "the organized and regularly practiced routines for bringing together students and instructional materials" (p. 101). In contrast, teaching practices encompass the thinking, judgments, and decision-making teachers use to prepare for and teach their courses (Speer et al., 2010, p. 101). Research in this underexamined area of mathematics education will be a valuable catalysis for the widespread adoption of empirically validated teaching practices—a key recommendation advised by PCAST (2012). Furthermore, this research will benefit the expansion of professional development opportunities for faculty as prior research has been limited in scope (Crooks-Monastra, 2021; Deshler, Hauk, & Speer, 2015; Speer, Guttmann, & Murphy, 2009). This study focuses on tenured and tenure-track faculty, as opposed to graduate teaching assistants, because these faculty are more independent and less transient. Concerns expressed by faculty may also be useful for designing professional development materials appropriate to this demographic.

Within the scope of faculty's teaching practices, this study examines the role of beliefs, orientations, and resources in the selection of grading and assessment systems. Assessing student learning is a core component of collegiate teaching and varies greatly by instructor, discipline, and institution type (Lipnevich et al., 2020). Variations of grading scales have been proven to amplify racial or ethnic inequities in introductory STEM courses (Paul & Webb, 2022). Moreover, arbitrary depression of grading scales has contributed to poor student perceptions of STEM courses and decreased persistence in STEM majors (PCAST, 2012). While a large and growing body of research has indicated a need to move toward alternative learning environments, traditional teaching practices have been resistant to change (PCAST, 2012). We believe that understanding the current landscape of collegiate teaching will improve strategies for implementing alternative grading practices. To address these concerns, we sought to answer the question: *What considerations do faculty make when selecting grading and assessment systems for their classes?*

Theoretical Framework

This study utilizes a post-facto implementation of Schoenfeld's goal-oriented decision-making theory. At the core of this theory is the idea that "one's decisions about what goals to pursue and how to pursue them, are made on the basis of one's current resources, goals, and orientations" (Schoenfeld, 2011, p. 8). This theory is especially prevalent in "well practiced" domains, like teaching, where individuals are engaged in established patterns of behavior. Instructors enter the classroom with an array of knowledge and resources that may be conceptual, social, or material. These knowledge bases and resources are then called upon to achieve goals at the macro and micro level of classroom instruction. In this study, we rely upon Schoenfeld's (2011) definition of goals as "something that an individual wants to achieve, even if simply in the service of other goals" (p. 20). In applying this theory to the study of college faculty, we seek to connect motivations for selecting grading and assessment systems to overarching goals for student learning. We rely solely on interviews for this study because assessment practices are generally not accessible to classroom observation (Speer et al., 2010). A comparative study of these interviews will provide insight on the rationale of faculty across the disciplines of math and physics.

Methods

Participants

An invitation to participate in the study was sent to all tenured and tenure-track faculty in the math and physics departments at a public mid-sized research university in the Midwestern United States. Two math and two physics faculty volunteered for the study. Including graduate school experience, the faculty averaged 22 years of teaching. Expanding the study's participant pool to include physics faculty provides greater context for drawing comparisons across and within disciplines.

Data Collection

The first author conducted in-person, 30–60-minute, semi-structured interviews (Browner, 1988) with each faculty member in the summer of 2023. Zoom was used to audio record and auto-generate transcripts. Each interview was followed by a short-written survey to collect demographic information about the participants. All transcriptions were cleaned for accuracy and anonymity by the first author, before being shared with the second author for data analysis. Transcripts were labeled "M#" and "P#" to represent participants' respective disciplines. The numbers indicate the order in which the interviews were collected.

The interview protocol focused on the implementation of grading systems in small and large enrollment courses. For the purposes of the study, small enrollment courses were defined as having 15 or less students and large enrollment courses were defined as having 150 or more students. To distinguish between the discussion of these courses in interviews, participants were asked to answer separate sets of questions about courses of each enrollment size. This section of the interview protocol included the following questions:

1. How do you determine grades for a course with an enrollment of 15/150 students?
    a. Could you describe the percentile breakdown of those different graded tasks?
    b. Why have you chosen these percentile breakdowns?
    c. What course are you using as a point of reference?
2. How long have you been using this grading system?
    a. What do you value about this system?
    b. Some past participants have said they value "ease" in their grading system. Is this something you consider?

Other interview questions included follow-ups about enrollment size that were asked if participants did not distinguish between these courses in their initial response. The interview protocol concluded with questions concerning faculty's consideration of alternative ways of determining a grade. When asked for the definition of "alternative" participants were told that "alternative" referred to systems different from their own.

Data Analysis

We employed generative coding (Otero & Harlow, 2009) to identify themes in participant's responses. Together, both authors read the transcripts and highlighted text segments that characterized participants' motivations for implementing grading and assessment systems within their classes. The highlighted segments were used to find emergent themes across participants. The first author then went through and compiled these motivations, generating a list of 17 items.

Preliminary Results

Our analysis found that faculty across the disciplines of math and physics were influenced by four dominant motivations: (a) grades reflect learning, (b) assumed maturity, (c) clear feedback, and (d) ease of grading. While these motivations were similar across faculty, their manifestations within individual faculty's courses differed greatly by course content and enrollment size. Table 1 summarizes these findings with examples from faculty interviews. We note that the motivations are not ordered hierarchically and were prevalent in all faculty's discussion of grading and assessment systems.

Table 1. Dominant motivations expressed by faculty when discussing grading and assessment systems.

Motivation	Definition	Example
Grades Reflect Learning	Faculty believe grades should be an accurate reflection of student learning.	Participant M2: So, if A is excellent, B is very good, C is average and D is just passing, then how can it be that a whole class gets just A's? **I don't know what the purpose of grades are if everybody's excellent.** How can everybody be above average? That makes no sense to me.
Assumed Maturity	Faculty assume students in upper	Participant M1: Whereas for the **higher-level class**, it was like there are things that I'm not measuring exactly

	division courses have developed more “mature” learning processes.	like are you reading the textbook and, uh, like are you actively trying problems outside of the ones that I specifically asked you? And so yeah, I hope that **there's some level of maturity** that is reflected in the, uh, grading breakdown.
Clear Feedback	Faculty desire systems that allow for clear and timely feedback.	Participant P2: Usually for [a] 20-minute exam, **I use at least the same time**, probably more, to just **discuss the solutions**. To discuss what are possible approaches to solve it and what were the difficulties and challenges and all these things.
Ease of Grading	Faculty rely on systems that simplify grading processes and optimize time spent grading.	Participant P1: We have so few, uh, graduate teaching assistants that we've been forced, and some of us at least. I know that others, I commend them for the effort they put in to, you know, give direct feedback to students. But, um, some of us have resorted, you know, **out of necessity**, to an online homework system.

Grades Reflect Learning reflects faculty’s desire for grading systems that accurately measure student learning. In our interviews, this perspective was captured with the question: “What does an ‘A’ grade represent in your class?” All participants expressed that an “A” student is someone who has a strong understanding of the course content and performs well in multiple graded categories. While the graded categories varied between courses, all participants emphasized the importance of grading systems that accounted for student performance on assessments and engagement in the learning process, e.g., completing and submitting homework on time.

Assumed Maturity reflects instances in which faculty’s perception of student maturity influenced their grading system. The “maturity” referred to by faculty is regarding students' approach to the learning process. Across all participants, we found that the inclusion of graded categories for procedural tasks—pre- and post-lecture assignments, clicker questions, and reading quizzes—was primarily done in lower-division courses. Whereas in upper-division courses, grading systems consisted almost exclusively of homework and exams. We found that this was because faculty believed that lower-division students were in the early stages of developing strong study habits and needed incentives to engage in these learning processes.

Clear Feedback reflects faculty’s concerns regarding clear and timely feedback processes. We found that participants used a variety of feedback systems in their courses from personalized written notes on assignments to whole-class discussions of exam solutions. Some participants emphasized the importance of “grade transparency,” e.g., always having overall course grades available to students through an online gradebook. All participants discussed difficulty with offering detailed feedback to students in large enrollment courses.

Ease of Grading reflects faculty’s consideration of time spent grading when selecting systems for their courses. When asked to discuss their grading procedures, all participants commented on having a reliance on grading assistance for large enrollment courses. When graders and teaching assistants were not available, participants utilized online homework systems to provide students with quick and direct feedback. For small enrollment courses, we found that faculty preferred to do all the grading because it gave them a better snapshot of student understanding.

Discussion / Conclusion

We initially approached this study with inductive analysis to determine whether broad themes would emerge in faculty's discussion of grading and assessment systems. Our study found that faculty consider four dominant motivations when making these choices for their courses. We believe the discussion around these motivations could additionally provide insight into the goals faculty aim to accomplish in the classroom. Employing Schoenfeld's goal-oriented decision-making theory, the motivations we found in our initial analysis can be mapped to overarching goals for student learning.

An example goal could be, "Create Timely Feedback Systems." This goal directly connects two of our previously identified motivations: *Clear Feedback* and *Ease of Grading*, (see Table 1). By considering faculty's beliefs, orientations, and resources, we can explain the stark differences between the implementation of grading and assessment systems in large and small enrollment courses. Faculty's lack of material resources—graders and teaching assistants—has led to the use of online, auto-graded homework systems in large enrollment courses. Whereas in small enrollment courses, material resources played less of a role in faculty's decision-making processes.

A second example goal could be, "Balance Process and Product Grading Criteria." This goal refers to faculty's decision making in determining graded categories for their courses and makes use of one previously identified motivation, *Assumed Maturity*. Process criteria reflect student behavior and/or the procedural tasks students complete throughout the learning process (Lipnevich et al., 2020). Product criteria reflect student performance at a point in time, assessed by written and oral exams (Lipnevich et al., 2020). Past research suggests that the most important faculty beliefs are those that concern faculty's perception of the causes of student behavior (Clark & Peterson, 1984). Our research found that faculty's perception of student maturity resulted in variations between grading systems in lower and upper division courses. For example, all participants believed that active student engagement in the learning process could only be accomplished by incentivizing lower division students with points for completing procedural tasks. While in their upper division courses, there were few or no points awarded for these tasks because faculty believed students had developed more mature learning processes.

As we continue to apply Schoenfeld's theory to our preliminary findings, we will build a deeper understanding of how faculty's beliefs, orientations, and resources shape their goals for student learning. These findings will shape the approach to wider implementations of alternative grading practices among tenured and tenure-track faculty.

Questions for the Audience

Is Schoenfeld's goal-oriented decision-making theory an appropriate tool for understanding faculty motivations, or are there other theoretical frameworks that would provide greater explanatory power?

We foresee multiple avenues for this research going forward. What next-step questions do you most want answered?

Acknowledgments

I want to thank Idris Malik for their continued guidance and feedback. I am also grateful for the innumerable other individuals who made this research opportunity possible.

VMQI Research Team

We present work in progress that addresses the question: How do researchers in mathematics education define and operationalize the concept of equity in their work? Using a wide search of articles published in mathematics education research journals over the 2000-2022 period, we identified an initial sample of 47 empirical and theoretical articles, which was then reduced to 28 articles that operationalized or defined equity. In 17 of the 28 articles that included a definition, we found that equity definitions encompassed mainly notions of fairness, access, participation, and demanding mathematics, and we observed several references to bridging, identity, agency, and power. We summarize the scholars' rationales, purposes, and motivations for addressing equity across the 28 articles and suggest that a more critical stance is needed in the operationalization of a definition of equity.

Keywords: equity, mathematics education research, literature review, instruction

Addressing equity in mathematics classrooms has been a concern for mathematics education researchers since the 1980s (Secada, 1989; Stanic, 1989) and for the RUME community at least since 2018, when the following Equity Statement was issued:

> The SIGMAA on RUME recognizes that equity issues are present and relevant in our research and practice. The SIGMAA on RUME affirms that as an organization we are committed to being critical and introspective about the ways that equity can be more meaningfully integrated into our discipline (http://sigmaa.maa.org/rume/Site/About.html)

The statement addressed "ways in which equitable practice can be furthered in the context of mathematics instruction" and "ways in which the SIGMAA on RUME aims to increasingly value and cultivate research on issues of equity in undergraduate mathematics" issuing "calls of action to the community to begin to remove or circumnavigate (…) barriers [to equity]." However, our perusal of the literature yielded very few research mathematics education studies addressing equity in undergraduate education and moreover, we found a multiplicity of definitions and in some cases, studies without a definition, perhaps suggesting that there is a common understanding of the construct. We believe that for advancing equity work through research, understanding how the community defines *equity* is critical. Most of the information, however, comes from work on K-12 contexts.

Prior to the 2000s, much work on equity was driven by significant differences in student outcomes by student characteristics such as gender, race, ethnicity, and socio-economic (e.g., Lee et al., 1997; Secada, 1995; Warren & Roseberry, 1995). The publication of the *Principles and Standards for School Mathematics* by the National Council of Teachers of Mathematics (NCTM) in 2000 marked the first time in which equity was explicitly addressed as a principle[1] for teaching and learning in schools, paired with a notion of ambitious mathematics (Lampert, 2001) that was expected to be made available to all students. From such work, we have learned that equity is not equality (Secada, 1989) and that equity and social justice are intertwined terms. Yet, to inform research that improves practice, the research community needs a definition that can be operationalized, so that equitable teaching can be systematically studied. For this reason, we engaged in a literature review process that would allow us to answer the following questions as related to the US context: (1) What are the definitions or operationalizations of equity used in articles published in mathematics education journals in the period 2000-2022? and (2) How do researchers justify and motivate their equity work?

Methods

We searched for empirical or theoretical articles in peer-reviewed scholarly journals under the assumption that such work would have been vetted by the mathematics education community. The journals included: *Cognition and Instruction*; *Educational Researcher*; *Educational Studies in Mathematics*; *Journal for Research in Mathematics Education*; *Journal of Mathematics Teacher Education*; *Journal of the Learning Sciences*; *Journal of Urban Mathematics Education*; *Mathematical Thinking and Learning*; *Race Ethnicity and Education*; *and Review of Educational Research*. We chose 2000 as the starting year for the review, when the *Principles and Standards of School Mathematics* (NCTM, 2000) were published. This was necessary because most of the work on equity has been advanced with the K-12 context and has been used to investigate tertiary contexts (e.g., Leyva et al. 2021).

We searched various databases (e.g., ERIC, ProQuest, PsychInfo) for articles that dealt with equity and mathematics instruction ("equit*" AND "instruct*", "equit*" AND "teach*", and "equit*" AND "classroom"; added "math*" for non-math specific journals). We only selected articles that collected United States data. This was done to provide a common historical, cultural, political, and social context (e.g., the legacy of slavery, the Civil Rights and women's movements, or immigration policies) for framing equity which is harder to assume for studies conducted in other countries. The process of identifying the analytical sample involved two steps (see Figure 1), screening (to eliminate articles that did not address equity) and focused reading (to identify key elements in the article related to equity). Eight researchers were involved in the process.

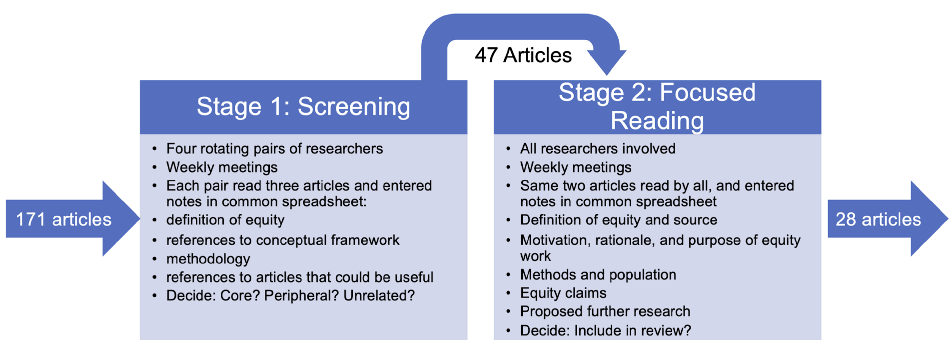

Figure 1. Article reviewing process. Note: Core: equity is central to the article. Peripheral: relevant topic for contextualizing equity. Unrelated: no mention of equity beyond reference list.

[1] **Equity.** Excellence in mathematics education requires equity—high expectations and strong support for all students. (NCTM, 2000, p. iv)

Preliminary Findings

The 28 articles included in this report were published in eight of the 10 journals chosen (see Table 1). Of these, five were theoretical papers and 23 were empirical studies. Twelve of the 23 empirical studies targeted students at various levels from elementary school through undergraduate students at university as the research population, eight on teachers, and three on both. Of the 12 articles that target students, three focused on elementary grades, six on middle school, six on high school mathematics, four combined data from middle school and high school, and four on undergraduate mathematics. Five articles did not specify a grade level. Sample sizes were relatively small: 1- 4 teachers for studies that focused on teachers and less than three classes for studies that focused on students. Two studies of students had large samples (288 and 522); two studies of teachers had over 20 participants (23 and 39). The theoretical papers did not specify a target population.

Table 1: Distribution of the 28 papers across the research journals

Journals	# Articles per Journal
Journal for Research in Mathematics Education, Journal of Urban Mathematics Education	6
Mathematical Thinking and Learning, Race Ethnicity and Education	4
Educational Studies in Mathematics, Journal of Mathematics Teacher Education	3
Review of Educational Research, The Journal of the Learning Sciences	1

In what follows, we present our findings on the definitions and operationalizations of equity and the rationales, motivations, and purposes for conducting equity research.

Definitions of Equity

Of the 28 articles included in this analysis, only 17 either defined or operationalized equity. The earliest two pieces, by Cobb and Hodge (2002) and Gutiérrez (2002), proposed two distinct conceptualizations of equity. Cobb and Hodge defined equity and diversity as correlated terms, with diversity referring to the different students' (in and out of school) practices that they participate in and with equity referring to how, once the common practices and less common practices are recognized, students can successfully access them, through mathematical reasoning that has "clout" (Bruner, 2009). Gutiérrez (2002) proposed that equity can be recognized when researchers can't predict inequities (in outcomes or in achievement) by individual traits. Her definition has three elements related to the practices enacted by teachers, students, and mathematics to (1) develop proficiency in dominant mathematics; (2) be critical of math and its role in society; and (3) improve the relationship between people, mathematics, and society to erase inequity (that requires the cultivation of individual agency and the recognition of power) (p. 174). These two definitions made references to mathematics tangentially, Cobb and Hodge in terms of classroom practices and discourse and Gutiérrez in terms of "dominant" mathematics.

Esmonde (2009a, b) published two articles in 2009, both of which addressed equity. In her conceptualization of equity, two key distinctions are made—first, that equity relates to *fairness* ("a qualitative sense of fairness", 2009b, p. 1010) and second, that equity and equality are not the same. Esmonde used a definition of equity that refers to a fair distribution of opportunity to learn and a fair distribution of opportunities to participate in ambitious mathematics. In the set of articles we reviewed, this is the first time we observed an explicit reference to the *kind* of mathematical content and instruction that teachers should be striving to offer, embracing students' contributions, beyond a general description of *dominant* mathematics.

The definitions present in the 12 articles published after 2009 have elements that strongly resonate with these four and in some cases advance the attention that researchers put on studying equity in classrooms. There are several constant features; for example, references to access to worthwhile, high level, or meaningful, rigorous, mathematics experiences and inquiry (e.g., Cross et al., 2012; Dunleavy, 2015; Felton-Koestler, 2019; Louie, 2018, Munter et al., 2019) or that all students should be offered such practices (Cho et al., 2022; Cross et al., 2012; Dunleavy, 2015; Hand 2012). But there are also differences, for example defining equity as a *process* (Gregson, 2013) with two components – first, giving students the opportunity to learn mathematics content, its processes and norms, and second, supporting those who do have not had access to those, in bridging their own cultural knowledge to get to the dominant one (e.g., Felton-Koestler, 2019; Lo & Ruef, 2020). The goal of this type of equity in mathematics is to reduce social inequity. This definition resonates with Gutiérrez's 2002 definition, but also with her 2012 article that framed equity as learning to "play the game" to being able to "change the game" (p. 11).

We observed other differences in how authors further specified the object of equity or how equity was to be realized; for example, in terms of how students relate to each other in classrooms and the recognizable actions that can lead to democratic learning communities (Sengupta-Irving, 2014), recognizing "competent sense-makers" (Dunlevy, 2015, p. 62), and acknowledging that racialized experiences can burden students when doing highly cognitive demand work (Munter, 2019); these scholars address agency, power, and identity, even when this is not explicitly stated. These definitions can be seen as influenced by Gutiérrez's (2012) chapter that defined equity along two axes, a dominant one that related access and achievement and a critical one that related to identity and power. The influence of this piece is seen throughout several of the articles, notably Mintos et al. (2019), who used this framing in their study of how equity was taught in secondary teacher education programs.

One final element of the definitions from the later articles refers to how researchers and teachers notice, become aware, or recognize equity or inequity, and indicate that such noticing is fundamental to social justice work. We note that while all 17 articles made some reference to fairness in access and opportunity to participate and learn, very few assumed a critical stance regarding the role of mathematics in maintaining the status quo or addressed specific individual identities. Almost all the articles emphasized that equity work should be for *all* (e.g., "broad range of learners from dominant and nondominant ethnic, racial, and linguistic backgrounds in rigorous mathematical inquiry", Hand, 2012, p. 237) which erases the need to attend to identity.

Purpose, Motivations, and Rationale for Conducting Equity Research

In our analyses, we defined *purpose* as the objective of the article, specifically the questions the authors wanted to answer or the argument they wanted to make; *motivation* as the reason why authors identified the purpose, or the broader context that made the purpose worth pursuing; and *rationale* as the authors' reasons for why equity is worth researching; the rationale signals macro-level aspects (e.g., society) whereas purpose and motivation are specific to the article. Empirical studies and theoretical articles had different purposes. The most common purposes in empirical studies related to analyzing teachers' practices and implications for equity (e.g., Battey, 2013; Gregson, 2013), teachers' learning about and understanding of equitable instructional practices (e.g., Felton Koestler, 2019; Mintos et al., 2019), understanding what specific curriculum or pedagogy works for whom (e.g., IBL for women, Ernest et al., 2019), and understanding the relationship between equity and how students work in groups (e.g., Esmonde, 2009a; Lo & Ruef, 2020). The most common purposes of theoretical pieces were to offer a new perspective on equity research, for example that equity research needs a critical perspective (Gutiérrez, 2002) or that equity is "a delusion" and antiblackness needs to be addressed (Martin, 2019). Motivations included (1) responding to or testing out a reform curriculum or pedagogy (e.g., Lubienski, 2000; Johnson et al., 2020), (2) addressing gaps in understanding of teacher practice and preparation (e.g., Gregson, 2013; Hunt et al., 2022), and (3) arguing that current perspectives on equity are incomplete (Gutiérrez, 2002; Louie, 2018). The latter was present in theoretical and empirical articles and includes motivations for countering a deficit-based lens (e.g., Berry et al., 2014; Boaler, 2002b). Rationales included the unequal access to learning mathematics and achievement gaps by social identity groups (race, gender, or SES). In this case, the rationale for researching equity was that students need or should be able to participate and succeed in mathematics, and that this is not currently happening. In contrast to unequal access, Martin (2019) and Gutiérrez (2002) centered the field of mathematics, not the students, as the rationale for why equity needs to be attended to. Gutiérrez (2002) noted that the field of mathematics could benefit from perspectives from marginalized groups and Martin (2019) pointed out that mathematics needs fundamental change to support the liberation of Black learners. Though all the articles argued for change in some respect, Gutiérrez and Martin are notable because they shifted attention to mathematics away from students' success and reminded researchers that students have agency in this process.

Discussion

Across the articles analyzed, we saw definitions and purposes that directly responded to, or challenged, reform practices and definitions of equity in the wake of NCTM's (2000) *Principles and Standards*. In post-secondary education, the two studies that investigated equity did so by identifying *inequities* (in performance, e.g., Johnson et al., 2020; in participation, Ernest & Reinholz, 2019), so equity is only possible to identify when it does not occur. We recognize the need for equity after inequity has been measured. Such approach is aligned with Gutierrez's 2002 proposal that we will be able to say that equity is achieved when we can't predict performance based on identity traits. Our findings suggest that such a strong focus on responding to calls for reform might prevent giving greater attention to taking a critical perspective on equity. The scholars' focus on the dominant axis of access and achievement (Gutierrez, 2012) may unintentionally disengage with the critical access that requires attention to both identity and power. Finally, we noted that the varied definitions are symptomatic of a field that has not grappled with unifying forces to collectively investigate equity so that it can further inform practice across contexts.

Predictive Effects of Students' Grades in Prior Mathematics Courses

DFW rates in first-year mathematics courses are a major concern for undergraduate institutions. In this study, we explored statistical trends in grades for students who repeat mathematics courses or transition to subsequent courses. We analyzed trends among final grades in courses from Intermediate Algebra through Calculus II over the past five years at a major midwestern metropolitan university. Our results show that students are statistically more likely to pass a class on their first attempt, and that DFW rates among students who repeat a course hover around 50% for subsequent repetitions of the same course. We also found that final grades are a strong predictor of grades in subsequent courses, with students who earn an A in the previous course being 3 and 4 times more likely to pass the subsequent course than students who earn a B or C, respectively. We conclude by discussing the implications of our results.

Keywords: DFW rates, First-year mathematics courses, Course trajectories

DFW rates in first-year mathematics courses are a concern for universities, four-year colleges, and community colleges alike. Many factors contribute to student success in a course, including past mathematical experiences and prior mathematical knowledge. In this preliminary study, we explore trends in student grades as students transition from prerequisite mathematics courses into subsequent courses along a standard course trajectory. In particular, we focus on a sequence of first-year courses ranging from Intermediate Algebra to Calculus II and analyze the relationship between students' grades in prior courses and DFW rates in subsequent courses.

Background

Enrollment in first-year mathematics courses is increasing. The College Board of Mathematical Sciences reported that estimated enrollments increased by 21% for precollege level mathematics courses, by 16% for introductory level courses, and by 8% for calculus level courses between fall 2010 and fall 2015 at four-year institutions (Blair, Kirkman, & Maxwell, 2018, p. 1). Over the same time period, Bressoud et al. (2015) found that DFW rates in Calculus 1 courses ranged from 22% to 38% among two-year and four-year institutions in the USA. Notably, no systematic data collection has yet taken place to provide statistics on DFW rates in precollege level mathematics courses or introductory level mathematics courses at the college or university level in the United States. Yet, administrators at many institutions cite their college algebra courses as significant challenges to student retention (e.g., Callahan & Belcheir, 2017; Gordon, 2008).

Success in a student's first college mathematics course is especially important for retention and persistence. In one study, Callahan and Belcheir (2015) found that only 55% of students earning a D, F, or W in their first mathematics course were still enrolled in college one year later (p. 168). To ensure that students succeed in passing their first college mathematics course, appropriate placement is critical (Bressoud et al., 2015; Harrell & Lazari, 2020). In their report on characteristics of successful calculus programs, Bressoud et al. (2015) highlighted the importance of effective placement procedures on student success and, in particular, the attention paid to students near the cutoff. It was found to be essential that students who were identified as "ready for calculus" but more at-risk than their peers, as well as students who did not place into calculus, were given special attention and placed into programs that suited their individual needs.

Our work adds to the body of research on factors affecting success in first-year mathematics courses. Rather than focusing on a single course in isolation, we instead examine a sequence of courses that STEM-intending students typically take as they progress through lower-level undergraduate mathematics courses. While we acknowledge that student "success" in mathematics encompasses many variables beyond just a student's final grade in the course, our preliminary work focuses on two primary research questions:

1. How does a student's grade in a prior course affect their likelihood of earning a passing grade in a subsequent course?
2. For students who do not pass a course, what is their likelihood of passing the course in a repeated attempt?

Methods

For our study, we gathered institutional data for all undergraduate students enrolled in any mathematics course at a major midwestern metropolitan university from Fall 2018 to Spring 2023, along with the enrollment records of any previous mathematics courses students had taken for a period of at least two years prior. Individual students were referenced within our dataset by anonymized identification numbers (pseudo-ID) along with the term, course, section, and registrar grade for all enrollments.

The first step of our analysis was to take this list of student enrollments and use it to build a data structure which captured the variety of paths students may take when progressing through courses. To begin, we loaded the enrollment data into a relational database and cleaned entries to ensure that the three-tuple of pseudo-ID, course name, and term of enrollment was unique. This cleaning step made it possible to accurately account for students repeating courses by computing the instance number of each student's enrollment in any given course. That is, for a student with a given pseudo-id enrolling into course X in term Y, we counted the number of times that this same student enrolled in course X in a term chronologically before term Y, then added 1. This yielded a natural way to find students taking a given course for the first, second, or *n*th time by searching for instance numbers of 1, 2, or *n*, respectively within those course enrollments and forms the basis for the analysis necessary to answer RQ2.

We then used these data to create a course transition table to track the history of what mathematics courses a student had taken prior to any given enrollment by identifying pairs of prior and subsequent courses. This transition table forms the basis of the analysis of student grades in subsequent courses necessary to answer RQ1.

The DFW rates we reference in our Results section are obtained by dividing the number of grades of D, F, W, and NC (No Credit) out of the total number of grades consisting of A, B, C, D, F, W, NC (No Credit) and CR (Credit). This excludes grades such as Incomplete or Audit which have no clear interpretation. Our analysis in this paper focuses on a sequence of courses typically taken by STEM-intending students within their first year or two of entering college: Intermediate Algebra, College Algebra, Pre-Calculus Algebra, Trigonometry, Precalculus, Calculus I, and Calculus II.

Results

Effect of Grades in Prior Courses

To analyze pass rates in subsequent courses, we first searched within the transition table for pairs of prior/subsequent courses associated with the sequence of STEM-intending courses described above. The data was then filtered to look only for cases where the student had passed (C- or above) the previous course within 24 months and was taking the subsequent course for the first time. Prior courses from the Fall 2018 semester onward were considered. The resulting DFW rates in subsequent courses are reported in the table below grouped by the grade the student achieved in the prior course. We group together +/- grades (i.e., earning an A means that a student earned an A+, A, or A- in the prior course). As an example, of the 2144 students who took Intermediate Algebra followed by College Algebra, students who earned an A in Intermediate Algebra went on to earn a grade of DFW or NC in College Algebra at a rate of 13.29%. Row and column totals refer to specific course parings and grades, respectively. That is, 31.11% of the 2144 students who took Intermediate Algebra followed by College Algebra received a grade of DFW or NC in College Algebra, whereas 12.64% represents the aggregate DFW rate of enrollments with a grade of A in the prior course.

Table 1. DFW Rates in Subsequent Courses

		Grade in Prior Course			
Sequence	*N*	A	B	C	Total
Int. Alg. → College Alg.	2144	13.29%	43.72%	66.47%	31.11%
College Alg. → Precalc. Alg.	679	3.30%	18.57%	37.14%	13.25%
Precalc. Alg. → Trig.	416	14.40%	36.67%	66.67%	25.72%
Trig. → Calculus I	339	22.06%	50.74%	61.19%	41.30%
Precalc. → Calculus I	435	25.37%	58.22%	72.62%	45.52%
Calculus I → Calculus II	936	7.99%	32.36%	43.18%	25.96%
Totals	4949	12.64%	39.61%	56.29%	29.20%

Looking over longer timescales, we can also see how DFW rates in courses compare with student grades in a prerequisite course several courses prior in the usual sequence. Table 2 provides a few examples of these course sequences with intermediate courses omitted. It is evident that far fewer students progress through the entire sequence of these courses – especially in the groups with lower grades in prerequisite courses. As such, data entries for groups with fewer than 15 students are left blank.

Table 2. DFW Rates for Sequential Courses with Further Separation.

		Grade in Prior Course			
Sequence	*N*	A	B	C	Total
Int. Alg. → Precalc. Alg.	285	5.53%	30.65%	45.83%	14.39%
Precalc. Alg. → Calculus I	261	34.24%	54.84%	66.67%	41.00%
Trig. → Calculus II	118	27.42%	36.59%	40.00%	32.20%
Precalc. → Calculus II	159	22.34%	48.89%	55.00%	33.96%
College Alg. → Calculus II	83	29.85%	46.67%		32.53%
Totals	906	21.78%	43.11%	50.67%	29.47%

Analysis of DFW Rates by Course Repetition

Students taking courses from Fall 2018 through the Spring 2023 semester were grouped by their instance taking (or re-taking) given courses. The values reported in the Table 3 are presented in the form "DFW Rate (*N*)," where *N* is the total number of students taking the course for the *n*th time. As with the prior analysis, entries with fewer than 15 students are left blank to avoid reporting on exceptionally small populations.

Table 3. DFW Rates for Students Retaking Courses

Course	1st Instance	2nd Instance	3rd Instance	4th Instance
Intermediate Algebra	32.06% (3656)	52.40% (521)	46.67% (60)	
College Algebra	30.32% (5301)	53.54% (693)	50.00% (148)	23.33% (30)
Precalculus Algebra	16.81% (2046)	42.64% (197)	52.27% (44)	64.71% (17)
Trigonometry	27.58% (689)	50.00% (106)	68.57% (35)	66.67% (18)
Precalculus	19.58% (715)	41.67% (72)		
Calculus I	34.10% (2217)	46.51% (458)	53.77% (106)	62.86% (35)
Total	28.78% (14624)	50.02% (2047)	52.22% (406)	52.83% (106)

As is the case for the preceding analysis of moving from one course to the next, one limitation of the method employed here it that it is not possible to determine if a student took any other prerequisite courses between instances of retaking the course in question.

Conclusions and Future Work

Our findings have implications for instructors at all levels as well as for course conveners and departmental administration. Our results seem to confirm that grades in previous courses are a strong predictor of whether a student will pass a subsequent course. To an instructor of a subsequent course, our results suggest that particular attention should be paid to students who passed their previous course with a final letter grade of B or C, as these students are at roughly three- and four-times higher risk, respectively, of not passing their present course as compared with students who earned an A in their previous course on the basis of Table 1. To the instructor of a student's prior course, our results underscore the importance of supporting and encouraging students to gain a deep understanding of what they are learning – and doing so the first time to avoid failing and repeating a course. It also brings into focus the reality that students leaving a given course with a grade in the C range have less than a 50/50 chance of passing their next math class on the first attempt. Preliminary results from future work confirm the fact that student grades decrease on average when students move between any of the course pairs detailed in our results section and emphasize the need to focus especially on STEM-intending students who begin the sequence in courses below Calculus. Instructors should consider how to incorporate specific interventions to better support these students to help them persist in their STEM majors.

Our preliminary results also provide a method whereby particularly troublesome pairs of course transitions could be systematically identified and investigated further. In future work, we hope to strengthen this case for efficacy of grades in predicting outcomes with a more rigorous statistical analysis and expound further on some of the other aspects of student demographics which may factor into these results. It is further worth mentioning that some of the most "difficult" pairs of course transitions (viewed either in terms of DFW rate or an average decrease in grade) may not be responsible for the greatest numbers of DFW grades issued within a given department. Future work will aim to further quantify the numbers of students transitioning between various course pairs with the aim of suggesting where limited resources to help students could be most effectively distributed.

The results for students who end up having to repeat a class are stark where, in aggregate, students are 1.75 times less likely to pass a course when repeating for the second, third, or fourth time as compared to taking it for the first time. Some courses (e.g. Calculus I) exhibit a nearly linear increase in DFW rates with each subsequent retake ($R^2 = 0.9883$) whereby a student is nearly 10% less likely to pass the course on each subsequent retake.

This somewhat surprising statistic raises questions about why students who repeat a course may be less likely to pass it. On one hand, one might expect that retaking a course would confer certain advantages to students such as familiarity with the content of assessments and insight into what aspects of the material are most relevant, in addition to having recently seen the material. On the other hand, if the student was not successful on a first attempt, then it may be unlikely that they will succeed on a second attempt if the instruction is not significantly different. Furthermore, students who repeat a course may feel more confident than their peers due to having seen material before, and as a result, they may be less likely to regularly attend class or study as much as their classmates who are taking the course for the first time.

Moreover, viewing DFW rates grouped by the instance in which a student is taking the course can provide a much more detailed picture than simply considering the aggregate DFW rate alone. That is, it allows the assessment of how well a given course is performing for students who are seeing it for the first time as opposed to those that are repeating it.

Another area of future work is investigating how students are distributed across sections of multi-section courses. Coordinators of larger courses should be aware that the mathematical background of students may not be comparable between different sections, and that the DFW rates alone may not give a complete picture of the success or failure of an instructor's or team's teaching; one must consider factors such as total enrollment across all sections, class sizes within individual sections, the mathematical backgrounds of the students enrolled, and other factors. This is especially important at any institution where faculty may have DFW rates included as part of their evaluation process.

Some technical limitations of this analysis were expounded upon in the methodology and results section: most notably the inability to exclude intervening classes in many instances. While there is reason to believe that such events may be comparatively rare, we plan to undertake a more thorough study of this in future work and switch to a more robust method of recording student progress through courses that could account for these factors if warranted.

Questions for the Audience

- Are there researchers or practitioners at other institutions who are performing similar analyses? Have you identified similar groups of students who might need additional supports and what interventions have you studied or tried?
- What are reasonable metrics to "assess" a course by? Is it useful to partition DFW rates by metrics like "instance re-taking a course" to better reflect course outcomes? What are the most representative DFW rates to consider?
- What do our results say about prerequisite knowledge and coursework? How might we use our results to ensure students are on a successful trajectory of courses?
- To help refine the range of factors which might affect students' grades, we are interested in looking at other data such as ACT scores, high school courses, placement exams, etc. What other factors would you recommend investigating more thoroughly?

Blending Office Hours into Scheduled Class Time in Gateway Math

Emily Braley
Johns Hopkins University

Melo-Jean Yap
Johns Hopkins University

A blended course model uses both classroom learning and online learning to create flexibility in the weekly schedule for students. In this paper, we describe a blended course model and the rationale for implementing it in Calculus I. We report on student responses to the model and the behaviors it encouraged. The design of the blended course model created the opportunity for office-hours-like interactions in scheduled class time to help reveal the hidden curriculum of office hours. Two goals the model strived to achieve for students were (1) normalizing help-seeking behaviors and (2) normalizing working with peers. Data collected through questionnaires and focus group interviews suggest that the blended course model achieved these goals and more.

Keywords: office hours, blended classroom

The term *hidden curriculum* was first introduced by Jackson (1968) to describe implied social norms of classrooms and schools. Today we commonly refer to the *hidden curriculum* of modern academic institutions as the norms, strategies, and expectations that students need to navigate their learning and networking on college campuses. Office hours are a component of the hidden curriculum; many teaching and learning centers reinforce the need for instructors and teaching assistants to explain office hours (*Using Office Hours Effectively,* n.d.; CTEI, n.d.; Office Hours/Helprooms, n.d.; CRTL, 2023) and invite and encourage students to attend. Jack (2020) highlights that professors at elite institutions expect students to attend office hours to make connections needed to request letters of recommendation, and to enhance their learning. Jack states that some students are ready to tackle these interactions upon arrival at college, while other students are less comfortable initiating these connections.

This paper describes a course model that created the opportunity for office-hours-like interactions during scheduled class time and the rationale for implementing it in Calculus I. The model uses both classroom learning and online learning to create flexibility mid-week for students. There is some debate about whether such a course structure should be considered a "partial-flip" (Lax, et al., 2017; Urquiza-Fuentes, 2020) or a "blended model" (Webster, et al., 2020); and we settled on Johnson's (2012) description of a "blended model" where students use "class-time to discuss, apply and clarify" the content and interact with online course components. The blended course model (BCM) described here was designed to provide accessibility to office hours and (1) normalize help-seeking behavior and (2) normalize working with peers. Data collected through questionnaires and focus group interviews support that the model achieved these goals and more.

Rationale for the Blended Course Model

The blended course model used in gateway mathematics builds on a typical course meeting structure of 3 class meetings per week in a large (n=150) lecture meeting with an instructor, plus a small (n=24) recitation meeting with a team of graduate student and undergraduate student teaching assistants (TAs). In the blended course model, interactive lectures (using think-pair-share, polling and exit tickets) are delivered in person on Mondays and Fridays. Recitation time (on Tuesday or Thursday) is used for an alternating schedule of group work, quizzes, and review. The Wednesday class meeting is repurposed for an office-hours-like large group meeting where instructors and TAs work together to facilitate the class. During this

50-minute class, students are prompted to prioritize what they need to work on or study, and the time is dedicated for students to do that work with opportunities to ask and answer questions. This prioritization is intended to help the class, as a community, identify difficulties that are arising in real-time and validate students' need for support. In this blended course model (BCM), the lecture content for the Wednesday classes is replaced by asynchronous video lectures created by the instructional staff and published on the learning management system. The schedule is depicted in Figure 1. Students watch the videos on their own time. The BCM pushes one hour of lecture into unscheduled time and replaces one hour of scheduled contact time with high-impact in-person office-hours-like interactions.

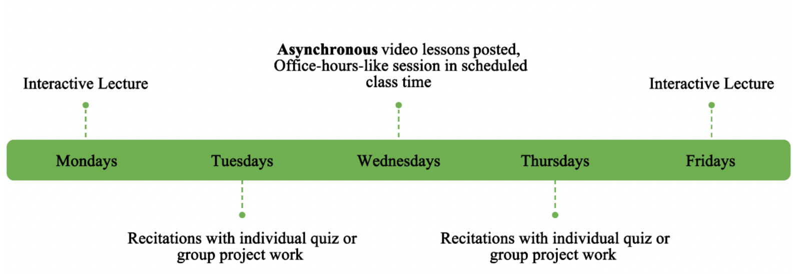

Figure 1. The weekly schedule in the blended course model.

The design goals of the BCM aimed to create access to office hours in scheduled class time to address two key goals:

(1) Normalize help-seeking behaviors
(2) Normalize working with peers and provide a scheduled meeting time for peer meetings

Data Collection

Methods

This study aimed to build a case study of a blended course model and used a convergent parallel mixed methods design in which a questionnaire and focus group interviews were used to collect data. In convergent parallel design, both qualitative and quantitative data were collected and analyzed to triangulate results (Creswell & Creswell, 2018).

This study was conducted at a private institution in the Mid-Atlantic region of the United States. The institution is a "very high research university," and we will refer to it as VHRU in this paper.

Data Sources. I. Questionnaire: The questionnaire collected enrollment information, demographic information (major, gender identity, racial/ethnic identities), and the option to self-identify as a first-generation student, limited-income student, person with a disability, international student, immigrant, etc. This paper will focus on student rankings and responses about the instructional components of the course that contributed most to their learning.

Respondents were asked to rank instructional components according to what worked best for them: blended course model, UPT (Undergraduate peer tutors) tutoring space, office hours in-person, office hours via Zoom, supplemental instruction sessions, recitations with TAs and UPTs, textbook, and in-class worksheets. Additionally, a five-point Likert scale portion asked the level of agreement on questions related to comfort interacting with instructors, TAs and peers, as well as feelings of support and workload.

II. Focus Groups. Dr. Yap interviewed 11 focus groups; 4 in person with 23 participants and 7 online via Zoom with 20 participants. The interviewer referenced trends in the instructional component ranking and responses from the questionnaire in interviews and encouraged participants to elaborate on their written responses.

Participants. In February 2023, first-year students from the 1,310-student incoming class in Fall 2022 who were enrolled in Calculus I were identified as the population of interest. From 161 randomly selected students from the top, middle, and bottom thirds of the final exam grade distributions, 43 students responded to the questionnaire; the response rate for recruitment was 26.71%. The 43 students participated in 11 focus groups. Participants came from a variety of majors, with the most represented as Computer Science (23.26%), Mechanical Engineering (16.28%), Pre-Major (16.28%), and Chemical and Biomolecular Engineering (13.95%). Just over half, 51.16% of participants identified as female, while 48.84% of participants identified as male.

Results and Discussion

Overall class experience. In general, participants had a positive experience in Calculus I. Think-pair-share, in-class activities and group projects contributed to participants studying with their classmates (76.75% of participants) and forming meaningful connections with Calculus I peers (88.37% of participants). One student reported that they "*ended up becoming good friends of [theirs].*" They continued, "*One of the TAs walked up to us and asked if Calculus I turned us all into friends, and we said, 'Yeah.' We had fun.*" 86.04% of participants felt encouraged by their Calculus I professor, and 72.09% felt comfortable participating in class discussions.
Ranking Instructional Components. Students identified the two most helpful instructional components to be the in-class worksheets and the blended course model (BCM). Students described the worksheets as "very structured", "easy to follow", and "organized." The in-class worksheets average ranking was 2.72 out of 10 with a standard deviation of 1.76. The BCM's average ranking was 2.84 out of ten with a standard deviation of 1.90.

The BCM created access to Office Hours (OHs) with instructors and TAs in scheduled class time. This addressed student feedback that OHs were not always scheduled conveniently and students had inequitable access to the instructional staff. Comments, like the two below, state explicitly that this was helpful for students and addressed issues with time-conflicts:

> I really like the Wednesday sessions where you could come in and then ask questions and I liked that it was the time of a class time because sometimes I wouldn't be able to go to office hours because of schedule conflicts. So I really liked starting the homework early and then coming up with questions that I would ask on Wednesdays, and I felt like that was really helpful.

> *Well, because you have more than one class. All of those teachers have different office hours. All of those TAs have different office hours in different buildings. It sometimes you're just too tired to go… you can't go. Also, clubs, organizations, the fact that you have to eat. It's kind of just the volley of being a human being who has to take care of his or her body, which gets annoying.*

In the sections below we will discuss evidence that the BCM addressed the intended design goals and provided flexibility for students. We will also comment on how students used the asynchronous videos and opportunities for improvement.

Achieving the Blended Course Model Design Goals. The first goal of the OH-like session was to normalize help-seeking behaviors. We wanted to make visible needing help from instructional staff on homework, project work and quiz/exam preparation. This strategically addressed previous student comments that some students are accustomed to working on their own and not confident asking for help. These sessions helped reveal some of the *hidden curriculum* of OH:

> Having Wednesdays as an in-person office hours when I couldn't usually attend [instructor]'s office hours was really nice for me because I would just work on homework and then have her... At my disposal is kind of a bad way to say it, but I would have her there to help me if I needed help, and that was nice.

> So a few of my friends and I would just take the homework problem sets to the in-class office hours and just kind of work through them as we were sitting there and if we ever just ran into a problems doing the homework, we can just ask conceptual questions or even just ask the professor or the TAs to go over the sample problems that we went over in class again. And that really helped me shorten the amount of time I needed to put into studying.

The OH-like session normalized working together to do homework or study in the class, which was the second goal the design hoped to address. It guaranteed scheduled time that students could collaborate on homework or project work. This strategically addressed previous complaints that scheduling group meetings outside of class time was a challenge for students:

> … you could work on projects or do homework or something. So I ended up not having to meet outside of class with my group other than once or twice, because we got most of it done on Wednesdays.

> And so on Wednesdays, I got together with my teammates and we worked on the project sometimes… So it prevented me from procrastinating, I'll say, the work session on Wednesday was most helpful.

Providing Flexibility and Support. Students reported that the BCM provided flexibility that they appreciated. Students were comfortable navigating the digital learning tools embedded in the model and liked the mixed mode of content delivery. Students reported that the asynchronous videos in the BCM provided an opportunity to pace their learning:

> I think the [BCM] was super helpful for me, especially first semester of college, learning how to study, learning how to keep up in all your classes, just having a little bit of flexibility in the middle of the week was super helpful.

> ...it also allows me to go home, study on my own time, especially with those videos, which I can pause, play, replay, pause, take notes, do whatever, and then study on my own and be able to go to a class and ask about the things I have trouble with and have more time dedicated to that.

> I like the fact that I could [watch videos] on my own time and because the concepts on the Wednesday videos were obscure, I liked having the ability to rewind and look over them again.

Many students used the videos as a reference and review while studying for quizzes and exams:

> The Wednesday videos… I would stay and watch the videos and they would be more or less of add-ons to the lectures. So for some of the quizzes, I would go back and watch some of the videos to review.

> "Oh, there's these videos I can watch." …if I was struggling on a topic, I would go to that video… So I used them as a textbook in a way or a resource.

A few participants felt that the videos were not well enough aligned with what happened in the Monday and Friday lessons, but still reported watching and using the videos as part of the BCM:

> When I started watching the hybrid videos, I was like, "These are off-topic." It just didn't feel like it was super relatable to the other content. There's a gap between what we were learning in class and what the videos were showing.

This is consistent with feedback from students about flipped-classrooms (Tague & Czocher, 2016) in other contexts. Messaging the planned cohesion of the asynchronous videos and the interactive lectures on Mondays and Fridays is an area for reconsideration and improvement in future implementations of the model.

Conclusions and Questions

In this blended course model, students are provided an office-hours-like learning environment during scheduled class time. Students can work independently and collaboratively and at the same time access help from instructors, TAs, UPTs, and classmates. Participants ranked the blended model, with the in-class-office hour, as one of the most valuable course components that contributed to their learning. This study has implications for math departments acknowledging that the evolving student population expects easy access to instructional staff and flexibility in their courses. This model helps reveal the hidden curriculum of office hours and makes accessible the valuable resource of attending office hours weekly.

Using Theory to Scale Innovation in Higher Education: Supporting the Implementation of Multiple Mathematics Pathways and Corequisite Support in Arkansas

Andrew S Richman
Lesley University

Heather Ortiz
Oklahoma State University
Institute of Technology

Ahsan Habib Chowdhury
George Mason University

Eric Henry
Concord Academy

The Charles A. Dana Center worked across all public colleges and universities in Arkansas through a project called Strong Start to Finish (SStF) Arkansas to support the implementation of corequisite support for underprepared students in mathematics and multiple mathematics pathways for all. Consistent with Reinholz, White, and Andrews' (2021) call to more effectively ground change efforts in change theories, the Dana Center designed its innovation using a change theory-based theory of change. This preliminary report describes this project's outcomes and how the projects' results further the field's understanding of Rogers' Diffusion of Innovations theory, one of the change theories on which the project's theory of change was based.

Keywords: Change Theory, Diffusion of Innovation, Corequisite Support, Multiple Mathematics Pathways, Higher Education

Introduction

STEM higher educational change is complex, multi-faceted, and a necessary constant to improve access, teaching and learning, and outcomes for diverse educational stakeholders. Although long-term research has documented innovation and outcomes for STEM projects emphasizing STEM higher educational change, fully scaled sustained change in these projects is less known. Furthermore, change efforts have rarely used change theory to directly inform their work, making it difficult to build knowledge across the field (Reinholz et al., 2021).

Reinholz, White, and Andrews (2021) have called for change efforts to more effectively rely on theory by using both *change theories* and *theories of change*. Reinholz and Andrews (2020) defined a change theory as a broad framework of ideas that employs theoretical and empirical knowledge to explain some aspect of change. They defined a theory of change as project-specific and connected to evaluation; it explicitly promotes underlying assumptions about how and what change will occur in a defined project and then uses desired outcomes to guide project planning, implementation, and evaluation. A single change theory can support multiple components of a theory of change, and a single theory of change can draw from many change theories. The call by Reinholz, et. al. urged change efforts to create theories of change that are directly informed by change theories so that the results of projects can be used to build fieldwide knowledge.

The Charles A. Dana Center at The University of Texas at Austin's Mathematics Pathways Project (DCMP) is a national STEM higher educational change initiative that has employed a theory of change to create broad, deep, and sustainable change in undergraduate mathematics pathways. The Dana Center based the projects' theory of change on four change theories and used the theory of change to design and implement this national change effort. In this preliminary research report, we will describe one element of this theory of change (the part based

Rogers' (1983) Diffusion of Innovation Theory) and how the interventions based on this theory of change impacted state-, region-, and institution-level reform across Arkansas public colleges and universities. We will show how the results of this intervention can be used to inform thinking about the change theory on which it is partially based. We will investigate the research question: *What can be learned about Rogers' Diffusion of Innovation Theory for STEM higher educational change by looking at the results of the DCMP project in Arkansas*. Future publication by the authors will address all four change theories used to create the DCMP theory of change.

Theoretical Framework

Change Theory

The DCMP project drew on four change theories to build their theory of change (Ortiz & Cook, 2019). In this paper, we will focus on the aspects of the theory that utilized Rogers' Diffusion of Innovation theory (DoI). In this section, we will discuss the aspects of Rogers' (1983) theory that are relevant to the theory of change.

Rogers described classifications of potential adopters of a new idea by how quickly they adopt innovation — a characteristic Rogers referred to as *innovativeness*. The quickest and slowest groups (*innovators* and *laggards*) are the smallest—estimated at 2.5% and 16% of the population respectively. The middle three groups (*early adopters, early majority,* and *late majority*) comprise the bulk of the population—estimated at 13.5%, 34%, and 34% of the population respectively. He characterized innovators as able to tolerate a high degree of uncertainty about an innovation at the time they adopt it. In contrast, even early adopters require higher amounts of legitimization to adopt a new idea.

Rogers described two different structures of diffusion systems: systems in which innovations originate from experts or other authoritative sources and then spread, or do not spread, to potential users without alteration (*centralized*), and systems in which innovations are created by users and spread to other users who may adopt the innovation as is or may alter it to suit their circumstances (*decentralized*). He pointed out that decentralized systems are likely to create innovations that better fit with the needs of the users and that users are more likely to take ownership of the innovation – creating deeper and more sustainable change. However, he argued that a centralized aspect of a system can be important if users are not aware of a need for innovation or if there are larger centralized structures that need to be modified to enable the innovation to operate effectively in the larger system.

Lastly, Rogers described how the nature of relationships between individuals in a social system impacts how innovations spread. When most communication in a system is between individuals that are similar in attributes such as beliefs and social status, etc. (homophilic communication), diffusion is hampered. This is because earlier adopters tend to have different beliefs, communication styles, economic status, and social status than later adopters. If there is little communication between people who are different (heterophilic communication), there will be no route for innovation to spread beyond the early adopters.

DCMP Theory of Change

Following Reinholz (2020), we organize our description of the DCMP theory of change by first discussing the context of the project, then the assumptions that connect the DCMP theory of change to DoI, then the intervention, and then indicators that were used to judge the success of the intervention and the validity of the change theory.

Context. Following a national call to action to modernize undergraduate mathematics, the state of Arkansas joined the Dana Center in 2015 in a multi-state initiative to lead a mathematics faculty task force to develop and publish recommendations that addressed barriers to equitable access and success in undergraduate mathematics. In 2019, the Dana Center expanded this work in Arkansas through the Strong Start to Finish Arkansas (SStF) initiative, which strategically coordinated three state-level agencies and two national advocacy organizations to collectively lead the work. The multi-prong leadership approach intentionally pulled together change agents within the state of Arkansas to help set the pace, process, and conditions for implementing and scaling mathematics pathways[1] and corequisite supports[2], creating a 'coalition of the willing' across state-, region-, and campus-level communities and actors.

Assumptions. Three assumptions of the DCMP theory of change were drawn from Rogers' DoI. The first is that *high-profile legitimization of change is an important factor in the decision-making of early and late majority adopter types.* This assumption is based on the relative conservatism that Rogers associates with all adopters aside from innovators. If an innovation is to spread past the 2.5% of the population that are innovators, it will be helpful if said innovations have support from influential regional or national stakeholders. The second assumption of the DCMP theory of change drawn from Rogers' DoI is that *deep, broad, and sustainable scaling requires a combination of top-down and bottom-up approaches.* This is based on Rogers' description of the advantages and disadvantages of centralized and decentralized diffusion systems. The third assumption is that *broad scaling requires initial change efforts to be distributed across the higher education ecosystem.* This is based on Rogers' contention that change does not diffuse well between different types of institutions (Rogers, 1983); an initial focus on any particular type of institution will limit the prospects for widespread dissemination.

Intervention. To achieve the SStF project outcomes, guided by the DCMP theory of change and its underlying change theories, The Dana Center worked across state, region, and institution levels. At the state level, interventions focused on two separate policy areas: (1) support state-level transfer and applicability work to expand implementation of Quantitative Literacy (QL) recommendations, and (2) establish a new task force on secondary-postsecondary mathematics alignment. At the region level, Dana Center interventions leveraged a previously established system of regional coordinators who strengthened their college and university partnerships. Each regional coordinator supported both breadth and depth across their assigned institutions through coordinated project activities that focused on transfer and applicability, secondary-postsecondary alignment, mathematics pathways and corequisite support implementation, local leadership capacity, and data-driven decision-making. Last, institution-level interventions focused on building depth of knowledge and leadership capacity within institutions. The Dana Center supported both individuals and institutions through multi-institution professional learning opportunities for mathematics faculty, academic advisors, and mid-level administrators. This professional development increased capacity in key roles, so practitioners were better positioned to lead and serve as models for others.

---

[1] Mathematics pathways are a mathematics course or sequence of courses that students take to meet the requirements of their programs of study. This concept applies to college-ready and underprepared students.

[2] Corequisite support refers to placing students who have been designated as underprepared directly into college-level courses and providing necessary additional support to help them effectively engage with the college-level coursework.

Indicators. Broadly speaking, the SStF-identified indicator of success was that all Arkansas public institutions of higher education would implement at least two mathematics pathways and 75% of underprepared students would be enrolled in corequisite support. For this analysis, we adopted three additional indicators to examine the extent to which the assumptions of the DCMP theory of change held. These were: (1) whether high-profile legitimization occurred and, if so, whether it was an important factor in the decision-making of potential adopters, (2) whether both top-down and bottom-up approaches were used and, if so, whether the combination impacted the depth, breadth, and sustainability of change, and (3) whether change efforts were distributed across a variety of institutions and if so did this enable broader scaling or is there evidence that heterophilic communication occurred, reducing the need for distributed initial change efforts.

Methods

Quantitative data was collected annually in 2020, 2021, and 2022. All public colleges and universities in Arkansas submitted a SStF Arkansas Data Collection Workbook which gathered data about degree-seeking students relevant to academic placement for mathematics, student enrollment and success in remedial mathematics in students' first year of college, and student enrollment and success in introductory college-level mathematics in students' first year of college.

Qualitative data was collected through ten 45- to 60-minute conversations each with between one and eight faculty and/or administrators. Fourteen institutions were represented, seven two-year and seven four-year institutions. Participating institutions were chosen in consultation with the regional coordinators to represent a range of experiences implementing mathematics pathways and corequisite support. Participants were asked about the extent to which multiple mathematics pathways and corequisite support had been implemented in their institutions, and about supportive and inhibiting factors in the implementation. Data addressing the second question was analyzed using thematic analysis (Braun & Clarke, 2006).

Findings

In order to assess the validity of the theory of change we must first look at whether change happened. The data suggests that mathematics pathways and corequisite support were implemented widely but, in many cases, not deeply. Every one of the fourteen institutions that participated in qualitative data collection offered corequisite support for college-level mathematics classes and had at least one pathway in addition to College Algebra, most commonly a quantitative literacy (QL) pathway. Statewide progress is being made in increasing enrollment in corequisite support and shifting student enrollment to multiple pathways. The statewide percentage of underprepared students enrolled in mathematics corequisite support increased from 55% in 2020 to 72% in 2022. The percentage of students in college algebra decreased from 69% in 2021 to 66% in 2022. It was lower in 2020 (59%) due to many community college students taking non-transferable classes – an issue that began to be addressed in 2021. Despite the prevalence of QL pathways and corequisite support, about half of the institutions represented in the conversations reported that the QL pathway was underutilized, and most institutions offered only corequisite support for QL classes but still required prerequisite developmental classes for some students taking College Algebra. Most of the institutions that participated in conversations reported that about 30% of students who required academic remediation for College Algebra took prerequisite classes.

Participants in the conversations reported that high profile legitimization did occur and was an important factor in stakeholder decision making. This legitimization took a variety of forms including (1) state education department expectations, (2) Dana Center advocacy, (3) example setting by peer institutions, and (4) the legitimacy of four-year institutions' adoption of mathematics pathways and corequisite support for two-year institutions.

Participants also reported advantages of the top-down, bottom-up intervention approach by the Dana Center. Advantages of the top-down approach were (1) the power of the state to push for change, (2) supportive accountability from the Dana Center in the form of data provision and check-ins from regional coordinators, (3) the ability of the Dana Center to spread information about the innovation including basic concepts, data that supported its feasibility, and technical assistance to support implementation, (4) logistical support from the Dana Center such as small amounts of funding and protected meeting time, and (5) the importance of four-year adoption in assuaging transfer concerns by two-year institutions. Advantages of the bottom-up aspects of the approach were (1) much of the persuading at the local level came from colleagues citing local data, and (2) local advocates could work out local issues such as strengthening communication between faculty and advisors, initiating curriculum review to establish need, creating course teams to support implementation, and navigating institutional politics.

Finally, participants described the advantages of distributing change efforts across institutions with some qualifications. Working with a variety of institutions ensured that the top-down aspects of the effort reached everyone. Furthermore, multi-institutional convenings enabled heterophilic communication. However, there is evidence that some heterophilic communication would have occurred in the absence of these convenings. Transfer issues require two-year institutions to pay close attention to what is happening in four-year institutions. It is unclear, however, whether an innovation that starts with two-year institutions would migrate to four-year schools.

Discussion

Thus, although SStF successfully supported change in Arkansas, its full-scale goals have not yet been completely realized. Multiple mathematics pathways and corequisite support have spread broadly in the state but could still be deeper within the institutions. The parts of its theory of change based on Rogers' DoI theory (1983) were largely shown to be valid with some exception. High-level legitimization was, indeed, important as was the combination of the top-down, bottom-up intervention design. It is less clear that initiating change across the institutional landscape was the only way to spread the innovations broadly. This suggests that Rogers' characterization of most potential adopters as conservative and needing external legitimization has merit as does his description of the affordances and constraints of centralized and decentralized diffusion systems. It is less clear that his concern about the diffusion-preventing character of homophilic communication systems applies to higher education in Arkansas. More research will be needed to illuminate this last question. What is clear is that Reinholz, White, and Andrews' (2021) call has merit. Creating a theory of change based on change theory(ies) and then building an intervention using the theory of change can enable a change effort to efficiently inform theory and provide usable information to the field about how change happens.

Questions for the Audience

1. What do you believe it means to have a change theory directly or rigorously inform a theory of change?
2. Please give us feedback on our effort to inform change theory.
3. What do you think of the call by Reinholz et al. for STEM higher education researchers and do you structure your change efforts in this way?

Confidence and Sense of Belonging: Undergraduate Mathematics Student Experiences with Calculus Support Course

Colin McGrane
San Diego State University

Chris Rasmussen
San Diego State University

Studying student experiences in undergraduate mathematics education serves as a fundamental aspect of understanding how mathematics departments can best serve the most at-risk populations of students who are often harmed by racial and gender inequities present in student success rates in undergraduate mathematics courses. In this study, we focus on support courses for Precalculus and Calculus I, where students engage in frequent Supplemental Instruction (SI) sessions and an online course run by the university Math Equity Coordinator. In analysis of a mixed-methods approach consisting of interviews and a survey, we examine the impact of these supports on students' sense of belonging and confidence in mathematics. Preliminary results from survey analysis show that students in the support course report higher levels of belonging and confidence in mathematics. Furthermore, interviews highlight the importance of instructor mentorship in enhancing students' confidence and sense of belonging.

Keywords: identity, belonging, calculus, student success

Introductory undergraduate mathematics, particularly the study of Calculus, often functions as a filtering and access-controlling mechanism that either impedes students' progress in STEM degrees or discourages them from continuing altogether (PCAST, 2012; Weston et al., 2019). A comprehensive examination conducted by Koch and Drake (2018) encompassing 36 higher education institutions throughout the U.S. revealed that a substantial 34.3% of students received a D, F, Withdraw, or Incomplete (DFWI) in Calculus. Even more unsettling were the statistics for Black or African American students and Hispanic or Latinx students, who faced even higher DFWI rates of 47.8% and 47.9% respectively. Furthermore, women are known to leave STEM fields 1.5 times more often than their male counterparts (Ellis et al., 2016). If the rightfully due pressure put on mathematics departments to close these racial and gender equity gaps is to be taken seriously, mathematics educators must dedicate time, money, and labor towards listening to student voices and understanding how we can support them through these historically difficult and harmful experiences.

The large, Southwestern University (SWU) that is the setting for our study has not been immune to the sustained racial and gender equity gaps in Calculus success observed across the U.S. In response, we are implementing a 2-year holistic approach to closing equity gaps present in our precalculus through calculus courses. One of the arms of this multi-faceted approach was to create support courses for Precalculus and Calculus I. The unique features of these courses are the nature of instruction and student engagement in that students opt-in to a 1-unit course that requires frequent attendance to university-provided Supplemental Instruction (SI) sessions and regular engagement with an online Canvas course hub run by a coordinator for the Math Equity Initiative. We see this definition of support course as fitting somewhere between a corequisite course that takes place in a classroom with a dedicated instructor and the regularly offered SI sessions.

In this preliminary report, we focus on the voices and experiences of students who opted-in to the new SI sessions in Precalculus and Calculus I through a mixed-methods study that utilizes semi-structured interviews and a comprehensive survey sent to all students enrolled in the precalculus and calculus courses in the spring semester of 2023. These experiences include their perception of the inclusivity of teaching practices, their praise of and suggestions for improvement to the SI sessions, and the impact on their confidence, enjoyment, interest, and sense of belonging in mathematics. Focusing on the experiences of the students who enrolled in the support course, this study is guided by the following research question: How has enrollment in the support course impacted students' sense of belonging in the math community and their confidence in mathematics courses?

Relevant Literature and Theoretical Perspective

Investigating the experiences of students in our courses requires an acknowledgment of the unique identities and voices they offer to our research. Understanding that student's identities are potentially redefined and reshaped every day, we view identities as dynamically designed by a variety of factors and constantly in flux (Collinson, 2006). More specifically focused on their identities within a mathematics context, Martin (2012) defines mathematical identity as the ways that students enact their own identities as "doers" and "learners" of mathematics. We extend mathematical identity to include students' self-reported interest, enjoyment, and confidence in mathematics. Since a sense of belonging is so closely tied with the inclusivity a student perceives, students' multiple identities, including their mathematical identity, are intertwined with their sense of belonging in mathematics. We believe that with a focus on identity and sense of belonging in mathematics we may begin to understand one of the myriad reasons why in the U.S. roughly half of the students who pursue a degree in science, technology, engineering, or mathematics (STEM) never complete it (National Center for Education Statistics, 2018).

Supplemental Instruction originated at the University of Missouri-Kansas City in 1973 and has since evolved into a widely adopted pedagogical approach practiced at over 1,500 education institutions across 29 countries. As explained by Arendale (1994), SI is designed to address historically challenging academic courses by providing free, voluntary sessions to all students. These sessions held several times throughout the week are led by SI Leaders, students who have previously excelled in the targeted course. The hallmark of SI is its collaborative nature, where students actively engage with course content and hone essential study skills. SI Leaders draw upon insights gained from attending all class lectures to facilitate active learning techniques, which include interactive board diagramming and group work.

While active pedagogical strategies have been found to be effective for learning and narrowing opportunity gaps (Freeman et al., 2014; Theobald, 2020), research has also demonstrated that the situations that transpire in active learning classrooms put students at most risk for marginalizing and anxiety-producing experiences (Aguillon et al., 2020; Cooper et al., 2018; Cooper & Brownell, 2018; Shah et al., 2020). Since our students experience a mostly traditional large lecture atmosphere when they meet with their instructors, we acknowledge that the effect of an active learning classroom only applies when students are in their twice-weekly discussion sections run by graduate teaching assistants and the SI sessions. It is important to note that the participants of our study experienced a variety of classroom atmospheres that all impact their overall experience in mathematics and more specifically their own sense of self as they interact, problem solve, and learn with groups of their peers.

Methods

SWU is a large, public 4-year HSI research university. The focus of this study are 26 students (gender and race/ethnicity shown in Table 1) who opted-in to enroll in the newly developed

Precalculus and Calculus I SI-based support course that also responded to a survey sent at the end of spring 2023 semester. Acknowledging our own identities of two cisgender, white, male researchers (one heterosexual and one gay) at this institution is important to note, because we aim to push back against and rectify the long history of the dominant race and gender performing studies that have often taken from underrepresented communities and not given back.

Table 1. Students self-reported identity. This table shows a count of each gender present by race/ethnicity.

Support Course Student Demographics						
Gender	Alaskan Native or Native American	Black or African American	Hispanic/ Latinx	Middle Eastern or North African	East Asian	White
Man	1	1	7	1	1	3
Woman	0	1	4	0	0	2

Three of these 26 students participated in a one-hour long, semi-structured individual interview that focused on a variety of topics related to their experiences in their current mathematics courses as well as their own histories of experiences with mathematics in general. Topics that were discussed included how their identity has impacted their learning of mathematics, how their confidence in their mathematics ability has changed, and the extent to which they have utilized university-offered support structures such as SI.

In order to develop a broader sense of experiences across all precalculus and calculus courses, the survey we administered was an amalgamation of items built from subsets of two existing surveys. One of these surveys is the student postsecondary instructional practice survey (SPIPS-M), which specifically targets students' interpretations of instructional practices, changes in attitudes towards learning and doing mathematics, and their perceptions of the climate in the classroom (Apkarian et al., 2019). Supplemental to the focus of this survey, the second survey developed by Brown and colleagues at Penn State University called the Inclusive Instructor Behaviors (IIB) survey was included to leverage student experience to determine various aspects of the perceived inclusivity of teaching behaviors and sense of belonging in mathematics.

Results

Comparing the 26 students who enrolled in the support course and the 700 students enrolled in Precalculus and Calculus I combined, the most notable statistical differences emerged among the questions that focus on a sense of belonging. In order to compare two independent groups with such variance in population size, a non-parametric statistical test called the Mann-Whitney U test was performed to determine effect size of agreement to a variety of statements. The resulting U statistic was then transformed into Cohen's d, which is a real number between 0 and 1 that has been stratified and defined by Cohen (1985) into categories of strength. An effect size less than 0.2 is "little-to-no effect", between 0.2 and 0.5 is a "small effect", between 0.5 and 0.7 is a "medium effect", and greater than 0.7 is a "large effect".

Students in the support course agreed with the statement, "I feel like I fit in" more than students who did not take the support course with an effect size of $d=0.301$ ($p<0.001$). More specifically attending to their sense of belonging in mathematics, students in these students also agreed more with the statements, "I feel like I am part of the math community" and, "I consider myself a member of the math world" more than students who did not take the support course with effect sizes of $d=0.246$ ($p<0.001$) and $d=0.242$ ($p<0.001$) respectively. Furthermore, these students also agreed with the statements, "I feel a connection with the math community" and, "I feel that I belong to the math community" more than students who did not take the support course with effect sizes of $d=0.237$ ($p<0.001$) and $d=0.221$ ($p<0.001$) respectively. Finally, students in the support course agreed with the statement "I feel valued" more than students who did not take the support course with an effect size of $d=0.219$ ($p=0.002$).

Regarding students' confidence in their mathematical ability, students who enrolled in the support course overall were more confident entering the course. When prompted to consider their confidence at the beginning of the semester, students who enrolled in the support course agreed with the statement, "I am confident in my mathematics ability" more than students who did not enroll in the support course with an effect size of $d=0.26$ ($p<0.001$). However, students were actually not confident in their mathematics ability, so the difference between the groups can be translated as the students who enrolled in the support course disagreed less with the statement, "I am confident in my mathematics ability" than the students who were not enrolled with the support course. In terms of the Likert scale range on the survey, students who enrolled in the support course "slightly disagreed" on average while the students who did not enroll in the support course "disagreed". This question was paired with a follow-up question that asked about their confidence in mathematics at the time of taking the survey, which was in the last 3 weeks of the semester. While both groups showed a statistically equivalent increase in confidence in mathematics ability between the beginning and end of the semester, the students who were enrolled in the support course felt a higher confidence overall.

Acknowledging that responses to a survey do not provide a complete picture of students' experiences and reasoning for their responses, three students interviewed near the end of the semester supplemented these findings with their own lived experience. The first student, Silvia, is an Italian female immigrant who went to primary and secondary schools in Italy before coming to SWU as a Biology major. She plans to attend medical school to become a doctor, with a passion for helping people. Before she attended SWU, she was not confident in her mathematics ability because of the teaching practices of her high school instructors. Specifically, she was made to feel that women do not belong in the mathematics community, which she attributed to a cultural difference between the old-time ways of her hometown and the liberal feeling of California. However, she speaks to how her confidence has changed since she came here:

> So I feel that I feel like more confident after taking this class. Probably in my math abilities. I work for the math department because I do like tutoring for college algebra. So I kind of start liking the math environment way more since I came here. So I think it has like changed my way to like see math and the fact that if I really understand I can like help other people to have success in the class.

Another student interviewed named Santiago is a male Mexican immigrant with the goal of becoming a computer scientist. He is a first-generation college student whose parents completed schooling through primaria, which is equivalent to 6th grade in the U.S. Due to the teaching practices he experienced in secundaria and preparatoria, equivalent to 7-9th grade and 10-12th grade in the U.S. respectively, he felt at a disadvantage to his peers at SWU. Not only because of the way mathematics was taught, but also the general lack of resources he found there to support him in his educational goals. When he approached his lecture instructor during office hours to comment on how he felt, he expressed his relief in their response by claiming, "I entered the room with insecurity, and I left the room feeling more confident about myself."

The third student who was interviewed named Bianca is a female Mexican immigrant who is a first-generation college student with the goal of going to medical school. She also spoke to the lack of resources she had going to school in Mexico, particularly in the teaching practices that left her feeling inadequately prepared for higher education. However, she felt that instruction at SWU changed her confidence in mathematics when she said, "the instructor knew how to explain it better. Like, I felt more confident here in college than in high school, with the problems."

All three of these students felt that their confidence was increased due to experiences with their instructors at SWU. While these experiences were not directly related to enrollment in the support course specifically, their experiences impacted their mathematical identities. Specific to the support course, Silvia and Santiago spoke to the canvas course instructor that served as a mentor to them and the benefits they gained from her being in that role. Silvia said,

> The professor that led the course, she was like, not like a math professor, but she worked more as a mentor… so [the support course] was more like a class to support myself, like 360 degree, like a total thing. Not just within my math, but also like enrolling into classes, understanding what to do next, what classes to take. So, I think it was really good.

Santiago also felt that a having this person in the role of a mentor was beneficial to his experience:

> So, it isn't like she's only the instructor of the class, but she's also like a huge mentor for me. And I think that it is very connected with the [support course] programs. So they've been super helpful.

In summary, we have found that well-guided mentorship and engagement from instructors are two emergent themes from the interviews that stand to bring some reason as to why students in the support course had higher confidence and more sense of belonging in mathematics. Experiencing support from the SI instructors, their GTA's and their course instructors that form the mathematical community on campus and one key instructor that assumed the role of a mentor for them made a powerful difference in their experience in introductory undergraduate mathematics courses. Future research and effort are necessary to understand how we may broaden our reach to the many students who are often failed by our institutional systems. However, one key take-away is that support courses like the one we implemented are a cost-effective way to provide much-needed support for our most at-risk students.

White Male Allies in STEM Diversity, Equity, and Inclusion Faculty Service

Joanna G. Jauchen
George Mason University

I describe findings from a hermeneutic phenomenological study of white male engagement in DEI faculty service. I frame the phenomenon of interest using the DEI Institutional Activism Framework, and questions of structure and agency through Strong Structuration Theory. Two major findings are reported here. First, that DEI service is disincentivized by contradictory institutional structures that devalue engagement. Second, that individual faculty agentically engage in DEI service because of relational connections to students, but also to women they know personally (daughters, wives, friends, colleagues). These preliminary findings are based on semi-structured interviews with four STEM faculty.

Keywords: diversity, equity, inclusion, structure, agency

Women faculty of all races and male faculty of color are more likely to engage in STEM diversity, equity, and inclusion (DEI) initiatives than white men (Jimenez et al., 2019; National Science Foundation, 2019).[1] This disproportionate engagement highlights how underrepresented faculty bear the burden of DEI service in STEM. This burden of equity service silos gender-based DEI initiatives, prevents critical mass from forming, and stifles progress in STEM departments where white men still compose a majority of tenure-line faculty (Jauchen, 2023). White men could contribute to equity progress in STEM fields and relieve some of the burden of DEI service that men of color and women currently bear. The research question in this study was identified through a review of gender-based work in other institutional spaces and centers on the experiences of faculty who have historically not been involved in gender-based DEI service: white non-Latino men. The goal of the study is to understand how individual agency and institutional structures impact white non-Latino male engagement in gender-based DEI service. I hope to understand how current structures are impacting white male engagement in equity work and how individual white men can agentically contest those structures. I focus on one major research question:

> What can we understand about structure and agency in DEI service through the lived experiences of white men?

Theoretical Framework

Service is "the catchall name for everything that is neither teaching, research, nor scholarship" which is still generally relevant for promotion, tenure, or evaluation (Blackburn & Lawrence, 1995, p. 22). DEI service is service faculty perform to encourage historically excluded students to enter, persist, and succeed in STEM fields. I have previously argued that DEI faculty service (the phenomenon of interest) is a form of institutional activism and can be

[1] The word "white," when not understood to be complex, socially constructed, and changing over time, can homogenize all people who are perceived to be white into a singular, hegemonic group. Other aspects of identity (gender, sexuality, class, education, and nationality) impact how white identities are experienced and performed (Crenshaw, 1995). Similarly, I use the phrase "people of color" to refer to people who are not white or who are perceived to be non-white. This phrase was originally embraced as a phrase of collective solidarity for oppressed groups, but it too can essentialize and homogenize a large, diverse group of people. I intend it to be a descriptor of a small part of a multiple, changing identity that is impacted by intersecting systems of privilege and oppression.

framed through the DEI Institutional Activism Framework (Jauchen, 2023). When engaging in DEI service, faculty develop a collective identify which includes: (1) Cognitive definitions regarding the environment, aims, and means of the engagement; (2) a network of relationships between individuals engaged; and (3) emotional investment in feeling a part of the engaged group (Jauchen, 2022, 2023; Melucci, 1996, p. 71). This framework was instrumental in developing the interview protocol for the study.

Questions of structure and agency are framed through Stones' Theory of Strong Structuration (2005). Based in Giddens' Structuration theory, strong structuration asserts that all social interaction is made up of moments where agency and structure are intertwined, what Giddens called the "duality of structure." Under this duality, social interactions are a result of external structures, internally held structures, and human agency. For this study, I focused on components of agency that included critical distance, motivations, hierarchy of purpose, horizon of action, and creativity. To analyze structure, I focused on "conjuncturally-specific structures" which are internal structures based in the immediate context of action and on the agent's position within that context (Stones, 2005, p. 85). These internal structures are "memory traces" within agents that help agents understand how things are supposed to be done. In this context, it is helpful to think of these conjuncturally-specific structures as participant understandings of "the way faculty are supposed to act" or "things faculty are supposed to do." These include position-practices (interdependencies, rights, and obligations), asymmetries of power, and social conditions (Cohen, 1989; Stones, 2005, p. 122).

Methods

Through a critical, intersectional, Western feminist lens, I utilize a structural-hermeneutic design based on Strong Structuration theory (Stones, 2005). Van Manen's (2016) approach to hermeneutic phenomenology guided me throughout. I pursue understanding of structure and agency in DEI service through agent conduct analysis and agent context analysis. In agent conduct analysis, I intentionally orient myself to the agent's knowledgeability, turning away (bridling away) from structures and toward the agent's understanding of the space and their hermeneutic interpretation of the actions available to them. In context analysis, I intentionally orient myself to conjuncturally-specific structures.

Through purposeful selection, I recruited seven white, non-Latino men who held PhDs in a STEM discipline, were employed full-time as faculty at primarily white institutions, and who self-described as being involved in DEI service. Because I am interested in the hermeneutic meaning that white men attach to their own DEI service, self-selection is appropriate as it foregrounds the men's perceptions of their commitment to DEI. I intentionally obscured most information about the participants (discipline, institution type, rank) to protect participant confidentiality. I interviewed men who worked at small regional public schools, large public schools, and small private schools. Four STEM disciplines were represented. I report findings from the first four participants only (some analysis is ongoing).

Each faculty participated in three 90-minute interviews following Seidman's (2019) phenomenological interview protocol. All interviews were recorded, transcribed, and coded according to the Structuration framework. Once that coding was complete, I engaged in phenomenological reflection, rereading the coded sections, asking "What statement(s) or phrase(s) seem particularly essential or revealing about the aspect of agency/structure?" and "What is the main significance of this passage as related to agency/structure and DEI service?" These reflections were then organized into broad themes, of which I present two here.

Findings

Contradictory Structures: DEI Service as Everyone's Work and No One's Work

While every participant said their university and departments wanted to support students and faculty from diverse backgrounds, they also told me that they understood DEI service was not highly valued in promotion and tenure. Faculty felt free to engage in DEI service but also didn't consider DEI service a formal part of their jobs. For example, Daniel, who had earlier argued that DEI service was primarily faculty responsibility, also knew that he would face little negative feedback if he avoided DEI work completely:

> Most faculty are on board with diversifying our university and our fields. But I'm not getting any pressure from the department or from the university more broadly to do these sorts of things. I have been told many times, especially pre-tenure, that things like this are not a formal part of our expectations for you. You have specific things you need to do, like research. And if you need to say, "Sorry student, I can't do this for you," that's okay. So, I have been told that and I hopefully have internalized it. I could decide to ignore these issues completely. I'm not really gaining a whole lot by doing extra stuff on the diversity and equity inclusion front.[2]

Similarly, John said that his university supported DEI service, but only cared about research during promotion and tenure evaluations:

> While institutions claim that they care about teaching, at tenure time they're only evaluating the research as long as you're not awful at the teaching, which is a mixed message, I would say, right? So, on paper, they'll tell you it's teaching, research, and service, right? But I think the people evaluating the tenure case in the end are looking at research the most.

While participants knew their DEI efforts counted broadly as service, they understood service to be undervalued by the university reward structure. In fact, participants were warned not to spend too much time on DEI service because it could impact research productivity.

These contradictions impacted the support universities provided participants. Participants told me that they had not been trained to engage productively in DEI service. Here's Josh speaking about how his graduate school training provided no information about DEI service.

> Outside of my certificate, I have no formal training in what to do. I took a bunch of STEM classes. They didn't really talk about any of this. So, it's really great to be able to go into Research Gate and enter in a few words and get like a view of literature.

Similarly, Grant developed some of his understanding of DEI through his own personal reading.

> I mean, I mostly set up training at the different places where I worked. I was the one who was instituting those sorts of things. And they're really difficult because most people think they're just blow off: "What am I gonna learn from this?" I think all my theoretical learning and training and understanding about this happened when I was in graduate school. I read widely. I would read business books. I would read Dale Carnegies, How to Win Friends, influence people. I did a lot of this stuff.

When university training was offered, it was not STEM specific (as with Josh above), or not practical. John expressed frustration because he attended DEI training to better understand race

---

[2] All quotes are phenomenological anecdotes (van Manen, 2016). Anecdotes are edited versions of participant quotes. In addition to extraneous words being omitted (um, and, like), participant stories were edited for clarity and space, but remain true to the themes identified by the phenomenological analysis.

and gender and those trainings morphed into conversations about how "people learn differently" that were not practical for his class size.

> On paper, I feel like the intention of some of these trainings was to discuss race and gender, but then they turn into this general, "Oh, well, the point is people learn differently." So, I attended one that was focused on how to assess student thinking. So, you give a student an exam and they don't put the right thing on the piece of paper, and you don't give them any points. But did you really understand what they were thinking? And ideally, I'd sit down with the student and say, "Explain to me what you're thinking here" but I can't do that for 300 students. So that bothered me a little bit that we're learning these ideas and trying to think about these things, which was great. But at the same time, is this really practical?

These contradictions in structures – that discursively the university voiced support for DEI initiatives, while functionally not providing resources is an indication of structural inequity.

Agency Amid the Chaos: Navigating Contradictions

In spite of these contradictory structures, participants cultivated a commitment to DEI service. While all participants described their engagement to the belief that DEI service was "the right thing to do," they also were motivated to engage in DEI service by relational commitments they held toward their students and/or toward women they knew personally (wives, daughters, friends, colleagues). For example, Daniel described a deeply held ethical commitment to know students as individuals and to communicate their inherent value as humans:

> I talked about this once with a woman who had worked with college students for a long time. She said that students would tell her all the time that "I just don't know if anyone at this university cares about me for myself and not me for my ability to do X, Y, or Z." That really struck me. I try to communicate to students that their performance in my class is not a make-or-break moment for who you are as a person or for your worth. Their value to the university community is not just about their ability to do well in specific classes. It's not at all about what they're able to do or not do, or what they're able to contribute or not contribute. And I see that belief as very much in opposition to a lot of things in the academy.

Josh was motivated to pursue grant funding for a DEI initiative because of his relational commitment as a dad to two daughters:

> So, I remember thinking, my youngest daughter was expressing interest in going into video game design or something like that. And I remember thinking like, "This grant wouldn't impact her life specifically, but what kind of environment would I want her to be in, or how could she be best supported?" Then I had this real desire to do that for our students: think of them like they are someone's daughters. Someone else feels this way about their daughter. I can care about them too.

These relational connections motivated participants to agentically engage in DEI service, even in the midst of contradictory messages from the university. In addition, participants told me they learned a lot about women as a result of these relationships. Here is Josh:

> I was talking to a fellow soccer dad. We played sports growing up, so we've been coached. We know about the culture and how it works, at least on the men's side. I learned very quickly the way we were coached as kids does not work at all on young girls' teams. Everyone that coaches girls every day understands this phenomenon either going in or right away. They don't question it. They just treat these groups a little bit differently. Still trying to promote the same skills. Both groups are equally good skill

wise. But then it's weird when you get to an academic setting, it's not really as accepted. It's like if you say something like that, the response is "We'll just treat everyone equally and kinda move on." I don't really understand that now, looking back on it.

And Grant, despite having committed a lot of time to understanding race and gender, told me that he learned so much when he met his partner, a Black woman.

> When I met my partner and I got to know her girls and I started raising her girls, I learned so much more about women of color, about all those extra things that I never had to think about growing up. And I was very sympathetic to it, but I mean, it was just like little dumb things. Like we'd be in a grocery store, and she'd be at the counter, and then I'd walk up and afterwards she said, "Did you notice the way the cashier's whole demeanor changed when you walked up to the counter? That's white versus black." But it's hard for people to really appreciate if they haven't experienced it.

Discussion

Universities have established a system that disincentivizes faculty from participating in DEI service while also discursively positioning diversity as a common good. DEI work is structured as an optional, individual pursuit. Individual faculty can engage, but it is not in their interest to do so. In fact, it is explicitly against their interest as an individual, working in a system that disincentivizes DEI service. This establishes a structure under which faculty are encouraged to engage in either/or thinking about their time – that they can do DEI work *or* work on their research. Since the tenure clock is ticking, the research part of this is considered urgent with DEI goals falling to the wayside. But faculty rarely make decisions based purely on university reward structure. Faculty weave together a sense of who they are, what they "should do," through their hermeneutic interpretations of their DEI engagement. In spite of little support from universities, men relied on personal relationships with women to develop understanding of DEI service and to motivate their engagement. This weaving is an agentic practice itself, of course. But it also creates new structures that guide future action, resist harmful university contradictions, and support students who have historically been marginalized. This early study raises many more questions about white male DEI engagement, but also supports so much of the research based on the experiences of marginalized faculty.

Positionality

I am a white, queer, cisgender woman (BS/MS Mathematics), currently teaching mathematics at George Mason University, a public, four-year university. I am part of a community of STEM faculty engaged in DEI service. I study DEI service through the lens of institutional activism, hoping to understand who is involved in DEI work in STEM, who is not involved, and how universities can strategically increase faculty engagement in DEI while retaining, valuing, and centering the work that underrepresented faculty have been doing.

Linear Algebra Students' Reasoning with Compositions of Linear Transformations

Lorna Headrick
Arizona State University

Michelle Zandieh
Arizona State University

We report on preliminary findings from a study of the ways in which linear algebra students used function composition to describe the result of applying two linear transformations, defined using symbolic vector notation, to a graphical region. Our current results from even a small set of data suggest that the students engage in function composition in a variety of ways. These results suggest areas for future exploration regarding how students engage in these forms of composition with linear transformations, and how their conceptualizations of individual transformations inform their understandings of the composition.

Linear transformation is an important idea within linear algebra. Furthermore, several areas of linear algebra rely on the idea of composing transformations, particularly in relation to multiplying matrices. These include the invertible matrix theorem (e.g., Wawro, 2014), and the diagonalization equation (e.g., Zandieh, Wawro, et al., 2017). Currently a few studies have investigated students' understandings of linear transformations, a small subset of which have included composition as one of the focal ideas (e.g., Bagley et al., 2015). Thus, a study of how linear algebra students conceptualize compositions of linear transformations as a form of function composition could have useful implications for the teaching and learning of linear algebra. This paper reports on our initial findings from pursuing this line of research.

Background and Literature Review

A large body of research has investigated students' understandings of function (early examples include Breidenbach et al., 1992; Carlson, 1998; Sfard, 1992). In contrast, few studies have had an explicit focus on function composition (e.g., Bagley et al., 2015; Bowling, 2014; Chen et al., 2023; Engelke et al., 2005; Headrick, 2023a; Kimani, 2008; Modabbernia et al., 2023). Most of these studies have focused on high-school or early college students (Bagley et al., 2015 being an exception). Furthermore, these studies have mainly used students' reasoning in the context of function composition to draw conclusions about their understandings of function. Some research has revealed evidence that students' reasoning with function composition extends beyond their reasoning with individual functions, suggesting a need for research that focuses on what is unique and important about students' reasoning with function composition specifically (e.g., Headrick, 2023a; Bowling, 2014).

Function composition has hardly been studied in linear algebra students' applications of linear transformations. A few studies have investigated students' understandings of linear transformations as functions (e.g., Andrews-Larson et al., 2017; Bagley et al., 2015; Oktaç, 2019; Turgut, 2019; Zandieh, Ellis, et al., 2017). One such study with a focus on composition of transformations (Bagley et al., 2015) found that students constructed the idea of an identity transformation as a "do-nothing function" and composing a transformation with its inverse as "doing" and "undoing." Our study will add to this research by investigating the reasoning linear algebra students use to describe the result of composing two distinct linear transformations.

Theoretical Framework

The theoretical framework currently guiding our data analysis in this study has two components. The first and primary component, which we refer to as *function composition* *reasoning*, is intended to explain students' reasoning unique to function composition specifically, accounting for ways students conceptualize multiple linear transformations and consider the result of applying them in sequence or in some other combination (Headrick, 2023b). The second component, called *clusters of metaphorical expressions*, focuses on the language students use to describe how they imagine individual transformations occurring (Zandieh, Ellis, et al., 2017).

Function Composition Reasoning

By function composition reasoning, we refer not only to previously described conceptualizations of function composition in research (e.g., Ayers et al., 1988; Breidenbach et al., 1992), but also other forms of reasoning students use to combine or apply multiple functions in response to a situation. Reviewing prior research led to identifying four distinct types of function composition reasoning high school and early college students engage in (Headrick, 2023b). Our current data suggests that these four types could also explain linear algebra students' reasoning with compositions of transformations. An example of each type of reasoning from our data is presented in the preliminary results.

The first type, *modifying a function with another function* (in short, *modifying*), involves conceptualizing a specific transformation and subsequently applying small tweaks or changes to this transformation via another, modifying transformation. The second type, *applying an operation on two functions* (in short, *operation)*, involves conceptualizing multiple transformations individually, and subsequently imagining the result of applying all of them together. The third type, *chaining input/output relationships*, involves taking some starting point (or input), applying one transformation to it, producing a particular result (or output), applying another transformation to the output of the first transformation, producing another output, and so forth. The fourth type, *chaining relationships between variables*, is an application of the third type in which the 'input' and 'output' of each transformation being composed is a variable.

Clusters of Metaphorical Expressions

Zandieh, Ellis, and Rasmussen (2017) presented five types of metaphorical expressions they found students to use when reasoning with linear transformations. Our current data suggests that students used these metaphors when composing transformations. The first, *input/output*, involves a transformation taking in or accepting some initial input, and giving some output in return. The second, *morphing*, involves an entity changing from one form to another through the transformation. The third, *machine*, involves the transformation doing something or acting on an initial entity to produce a result. The fourth, *traveling*, involves an entity moving from one location to another through the transformation. The fifth, *mapping*, involves an assignment of a one entity or value to another through some rule of correspondence.

Research Question

In light of existing research, we consider the question: In what ways do linear algebra students use function composition reasoning when composing two vector-defined linear transformations in a graphical context?

Method

Data Collection

The first author conducted one-on-one task-based clinical interviews with six students. The students had recently finished a Linear Algebra course taught by the second author and in which the first author served as a teaching assistant, at a large, public university in the United States. The Linear Algebra course was designed from a research-based curriculum (Wawro et al., 2013). The interviews were audio and video-recorded, and all written work was retained for additional evidence of the students' thinking.

Each task involved describing the result of applying a transformation to a 1-unit by 1-unit square region in the standard Cartesian plane, with its bottom-left vertex at the origin. Each task was structured identically with a three-fold structure: (i) predicting the result of applying a particular transformation, (ii) explaining the role of the notation used in the task to define the transformation in making the prediction, and (iii) sketching the transformed region, which for some (but not all) students, involved more precise calculations for determining points in the transformed region. Students applied these prompts to a single transformation T, another single transformation U, and the results of composing T and U: T(U(original square)), and U(T(original square)). Transformations in the tasks were defined using two different notations: vector notation, and matrix notation (different transformations were defined for each notation). Our preliminary results are from compositions of transformations T and U from the vector notation tasks.

Data Analysis

Since there are few prior studies on how students make sense of compositions of linear transformations, we began with an open-ended analysis in which we examined the video data to determine what themes might emerge from the students' reasoning. Upon further examination, we determined that existing frameworks for function composition reasoning (Headrick, 2023b) and for students' reasoning with transformations as clusters of metaphorical expressions (Zandieh, Ellis, et al., 2017) could enable us to develop a useful coding scheme.

Preliminary Results

In this section we present three distinct examples from our data to illustrate how the four types of function composition reasoning (underlined and italicized) appear to have emerged so far. Within each of these examples, the students appeared to use at least one cluster of metaphorical expressions (underlined). These examples suggest that linear algebra students could imagine composing linear transformations from a single problem context in a variety of ways. The data presented in this section are from students' predictions of how a composition of two transformations, defined as $T\left(\begin{bmatrix} x \\ y \end{bmatrix}\right) = \begin{bmatrix} 2x \\ y \end{bmatrix}$ and $U\left(\begin{bmatrix} x \\ y \end{bmatrix}\right) = \begin{bmatrix} 2x + y \\ y \end{bmatrix}$, will transform a 1-unit by 1-unit square region drawn in the standard Cartesian plane with its bottom-left vertex at (0, 0).

Luna: Chaining Input/Output Relationships with Input/Output Transformation Metaphor

To consider the potential result of T(U(original square)), Luna evaluated the vector-components definition of U, then T at the original square's top-right vertex: 1, 1.

Luna: Yeah, the T, U. Then, yeah, it would be--you would use the U which would turn it--the 1, 1 into 3, 1 and then you plug 3, 1 into T, which would give you 6, 1…

Luna described first applying U to the point, getting particular coordinates as a result, and then applying T to the resulting coordinates, suggesting she was *chaining input/output relationships*. She appeared to use the input/output metaphor when describing how she would apply individual transformations ("then you plug 3, 1 into T, which would give you…"), and perhaps a morphing metaphor ("turn it—the 1, 1 into 3, 1").

James: Modifying and Operation Function Composition Reasoning with Morphing

James appeared to focus on describing the entire square as a completed shape. When initially describing his prediction for the result of T(U(original square)), James said,

James: So if I do U on the original square that's going to turn it into the--that parallelogram that I--I drew. But if I do the T after that, that's just gonna stretch that parallelogram twice its x-value. So if I would just like to take that side and just pull it 'til it's twice it's x-value, I think that's what would--oh, wait, is that what would happen? 'Cause that 2 (pauses) Oo, it's also italicizing it further.

After further consideration, James concluded that:

James: …It basically doubles the size, but it also becomes twice as italicized.

James' overarching reasoning, including a description of applying U "to the original square", producing a result ("that parallelogram"), and applying T to the result ("if I do the T after that") suggest he imagined the composition as a *chain of input/output relationships*. He appeared to engage in *modifying* reasoning when he initially predicted the result of T(U(original square)). He began by focusing on the parallelogram he described as resulting from applying U to the original square ("that parallelogram I drew"). Then, he described how applying T would change the shape of the parallelogram ("stretch…twice its x-value"; "italicizing it further"). Thus, when forming his initial prediction, James appeared to think of applying U as the emphasis and applying T as tweaking the results of applying U. However, when drawing a final conclusion about the transformed region, James also appeared to put greater emphasis on how T as an individual transformation would transform the parallelogram resulting from applying U to the square ("doubles the size"; "twice as italicized"), suggesting potential *operation* reasoning.

Throughout his description, James' language suggests he imagined a region of interest changing from one shape to another through the transformations ("turn...into"; "stretch"; "italicizing"; etc.). Thus, James appeared to use predominantly morphing metaphors.

Olivia: All Four Types of Function Composition Reasoning with Machine and Morphing

Olivia seemed to imagine applying transformations to a collection of points that she said comprised the square. She illustrated this idea by using vector notation to denote the points being transformed (later she said, "x, y is really just the same as the whole bunch of points that make up our square"). Olivia's orientation to the task and written work (Figure 1) are given below.

Olivia: So T of U of--we're gonna call it x y, 'cause the original square freaked me out. So that means U is gonna transform x y first, and then T will do it.

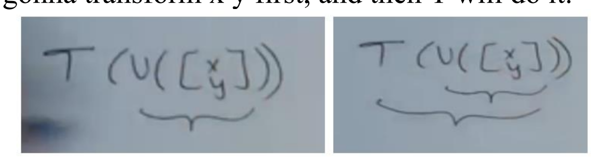

Figure 1. Olivia's Illustration of Applying U, then T to a Set of Points in the Cartesian Plane

Olivia's initial description of applying U, then T to the set of points suggests she imagined a *chain of input/output relationships*. When predicting the result of T(U(original square)) in more detail, she drew diagrams for the individual result of applying each transformation to the square and the combined result of applying both (see Figure 2). Meanwhile, she said,

Olivia: So this is our whatever x y is we call the original shape. This is my square. U took the square and made it like a parallelogram. That's what U did. And if we remember what T did, T took it and made it like, boop, it stretched it. So then, T would take this U thing, and stretch that to be like twice as long…

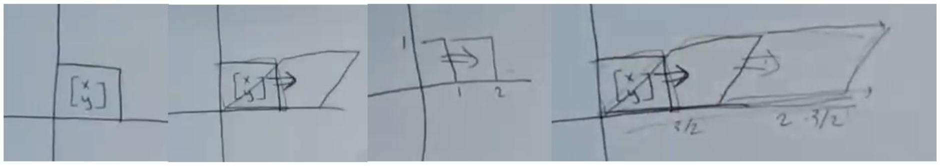

Figure 2. Olivia's Diagrams to Illustrate (left to right) the Original Square as a Set of Points, Applying U to the Square, Applying T to the Square, and Applying U, then T to the Square

Olivia appeared to imagine both U and T as having some individual effect on the square and T(U(original square)) as applying a combination of their individual effects (suggesting *operation* reasoning). There is also subtle evidence of her engaging in *modifying* when she described how T would change the result of U ("take this U thing, and stretch that…"). When asked what would happen to the corner points of the square "when you do T of U", Olivia described the transformation affecting the x-coordinates of multiple points. This reasoning, along with her earlier references to the square as a set of points suggests Olivia conceptualized T(U(original square)) as a *chain of relationships between variables*.

Olivia: …you stretch everything, all the x-coordinates by 2. So I guess that would include these, like, these points [points to the edges of parallelogram for T(U(original square))]. Their x-coordinates have to get shifted by 2 too, so then the diagonals would have to.

Throughout her description, Olivia used machine metaphors, describing transformations as doing particular actions to points or figures ("U took…and made it"; "U did"; ect.), and morphing metaphors ("made it…a parallelogram"; stretched it; etc.).

Discussion

All three students in the results presented above appeared to use chaining of input/output relationships in some form. They all described some starting shape or value, applying the inner transformation to that starting shape or value to produce a result, and then applying the outer transformation to the result of applying the inner transformation. The pervasiveness of this reasoning in the data thus far could be partly due to the nature of the tasks posed; the two transformations were pre-defined and the task prompts involved the notation T(U(original square)) and U(T(original square)). This is an area for further exploration.

On the other hand, each student described the chain of input/output relationships they appeared to conceptualize quite differently. Chaining input/output relationships as a form of function composition reasoning was most prominent for Luna, and her reasoning with each individual transformations appeared to be largely connected to input/output metaphors. James' focus on transforming entire shapes and morphing seemed to naturally give rise to his modification reasoning. Olivia's focus on transformations as machines performing actions on a set of points seemed to inform her operation reasoning (i.e., first describing how each transformation would act on points individually and then constructing the composition), and chaining relationships between variables (i.e., describing how multiple points were transformed). Our results thus far lead us to consider the following questions: (a) What contexts for linear transformation problems might lead to specific types of function composition reasoning; and (b) How might different types of function composition reasoning with linear transformations support students in studying related ideas in linear algebra, such as inverses or diagonalization?

Assessing Student Learning Experiences in a Corequisite Calculus Course

Amelia Stone-Johnstone
CSU Fullerton

Cherie Ichinose
CSU Fullerton

Adam Glesser
CSU Fullerton

The corequisite model of academic support has been touted as an efficient way of supporting student learning while decreasing the time to degree completion for students needing academic support. With the learning losses that have occurred globally as a result of the global coronavirus pandemic, the Department of Mathematics at California State University, Fullerton piloted a corequisite course to support one section of Calculus I, a course historically riddled with high DFW rates. In this paper we share preliminary results of our department's implementation of the corequisite model. While corequisite students from the first iteration of the course earned higher GPAs than their non-corequisite peers, more data (including longitudinal data) is needed to determine the lasting impact from the Calculus I corequisite experience.

Keywords: Corequisite mathematics, academic support, curriculum development

Background

Introductory mathematics courses have historically been a roadblock for students intending to major in the Science, Technology, Engineering, and Mathematics (STEM) fields. For most STEM majors, students must complete a sequence of calculus courses before commencing their major coursework. Historically Calculus I and Calculus II have been identified as bottleneck courses at California State University, Fullerton (CSUF). From 2012-2022, the Calculus I course was ranked eighth highest in terms of DFW (grades of D, Fail, or Withdraw) with a rate of 33%, while Calculus II ranked sixth highest with a 38% DFW rate. Given this institutional data, the authors developed an academic support course to try to combat this systemic issue through the creation of a Calculus I corequisite, and piloted the course with first-time-freshmen beginning their academic journey at CSUF with a declared Mathematics major.

The primary goal of the Calculus corequisite course at CSUF was to reinforce student conceptual understanding of prerequisite mathematical content knowledge, provide students with additional opportunities to engage with course content, and to help students develop the required skills to perform and succeed in college. Research (e.g., Hancock et al., 2021; Kashyap & Matthew, 2017; Logue, 2014; Richardson, 2021; Stone-Johnstone, 2023) on corequisite courses like the one created here at CSUF, have demonstrated benefits to student learning, as well as supported the placement of students directly into gateway courses (with academic support) as opposed to a long sequence of prerequisite courses.

The primary goal of this work is to increase access to Calculus I and Calculus II. We do this by creating a course with the aim of helping students better communicate mathematically (in writing and in speech), supporting students in problem solving, and developing their skills in using technology when doing mathematics. We hypothesize, based on previously research, that this corequisite course will help decrease the time to graduation at CSUF by providing students with targeted academic support. The driving research questions in this study are:

1. What effect does a Calculus I corequisite course have on student success in Calculus II?
2. What effect does a Calculus I corequisite have on students intending on majoring in mathematics?

Methods

This study employs a convergent mixed methods approach (Creswell, 2012) where quantitative and qualitative data were collected to assess the efficacy of the Calculus corequisite. Quantitative data in the form of Calculus I course outcomes of all course sections from the Fall 2021 semester and the Calculus II course outcomes from a special section of Calculus II composed primarily of mathematics majors in the Spring 2022 semester were collected and analyzed. Comparisons were made between the subgroups (corequisite and non-corequisite students) by performing a series of one and two-sample independent t-tests.

Qualitative data in the form of student focus groups and classroom observations of the corequisite course during the Fall 2021 semester were collected and subsequently analyzed. Fifteen corequisite students were interviewed during the data collection period, and from interview data, structural codes (Saldaña, 2021) based on the focused research questions were used to categorize and interpret their narratives around their experiences in mathematics during and after participating the Calculus corequisite course.

Preliminary Findings

The Calculus corequisite course was piloted during the Fall 2021 semester with only mathematics majors. Incoming students who intended to major in mathematics were advised to take the course in conjunction with their regular Calculus I course. Certain students who would have normally been placed into Pre-Calculus were also invited to take Calculus I with a corequisite support course during their first semester at CSUF. In this section we report both preliminary quantitative and qualitative results from the first iteration of the corequisite course at CSUF.

Quantitative Results

In Fall 2021, 38 math majors were enrolled in the corequisite course. Preliminary results from the quantitative analysis of the Calculus 1 course data shows that students who participated in the corequisite (versus all other students in other sections of Calculus 1) had higher overall course GPAs (grade point averages) and lower DFW rates. In addition, when only considering those students who received a non-DFW grade, the corequisite students outperformed the non-corequisite students (see Table 1). This latter category is infrequently reported, but at CSUF we have noticed that students who pass with lower grades in Calculus I tended to struggle more in their subsequent calculus and upper-division STEM courses. Out of the 38 corequisite students, 23 enrolled in the special section of Calculus II that was composed of only mathematics majors in the semester that followed. Nine of the other students did not pass Calculus I with a C or better (a requirement for STEM majors at CSUF), and the six others changed to a major that did not require any additional mathematics coursework.

Table 1. Calculus I Course Data from Fall 2021 across all sections

	Corequisite Students	Non-Corequisite Students
n	38	410
GPA	2.66*	1.88
DFW	24%**	41.8%
GPA (excluding DFW)	3.36*	2.93

*Significant at the .001 level
** Significant at the .007 level

Course data from the Spring 2022 Calculus II special course shows that students who were enrolled in the corequisite during the previous semester had slightly higher course GPAs and lower DFW rates in that course than those students who did not take Calculus I with a corequisite support course. When comparing all students that did not receive a DFW in Calculus II, the corequisite students earned higher GPAs relative to their non-corequisite classmates (see Table 2). It is important to note, of the 21 non-corequisite students, only two were first-time-freshmen and the rest were either upper-classmen or students repeating the course for credit.

Table 2. Calculus II Special Course Data from Spring 2022

	Corequisite Students	Non-Corequisite Students
n	23	21
GPA	2.178	1.952
DFW	26%	33%
GPA (excluding DFW)	2.88	2.786

*Significant at the .001 level
** Significant at the .007 level

Qualitative Results

There were two dominant themes that arose from the qualitative analysis: *Students valued the course structure of the corequisite course*, and *Students valued opportunities for community-building*. During the Fall 2021 semester, the corequisite students received more than six hours per week of course contact with their course instructor and peers. They were scheduled to attend their Calculus I course in person on Mondays and Wednesdays for 1 hour and 50 minutes each, and their corequisite course virtually on Tuesdays and Thursdays for 1 hour and 15 minutes each. During the corequisite sessions, students spent their time actively engaging in either Calculus I review or Pre-Calculus and Trigonometry activities that prepared them for the new Calculus content they would cover during the following day. In contrast, the instructor focused Calculus I class time on presenting new course material through a mixture of traditional lecture and active learning methods.

The first theme, *Students valued the course structure of the corequisite course*, arose as students were describing the nature of the corequisite course. One student shared that,

> [the corequisite course] helps us refresh and review … like with radicals and radical numbers and rationalizing numbers and stuff like that, so I feel like that was really helpful … I feel like it's pretty helpful and backing up like you're just reviewing - to help support what you're learning in calculus …"

Students recognized that the purpose of the corequisite course was for review and developing a deep conceptual understanding of their Calculus material. This course was a low-stakes support course where students could seek and receive help from their instructor, teaching assistants, and peers. Another student elaborated,

> So [the corequisite course] kinda introduced to us what we're going to do the next day. So it's not as hard the next day we're kind of like we know what we're about to do, like we have a taste of it. And it was really nice seeing all my classmates, all my groupmates day in, day out and seeing [my instructor] four days a week. And yeah … it wasn't that hard - it's like I wouldn't go stressing … like I have this class, like, I look forward to it. Because the problems aren't that hard and they're a good introduction to the next day and yeah it was fun.

The second theme, *Students valued opportunities for community-building*, showed up in all the interview data. For instance, when asked what they have gotten out of the corequisite course, one student shared,

> I mean, uh, I mean as cheesy as it might sound … like a community. I feel comfortable talking in front of those people, there's like 30 of them. I asked the teacher questions. In a class last year I wouldn't be doing that because I wouldn't be comfortable. We would be on ourselves most of the time. Now, we're like actually like you have people that you know and that you trust and that are actually helping you and want to help you too. If you're actually struggling and you wanna help them if they're struggling, it's more like personable I guess. You know everyone I guess too. Like even if I haven't talked to someone, I feel comfortable talking to them, which is odd because I've never really done that before, but yeah this class has definitely helped that.

Another student added,

> We engaged a lot, as a group ... We sat in groups of four and we engaged a lot … and I feel like that also helped us understand the material more because it's just you're figuring it out not by yourself, this time, but with, with the group, and I feel like, figuring it out together also helps us understand the material.

The corequisite students engaged in active learning and discovery within both their Calculus I and corequisite course four days per week. The early and consistent engagement among the students helped foster relationships that spanned past the Fall 2021 semester and into their Calculus II course during the following semester. When asked again, during the Spring 2022, to reflect on their corequisite course, several students reiterated the benefits of the collaborative learning experience. From their experience in the corequisite, students developed friendships and study groups that have helped them navigate Calculus II.

Discussion

The first driving research question for this work was, what effect does a calculus corequisite course have on student success in Calculus II? The preliminary data demonstrates that the corequisite course has the potential to support student learning in their Calculus I course as well as equip them with the tools for success in Calculus II. The Fall 2021 corequisite students attributed their success to the greater mathematical foundation they obtained from their corequisite course as well as the community they were able to build to help support them in their studies in Calculus II.

The second driving question was, what effect does a calculus corequisite have on students intending on majoring in Mathematics? While some students who intended to major in Mathematics ended up switching majors by the end of the semester, many others persisted into Calculus II. However, one student that ended up switching majors shared,

> I was struggling, I think more than I needed to. Or, more than like most of my peers. And, when I did my major advising, I was telling her that I was struggling and she was like "It's only going to get harder" and I was like "Hmm" and I was like "I don't know how much more of this I can take" so I did change my major.

This student was discouraged by an academic adviser to continue her mathematics pursuit based on her present academic struggles in Calculus I. It is unknown whether this student could have passed the course should they have stayed the course and sought extra help outside of what was offered in the corequisite course and the instructor's office hours.

While 23 of the original 38 students persisted to Calculus II, it is too early to firmly measure the effect a Calculus I corequisite will have on student persistence in STEM in general. A full assessment of the benefits of the corequisite requires a longitudinal study, where we can track student progress throughout the tenure of their college experience. Based on the prior research and the preliminary findings reported here, we hypothesize that a Calculus I corequisite course has the potential to increase student success in Calculus I and Calculus II. The findings from this study will be used to optimize future iterations of the corequisite course to support student learning and achievement. As we collect more data, we will better understand the potential of the corequisite model in supporting our student learning and academic success in STEM.

1. What kinds of data would convince you that a corequisite course is doing its intended job, of academically supporting students and helping them to persist in mathematics?
2. Does it make sense for an institution to adopt a corequisite model when they also have a Supplemental Instruction program?

Exploring How Undergraduate Students Engage in Computational Thinking with Data

Alyssa Hu
Pennsylvania State University

Neil J. Hatfield
Pennsylvania State University

Matthew D. Beckman
Pennsylvania State University

Modern statistics education requires that we support students in building powerful and productive ways of computational thinking. In this paper, we seek to understand the ways of computational thinking that undergraduate students employ as they engage with data. To address this question, we administered task-based interviews with three participants using the R programming language. Problem-solving approaches focusing on formatting data and efficient coding emerged as early aspects of student thinking. We are still reviewing interview transcripts and intend to compare our findings with existing frameworks from the literature, working towards a framework highlighting beneficial ways of thinking. This work is part of a larger study with additional tasks and additional individuals with varying levels of experience and expertise.

Keywords: computational thinking, data, statistics education, student thinking

The Guidelines for Assessment and Instruction in Statistics Education (GAISE) College Report endorsed several recommendations for introductory statistics courses, such as “use technology to explore concepts and analyze data”, “integrate data with a context and purpose”, and “teach statistics as an investigative process of problem-solving and decision-making” (Carver et al., 2016). These require that instructors support students in building powerful and productive ways of computational thinking.

Wing (2006)’s seminal paper on computational thinking emphasized that it is a “fundamental skill for everyone” that “involves solving problems, designing systems, and understanding human behavior by drawing on the concepts fundamental to computer science” (p. 33). Aho (2012) defined computational thinking as “the thought processes involved in formulating problems so their solutions can be represented as computational steps and algorithms” (p. 832). Lockwood et al. (2016) built upon Aho’s work, by studying the role of such thinking in mathematics through interviews with mathematicians. They arrived at the working definition “a logical, organized way of thinking used to break down complicated goals into a series of (ordered) steps using available tools”, which they termed “algorithmic thinking” (Lockwood et al., 2016, p. 1591). Shute et al. (2017) considered research in K-12 and higher education settings to define computational thinking as “the conceptual foundation required to solve problems effectively and efficiently (i.e., algorithmically, with or without the assistance of computers) with solutions that are reusable in different contexts” (p. 151). These definitions may appear overly broad, so we discuss existing frameworks to ground them.

Background

Computational thinking cuts across multiple disciplines including computer science, statistics, and mathematics; further, computational thinking appears at all levels of education. Working from a computer science education perspective, Barr and Stephenson (2011) discussed the core computational thinking elements that emerged during a Thought Leaders meeting for K-12 implementation organized by the Computer Science Teachers Association and the International Society for Technology in Education. Focusing on a particular environment, Brennan and Resnick (2012) studied young programmers (ages 8-17) through workshops and online project portfolios. To study the effect of age and gender on the development of computational thinking skills, Atmatzidou and Demetriadis (2016) conducted robotics training seminars in Greek junior high (age 15) and high school (age 18) classrooms. Weintrop et al. (2016) focused on creating a taxonomy of computational thinking practices to incorporate in math and science curriculums at the high school level. Lastly, Shute et al. (2017) proposed their own model after a thorough literature review and extensive discussion of the four previously mentioned works.

Despite these different contexts and methods, common themes emerged among each set of researchers' frameworks, speaking to the widespread relevance and applicability of computational thinking. One such common theme is the role of data. Barr and Stephenson (2011) discuss data collection, data analysis, and data representation as part of the core elements and capabilities of computational thinking. Brennan and Resnick (2012) refer to data as a key concept with regard to the storage, retrieval, and updating of values within computing environments. Within their taxonomy, Weintrop et al. (2016) consider five data practices– collecting data, creating data, manipulating data, analyzing data, and visualizing data. Shute et al. (2017) referenced data collection and analysis. Thus, we see that anticipating and planning data wrangling as early and vital components to computational thinking. Additional commonalities appear in Table 1.

Table 1. Additional commonalities with accompanying references.

Theoretical Perspective

When discussing these five computational thinking frameworks, we find utility in thinking about them through the lens of Harel's (2007) DNR determinants. Harel (2007) proposed the DNR system for curriculum development and instruction which consist of premises, determinants, and instructional principles (specifically: Duality, Necessity, and Repeated reasoning). Harel describes the determinants of *mental act* (actions performed in constructing knowledge), *way of understanding* (product or outcome of a mental act), *and way of thinking* (character or feature of a mental act). An example provided in the paper illustrates how proving is a mental act, a proof is a way of understanding, and a proof scheme is a way of thinking. Within the present study, the code that a participant writes to import data would reflect their way of understanding data importing while their imagery for and anticipations of loading data into an environment would reflect their way of thinking about data importing. With this backdrop in mind, we define computational thinking as *the ways of thinking that individuals employ when using computational tools to problem-solve efficiently and effectively.*

Many of the common themes (see Table 1) and our own definition involve the mental act of problem-solving. Barr and Stephenson (2011) also discuss some dispositions and pre-dispositions (e.g., "confidence in dealing with complexity") and classroom culture (e.g., "increased use of computational vocabulary") that would facilitate productive ways of computational thinking. These appear to be outcomes of problem-solving. Similarly, Brennan and Resnick's (2012) computational thinking concepts (e.g., "loops") and computational thinking perspectives (e.g., "questioning") appear to be products of problem-solving. We consider these to be ways of understanding. Our research focuses on the question: **What are ways in which computational thinking appears as part of undergraduate students' thinking as they work with data?**

Methodology

This project is part of a larger study regarding computational thinking for individuals of varying levels of experience and expertise. In this report, we narrow our focus to two tasks designed to probe attributes of computational thinking while participants engage and wrangle with complex data to achieve a defined purpose. While many computational tools exist, we focused on the R programming language and its related software (e.g., R Studio).

Participants

We interviewed three undergraduate students enrolled in a data science course focusing on statistical reasoning and computation, which has a pre-requisite of an introductory R course. The task-based interviews (Goldin, 2000) were recorded over Zoom. Students also submitted their R file in which they worked. We refer to the students as S1, S2, and S3.

Tasks

The two tasks are based on the 2021 American Time Use Survey dataset (ATUS; U.S. Bureau of Labor Statistics, 2022). Participants are provided with: (a) the raw Activity Summary data file from the 2021 ATUS, (b) a simplified data dictionary we created for demographic variables in the data file, (c) an activity lexicon to describe the activity variables in the data file, and (d) task prompts. The ATUS data was selected due to the topic requiring minimal background knowledge and its relevance as real (not simulated) data with practical applications. Both tasks follow a similar format, where we present a data visualization, ask participants regarding their observations of the chart, and then observe the participants as they explore and analyze the data to calculate a particular estimate that is displayed using the ATUS data.

Task 1 prompt. Consider the visualization below (Figure 1) made by the U.S. Bureau of Labor Statistics which tells us the average hours per day spent in selected activities. "Average per day, total" is selected. What does this chart tell you about the average hours per day, total, spent on personal care, including sleep? Would you walk me through how you would recreate this estimate using the atussum_2021.dat file?

Task 2 prompt. We maintain the same format of Task 1, but the context of the problem is modified. In Task 2, both "Average per day, men" and "Average per day, women" are selected and compared in a data visualization. We are interested in how participants address the coding for sex in the dataset and how they adapt or modify their previous solution to Task 1. (We omit the full prompt and figure in this report for brevity.)

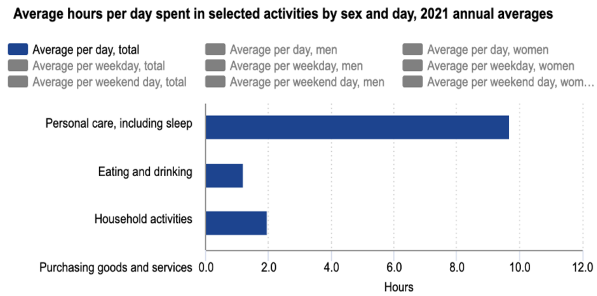

Figure 1: Task 1 Data Visualization from U.S. Bureau of Labor Statistics (truncated for space constraints)

Results

Preliminary analyses are currently underway. Below, we share some excerpts from participants and a couple of potential ways of thinking (pertaining to problem-solving approaches) that could be emerging.

Problem-Solving Approach: Ensure Proper Format of Data

All participants considered how to load data into RStudio. They used different coding environments; S1 used an R script, S2 used an R Markdown file, and S3 opted for an R Notebook file. S1 proceeded to directly write a *read.csv*() command and ran the line of code which provided a preview of the data frame in the console. S2 and S3 both used the data import wizard (GUI) of the RStudio IDE. Despite the two different ways of data importation, all students performed a visual inspection of the data frame; S1 checked post-import while S2 and S3 checked during import. They all commented on what they perceived to be correct format:

S1: So everything is already separated in columns.

S2: Let's see, and I see that there is a heading so "Yes", import that.

S3: The variable column headings are stuck as V1, V2, it goes on. So what I did was switch Heading to "Yes" and this makes it the proper headings.

In contrast to S2 and S3, S1 added in a couple of lines of code using the *complete.cases*() and *unique*() commands. It appeared that S1 had additional data cleaning procedures to apply regardless of the data context, based on the following conversation:

S1: That's usually what I do first, I think.

Interviewer: And can you remind me again, what these 2 lines of code will do?

S1: So, this, the first one, is to make sure all, everything is completed. There's nothing empty, nothing like the rows. There's no one with missing information. And then, the second one is to make sure there's nothing repeated.

Interviewer: Gotcha. And you mentioned that you, you said that this is sort of what you normally do. So are these things that you check every time you code, normally?

S1: I think so, to make sure everything is more clean.

Problem-Solving Approach: Find Efficient Way to Write Code

When the interviewer asked participants to talk about their approach for Task 2, all participants attempted to find the average hours for men and average hours for women using two distinct code blocks. They all expressed a desire for alternative ways to write the code:

S1: Maybe there is way to do female on the same dataset as the male and then write a code to do the rest. I'm just not sure how I'd write that, but I think, the easiest way for me to do [it] would be [to] do separately, but I'm sure there's probably a way to do it together.

S2: If I want to do it together, how would that work? So then I'm thinking, like, okay, I, the very beginning part's the same. Uh, I'm just thinking about when I plot it, how am I gonna be able to distinguish between male and female and how I want it, I guess. Like, your code running is very important but also I think having it be very concise and clean is also pretty important.

S3: So, there probably is a way to do it within one data set, but it's just the first thing that came to mind.

Based on their terminology ("do it together" and "do it within one"), all three participants had considerations of reducing redundancy and increasing efficiency. S2 specifically verbalized the reason for doing so, including anticipation of future analysis (plotting) and what they considered to be best practices of coding.

Discussion

We have outlined some initial ways of thinking that undergraduate students possess and will continue to analyze our data. Our next steps will be to consider the points of commonality with (and departure from) existing frameworks. This would involve additional coding of the data based on these frameworks, and it may be useful to note the frequency and length of time that participants spend in each unique code.

We note some planned future work as this work is part of a larger study. One direction is collecting data from individuals with additional experience and expertise, including graduate students, faculty, and industry professionals. This would allow us to consider a new research question: What similarities and differences do we observe among individuals who self-identify along the novice-expert continuum? We will also consider how an individual may move along the expert-novice continuum in terms of their data-ing and computational thinking skills. Another direction is analyzing participant responses to several additional tasks, including: (a) creating a visualization, (b) brainstorming their own question about the dataset, (c) discuss coding challenges and review code, and (d) verbalize how they would approach a new prompt about the dataset. The purpose of (a) and (b) are to highlight how and what we can communicate with data. We hope to spark a discussion regarding effective problem-solving with (c) and how computational thinking transfers across different contexts with (d).

A key outcome from our study will be understanding the role of computational thinking, in conjunction with interrogating data sources, in reshaping the statistics curriculum. In creating our framework, we will highlight concepts and skills that we might want to foster and support as educators. This would support the generation of hypothetical learning trajectories, which can then inform classroom interventions and expectations while engaged in data exploration, analysis, and communication. In addition, we can reflect and learn from participant feedback regarding the tasks we created, which can inform the way we design future tasks and instruction in statistics, data science, and related courses. A possible extension in the future would be to develop an assessment to measure student development of computational thinking skills.

Intended Questions for Audience

1. What similarities or differences in students' thinking have you noticed in your classroom experience compared to our (preliminary) results?
2. What are your thoughts on or suggestions regarding our planned future work?
3. What suggestions do you have for supporting students in further developing their computational thinking?

Abstract Mathematics as Perceived by Pre-Service Mathematics Teachers: "It is Not Gonna Benefit Me in Teaching"

Seyda Uysal
The University of Southern Mississippi

The secondary-tertiary transition (STT) in mathematics presents university students with multiple cognitive-epistemological, didactical, sociocultural, and affective challenges. This qualitative study explores the perceptions of two pre-service mathematics teachers regarding the relevance of abstract mathematics to their future teaching practices. Using three interviews and eleven reflections, the investigation yields in-depth insights. In addition to highlighting the affective aspects of the STT in mathematics, the study addressed certain difficulties pre-service teachers encountered while dealing with advanced mathematics courses.

Keywords: affect, perception of abstract mathematics, pre-service mathematics teachers, secondary-tertiary transition

The secondary-tertiary transition (STT) in mathematics represents a significant milestone in the academic journey of pre-service mathematics teachers as they progress through university. While these individuals possess a deep passion for mathematics and aspire to become educators, they often encounter formidable challenges as they navigate the shift from concrete, school-level (i.e., empirical) mathematics to the more abstract and theoretical realms of university mathematics. This transition is of paramount importance, as it not only influences their own understanding of the subject but also shapes their ability to effectively teach complex mathematical concepts to future students. This research study seeks to explore the multifaceted challenges that pre-service mathematics teachers encounter during this pivotal transition to abstract mathematics in university settings. By examining these challenges in-depth, I aim to further understand the pertinent issues and identify potential strategies to better prepare pre-service mathematics teachers for the unique demands of abstract mathematics, ultimately enhancing the quality of mathematics instruction in the classroom.

Theoretical Perspectives

The secondary-tertiary transition (STT) in mathematics education has been extensively explored in the literature, with scholars identifying various categories of challenges. De Guzman et al. (1998) categorized these challenges into three main areas: cognitive-epistemological, didactical, and sociocultural, with recent studies adding affective factors as a fourth component (Di Martino & Gregorio, 2019). The nature of mathematics changes as students transition to university, becoming more formal and abstract (Tall, 2008). This shift requires advanced thinking and can lead to cognitive and affective challenges when there is a lack of alignment between the mathematical expectations of secondary and tertiary institutions (Pepin, 2014). Affect in mathematics learning, including beliefs, attitudes, and emotions, plays a pivotal role in shaping students' engagement and performance in the subject (McLeod, 1998). Understanding and addressing the affective aspects of mathematics education is crucial for fostering a positive and productive learning environment.

The Study

The current study focuses on exploring the secondary-tertiary transition experiences in university mathematics from affective perspectives. Five women and/or racially ethnically minoritized women participated in this research who were majoring in mathematics at a large university in the southeastern United States. The semi-structured interviews and reflection videos were used as data collection method focusing on students' experiences in demographic information, secondary school mathematics, decision to major in mathematics, current experiences in the major, vision of mathematics, perceived competence in mathematics, approaches to and assessments of learning mathematics, and mode of belonging.

In this study, I focus on Nia and Bethany, both pre-service mathematics teachers who frequently brought up the disparities between university-level mathematics and secondary school mathematics. This emphasis on their experiences arises from the study's primary focus on the differences between secondary school and university mathematics, which is recognized as a "knowledge gap," or "discontinuities" between two institutional settings (Gueudet, 2008). It is noteworthy to highlight that both Nia and Bethany were first-generation college students who also openly discussed their financial challenges in pursuing a college education. Nia identified as a biracial female with Black and White heritage, while Bethany was a White female student. Nia and Bethany participated in three monthly interviews and recorded eleven weekly reflections in the semester of Spring 2022. Following stages of open, axial, and selective coding, the grounded theory method guided data analysis and enabled the identification of themes that emerged from student responses (Charmaz, 2006).

Preliminary Findings

I explore the specific beliefs held by Nia and Bethany about abstract mathematics, which arose as they reflected on their mathematical skills and the nature of advanced mathematics at the university level. These beliefs contribute to their skepticism about the relevance of advanced math to their future careers. Using several direct quotes, I delve deeper into Nia's and Bethany's views on abstract mathematics, which are rooted in their perceived ability to grasp abstract concepts in proof-based courses. The following excerpt illuminated Nia's first proof experiences in the Introduction to Advanced Mathematics (IAM) class:

> I didn't like that [IAM] course mainly because the proofs weren't really interesting to me. Because it was me memorizing how to do the proofs and really understanding how to prove something in math, which is something that I couldn't kind of wrap my brain around like, 'okay, where do you start?' It wasn't concrete. These are always like, 'do the proof this way' it was like well, 'maybe the proof is this way, maybe it's that way.' So, I have to assume a lot of information. It was pretty hard to keep up. I mean, I ended up with a B in there. But it was not my favorite math course. (Nia, Interview 1, February 2022)

Nia shared her experience in the Introduction to Advanced Mathematics (IAM) course, primarily expressing her dislike for it. She found the memorization of proofs uninteresting and struggled to grasp the abstract nature of mathematical proofs. This aligns with her preference for mathematics that involves practical application and processes. Nia's frustration stemmed from not being able to determine the correctness of her proofs, as she lacked clear expectations and the means to verify her work:

> When I don't know the expectations or when I am not able to check my work, that's when I am unsure, as I will be 'is this right thing?' is my problem with the proofs as well. Well, I took the [Introduction to] Advanced Math, and I couldn't determine for myself, like 'is this right, is this the answer?' I don't understand how I know if I'm writing this proof right and if it's an accepted answer. (Nia, Interview 1, February 2022)

Similarly, Bethany had her own perspective on proof-based classes. She believed that exam questions should closely resemble the material covered in class, and when they didn't, she considered the course difficult. Bethany didn't enjoy proofs, especially in courses like Abstract Algebra and Analysis, where the abstract nature of the subject made it challenging for her to connect with the content. She believed that her future teaching career wouldn't require knowledge of such abstract proofs and preferred mathematics with practical applications:

> I don't like the proofs as much. Well, I guess it depends on what it's about, because I think groups in Geometry were really fun because I could do it. It was really tangible, I could understand angles and shapes. But in Abstract Algebra and Analysis, I definitely struggled more because it was more abstract. I think for teaching, like, even in high school, I don't need to know proofs for abstract things. It's not gonna benefit me in teaching, really. So I don't think it'll be a problem in that context. (Bethany, Interview 2, March 2022)

Bethany's responses revealed a mix of emotions, including both satisfaction and aversion, when she contemplated abstract mathematics. She provided several explanations for her lack of enthusiasm towards mathematical proofs. Initially, Bethany linked this sentiment to the inherent abstractness of proofs, where the concepts lacked a tangible quality. In her first interview, she also conveyed that the majority of her university mathematics courses were formal and did not align with her aspirations in teaching. Bethany's perspective on mathematics in her initial and subsequent interviews remained consistent. Specifically, she conveyed a preference for mathematics with practical applications, believing it would have greater relevance to her future career in teaching. Bethany also mentioned her preference for what she termed a "straightforward course," where lectures were followed by problem-solving sessions, and exams focused on class exercises. In contrast, she perceived proof-based classes as less straightforward because they required students to think independently rather than follow step-by-step instructions:

> I guess the courses are just lectures, and then you do the problems. Like in Linear Algebra, you just write on the doc camera, doing the problems, and then you'd go home and do the same problems. The tests were about the exercise problems from class. So, I thought that was pretty straightforward, versus proof-based classes, they don't tell you how to do the problems. You have to figure it out. In Calc II, we also had some group projects which required more thinking on our part and not just doing what we were told to do. (Bethany, Interview 3, April 2022)

Bethany's perception of proof-based classes as challenging due to their requirement for independent thinking rather than following explicit instructions reflected her initial beliefs. These beliefs highlighted a mismatch between in Bethany's expectations of upper-division mathematics courses and the actual classroom experience in secondary school teaching. Consequently, both Nia and Bethany viewed abstract mathematics as less relevant to their career aspirations. This misalignment led to their disengagement from proof-based courses. They did not see a connection between their mathematical abilities and the demands of these courses. Additionally, both students expressed little interest in pursuing careers that involve abstract mathematics, possibly due to the perceived gap in their mathematical background and competency required for such careers.

Significance and Implications

When analyzing Nia's and Bethany's cases, several noteworthy patterns surfaced in their experiences with university-level mathematics, with a specific focus on abstract mathematics. Both Bethany and Nia raised doubts about the relevance of abstract mathematics, as they believe it is disconnected from their future teaching practices (Wasserman et al., 2019). Some of their concerns stemmed from instructional practices encountered in university, which predominantly adhered to traditional lecture formats. Additionally, their doubts were further fueled by the perceived difficulty in discerning the validity of mathematical proofs, shedding light on challenges related to mathematical competence. Furthermore, Nia and Bethany commented on the abstract nature of mathematics at the university level, contrasting it with the more tangible mathematics of secondary education, which also influenced their attitudes toward learning abstract mathematics. Schoenfeld's assertion that "formal mathematics has little or nothing to do with real thinking or problem solving" (1985, p. 43) seemed to resonate with the beliefs held by Bethany and Nia about the nature of mathematics. Their reactions to the changing nature of mathematics towards upper-division courses corroborated the findings of Geisler and Rolka (2021), which highlighted that students anticipate university-level mathematics to align with the practical and applied aspects of the discipline. This observation underscores the disparities in students' perceptions of mathematics, particularly in the context of secondary school mathematics and university-level mathematics courses (Rach & Heinze, 2017).

Solomon and Croft (2016) proposed that when undergraduate students feel a challenge to their sense of ownership of mathematics, they tend to disengage from the subject. This disengagement often stems from mathematics either not meeting their high expectations for success or failing to reveal its inner workings while imposing strict adherence to its rules. The experiences of Nia and Bethany, who both excelled in high school mathematics and currently perceive themselves as rule followers in college mathematics, align with these ideas.

High school preparation significantly impacts students' experiences in university mathematics courses. Nia and Bethany, who are first-generation students appeared to be less prepared and struggling with advanced mathematics courses. Both students highlighted their difficulties in keeping up with their peers, attributing it to their limited background in advanced mathematics or the instructional style and expressing a need for additional resources to grasp the course materials effectively. Future research should investigate the alignment between pre-service mathematics teachers' teaching goals and the content of the advanced mathematics courses, with the purpose of tailoring these classes to their specific needs. Furthermore, future research should investigate the relationship between the experiences of first-generation college students and their views on abstract mathematics. Investigating the requisite support systems necessary for their success and their development into proficient mathematics educators should also be a priority.

The Meta-Narratives about Function Conveyed by a Commonly Used Multivariable Calculus Textbook

Brady A. Tyburski
Michigan State University

Function is a unifying, cross-curricular theme that plays a central role in nearly every subdiscipline of mathematics. Yet, this cultural meta-narrative that is widely accepted by mathematicians is not one students readily adopt. In this report, I share a preliminary analysis of the stories told about three different types of multivariable functions in a commonly used calculus textbook. In doing so, I juxtapose these stories and consider how this textbook—a cultural artifact of the discipline of mathematics—might support or hinder the transmittal of desirable cultural meta-narratives about the role of function. Ultimately, I find that real-valued functions are consistently positioned as functions, while the function properties of both types of vector-valued functions are de-emphasized. As only one of the three function types are positioned as functions, this suggests that the stories in the textbook could hinder students' adoption of the meta-narrative of function as a unifying mathematical theme.

Keywords: Function, Multivariable Calculus, Curriculum as Story, Textbook Analysis.

Function is a crucial recurring theme across the story of the K-16 mathematics curriculum. (e.g., CCSSM, 2010; Zorn, 2015). Some mathematics education researchers even go as far as to contend that the concept of function is "the single most important mathematical concept studied from kindergarten to graduate school" (Harel & Dubinsky, 1992, p. vii). Mathematicians have also spoken about the centrality of the function concept. For instance, Gowers et al. (2008) stated how "One of the most basic activities of mathematics is to take a mathematical object and transform it into another one" (p. 10). In this sense, function is a unifying, cross-curricular theme that occurs across nearly every subdiscipline of mathematics.

This cultural meta-narrative about the role of function has endured for decades. Yet, this is not a narrative that students readily adopt, as a large body of research suggests (e.g., Martínez-Planell & Trigueros, 2021; Melhuish, 2020; Zandieh et al., 2017). While there are several reasons for this, in this preliminary report, I examine the role that the stories told in a commonly adopted calculus textbook (Stewart et al., 2021)—a cultural artifact of the discipline of mathematics (Plut & Plesic, 2003)—might play in transmitting or failing to transmit this cultural meta-narrative to students. Specifically, I examine the stories told about the three different types of multivariable functions featured in multivariable calculus (MVC)—parametric, vector-valued functions; multivariable, real-valued functions; and vector fields—in the chapter they are first introduced. In this arts-based textbook analysis, I lean into the metaphor of curriculum as story (Dietiker, 2015) and treat each of these function types as mathematical characters. I investigate two questions: *(1) How are these characters portrayed in the chapters they are introduced and how do these portrayals compare with one another? (2) What meta-narratives about function(s) are conveyed collectively by these character introductions?*

Background

MVC textbook analyses that focus on the concept of function are admittedly limited. Notably, McGee et al. (2015) observed that in commonly used calculus textbooks, explicit conversations linking representations of single-variable and multivariable functions are virtually nonexistent, even though students may not spontaneously draw these connections on their own (Martínez-Planell & Gaisman, 2012). More generally, Harel (2021) noted that traditional MVC textbooks tend to introduce key concepts without proper motivation and introduce computational shortcuts prematurely. While other analyses attend to the meta-narratives conveyed by textbooks, they tend to be with an eye to a particular topic, like line integrals (Dray & Manogue, 2023).

Textbooks as Cultural Artifacts & Curriculum as Story

In undergraduate education, many instructors use textbooks as a primary curricular guide (Fraser & Bosanquet, 2006). So, even though mathematics students do not read them cover to cover (Weinberg et al., 2012), the stories conveyed (or not) in textbooks play a powerful role in the reproduction of mathematical culture and specifically the meta-narratives that are valued by the discipline (Plut & Plesic, 2003). By a *meta-narrative*, I mean a "cultural narrative schema which orders and explains knowledge and experience" (Stephens & McCallum, 1998, p. 6). In other words, meta-narratives are narratives that recur (implicitly or explicitly) across cultural artifacts which individuals subsequently leverage to frame and explain their past and subsequent experiences. For example, the meta-narrative that "good always conquers evil" is common across children's books. That said, as Brown (2022) demonstrated, the meta-narratives perpetuated by undergraduate mathematics textbooks do not always align with those held by members of the discipline of mathematics. In these cases, textbooks might actually convey messages that serve a counterproductive role toward enculturating students into the discipline.

I adopt the perspective that mathematics curriculum (and therefore textbooks) can be conceptualized as a story (Dietiker, 2015; Gadanidis & Hoogland, 2003). Like a story, curricula features (mathematical) characters inhabiting settings and engaging in actions that constitute the plot. A curriculum also features literary themes and morals in the same way a good story might. As textbooks are used for enculturating students into the discipline of mathematics, the stories contained within them should not merely be an afterthought. After all, the stories we are told and then re-tell influence how we organize our experiences (Clark & Rossiter, 2008). Indeed, the power of story has been acknowledged repeatedly by mathematicians (Doxiadis & Mazur, 2012) as well as mathematics educators (Burton, 1999), but analyses of the stories conveyed in textbooks from a literary and aesthetic angle remain rare (e.g., Dietiker & Richman, 2021).

I employ Dietiker's (2015) framework for analyzing mathematical stories based on the narratological work of Bal (2017). Specifically, I attend to the characters, action, settings, and plot. Mathematical characters are those concepts that get objectified in the text, including functions, numbers, etc. They are often imbued with *character traits* (e.g., a function may be 1-1, even, etc.). I attend specifically to which mathematical characters are positioned as *protagonists* and *side characters*, as well as the *relationships* between characters. Mathematical action refers to moments where a new character is created or introduced as well as when characters are manipulated mathematically (e.g., the characters "2" and "3," might be added to form a new character, "5"). The setting of mathematical stories includes different representations (tables, graphs, etc.) as well as physical contexts. Finally, the mathematical plot includes a reader's aesthetic reactions to the unfolding story as they attempt to discern its structure.

Data & Methods

I analyzed the character introductions of three different multivariable function types in Stewart et al.'s (2021) *Calculus*, a commonly adopted textbook in U.S. undergraduate classrooms for teaching the calculus series (Mesa, 2010; Mkhatshwa, 2022). By "character introduction", I mean the first section within the unit in which each function type is introduced (e.g., 13.1). Hereafter, I refer to these sections as "chapters" as a reminder that I am conceptualizing the textbook as a literary story. The three chapters analyzed were: (1) 13.1: Vector Functions and Space Curves, within the Vector Functions unit, in which parametric, vector-valued functions are introduced; (2) 14.1: Functions of Several Variables, within the Partial Derivatives unit, in which multivariable, real-valued functions are introduced; and (3) 16.1: Vector Fields, within the Vector Calculus unit, in which vector fields are introduced. I also included the paragraph overview of each unit because they immediately precede each chapter and briefly introduce each function type.

Methods

I first read the story of each chapter three times while making marginal notes in the same way someone might while trying to interpret literary fiction. Following an arts-based approach (Leavy, 2018; McNiff, 2018), I did not restrict the structure or modality of these notes. Instead, I focused on recording my thoughts, feelings, and observations in whatever modality was most appropriate. Sometimes, I would write a comment or pose a question; other times, I would draw a sketch or write a quick poem to artistically convey my reactions as a reader.

To add focus to my analysis, I attended primarily to the story elements outlined in Dietiker's (2015) framework (character, action, setting, plot). However, I did not shy away from attending to other dimensions that were salient in my reading of each story, especially those related to my aesthetic interpretations of how the story was told or the overall moral of each story. My intent was to lean into my subjectivity (Tremaine & Hagman, 2023) and unique positionality as a reader who is a disciplinary expert and has taught MVC multiple times. This involved engaging my full senses and emotions: I did not restrict myself to purely logical analysis of structure, mathematical content, etc. I allowed myself to wonder about what came next, why the textbook was or was not introducing certain elements, and to make aesthetic judgements.

Following this open-ended analysis, I re-read and reflected across my marginal notes and conducted secondary analyses to follow up on recurring themes and questions that had appeared across all the character introductions. In this report, I share the preliminary results from two such analyses: (1) a "nickname analysis" of the changing names and phrases used to refer to each character (e.g., function, equation, curve) paired with (2) a plot structure analysis of each story.

Story Analyses

Parametric, Vector-Valued Functions (PVVFs)

As soon as the unit introduction, the purpose of introducing PVVFs is clearly signposted: "We now study functions whose values are vectors because such functions are needed to describe curves and surfaces in space" (p. 927). While PVVFs are introduced formally as "a function whose domain is a set of real numbers and whose range is a set of vectors" (p. 928), they are soon relegated to a side character used primarily to introduce the main character of space curves. In fact, once the relationship between these characters has been established, the word function only appears two more times. Additionally, across the entire chapter, "function" is mentioned only about half as frequently as "curves" and about the same number of times as (parametric) "equation". The set theoretic functional properties (e.g., domain and range) of PVVFs are effectively backgrounded in favor of sketching curves and writing parametric equations in the subsequent examples.

Ultimately, the character of PVVFs appears to have been introduced as a technicality: even before space curves are introduced, the (unboxed) function definition is followed quickly by the introduction of component functions. After this, the primary action involving PVVFs is to quickly reduce them to their component single-variable functions for further computation. This backgrounding of PVVFs as functions sends a strong message about the defining traits of such functions: they decompose into multiple other single-variable functions and *these* functions are the most important.

Multivariable, Real-Valued Functions (MRVFs)

The character of MRVFs, on the other hand, is treated as a function from beginning to end. Unlike both other chapters analyzed, this one starts by outlining four points of view for studying MRVFs: verbally, numerically, algebraically, and visually (by a graph or level curves). This phrasing positions the words, tables, formulas, graphs, and level curves as in service of MRVFs, rather than the other way around (as was the case with PVVFs and geometric space curves). Additionally, this is the same framing used to introduce the function concept in the first (single-variable) chapter of the textbook, further affirming that MRVFs are, by their nature, functions.

Unlike with PVVFs, the formal set-theoretic definition of MRVFs of two variables is boxed and even "domain" and "range" are bolded, further emphasizing their functional characteristics. Next, the independent and dependent variables of a MRVF are defined and followed immediately by an aside to the reader that draws a comparison between single- and multivariable RVFs: "Compare this with the notation y = f(x) for functions of a single variable" (p. 927). Interleaved throughout the remaining pages are recurring explicit references to the domain and range in text and in the examples. Finally, the chapter ends by introducing the formal definition of MRVFs of three or more variables, returning to highlight that these characters are functions.

"Function" is far and away the most common name used to refer to MRVFs (87 instances). This use of this name does not subside, even as "level surfaces" (51 instances) and geometric names (such as "graph" or "surface", 44 instances) are introduced as alternatives.

Vector Fields

The caption for the image featured in the vector calculus unit introduction immediately states how "vector fields can be used to model such diverse phenomena as gravity, electricity and magnetism, and fluid flow" (p. 1161). Nearby, the first sentence of the main text reads, "In this chapter we study the calculus of vector fields (These are functions that assign vectors to points in space)" (p. 1161). The use of parentheses to convey the technical details persists throughout this paragraph and feels almost like the narrator is whispering to the reader, implicitly conveying that perhaps the function definition of vector fields is a sidenote.

The emphasis on modeling realistic phenomena carries into the beginning of the chapter introducing vector fields, which features nearly a full page of four example velocity fields depicted visually alongside written interpretations of what meaning the plotted vectors convey. Afterwards, the general definition of vector field is introduced (unboxed) as "a function whose domain is a set of points in $\mathbb{R}^2$ (or $\mathbb{R}^3$) and whose range is a set of vectors in V_2 (or V_3)" (p. 1163) followed by separate boxed definitions of a vector field on $\mathbb{R}^2$ and on $\mathbb{R}^3$. Curiously, the language of domain and range is less explicit in the boxed definitions: "Let D be a set in $\mathbb{R}^2$ (a plane region). A **vector field** on $\mathbb{R}^2$ is a function **F** that assigns to each point (x,y) in D a two-dimensional vector **F**(x,y)" (p. 1163). After each definition, component functions are introduced, with a brief mention that the reader should already be familiar with these characters from reading about them alongside PVVFs.

After two examples concerning how to sketch some specific vector fields, the story shifts primarily to what can best be described as extended vignettes of notable types of vector fields (e.g., a gravitational field, electric field, gradient fields, etc.). Aside from using function and vector notation as a symbolic necessity, once technology is introduced as a way of plotting vector fields, the functional aspects of vector fields go almost entirely unmentioned. Indeed, there are only 5 explicit references to vector fields as "functions" across this entire chapter, most of which occur near the formal definitions.

Discussion

These story analyses emphasize key differences between the character introductions of these three types of multivariable functions in one commonly used MVC textbook. While real-valued functions are clearly positioned as a main character and repeatedly portrayed as a type of function, the same cannot be said about both types of vector-valued functions. The difference is most extreme in the case of parametric, vector-valued functions, which play the role of a secondary character meant to introduce space curves and whose function character traits are quickly backgrounded. Vector fields remain the main character of their story; however, their functional character traits are mostly de-emphasized across a series of vignettes that focus on introducing and interpreting the physical meanings of specific vector fields (e.g., velocity fields, gravitational fields, etc.). Considered collectively, these stories perpetuate the meta-narrative that the most important type of multivariable functions in MVC are the real-valued ones. Vector-valued ones are also functions—at least formally—but this is portrayed as a mere technicality and not a fact used frequently in practice. Readers (our students) are more likely to come away with alternative messages about vector-valued functions that are foregrounded in these stories, such as how readily they can be decomposed into component functions ("the truly important functions") for the purposes of further computation. Or, in the case of vector fields, the importance of physical interpretation of vector outputs.

Whether these alternative messages are consistent with the curricular goals of MVC is beyond the scope of this preliminary report. However, it is worth noting that the dominance of such messages may hinder students from picking up on the cultural importance of function as a unifying, cross-curricular theme that includes both RVFs and VVFs. Rather, readers may be led to believe the meta-narrative that function is an unnecessary boondoggle, "extra", or formalism that only plays a passing role in the overarching story of MVC and, more generally, mathematics. Already, research suggests MVC students often need support in making sense of MRVFs as a generalization of single-variable real-valued functions. The same may well be true for making sense of vector-valued functions as multivariable functions, *especially* if there are even fewer textbook supports for making this generalization.

There is emerging empirical evidence suggesting students benefit from reasoning about different function types as instantiations of the same overarching function concept (Melhuish et al., 2020; Zandieh et al., 2017); however, none of these studies are in the context of MVC. I hypothesize that MVC students may similarly benefit from recognizing PVVFs, MRVFs, and vector fields as functions, as this would better position them to recognize structural similarity across the different types of calculus required for each function type (e.g., the Chop, Multiply, Add conceptual pattern for integration, Dray & Manogue, 2023). Simultaneously, I recognize that while an overarching story for MVC centered on function may support students' enculturation into the discipline of mathematics, it may have the opposite effect on students' enculturation into other STEM disciplines, given the differing ways that scientists and mathematicians conceptualize functions (e.g., Dray & Manogue, 2004). This suggests further cross-disciplinary research collaboration is needed to ensure that our MVC curricula feature coherent stories which set up our STEM students to be successful, regardless of their discipline.

Student Use of Series Expansions as an Approximation Technique in Physics Modeling Tasks

Michael E. Loverude
Department of Physics, California State University Fullerton

As part of a larger project to investigate student use of mathematics in upper-division physics courses, we have examined how students use series expansions as a means of approximating and simplifying complicated expressions in theory-oriented physics courses. Student responses were collected on pre- and post-instruction written tasks in which students were prompted to use a series to approximate an expression arising from a problem in electricity and magnetism. Despite prior experience with series in calculus and physics, students struggled to determine appropriate quantities in which to expand and did not attend to units or the convergence of their series. While student success rates improved after targeted instruction, many students expanded in quantities that were neither dimensionless nor small, and thus unproductive for modeling.

Keywords: calculus, series, physics, applications

This work is part of a project to investigate student use of mathematics in upper-division physics courses. A key lens has been the study of how concepts studied in calculus and other mathematics courses are implemented in modeling tasks in physics, and how students perceive and take up these concepts given the different disciplinary context. For this study, the research questions are: To what extent are upper-division physics students successful in using series to model simple physical systems? What aspects of this task are challenging? What implications does this have for instruction, both in physics and in mathematics?

Background and Previous Research

Power series are commonly covered in an introductory calculus sequence. In physics, Taylor and Maclaurin series are used frequently as modeling tools, for simplifying analytical solutions and constructing approximations. As part of a project to study student use of mathematics in upper-division physics and support curricular interventions, we have investigated the reasoning used by students in using series to manipulate physics expressions and use mathematical tools for modeling physical systems, including the use of series as approximation tools.

While often physics students will be asked to perform a full Taylor series expansion, in many cases it will suffice to use a binomial expansion. A typical usage is to generate an exact expression from a physical and mathematical model, then to replace a portion of this expression with a power series, in powers of a small, dimensionless ratio of two physical quantities. For example, for the expression for the electric field of an electric dipole (a pair of charges with equal absolute value but opposite sign), shown in Figure 1, the task directs students to consider points far from the dipole. The statement 'far from the dipole' can be interpreted to mean that the distance y is considerably greater than the distance d between the two charges, and thus mathematized as $y>>d$. Students can perform algebraic manipulation to produce an expression proportional to $(1-d/2y)^{-2}$, which is of the form $(1+x)^p$ with $|x|<1$ as stated in the course text (Boas, 2006). With $|x|<1$ the series will converge, and higher-order terms fall off quickly, allowing the complicated expression to be replaced with a relatively simple polynomial.

Previous research on student learning of series comes from both the mathematics education and physics education research (PER) communities. RUME studies have tended to focus on conceptual understanding and visualization. Alcock and Simpson (2004) focused on use of visualization of series. Martin and Oehrtman (2011) investigated the concept of convergence in terms of metaphors, including a part / whole metaphor and a cutting metaphor. Champney and Kuo (2012) focused on visual images of the Taylor series as an approximation.

PER studies have often focused instead on application to problems, Smith et al. (2013) reported that students lacked fluency in both creating and using series, despite prior exposure in mathematics and physics as well as evidence of conceptual understanding of the graphical meaning of series terms. Wilcox et al. (2013) investigated Taylor series as a modeling tool in upper-division classical mechanics. From this analysis they developed the ACER framework for student use of mathematics in physics, named for its four components: activation of a tool, construction of a model, execution of the relevant mathematics, and reflection on the result. Student difficulties in each of the four phases were described, including those with expansions about a point other than zero and a lack of meaningful reflection. In both PER studies, students had to make choices about the series expansion, but in neither case was it necessary to manipulate an expression to produce a small, dimensionless ratio with which to expand.

Context and Methods

Context for the Research

This work has taken place in the context of a course on mathematical methods for physics ("Math Methods"), a required course in many physics departments that is generally intended to prepare students for the mathematics encountered in upper-division theory courses. Course prerequisites include three semesters of calculus and two semesters of introductory physics; all students would have encountered series and the relevant physics concepts. For this report, we describe data that were collected in twelve in-person sections of the course from different semesters over the period 2009 to 2022, all taught by the same instructor at a comprehensive university serving a diverse student population. Instruction focused on mathematical ideas used as modeling tools in physics and included relevant post-tests on course quizzes. Total enrollment over these semesters is approximately 160 students and the performance was roughly similar across sections while accounting for fluctuations. Approximate demographics for these semesters were: 78% male, 22% female, 45% white, 33% Latino, 18% Asian.

Instruction in Math Methods was interactive and used instructional materials developed in response to both prior research and results from early versions of the ungraded quiz. Students in small groups worked on guided worksheets. Tasks in the worksheets included qualitative questions about the first three terms in a Taylor series for several points on an arbitrary graph (adapted from Smith et al., 2013), followed by procedural tasks including evaluation of terms of series for sine and cosine. Students were then asked to interpret their results by comparing their series for sine and cosine to the original functions in terms of values and behavior (slope, curvature). Student groups then revisited the dipole task and executed the expansion, with guiding questions that directed their attention to the units and magnitude of the expansion variable and what implications this had for series convergence and meaning. The purpose of this report is to examine aspects of student reasoning, but the results also have implications for the instructional materials that are addressed in the discussion section.

Method

For this study, we present the results of written responses to tasks administered as part of course assessments, including ungraded and graded quizzes. Each task involved the use of series to derive an approximation from an exact analytical result. In all cases, the generic form of the

Consider the electric field at points along the axis of an electric dipole, $E = \frac{+kQ}{\left(y - \frac{d}{2}\right)^2} + \frac{-kQ}{\left(y + \frac{d}{2}\right)^2}$ for a point far from the dipole, with y much larger than d.

The first term of the expression is $\frac{+kQ}{\left(y - \frac{d}{2}\right)^2}$. Use the binomial expansion (given) to construct the first three terms of a series for this term given that $y >> d$. Explicitly identify what x and p you are using. What simplification is allowed by the fact that $y >> d$?

Figure 1. Task from initial ungraded quiz. A diagram was included (not shown due to space considerations). The problem statement in the quiz included the expression for the binomial expansion from the course text (Boas 2006), with the form $(1+x)^p$. *Graded quizzes were similar but included different contexts (E field from charged ring, potential from charged disk).*

terms of a binomial series was available to students, either as explicit information included in the problem statement, or as a supplemental sheet of equations (e.g., in given information on a quiz).

The initial task for the ungraded quiz involved a series expansion for an expression for the electric field of a dipole for points along the axis containing the two charges (Fig. 1). This task is often encountered in introductory electricity and magnetism as an example and/or textbook problem (Halliday et al., 2011), and the approximate field proportional to the inverse cube of distance is familiar to experienced physicists. Graded quizzes after instruction included other tasks of similar structure (expression given, perform expansion to generate approximation) that are not shown due to space limitations. These tasks included four examples from electricity and magnetism, involving expressions for the electric field or potential for an extended object with a distributed charge (e.g., a ring or disk) or for a simple model of a crystal lattice.

Written responses were collected on an ungraded quiz (dipole, Figure 1, $N = 156$) on the first day of instruction in the Math Methods course over twelve semesters. Additional responses were collected on the first graded quiz (other tasks, not shown, $N = 161$). Student responses were coded by the lead researcher and student assistants using qualitative inductive analysis (Otero and Harlow, 2009); the initial data were coded without *a priori* categories, based on correctness and the overall approach taken. Initial codes were then refined, informed by an analysis of the steps in the task. Categories are described in results, below.

Results

Categories coded for included: mathematization of relative distances (e.g., $y>>d$), choice of expansion variable, dimensionality and magnitude of expansion variable, identification of exponent, execution of expansion, and interpretation of results (see Table I). For each category, specific choices in the response were recorded, e.g., whether to expand in powers of (y-d/2) or to factor the expression and expand in powers of $d/2y$ or $2y/d$. For example, expanding in (y-d/2) would be coded as neither small nor dimensionless. In contrast, $2y/d$ is coded as dimensionless but is not small compared to one. Nearly all codes of 'small' were also coded 'dimensionless.'

Responses on the initial ungraded quiz, before instruction in the Math Methods course, illustrated the difficulty of the tasks but provided relatively little insight into student reasoning. Very few students produced complete and correct responses to the task. A third of the responses

Table 1. Categories coded for in student responses, and examples of the coding. Examples are drawn from post-test questions involving a ring or disk.

Step	Examples
Mathematize	"far from the ring so z>>R"
Choose expansion variable	
dimensionless	"$x=R^2/z^2$"
small compared to one	"use z/L, <<1 b/c L>>z"
Identify exponent in binomial	"p=-3/2, negative brings to numerator"
Execute expansion	[omitted due to space constraints]
Interpret results physically	"we can cut out [terms] so →kQ/z which is a point charge from far away"

were either blank or nonproductive and uncodable, despite ample time to respond. Under 10% of responses transformed the expression into a form suitable for the expansion, i.e., $(1+x)^p$ with x dimensionless and $0<|x|<1$. Students who identified such a dimensionless quantity frequently neglected to attend to convergence, choosing a series with powers of a quantity large compared to one (e.g., y/d). Around 3% of students expanded in a dimensionless quantity small compared to one, one that would lead to a series that converges.

Student responses to the question about the significance of $y>>d$ further suggest the importance of the interplay between mathematical calculation and more qualitative physical reasoning. A large group of coded responses included answers stating incorrectly that the electric field would be zero. This category included two subcategories. One set of codes (~20% of students) included assertions, without calculation, that the electric field is zero because y is large. The second group of codes (~30%) included an algebraic calculation or symbolic argument, stating explicitly that $y>>d$ allows one to set d=0 or set $y-d/2=y$, in which case the expression for E reduces to zero. It is not clear whether the students in the second group force the mathematics to support their intuition that E=0 or simply perform the calculations and reach that result. The former might be explained with a dual-process model (Kryjevskaia et al., 2021).

Table 2 compares results before and after instruction. The post-test quizzes involved four tasks different from the dipole, all involving electricity and magnetism. The results are shown as a single combined entry because there was very little difference in response patterns. (For example, the fraction of students choosing a dimensionless x with which to expand was 72% in tasks involving electric potential of a disk, 78% in tasks involving electric field of a ring, and 76% in tasks involving electric forces in a crystal lattice.)

Table 2. Responses to series approximation tasks before and after tutorial instruction. In the table, x and 'exponent' refer to the binomial $(1+x)^p$ from the course textbook (Boas, 2006).

Instruction	Appropriate quantity x	x unitless	($\|x\|<1$)	Appropriate exponent
Pre (N = 156)	3%	8%	3%	3%
Post (N = 161)	56%	76%	60%	67%

More students successfully chose a dimensionless quantity with which to expand, but roughly 20% of those who did still chose quantities that were large compared to one, expanding in a series that would not converge and was not productive in modeling.

All post-test examples led to series in which there were fractional and/or negative exponents, which proved to be challenging. For example, given the expression for electric potential of a charged disk, $V = 2\pi k\sigma\left(\sqrt{z^2 + R^2} - \sqrt{z^2}\right)$, the students who answered incorrectly frequently expanded with a positive integer exponent (1 or 2, rather than $(1 + {R^2}/{z^2})^{1/2}$ with exponent ½).

While the algebraic manipulation required means that success on these tasks will be linked, there may also be a hierarchy of ideas; most of the students who correctly identified a small argument also chose a dimensionless argument and the correct exponent. The converse was not true; roughly one in three students who identified the correct exponent had incorrect series terms.

Discussion

Prior research may have underestimated the difficulty for students in using this technique by providing examples in which the variable of expansion was already dimensionless and small compared to one. Even after targeted instruction, nearly half of the students expanded these symbol-rich expressions in powers of a quantity that would not be productive for modeling.

While series are a point of shared emphasis in calculus and physics courses, the emphasis differs in important ways. Power series in physics must be dimensionless, but few students on the pretest chose to expand in a dimensionless quantity. Whereas a mathematics course might provide a 'cleaned up' expression to simplify student calculations (and instructor assessment), students in physics will encounter expressions that are symbolically rich and quantities that have units. Despite the strong emphasis in calculus on convergence, physics students need support to understand how this idea plays out in physics contexts. Students are likely to encounter an expression in a form inconvenient for expansion and must make choices consistent with convergent behavior that consider the dimensionality of quantities in physics. In our data set, many students have chosen to expand in powers of a quantity greater than one, for which a series would not converge and thus would not be useful in modeling. Instructors should be cognizant of the disciplinary differences their students will encounter and provide appropriate support.

The case of the dipole illustrates that it is sometimes necessary to perform an expansion rather than simply arguing that $y \gg d$ implies that $d \sim 0$. While ignoring a small quantity might be productive in certain circumstances while modeling, here it eliminates the interesting physics of the dipole configuration, in which the small extra distance to one charge has important physical consequences, thus highlighting disciplinary practices.

We are using these results to modify the instructional materials and develop a set of modular curricular materials that can be adapted to the purposes of different upper-division physics courses. Preliminary materials seem to provide support for students in identifying dimensionless quantities but students seem to need additional scaffolding to recognize when and whether their series are convergent. Additional research and development in ongoing. Current versions of the materials are hosted at PhysPort.org.

Analysis Across Geometry Textbooks to Link Content, Curriculum and Children's Reasoning

Ayse Ozturk
The Ohio State University, Newark

Research showing that geometry textbooks for teacher candidates primarily focus on expanding the content knowledge in geometry by applying geometry to real-world problems (Litoldo & Amaral-Schio, 2021) and using technology to support problem-solving activities and create multiple representations (Jones et al., 2017). In this study, building on the previous research, we looked for how textbooks used in geometry content courses for elementary school teacher candidates might support their pedagogical content knowledge.

The conceptual framework of this study is Ball et al.'s (2008) practice-based theoretical model that refines pedagogical content knowledge which blends content knowledge, pedagogy and curriculum that highlights teacher's knowledge of standards, grade levels when particular topics are taught, and more. The framework guided the current study's data creation and analysis process to learn how textbooks support prospective teachers' pedagogical content knowledge in geometry teaching.

We collected the commonly used textbooks reported by U.S. mathematics courses instructors for elementary teachers (Max & Newton, 2017; Ozturk et al., 2023). Drawing from relational content analysis methodology (Elo et al., 2014), we first analyze the content of five geometry textbooks and identify the instances of pedagogical content knowledge elements while considering the conceptual framework and examine the differences and similarities across the textbooks. We engaged in a selective reduction process that entailed reading the book and reducing the text to categories, from which we could focus on developing codes for informing our research question. After creating the initial codes, we examined the books individually and then came together to compare and contrast the patterns found in each book. After six meetings (about 14 hours), we finalized five codes including *instancing children's written work*, *instancing children's ideas*, *instancing teacher's role and their activities in K-5 classrooms*, *using of learning standards and connection to K-5 curriculum*, and *using of standardized assessment questions*. Next, we created the final table containing the code frequencies within each textbook and across all codes to draw conclusions.

Analysis revealed that of 780 total codes, the highest percentages of codes focused on children's ideas which provides many examples of how children reason through geometric concepts. The second-highest code percentages focused on the teacher's role and classroom connections, such as discussing teachers' responses to children's ideas to advance the latter's geometric reasoning. The third-highest percentage of codes focused on the use of learning standards, which was often listed next to each relevant book session to show how standards could be linked with instructional activities in progressing through grades K–5. The fourth-highest percentages were related to the code for children's written work which would allow prospective teachers to see concrete examples of children's reasoning through geometric concepts. The code with the least frequency related to the use of assessment questions, providing sample questions from actual standardized tests for K–5 students to familiarize prospective teachers with the content for different grade levels. Depending on the instructor's purposes and practices, the coded instances of pedagogical content knowledge in the textbooks could be used to support prospective teachers' knowledge in geometry content courses (Ozturk et al., 2023).

Exploring Students' Mathematical Convictions Through a Script-writing Task

Mario A. Gonzalez
Texas State University

Some empirical studies that report on mathematical convictions include proof comprehension (Stylianides et al., 2007) or evaluation (Inglis & Mejia-Ramos, 2008). Some focus on students' convictions (Lockwood et al., 2020; Zaslavsky, 2005). One underreported method in the literature for this topic of research is s*cript-writing*—the creation of a dialogue, between oneself and an imaginary student or classmate, focused on issues that may be encountered and resolved (Zazkis & Zazkis, 2014). This method is often used with teachers as a form of lesson-play (Koichu & Zazkis, 2018; Zazkis et al., 2013) while others have used it to investigate proof comprehension (Brown, 2018; Zazkis, 2014).

The purpose for this study was to explore this method's utility when investigating students' mathematical convictions. The guiding research question was: how do students' responses to a script-writing task describe their mathematical convictions? Take-home script-writing tasks, initial interview recordings, and one follow-up interview recording were collected. The statement and argument presented to students for their task were:

Statement: For $n \in \mathbb{N}$, the sum of the first n consecutive odd numbers is n^2: $1 + 3 + 5 + \ldots + (2n - 1) = n^2$.

Argument: Let n be a natural number and consider $n = 1$. We have $2(1) - 1 = 2 - 1 = 1$ which is 1^2. Assume that $1 + 3 + 5 + 7 + 9 + \ldots + (2n - 1) = n^2$ is true for the natural numbers: $1 + 3 + 5 + 7 + 9 + \ldots + (2n - 1) + (2n + 1) = [1 + 3 + 5 + 7 + 9 + \ldots + (2n - 1)] + (2n + 1) = n^2 + (2n + 1) = n^2 + 2n + 1 = (n + 1)^2$. Therefore, $1 + 3 + 5 + 7 + 9 + \ldots + (2n - 1) = n^2$ is true for the natural numbers.

The task had instructions on creating a dialog between them and a classmate named Gamma. These instructions asked to introduce and explain the statement and argument to Gamma and to identify problematic points (see Brown (2018, p. 66) for similar instructions).

Taylor, in his final semester, was completely convinced that the statement was true and the argument proved the statement in the initial interview. For his script, he used an example showing the statement to be true and invited Gamma to try examples. In the follow-up interview, Taylor explained he tried to help Gamma "understand intuitively" because it's easier to do that with examples. When asked how he would resolve the issue if Gamma was still not convinced that the statement was true, he responded with "like if I lay down a whole proof?... I guess they're just not convinced…." This was interpreted that Taylor had an assumption that proofs should be convincing. I asked Taylor if he agreed that if Gamma understood the statement and argument more, then Gamma would be more convinced. He responded with "definitely."

Stewie was a fifth-year student who recently completed a transition-to-proof course. In the initial interview, he was 99.99% convinced by the statement and argument saying, "it's hard to be 100% certain on anything." He cited possible human errors for this judgment. In his script, he identified issues regarding the formatting and clarity of the proof. Stewie appeared to explain the components of the proof, like the purpose of the base case, to help Gamma.

In this study, I hoped that the scripting task would influence participants' convictions. However, their convictions remained the same throughout the study. The script-writing task revealed that they viewed ideas of helping a classmate in: 1) comprehension and clarify of the method of proof and 2) conviction in the statement's truth. Future research may include more complex statements and arguments to explore the script-writing task's influence on convictions.

The Precalculus Concept Assessment (PCA) and Prospective Secondary Teachers

Kevin C. Moore
University of Georgia

Irma E. Stevens
University of Rhode Island

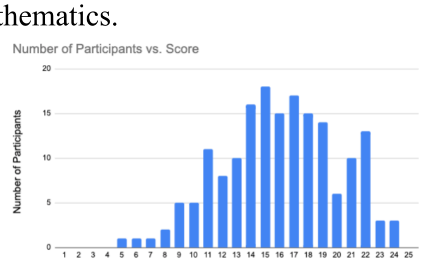
Anne Waswa
University of Georgia

Sohei Yasuda
University of Georgia

Keywords: Student Cognition, Covariational Reasoning, Pre-Calculus

Carlson et al. (2010) developed the 25-item multiple choice Precalculus Concept Assessment (PCA) to investigate reasoning abilities and meanings researchers (e.g., Carlson et al., 2002; Dubinsky & Harel, 1992; Oehrtman et al., 2008; Thompson & Silverman, 2007) have established as critical for pre-calculus and calculus learning. Since its initial development and validation, the PCA has been administered to thousands of secondary and post-secondary students, providing key insights into their reasoning abilities, as well as their potential success (as measured by grades) in future calculus courses. For instance, using a population of 248 students who were entering a first-semester calculus course taught by six different instructors, Carlson et al. (2010) identified that 77% of the students who scored 13 or higher passed the course (i.e., C or better). Meanwhile, 60% of the students who scored 12 or lower failed (i.e., D, F, or W). The authors illustrated that the correlation between course grades and PCA score were as strong or stronger than other popular educational math tests including the MAA placement test.

Given the insights the PCA provides relative to pre-calculus and calculus students, we grew interested in the extent the PCA can provide useful insights with other populations. Across several semesters, we administered the PCA to 174 undergraduate students upon their entry to a secondary mathematics teacher preparation program. Their program entry typically occurs during their sophomore or junior year of undergraduate studies, and after having taken two math courses beyond a calculus sequence. In this poster, we present on the results of that administration. Specifically, we report on an analysis of the aggregate scores of the population (Figure 1a), as well as their performance on covariational reasoning items (Figure 1b). With respect to the covariational reasoning item performance, we draw on our expertise and research (Moore, 2021; Moore et al., 2022; Moore et al., 2019) to develop hypotheses regarding discrepancies in performance. Specifically, we highlight differences between items based on the level of covariational reasoning targeted by the item. We also explore differences between items based on the items' figurative material and the extent the material afforded enacting quantitative operations versus numerical operations. These differences provide potential insights and implications relative to the participants' grounding to reason about and teach for key concepts of secondary mathematics.



(a)

Covariational Reasoning Items

Question	Correct	Incorrect	% Correct	% Wrong
7	101	73	58.05%	41.95%
8	50	124	28.74%	71.26%
15	70	104	40.23%	59.77%
18	140	33	80.46%	19.54%
19	125	49	71.84%	28.16%
22	74	100	42.53%	57.47%
24	134	40	77.01%	22.99%
25	81	92	46.55%	53.45%

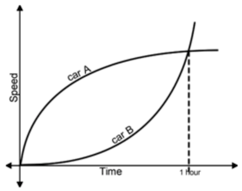
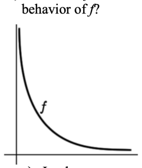
The given graph represents speed vs. time for two cars. (Assume the cars start from the same position and are traveling in the same direction.) Use this information and the graph below to answer item 8.



8) What is the relationship between the ***position*** of car A and car B at $t = 1$ hr.?

a) Car A and car B are colliding.
b) Car A is ahead of car B.
c) Car B is ahead of car A.
d) Car B is passing car A.
e) The cars are at the same position.

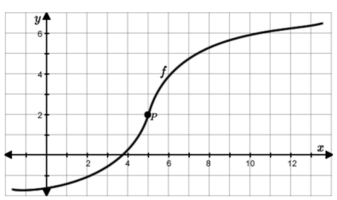
24) A function f is defined by the following graph. Which of the following describes the behavior of f?



I. As the value of x approaches 0, the value of f increases.
II. As the value of x increases, the value of f approaches 0.
III. As the value of x approaches 0, the value of f approaches 0.

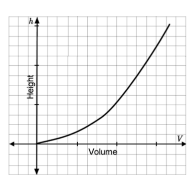
a) I only
b) II only
c) III only
d) I and II
e) II and III

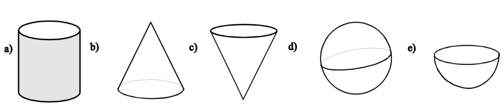
19) Using the graph below, explain the behavior of function f on the interval from $x = 5$ to $x = 12$.



a) Increasing at an increasing rate.
b) Increasing at a decreasing rate.
c) Increasing at a constant rate.
d) Decreasing at a decreasing rate.
e) Decreasing at an increasing rate.

15) The following graph represents the height of water as a function of volume as water is poured into a container. Which container is represented by this graph?





Differences in responses to covariation items provide insights into their covariation meanings.

The prospective teachers have formed indexical associations between graphs and covariation statements, but that does not imply their having abstracted graphs in terms of re-presenting quantitative and covariational operations.

An Exploratory Study of Students' Understanding of Graphical Optimization in a Cost Minimization Context

Thembinkosi P. Mkhatshwa
Miami University

This study reports on first-semester calculus students' reasoning about a univariate optimization problem that involves finding the production level at which the cost per yard is minimized when given the graph of a function that represents the relationship between the cost per yard and the number of yards produced by a factory. Analysis of verbal responses and work written by four students when solving the problem revealed that determining the production level at which the cost per yard is minimized was straightforward for all the students. However, explaining how this production level is related to the first derivative of the given function was problematic for most of the students.

Key words: Optimization problems, graphical optimization, problem solving, calculus education

Unlike algebraic optimization that uses algebraic methods (that may sometimes be sophisticated, especially when working with complex objective functions) to solve univariate optimization problems or numerical optimization (that requires some level of technical skills such as proficiency in MATLAB programing) to solve univariate optimization problems, graphical optimization (Bhatti, 2000) is the simplest method for solving univariate optimization problems (UOPs) in that it only requires making sense of graphs of objective functions. A number of studies have reported on several difficulties typically exhibited by students when solving optimization problems algebraically, including formulating the objective function, finding and interpreting critical values or extrema of the objective function, and determining if a critical value(s) results in a minimum/maximum value of the objective function (cf. Borgen & Manu, 2002; Dominguez, 2010; LaRue & Infante, 2015; Mkhatshwa, 2019; Swanagan, 2012). We are not aware of any research that has examined students' thinking in the context of graphical optimization, which is the motivation for this study. To address this knowledge gap, task-based interviews (Goldin 2000) were conducted with four calculus students.

Contrary to findings of studies that have reported on students' thinking about algebraic optimization (cf. Borgen & Manu; Swanagan, 2012), nearly all the students in the present study were successful in finding the critical value or extremum as well as justifying extremum while working with a UOP where the graph of the objective function was provided. To some extent, this may suggest that while students may struggle with solving UOPs algebraically, partly due to the lack of facility with some algebraic techniques such as calculating derivatives of complex objective functions, students have better success with solving UOPs graphically not only because they can visualize the objective function, but also because having access to the graph of the objective function supports their quantitative reasoning (Thompson, 1993; 2011) such as the ease of identifying critical values and extrema. Additionally, three of the four students made remarks that suggested that they had difficulty understanding that the derivative of the objective function ought to be zero at the critical value (i.e., the cost minimizing quantity), something that generally comes easy for students when solving UOPs algebraically.

Students' Attitudes and Perseverance in Problem-solving in Undergraduate Precalculus

Amy Daniel
Montclair State University

Joseph DiNapoli
Montclair State University

Keywords: precalculus, curriculum enactment, attitudes, perseverance in problem-solving

This exploratory study investigated the relationships between professors' enactments of a research-based precalculus curriculum and changes observed in students' attitudes towards mathematics and perseverance in problem-solving. While much research focuses on improving student achievement in undergraduate STEM courses, we must also support them in developing the positive dispositions and practices needed to sustain them through years of mathematics-based STEM coursework (Bressoud et al., 2015). When students hold positive attitudes towards mathematics, they are more likely to both succeed in calculus (Sonnert et al., 2020) and persist in completing a STEM degree (Wu et al., 2022). When students persevere in their problem-solving amidst challenges, they make meaning of mathematics and develop productive dispositional factors for STEM majors, including building resilience for overcoming setbacks (Middleton et al., 2015). The Pathways precalculus curriculum (Carlson et al., 2021) leverages research on student thinking to support them in developing problem-solving skills and in making connections across concepts (Moore & Carlson, 2012), and has been tied to improvement in students' covariational reasoning and subsequent success in calculus (McNicholl et al., 2021). However, since curriculum and its enactment can transform students' opportunities to learn in various ways (Stein et al., 2007), including outcomes related to disposition and mathematical practices (DiNapoli & Morales, Jr., 2021; Ruthven, 2011), we chose to focus on the relationships between different enactments of Pathways and students' attitudes and perseverance measures.

Three precalculus professors (Profs. A, B, and C) and 33 of their students participated in this study. Two classroom observations for each professor were video recorded and transcribed. The professors' pedagogical choices were scored on a 0-3 scale along three Pathways-aligned dimensions: support of student problem-solving, understanding and advancing student thinking, and making connections (rubric adapted from Schoenfeld et al., 2014). Student participants completed an Attitudes Towards Mathematics Inventory (ATMI; Tapia & Marsh, 2004) pre- and post-survey, which measured students' mathematical self-confidence, value, enjoyment, and motivation. Student participants also engaged in 12 video-recorded problem-solving sessions. Students' perseverance was measured using the Three-Phase Perseverance framework (3PP; DiNapoli & Miller, 2022), which considered the extent to which students initiated and sustained, and re-initiated and re-sustained upon impasse, productive struggle on a challenging task.

Profs. A, B, and C implemented Pathways in different ways along the dimensions analyzed; over the two observations, Prof. A's scores were almost uniformly low, Prof. B's consistently high, and Prof. C's scores were medium-to-high. Each professor's students exhibited changes in attitudes: Prof A's students shifted towards more negative attitudes across the semester, whereas Profs. B and C's students exhibited positive attitude shifts. Finally, students in all three classes averaged positive 3PP slope scores, indicating some perseverance growth for all, yet Prof. B and C's students experienced about 5 and 4 times the growth, respectively, compared to Prof. A's students. More detailed qualitative and quantitative evidence of our findings will be shared in our presentation. These findings suggest that although the Pathways precalculus curriculum may support the development of positive attitudes toward mathematics and improved perseverance in problem-solving, this potential is influenced by professors' pedagogical choices.

Students' Attitudes and Perseverance in Problem-solving in Undergraduate Precalculus

Amy Daniel – daniela4@montclair.edu Joseph DiNapoli – dinapolij@montclair.edu

MONTCLAIR STATE UNIVERSITY

This project was supported by a grant from the State of New Jersey

Introduction and Rationale

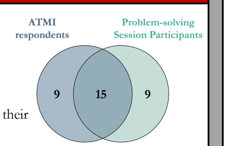
- Student achievement in precalculus is necessary, but not sufficient
  - **Positive attitudes towards mathematics** help students succeed in calculus and persist in completing a STEM degree (Sonnert et al., 2020; Wu et al., 2022).
  - **Persevering in problem-solving** helps students make meaning of mathematics and build resilience for overcoming setbacks (Middleton et al., 2015).
- The **Precalculus: Pathways to Calculus** curriculum has the **potential** to support students in developing positive attitudes and improving their perseverance
  - Content development embedded in **rich, real-world contexts**
    - Reduces **math anxiety** (Karunakaran, 2020)
    - Supports students' value of mathematics (Aikens et al., 2021)
  - Focus on developing students' **problem-solving skills** and **covariational reasoning**
    - Increases **enjoyment** (Schettino, 2016) and **motivation** (Peterson, 2019)
    - Supports **perseverance** development (Barnes, 2019; DiNapoli & Miller, 2022)
  - **Scaffolded questioning** based on research on how students make sense of precalculus concepts (e.g., Frank, 2017; Kuper, 2019; Moore, 2010)
    - Improve students' mathematical **self-efficacy** (Jatisunda, 2020)
    - Helps students initiate and sustain **productive struggle** (Reiser & Tabak, 2014), and thus, their **perseverance** at times of impasse (DiNapoli & Miller, 2022)
- Curriculum enactments can differentially impact
  - Students' **opportunities to learn** (Stein et al., 2007)
  - Students' **attitudes** towards mathematics (Ruthven, 2011)
  - Students' improvement in **perseverance** in problem-solving (DiNapoli & Miller, 2022)

Research Question

What are the relationships between professors' enactments of a research-based precalculus curriculum and changes observed in students' attitudes towards mathematics and perseverance in problem-solving?

Methods

Context and Participants

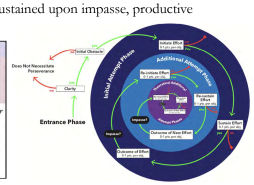


- Public research university in the Northeast U. S.
  - ~23,000 students, HSI, R2: Doctoral University
- Coordinated, entry-level precalculus course
  - ~40 sections and ~1200 students per year, optional PD
- Three precalculus professors (Profs. A, B, and C) and 33 of their students participated.

Data Collection and Analysis

- Two **classroom observations** for each professor were video recorded and transcribed.
  - The professors' pedagogical choices were scored on a 0-3 scale along three Pathways-aligned dimensions: support of student problem-solving, understanding and advancing student thinking, and making connections (Schoenfeld et al., 2014).
- Student participants completed an **Attitudes Towards Mathematics Inventory** (ATMI; Tapia & Marsh, 2004) pre- and post-survey, which measured students' mathematical self-confidence, value, enjoyment, and motivation.
- Student participants also engaged in 12 video-recorded **perseverance in problem-solving sessions**.
  - Students' perseverance was measured using the Three-Phase Perseverance framework (3PP; DiNapoli & Miller, 2022), which considered the extent to which students initiated and sustained, and re-initiated and re-sustained upon impasse, productive struggle on a challenging task.

Pathways Implementation Observation Rubric		
Engaging and Supporting Students in Problem-solving	Understanding and Advancing Students' Thinking	Providing Opportunities for Students to Make Connections
To what extent do classroom activities actively engage students in problem-solving? To what extent does the professor discuss, model, and encourage productive problem-solving practices?	*To what extent does the professor endeavor to understand students' thinking about content and respond in ways that help them to construct more productive understandings?*	*To what extent does the professor support students in making connections: to real-world contexts, across course content, and between functional representations?*



Results

Classroom Observations

		Engaging and Supporting Students in Problem-solving	Understanding and Advancing Students' Thinking	Providing Opportunities for Students to Make Connections
		Pathways Implementation (0 to 3 point scale)		
Prof A	Obs 1	1.00	1.40	2.10
	Obs 2	1.00	1.14	1.70
Prof B	Obs 1	2.25	2.17	2.38
	Obs 2	2.00	2.31	2.40
Prof C	Obs 1	2.20	2.14	2.40
	Obs 2	1.70	1.97	1.40

Classroom Observation Findings

- Prof A had somewhat lower scores across the board compared to Profs B and C, particularly in the Problem-Solving category.
- Prof B's scores were consistent across all categories and were generally highest.
- Prof C's scores were mixed, a bit higher for their first observation than their second.

Note: Maintaining a level 3 in all three categories would be impossible.

Examples of Understanding and Advancing Student Thinking

Prof A's Level 1 Interaction

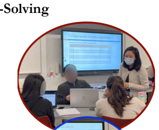
Prof A: As my angle gets bigger, if I measured this, what's this distance relative to the one down here, bigger or smaller?
Student: Smaller.
Prof A: Smaller. … And now as I move further, between pi over two and pi, this distance here is getting bigger because it's moving away. But because it's on the left-hand side, is it positive or negative?
Student: Negative.
Prof A: Negative…

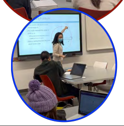
Prof B's Level 3 Interaction

Prof B: So, I know the 10-hour decay factor [is .2722], how can I use [this] to find the five-hour decay factor?
Student 1: You could try and divide it by half…
Student 2: Square root of .2722?
Prof B: Ah. We should explore these options … [Student 1], would you mind telling me your reasoning … for this?
Student 1: Well, since it's a 10-hour decay, and they ask you for like the five-hour growth decay. I just thought if we just divided by two.

Prof B: [Student 2], what's your reasoning for this?
Student 2: Because the five-hour times the five- hour would be the 10 hour.
Prof B: [Takes a class poll, which is split] So, I want to talk about how we can use our intuition to maybe rule this out a little bit. …if [.2722 divided by 2] was the five-hour growth or decay factor, this is … .1372… in five hours, I only have about 14% [of the caffeine] left in my system. But in 10 hours, I have more than that left in my system. That feels weird, right?

Examples of Engaging and Supporting Students in Problem-Solving

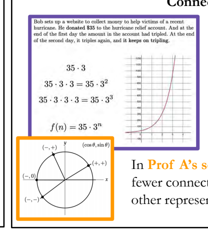




In **Prof C's first observation**, students spent the majority of class working in small groups with Prof B circulating around the room in a supportive role.

In **Prof C's second observation**, they spent more time at the board delivering content.

Examples of Providing Students with Opportunities to Make Connections



In **Prof A's first observation**, they developed the exponential function formula using a real-world context, connected symbolic and graphical representations, and contrasted exponential and linear growth.

In **Prof A's second observation**, they made fewer connections to real-world contexts, other representations, and other content.

Attitudes Towards Mathematics and Perseverance in Problem-Solving

	Average ATMI Changes (Post – Pre, 5-point Likert Scale)					3PP Slope
	Self-Confidence	Value	Enjoyment	Motivation	Overall Shift	(Avg increase per session)
Prof A	0.00	-0.31	-0.17	-0.25	-0.15	0.09
Prof B	0.17	0.37	0.10	0.20	0.21	0.44
Prof C	0.72	0.16	0.30	0.20	0.41	0.34

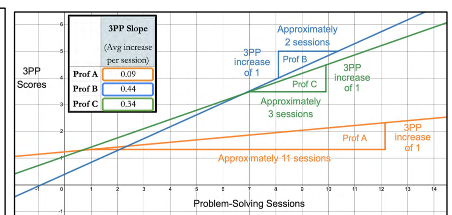
Attitudes Findings

Small shifts in ATMI outcomes:

- Prof A's students: mostly negative shifts in attitudes
- Profs B's students: mostly positive, particularly in value
- Prof C's students: mostly positive, particularly in self-confidence.

Perseverance Findings

- All students showed perseverance growth
  - Prof B & C's 3PP growth ~4-5 times greater than Prof A's
- To show 1 point of 3PP growth:
  - Prof A: ~11 problem-solving sessions
  - Prof B: ~2 problem-solving sessions
  - Prof C: ~3 problem-solving sessions
- Interpreting 1 point of 3PP growth, e.g.:
  - 0→1: none → some effort
  - 2→3: sustaining → productive effort
  - 3→4: first → second effort upon impasse



Discussion

In this early exploratory study, we were able to see some potential connections between different ways of implementing Pathways and students' changes in attitudes towards mathematics and perseverance in problem solving, and many of these perceived connections are consistent with the literature.

- We saw evidence of the **links between actively engaging students in problem-solving and improvements in attitudes and perseverance in problem-solving** (Barnes, 2019; DiNapoli & Miller, 2022; LeSage et al., 2021; Peterson, 2019; Schettino, 2016; Schoenfeld, 1992).

		Problem Solving	ATMI Changes	3PP Slope
Prof A	Obs 1	1.00	-0.15	0.09
	Obs 2	1.00		
Prof B	Obs 1	2.25	0.21	0.44
	Obs 2	2.00		
Prof C	Obs 1	2.20	0.41	0.34
	Obs 2	1.70		

- Prof A's lack of problem-solving pedagogies were due, in part, to COVID concerns.
- Prof B's best problem-solving pedagogies involved leading interactive, whole-class discussions.
- Prof C's best problem-solving pedagogies involved small group work.

- We saw evidence of the **links between understanding and advancing student thinking to improve students' self-confidence, motivation, and perseverance in problem-solving** (DiNapoli & Miller, 2022; Harper et al., 2019; Jatisunda, 2020; Reiser & Tabak, 2014).
  - Valuing student thinking in class can help them develop their mathematical agency.
  - Students seeing how their in-progress thinking can lead to mathematical productivity in class can reinforce the value of productive struggle.

		Student Thinking	Self-Confidence	Motivation	3PP Slope
Prof A	Obs 1	1.40	0.00	-0.25	0.09
	Obs 2	1.14			
Prof B	Obs 1	2.17	0.17	0.20	0.44
	Obs 2	2.31			
Prof C	Obs 1	2.14	0.72	0.20	0.34
	Obs 2	1.97			

- We saw evidence of the **links between providing students opportunities to make connections between content and real-world contexts to their perception of the value of mathematics** (Aikens et al., 2021).

		Making Connections	Value of Math
Prof A	Obs 1	2.10	-0.31
	Obs 2	1.70	
Prof B	Obs 1	2.38	0.37
	Obs 2	2.40	
Prof C	Obs 1	2.40	0.16
	Obs 2	1.40	

- Whether the professor or the students make connections may influence students' value of math.
- Prof A and Prof C scored similarly, but Prof C more often provided students with opportunities to make these connections for themselves.
- Prof B often used real-world scenarios suggested by students to create contextualized problems for in-class discussion.

Main Takeaway of Research #betterposter

This research suggests that although the Pathways precalculus curriculum may support the development of positive attitudes toward mathematics and improved perseverance in problem-solving, this potential is influenced by professors' pedagogical choices.

Summarizing the Experiences and Beliefs of Community College Instructors and Students in a Corequisite Mathematics Course

Brianna Bentley
Alamance Community College

Keywords: developmental mathematics corequisite course, community college, mindset, math anxiety, math self-efficacy

At community colleges in North Carolina, the corequisite course model has been adopted for all the entry-level mathematics courses. Research about the corequisite course model has shown that these courses can successfully help students earn their mathematics credit (e.g., Childers et al., 2021; Kashyap & Matthew, 2017; Logue et al., 2019) and can increase students' interest in mathematics (e.g., Campbell, 2015). The purpose of this poster is to summarize my three-article dissertation study that described the experiences, mindset, math anxiety, and math self-efficacy of students taking corequisite courses and instructors teaching corequisite courses, the interactions between student and instructor experiences, and the influence of instructors on students' mindset, math anxiety, and math self-efficacy over the course of the semester.

The first article explored the experiences of students taking a corequisite course and instructors teaching a corequisite course, specifically, what characteristics of corequisite courses students and instructors found to be effective, ineffective, and what changes they would make to corequisite courses. A multiple case study design was used to analyze the student and instructor perspectives of corequisite mathematics classrooms. Semi-structured interviews were completed with 11 students and 13 instructors from four community colleges. Interviews were transcribed and coded, and then codes were grouped into four broader themes: (1) corequisite courses characteristics determined at the college and department level; (2) corequisite courses characteristics determined at the classroom level; (3) changes that have been or that could be made to corequisite courses; and (4) their overall recommendation of corequisite courses.

The second article was a convergent parallel mixed methods study that investigated community college students' change in mindset, math anxiety, and math self-efficacy in a corequisite mathematics course and what characteristics of corequisite courses influence these changes. Student's math self-efficacy significantly increased, while their math anxiety decreased over the course of the semester. Student's mathematical mindset did not significantly change over the course of the semester. Student interview comments could be categorized into two larger themes: (1) how students felt at the beginning of the semester when they signed up for a corequisite course; and (2) how the characteristics of the corequisite course influenced their mindset, math anxiety, and math self-efficacy.

The third article was a convergent parallel mixed methods study that investigated the extent to which community college students' change in mindset, math anxiety, and math self- efficacy in a corequisite mathematics course varied among instructors and how corequisite instructors influenced these changes in students' beliefs. The results from an ANOVA analysis showed that there were significant differences across the seven instructors in students' mean math anxiety gain scores. To investigate how instructors influenced students' mindset, math anxiety, and math self-efficacy, semi-structured interviews were conducted at the end of the semester with 11 students and 13 instructors at four community colleges, and student and instructor comments were grouped into four larger themes: (1) pedagogical decisions; (2) instructor disposition; (3) the classroom environment; and (4) instructor and student interactions.

A Peer Tutor with a Partial Growth Mindset

Katie Bjorkman
Richard Bland College

Keywords: Growth mindset, peer tutors, motivation, self-regulation

An undergraduate mathematics peer tutor gave various reasons why not all students were successful in mathematics. I consider his reasons in light of the growth mindset framework and common misconceptions about what it means, reflection on the fact that the beliefs of mathematics educators have been shown to alter student outcomes (Dweck, 2015; Rattan et al., 2012). The undergraduate mathematics peer tutor, Jake (gender-preserving pseudonym), was a case-study participant that participated in an ethnographic study of a mathematics learning center as a figured world (Bjorkman, 2019). The study consisted of ethnographic field notes, video-recording of tutoring interactions used in stimulated recall, and semi-structured interviews of peer tutors which were analyzed using grounded theory methodology (Corbin & Strauss, 1990; Dempsey, 2010; Emerson et al., 1995; Lyle, 2010; Muir, 2010; Strauss & Corbin, 1994).

Jake expressed belief that everyone can learn mathematics, but only if they were willing to "put in the effort." He made statements like "I believe that everyone can do math" and "I think it's important to get things wrong and then you understand." However, Jake also said that "weeding out" through failing a mathematics class, rather than changing learning behavior, is good – then clarified that he didn't think that weeding out was for those who were intellectually unable to do math since, "I believe that everyone can do math… but there's some people who just don't put in the effort." Jake talked elsewhere about this group of unmotivated students as "[W]hen they say they don't go to lecture or don't take notes I almost don't want to help." Jake's model for student success and failure, while on the surface aligned with a growth mindset, is, in fact a limited growth mindset model that does not see self-regulation skills as areas where students can learn and grow and does not consider other factors that may lead students to perform poorly (Dweck, 2015; Granberg et al., 2021; Michaelson, 2017). It is likely that he implicitly communicated his belief about those students' identities as "bad students" to them through his interactions (Holland et al., 1998; Rattan et al., 2012). If Jake as a peer tutor isn't the one to help students who don't yet know "how to college" where should they turn?

The idea of a "growth mindset" has become quite popular in educational circles since the framework was put forward in the 1980's, and more recent research has indicated it can be a useful construct for helping students learn (Denworth, 2019). Yet, in my personal reflection, and experience with other professors, this fixed mindset in terms of student effort and self-regulation seems to exist in more educators than Jake, perhaps even more saliently now as students and educators struggle with the new normal after the pandemic (Bozkurt, 2022). We have long had evidence that teacher beliefs about students are influential in student outcomes (Rosenthal et al., 1966; Timmermans et al., 2021). Explicitly extending a growth mindset to students' self-regulation and motivation and designing courses toward fostering self-motivation and self-regulation as skills may help these "bad students" succeed in mathematics courses, rather than giving up or expending effort on ineffective learning strategies (Granberg et al., 2021).

A Peer Tutor with a Partial Growth Mindset

Katie Bjorkman
Richard Bland College of William & Mary

The failure of educators to consider motivation and academic skills as areas of possible growth creates a partial growth mindset that can further disadvantage struggling students.

What is the Context?

The undergraduate mathematics peer tutor, Jake (gender-preserving pseudonym), was a case-study participant in an ethnographic study of a mathematics learning center as a figured world (Bjorkman, 2019).

Data Corpus:
- Ethnographic field notes (Emerson et al., 1995)
- Online survey of tutors
- Video-recording of tutoring interactions used in
- Stimulated recall (Dempsey, 2010; Lyle, 2010; Muir, 2010)
- Semi-structured interviews of peer tutors

which were analyzed using grounded theory methodology (Corbin & Strauss, 1990; Strauss & Corbin, 1994).

[The MLC] gives you a place to socialize with people ... First semester, I wasn't a tutor I found it pretty hard to make friends in engineering… I kind of felt isolated and alone. But once I started working here, and coming here a lot…then you make good friends through that.
Jake, Mathematics Peer Tutor

Who is Jake?

Jake (pseudonym) is a male, white/Caucasian sophomore engineering major who had worked as a tutor in the mathematics learning center (MLC) for less than a year at the time of the study. He expressed strong identification with the MLC and the other peer tutors.

Jake's view of others in the MLC related to their perceived mathematical maturity. The transcripts of Jake's interviews reveal that the likelihood of him using "us/we" pronouns instead of only "I/them" pronouns used to describe tutoring interactions increased as the course level of the student increased. For example, Jake was more likely to say "we worked on a problem" for an interaction with a student in Transition to Higher Mathematics (intro to proofs, 300 level) and more likely to say "I showed them how to do a problem" for a student in Calculus I (100 level).

A common theme for Jake was the role of struggle in attaining mathematical maturity and ability, that is, those 'below' his level could reach it through hard work if they were willing to so.

[The MLC is a place] with a lot of nerds who are struggling just as much as you are… You meet good people. It's a great work environment, a lot of intelligent people which helps you want to be smarter I know that's a big thing I like being here.
Jake, Mathematics Peer Tutor

I believe that everyone can do math… but there's some people who just don't put in the effort.
Jake, Mathematics Peer Tutor

Must it always come back to finding a reason why some children just can't learn, as opposed to finding a way to help them learn?
(Dweck, 2015, p. 2)

PDF of Poster | **Paper (including references)**

Use QR codes to access a PDF version of this poster and the one-page paper with references.

[W]hen they say they don't go to lecture or don't take notes I almost don't want to help…It's when I see students who haven't even tried the problem yet, that I usually get pretty frustrated…. I just kind of interpret that they're here to get the answers to get the grade and leave.
Jake, Mathematics Peer Tutor

Who 'Deserves' Jake's Help?

Jake expressed his beliefs throughout the study of what his role was – and wasn't – as a tutor as well as the ways he felt "really learning" math took place. Students that Jake wanted to help were characterized by having good academic habits like:
- Attending class
- Taking good notes
- Attempting problems before asking for help
- Looking back over their work after checking final answers
- Seeking help from their TA and professors

Jake saw value in mathematics courses "weeding out" students, not on the basis of ability, but of effort they put into learning. This effort was measured in good academic habits and Jake did not express a belief that students could grow to improve these habits/increase their effort or that he had a role in that growth and improvement.

I don't think that [students] should babied because I think they're - I think some sort of weeding out is good, in mathematics especially…. So weeding out I know is a bad term, because it means fail, but, there's some people who just don't put in the effort
Jake, Mathematics Peer Tutor

Discussion

Jake's model for student success and failure, while on the surface aligned with a growth mindset, is, in fact a limited growth mindset model that does not see self-regulation skills as areas where students can learn and grow and does not consider other factors that may lead students to perform poorly (Dweck, 2015; Granberg et al., 2021; Michaelson, 2017). It is likely that he implicitly communicated his belief about those students' identities as "bad students" to them through his interactions (Holland et al., 1998; Rattan et al., 2012). If Jake as a peer tutor isn't the one to help students who don't yet know "how to college" where should they turn?

The idea of a "growth mindset" has become quite popular in educational circles since the framework was put forward in the 1980's, and more recent research has indicated it can be a useful construct for helping students learn (Denworth, 2019). Yet, in my personal reflection, and experience with other professors, this fixed mindset in terms of student effort and self-regulation seems to exist in more educators than Jake, perhaps even more saliently now as students and educators struggle with the new normal after the pandemic (Bozkurt, 2022). We have long had evidence that teacher beliefs about students are influential in student outcomes (Rosenthal et al., 1966; Timmermans et al., 2021). Explicitly extending a growth mindset to students' self-regulation and motivation and designing courses toward fostering self-motivation and self-regulation as skills may help these "bad students" succeed in mathematics courses, rather than giving up or expending effort on ineffective learning strategies (Granberg et al., 2021).

Richard Bland College of WILLIAM & MARY

Learning to Learn Mathematics

Kathleen Guy
Center for the Transformation of Teaching Mathematics
Florida International University

The Workshop

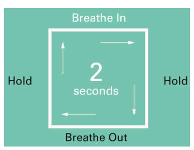
The workshop is being embedded into an extended section of Business Calculus where students meet for 2 hours twice a week vs the standard 75 minutes twice a week.

The workshop has three main educational objectives beyond the goals of the research:
1) Increase the academic success of students in Business Calculus.
2) Expose students to skills that can be used in future classes and their careers.
3) Bring value to the overall academic experience of students.

- Workshop focuses on helping students with nonacademic and mathematics strategy skills specifically tailored for Business Calculus
- Topics include growth mindset, metacognition, time management, mathematics anxiety, mathematics test-taking strategies, calculator skills, procrastination, feedback, goal setting, communication skills, mathematics literacy, and more.
- Workshop includes class discussions, group discussions, personal reflections, group activities, and videos.
- Workshop was piloted in Fall 2023.

Box Breathing

To delineate from regular class time (first 75 minutes) to workshop time (last 45 minutes), I guide the students through the box breathing exercise for around 2 minutes. We started this on the first day of class and do it every class time. This allows students to be exposed to a technique which can reduce stress and anxiety. I also guide them through this on exam day for a longer period.



Examples of Activities

Example 1: Communication Skills
(After watching a short video) On your own, think about how you feel working with others in a school or work setting. Do you enjoy or not enjoy working with others? What do you think makes a good group work? How do you plan on making your calculus group work this semester?

Example 2: Metacognition
(After watching a short video) Have you heard of metacognition before? How would you rate your own metacognition? Using some of the tips in the video, ***how do you plan to study for exam 1***? Be as detailed as possible.

Example 3: Reflecting on an Exam
Let's take some time to dissect the exam. Go through each question and **circle** whether you felt comfortable with the question or not while taking the exam. If the question was partially incorrect or fully incorrect, write the mistake(s) you made or what might have confused you while attempting it.

Learning mathematics in higher education is so much more than learning content. It requires students to have metacognition skills, growth mindset, time management, emotion control, and more! **HOW CAN WE HELP OUR STUDENTS???**

I have created a special workshop which is being facilitated as an educational intervention that helps students learn to learn mathematics by focusing on nonacademic skills and mathematics strategy skills specific to learning Business Calculus.

Conceptual Framework

Scan to **download lesson plans, activities, data collection tools, and more.**

Investigating the effectiveness of the intervention by measuring mathematics anxiety, self-efficacy, and academic achievements throughout the semester. Additionally, investigating the usefulness of the intervention from the student perspective.

FIU FLORIDA INTERNATIONAL UNIVERSITY

The Research

To measure the effectiveness and usefulness of the intervention, I am conducting a quasi-experimental study within an action research paradigm using mixed methods.

Research Questions

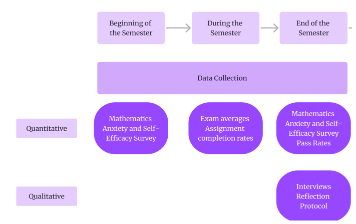
1) What is the effectiveness of an intervention for Business Calculus focused on nonacademic and mathematics strategy skills regarding students' academic achievements, mathematics anxiety, and mathematics self-efficacy?
   a) How do the academic achievements, mathematics anxiety, and mathematics self-efficacy of students enrolled in an intervention for Business Calculus vary, if at all, over the course of a semester with demographics of students as covariates?
   b) How do the academic achievements, mathematics anxiety, and mathematics self-efficacy of students NOT enrolled in an intervention for Business Calculus vary, if at all, over the course of a semester with demographics of students as covariates?
   c) How do the changes, if any, in academic achievements, mathematics anxiety, and mathematics self-efficacy compare between the students enrolled in the intervention and the students not enrolled in the intervention?
2) How do students enrolled in the intervention perceive the usefulness of that intervention?
3) What is the relationship between students' perceived usefulness of the intervention and students' academic achievements, mathematics anxiety, and mathematics self-efficacy?

Data

Two sections of Business Calculus:

Control Group: Standard twice a week 75 min course
Intervention group: Twice a week 2 hours course (where the workshop is embedded in the extra 45 minutes)

Both quantitative and qualitative data are being collected throughout the semester.



The GOAL:

To investigate if providing an innovative, unique, and engaging experience in higher education relating to **learning to learn mathematics** can impact student outcomes in a positive way and provide a resource students find useful

Using Stories to Understand the Attitudes of Students in Entry-Level Mathematics Courses

Samuel D. Reed
Lander University

Chase T. Worley
Lander University

Keywords: Mathematical Attitudes; Mathematical Autobiographies

It has long been recognized that attitudes towards mathematics impact how students learn and the degrees to which they achieve in mathematics (Hwang & Son, 2021). Most work on college students' attitudes towards mathematics revolve around students who are pre-service teachers (Watson, 2019; Zazkis, 2015) or in-service teachers (Drake et al., 2001) and its impact on teaching. In this study, we describe the types of mathematical autobiographies that students possess in an entry- or freshman-level mathematics course (e.g., College Algebra). Namely, we add on to Watson's (2019) dissertation findings where she found that pre-service teachers' prompts to humanize mathematics fit into three categories: (1) Friendly - mathematics has been a lifelong friend; (2) Familial - mathematics is like a brother, sister, father, grandmother, etc; and (3) Antagonist - mathematics is a bully or trying to hold a person back.

The goal of our study was to further examine and refine these categories and to assess whether these categories were useful in describing other populations of students, such as those enrolling in a freshman-level, non-majors, mathematics course. To assess this, we asked students participating in a 'Launch into the University' initiative over the summer of 2023 to humanize mathematics and tell their story or relationship with mathematics throughout their schooling. These students were taking the university's freshman-level English and Mathematics courses (e.g., English 101 and College Algebra) with extra support from embedded tutors. Many of these students had their high school learning impacted by COVID-19 and the ensuing pandemic. In our analysis, we found that Watson's (2019) categories remained useful and accurate in describing the types of stories that students wrote in regard to their relationship with mathematics. We also found that an additional category was useful in describing these students' stories. Namely, that mathematics can be a 'Frenemy.' Watson (2019) described Frenemy to be under the category of Antagonist; however, we found that this description was useful as a separate category and more akin to Drake and colleagues' (2001) 'roller-coaster' relationship. We found this distinction to be important as students in the Antagonist category had (mostly) negative leaning stories. This was in contrast to what we saw as a Frenemy or roller-coaster type of relationship, where students expressed how they used to be friends with mathematics (or had a more positive view), and some experience or experiences caused their relationship to change directions. It was also noticeable how impactful the teacher is in impacting a student's story, consistent with previous work on this subject (e.g., Watson, 2019)

In this poster session we hope to prompt the following discussion: *What can we do as instructors to help to shift student's perceptions about mathematics? How can we leverage student's stories to help them succeed in early mathematics courses?*

Professional Mathematicians' Levels of Understanding and Pseudo-Objectification

Kyle Flanagan
Virginia Tech

Keywords: Abstraction, Mathematical Understanding, Professional Mathematician

The notion of mathematical understanding has always been central to mathematics education research, including how students understand mathematical concepts (e.g., Wawro et al., 2019; Zandieh, 2000). More recently, researchers have been interested in the mathematical practices of mathematicians, including how they understand mathematical concepts (e.g., Flanagan, 2022; Oehrtman et al., 2019; Shepherd & van de Sande, 2014; Wilkerson-Jerde & Wilensky, 2011). Related to understanding is the notion of abstraction, which includes various process-object theories (e.g., Dubinsky & McDonald, 2001; Sfard, 1991). Likely the most prominent theory of abstraction is Piaget's reflective abstraction and his broader genetic epistemology (Piaget, 1970). In this broader theory, Piaget (1964) distinguished between two different ways to understand a mathematical concept, namely "act on it," and to being able to "understand the process of this transformation, and as a consequence to understand the way the object is constructed" (p. 176).

Using this distinction by Piaget, this study introduces three different theoretical levels of understanding: pseudo-object-level, process-level, and object-level. Pseudo-object-level understanding consists of being able to act on the concept like an object without understanding the underlying processes. Process-level understanding consists of being able to understand the underlying processes of the concept. Object-level understanding consists of being able to both act on the concept and understand the underlying processes. Pseudo-object-level understanding also closely aligns with the notion of a pseudostructural conception (Linchevsky & Sfard, 1991; Sfard, 1992; see also Zandieh, 2000).

Through using these levels of understanding, this study addresses the following two research questions:

1. In what ways do professional mathematicians operate with highly-abstract, advanced mathematical concepts at different levels of understanding?
2. What factors can influence a professional mathematician's level of understanding for a given mathematical concept?

To answer these research questions, three semi-structured Zoom interviews (Hammer & Wildavsky, 1993) were conducted with six professional mathematicians specializing in algebra research. The first interview was a semi-structured task-based interview, where the participants completed two tasks with category theory concepts unfamiliar to the participants. The second interview utilized the participants' own research journal publications to generate discussion on what influenced their understanding of the concepts they used in that journal article. The final interview was more reflective, utilizing stimulated recall to triangulate the other two interviews.

The primary forms of data analysis consisted of conceptual analysis (Thompson, 2008) and thematic analysis (Braun & Clarke, 2006). The results provided evidence that professional mathematicians often function at a pseudo-object-level understanding for various mathematical concepts, and that they tend to operate differently with the concepts depending on their level of understanding. Moreover, numerous factors were shown to influence mathematicians' level of understanding, including the particular way the concept is being utilized in their work, as well as other sociocultural factors like one's field of study or what their research community values.

Is it “fast enough?”: Two undergraduate students’ guided reinvention of the comparison test

Catherine Davis
Michigan State University

Kristen Vroom
Michigan State University

Keywords: Comparison test, series, sequences, guided reinvention

Series convergence is a key part of the calculus curriculum. Much of the related education research has focused on students’ understandings of sequences and series (Earls, 2017; Eckman & Roh, 2022; Askgun & Duru, 2007; Kung & Speer, 2013; Martínez-Planell et al., 2012), the notation (Larsen et al., 2022), or textbook analysis (González-Martín, 2010). However, there is limited research on ways to support students’ conjecturing about series convergence.

Our data comes from a teaching experiment (Steffe & Thompson, 2000) with two post-Calculus I students, Lara and Stella. Instruction during this experiment was informed by Realistic Mathematics Education’s guided reinvention heuristic (Freudenthal, 2005; Gravemeijer & Doorman, 1999). Here, we focus on the last four (of 11) sessions in which the students were guided to reinvent statements about series convergence. During these sessions, the students played a game in which they imagined moving an object a certain number of feet each day. A sequence $\{x_n\}$ indicated how many feet x_n to move the object on any given day n. Winning the game required predicting the object’s location if the experiment continued indefinitely (i.e., $\sum x_n$ converged and the students reported the value that it converged to). After playing the game with various sequences, the students wrote a “cheat sheet” with tips for which sequences win/lose the game and some warnings for future players. We interpreted much of their cheat sheet as common tests for series convergence (i.e., p-series test, comparison test). For this study, we investigated: *How did two undergraduate students reinvent the comparison test?* We explored how their version of the comparison test emerged from their previous informal ideas by rewatching videos and re-reading transcripts to identify relevant key moments.

Stella and Lara’s reinvention was tied to their understanding of the sequences n^{-1} and n^{-2} and their corresponding series. Using speed as a metaphor, they identified that a winning sequence must converge to zero at a certain “rate” using n^{-2} and n^{-1} as their benchmarks for a sequence which decreased “fast enough” or “too slowly,” respectively. The teacher-researcher then graphed the sequence n^{-1} and a generic sequence that was greater than n^{-1} for all n, asking the students if the generic sequence would win. Lara quickly inferred that it would lose, and Stella explained it converges to zero “at a slower rate” than n^{-1}. They formalized this on their cheat sheet as “if a sequence is always above the sequence n^{-1} it will lose the game” (which we interpret as a specific case of the comparison test). They compared other sequences to n^{-1} and were unsure whether sequences in between n^{-1} and n^{-2} won the game since they decreased “faster” than n^{-1} but “slower” than n^{-2}. To find clarity, they played (and lost) the game with the sequence $(2n)^{-1}$. They generalized this with two warnings: “sequences that are below n^{-1} will not necessarily win the game” and “sequences above n^{-2} might lose,” which we interpret as the comparison test’s possible inconclusiveness. Finally, with the teacher-researcher’s guidance, the two students considered their benchmark sequences (n^{-1}, n^{-2}) as hypothetical losing and winning sequences, and this encouraged them to write the conjecture which we interpret as (part of) the comparison test: “any sequence that is below a known winning sequence but above 0 will win.”

Our study is an existence proof of two students being guided to reinvent the comparison test, showing that students can be supported to conjecture tests for series convergence. In the poster session, we will elaborate on our data and discuss our future work.

Supporting Mathematical Connections Between Abstract Algebra and Secondary Mathematics for Preservice Teachers

Cammie Gray
Colorado Christian University

Keywords: Abstract Algebra, Secondary School Mathematics, Preservice Teachers, Connections

The numerous mathematical connections between abstract algebra and secondary school mathematics have led professional organizations and mathematics education researchers to identify abstract algebra as an important course for preservice mathematics teachers (CBMS, 2001; CBMS, 2012; Wasserman et al., 2017). Despite what experts might say are clear mathematical connections between abstract algebra and secondary mathematics, many preservice teachers do not see the relevance of an undergraduate abstract algebra course to their teaching practice. In fact, many of them see no relation at all between abstract algebra and secondary school mathematics (Christy & Sparks, 2015; Ticknor, 2012). To address this need for direct connections between mathematical knowledge and pedagogical practice, this poster presents a portion of the results from a larger qualitative study that followed students with an interest in secondary mathematics teaching through their enrollment in an abstract algebra course (Gray, 2021). In particular, the study investigates the types of tasks and course activities that aid preservice teachers in establishing connections between abstract algebra and secondary school mathematics.

For the larger project, survey data was collected from collegiate mathematics faculty and practicing secondary mathematics teachers regarding mathematical connections between abstract algebra and secondary school mathematics. Mathematical connections that these participants identified as important were subsequently utilized to create short instructional tasks that were situated in secondary school mathematics contexts. The abstract algebra course involved in the larger study included undergraduate and graduate students with various majors meaning that the course was not explicitly designed for preservice teachers. The instructional tasks were implemented as warm-up activities before and after the relevant abstract algebra material was taught. This was an adaptation of Wasserman and his colleague's (2017) model *building up from/stepping down to teaching practice*. While all students in the course completed these activities, this study focuses on seven participants: six undergraduates, all of whom expressed interest in teaching careers, and one graduate student with secondary teaching experience. Data collection for these participants included written work on eight warm-up activities, two written student questionnaires (pre/post course), two individual interviews, one midsemester group interview with the undergraduate participants, and classroom observations of 38 class sessions.

Grounded theory coding (Charmaz, 2006) was used to analyze all data sources. The most common mathematical content connection that the participants made is the connection between algebraic structures and their properties in abstract algebra to various concepts in secondary school mathematics. For example, one task asked participants to solve a system of linear equations and justify/explain each step. Six of the seven participants were able to connect this secondary mathematics problem to abstract algebra concepts like inverse and identity. The seventh participant could identify that connections exist making abstract algebra an important course for preservice teachers but did not display evidence of making any connections. Results suggest that abstract algebra instructors can support preservice teachers by providing them opportunities to explore connections themselves.

Obstacles of Learning Proof by Cases

Ahsan Chowdhury, George Mason University
Andrew Miller, George Mason University
Emma Feinstone, Virginia Tech
Michael Holman, Virginia Tech

Keywords: Introduction to Proofs, Proof by Cases, Lesson Analysis Manuscript

Epistemological Obstacles (EOs) are defined as challenges that students face when exposed to concepts that contradict their pre-existing mathematical intuition (Norton & Arnold, 2023). The objective of our poster is to address EOs that emerge during the lesson on proving by cases, rather than circumventing them. This approach, as pursued by Norton and Arnold (2023), elicited EOs such as the Principal of Universal Generalization (PUG) and understanding the difference between the role versus the value of a quantified variable (Qrv). PUG entails proving "for all" statements with an arbitrary value. It was mainly encountered during mathematical induction by Norton and Arnold (2022), but its relation to proofs by cases was not studied. When proving statements with PUG, it may not occur to students that they need specific (x=0), or arbitrary (x is even) cases. Qrv teaches students to prioritize maintaining generality; however, loss of generality is allowed with proof by cases as it is preserved in the aggregate. The obstacle comes from students struggling to understand that generality is maintained differently depending on the situation. The two EOs are closely related; Qrv can be thought of as a direct product of PUG.

At the study institution, students generally take introductory proofs their Junior or Sophomore year and are required to have passed the second of a three-part calculus sequence and discrete math. As such, they are expected to have experience with symbolic logic and operations on conditional statements (converse, contrapositive, negation), set theory and proofs on sets, and mathematical induction. Many upper-level students transfer from the local community college, which introduces a deficiency in the information on what students have and have not covered.

Class size ranges from 12-20 students in a room with whiteboards on most walls. An undergraduate learning assistant was present to walk around during group discussions to aid students and note student reactions for post lesson reflections. The instructor has a degree in mathematics, with a specialization in undergraduate mathematics education. He relied on that background to focus the course goals on inculcating social practices, specifically the norms and practices of the mathematics community. He intentionally structured the class to get students to 'play mathematician' by questioning arguments, positing hypotheses, and proving or disproving those hypotheses through routine think-pair-share cycles.

Our course begins with a review of symbolic logic. We then cover translating written propositions into logical forms, performing operations on those propositions, and discovering how universal and existential quantifiers modify them. After covering our first proof method, the direct proof, we move on to proof by cases. This lesson was immediately after direct proof because the instructor was following the order of topics set out in the course textbook suggested by the department. Our poster will detail the lesson tasks, the rational behind the tasks, and student thinking that came up during the lesson. In particular, the instructor was aiming to introduce students to proof by cases, when to use cases, what cases to consider, and how to use the statement 'without loss of generality'. Through reflection on student reactions to lecture content, certain areas of the lesson could be improved. In particular, in-class examples can be chosen in a way that requires students to think more about how the constructs are used. Our intention with this poster is to get ideas on how we can improve the lesson and produce a lesson analysis manuscript (Corey & Jones, 2023) from this material for a future journal submission.

Obstacles of Learning Proof by Cases

Ahsan Chowdhury Andrew Miller
Emma Feinstone Michael Holman

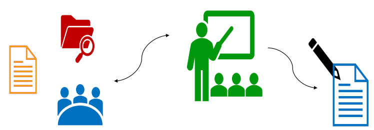
Teaching Materials:

Feedback:

BACKGROUND: Epistemological obstacles (EO's) are challenges students face when exposed to concepts that contradict their pre-existing math intuition. A framework of eliciting and addressing EOs was developed by and practiced at a partnering institution. The particular purpose of this work was to use that EO framework in crafting a proof by cases lesson.

METHODS/CONTEXT

1. Lesson was taught at Eastern US University, class size about 15-20 students.
2. Student Population: had discrete math pre-requisite where a bit of proof was introduced
3. Structured lesson to elicit the EOs that arise in proof by cases- based on suggestions from collaborators



Like the Following:
Task 1) ... For each 'for all' statement, discuss what might make proving the claim tricky. What additional info might you want to know about the arbitrary variables to prove the statement?
a. If n∈"Z", then n^2+n is an even integer
b. Given two integers a, b, if a and b have opposite parity (i.e. characteristic of being even or odd), then a+b is odd
c. ∀x∈R, x≤|x|
d. ∀(x,y)∈R^2 , y=mx for some m∈"R"
e. If x^2−5x+6>0, then x>3 or x<2

RESULTS

- Students found it difficult to determine whether to use cases and which cases to use
- Were some tasks too basic & didn't elicit obstacles? We need insights on how to improve the lesson if so
- Or is proof by cases too easy & there aren't many EOs?
- Or is there only 1 EO (identifying cases thinking is needed and what are the cases) but that itself is a huge challenge?
- Or are things more nuanced because of contextual differences: students at the study institution had experience with baby proofs in discrete mathematics

Students find it difficult to determine **whether** to use cases and **which** cases to use early in the proof writing process.

How might you address such obstacles? What would be productive tasks to move students through this struggle?

Some tasks are too easy:

4) Look over the following proofs. Discuss with your peers whether you think they appropriately prove the statements they address. Note any critiques

b) Prove: $\forall\, a, b \in \mathrm{R}, |ab| = |a||b|$

Assume WLOG, that a>0 and b<0, then

$$|ab| = a(-b) = |a||b|$$

4) Look over the following proofs. Discuss with your peers whether you think they appropriately prove the statements they address. Note any critiques

a) Prove: $\forall\, a, b \in \mathrm{R}, |a+b| \ \leq |a| + |b|$

Case 1: assume a>0, b>0, then $|a+b| = a+b$, and $|a| + |b| = a+b$. Since $a+b = a+b$, then $|a+b| = a+b \leq a+b = |a|+|b|$ as well

Case 2: assume a<0, b<0, then $|a+b| = -(a+b)$, and $|a|+|b| = -a+(-b)$. Since $-(a+b) = -a-b$, then $|a+b| = -(a+b) \leq -a+(-b) = |a|+|b|$ as well

Case 3: assume a and b have opposite sign. Without loss of generality (wlog) assume a>0 and b<0 then

$$|a+b| = a-(-b) = a-|b| \leq |a|+|b|$$

How might **you** adjust these problems?

3b) Given two integers a, b, if a and b have opposite parity (i.e. characteristic of being even or odd), then a+b is odd

2) Find all cases that help prove the following. Time permitting, then prove/disprove the statements

c. $(\forall\, a, b \in \mathrm{R}, ab{=}0)\ (a = 0 \vee b = 0)$

d. $\forall\, n \in \mathrm{Z}$ where n is odd, n divided by 4 leaves a remainder of 1 or 3

This task was added to the second implementation in the current spring semester. Part (d) specifically was added as a challenging problem for students to think about which cases are needed.

4) Look over the following proof. Discuss with your peers whether you think they appropriately prove the statements they address. Note any critiques

Prove: $\forall\, a, b \in \mathrm{R}, |a+b| \ \leq |a| + |b|$

Case 1: assume a>0, b>0, then $|a+b| = a+b$, and $|a| + |b| = a+b$. Since $a+b = a+b$, then $|a+b| = a+b \leq a+b = |a|+|b|$ as well

Case 2: assume a<0, b<0, then $|a+b| = -(a+b)$, and $|a|+|b| = -a+(-b)$. Since $-(a+b) = -a-b$, then $|a+b| = -(a+b) \leq -a+(-b) = |a|+|b|$ as well

Case 3: assume a and b have opposite sign. Without loss of generality (wlog) assume a>0 and b<0 then

$$|a+b| = a-(-b) = a-|b| \leq |a|+|b|$$

Compared to the first implementation, many students did not realize that we need the zero case

6) Determine if the follow statement is true or false. If true, prove your claim. If false, give a counter example: '$\forall\, n \in \mathrm{Z}$ where n is odd, n divided by 4 leaves a remainder of 1 or 3'

This problem was skipped in the first implementation due to time constraints. But in the second implementation, the problem was tackled and asked students to identify cases.

The EO we most frequently noticed was the Principle of Universal Generalization (PUG), which is when students struggle with the concept of maintaining generality in a proof. In our case, they confuse the generality of the proof with the generality of cases. Another is Qrv which is when students mistake the role and the value of a quantified variable.

Online Real Analysis for In-Service Teachers' Meanings for Continuity and Differentiability

Zachary Bettersworth, Western Kentucky University
Nicholas Fortune, Western Kentucky University
Sarah Hartman, Western Kentucky University

In this poster presentation, we present pilot data that emerged from working with secondary math teachers enrolled in a fully online, Introductory Real Analysis course in the Southeastern United States. This pilot data will inform our second attempt at implementing the recommendations of the Project ULTRA (Wasserman et al., 2022) research group in an online context with in-service teachers in a future academic semester.

Keywords: Secondary Teachers, Real Analysis, Continuity, Differentiability, Online

Calculus, and the related mathematical content, is one of the most important, foundational areas of mathematics for people intending to pursue careers in STEM (Bressoud et al., 2016; Rasmussen et al., 2019). Teachers serve a crucial role in the community by providing students with early and continued education about mathematical ideas which build throughout students' K-12 education, up to and including AP Calculus courses (Ball, 2003; Bressoud et al., 2016; Frank & Thompson, 2021). Understanding how in-service teachers develop their own mathematical understanding of ideas related to Real Analysis topics will therefore provide important insights to researchers about the development of teachers' mathematical meanings (Thompson, 2016), or mathematical knowledge, for teaching calculus (Ball, 1990; Hill et al., 2008). Several researchers have reported on students' understanding of mathematical logic in the context of limit and the Intermediate Value Theorem (Roh, 2010; Sellers et al., 2017), and the format of proof-based mathematics courses as well as secondary teachers' views of the utility if proof in their own teaching (Wasserman et al., 2018; Weber, 2004). This work adds to the current RUME literature by demonstrating a burgeoning relationship between secondary teachers' understanding of continuity and differentiability in the context of a fully online Real Analysis course for teachers and their perception of the impact understanding these mathematical ideas has on their teaching.

Our research team collected pilot data during the Fall 2023 academic semester with the goal of better understanding how in-service teachers develop deeper conceptual understandings of important concepts for understanding introductory Real Analysis. The students are currently employed at secondary schools in the surrounding area teaching secondary mathematics. Our research questions are: *1) What meanings for continuity and differentiability do in-service teachers construct in an online analysis course? How are these meanings related? 2) In what ways can the instructional recommendations of Project ULTRA be implemented in the context of an online course for in-service teachers?*

In this poster, we will present preliminary results from our initial implementation of the instructional recommendations from the Project ULTRA research group in their textbook *Understanding Analysis and its Connections to Secondary Mathematics Teaching* (Wasserman et al., 2022). This work represents an initial attempt to extend this research group's instructional recommendations in a fully online Real Analysis course for in-service teachers in the Southeastern United States. We borrowed and added tasks from Sellers et al. (2017) to better understand the teachers' attention to mathematical logic in addition to their conceptual understanding of the concepts of continuity and differentiability when interpreting alternative statements for the Intermediate Value Theorem and the Mean Value Theorem.

Wasserman, N., Weber, K., Villanueva, M., & Meija-Ramos, J. (2018). Mathematics teachers' views about the limited utility of real analysis: A transport model hypothesis. *The Journal of Mathematical Behavior*, *50*, 74–89.

Weber, K. (2004). Traditional instruction in advanced mathematics courses: A case study of one professor's lectures and proofs in an introductory real analysis course. *The Journal of Mathematical Behavior*, *23*(2), 115–133.

Understanding the IVT and the MVT does not necessarily mean that **secondary teachers view their students' learning** as **metaphorically "continuous."**

Statement 3 = False Not every c value in (a,b) is equal to a corresponding y value, N, between f(a)=2.5 and f(b)=0.
Statement 4 = False. Each y value between f(a)=2.5 and f(b)=0 do not have the same x value in (a,b). This would make the graph not be a function.

-Student E (Graph 1)

Statement 3 – False
There exist real numbers c in $[a, b]$ such that

$f(c) = N$ is not between $f(a)$ and $f(b)$.

Statement 4 – True
Since f is continuous, every N between $f(a)$

and $f(b)$ corresponds to a c in domain (a, b).

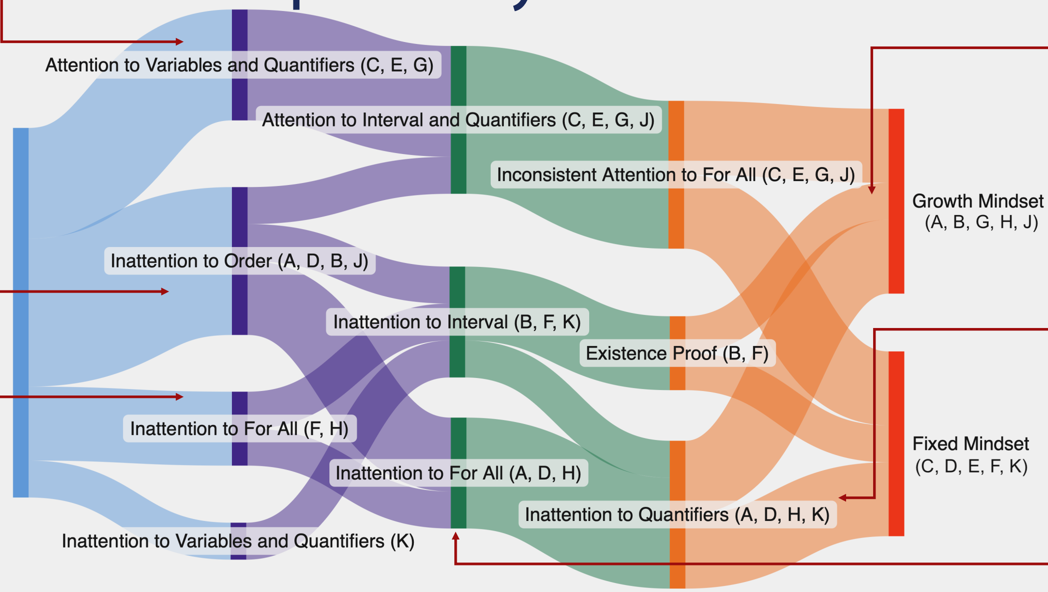
-Student A (Graph 1)

- Statement 3 is true because for all the c values, the N value is always between f(a) and f(b), so we can definitely find at least one case.
- Statement 4 is true because all the N values between f(a) and f(b) correspond to at least one c value, so we can definitely find at least one case.

-Student F (Graph 4)

"I think this statement is a **good preliminary definition** for the graph of a continuous function, but it is **not at the caliber that is necessary** for analysis."

-Student B (Reflection 1)



"**This book is almost antagonistic with its problems** that keep bringing up things to consider, (I know a good textbook should and we are grad students) But **with our kids** we are at the same time trying to **teach then skills to use that work**."

"… it seems to me **such a huge gap** between general Algebra 2 and what the text is saying it is **almost not useful at all**, it has to be **translated several times into a language that they can understand**, and with that translating come the inferences and ambiguity that has caused the problems all along."

-Student D (Reflection 1)

Since Statement 1 says that there exists a point c in [a,b] where $f'(c) = \frac{f(b)-f(a)}{b-a}$. There exists means that there just has to be one c in (a,b) where this is true.

-Student K (Graph 3)

Western Kentucky University

LITERATURE & PROBLEM STATEMENT

Students' attention to logical quantifiers in the context of theorems related to continuity and differentiability impacts their understanding of theorems in Real Analysis courses (e.g., Roh et al., 2010; Wasserman et al., 2018).

There need to be clear connections between content and teaching, and those connections need to be authentic from a pre-service teacher's perspective (Wasserman et al., 2017).

But what does this look like for in-service teachers?

CONTEXT

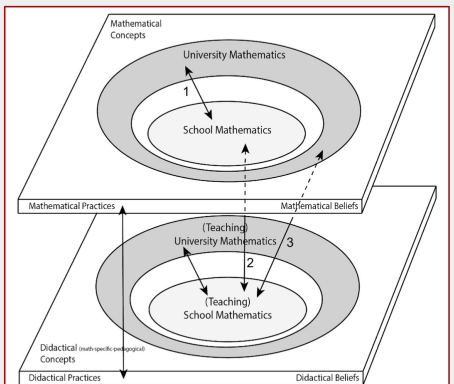
<u>In-service</u> secondary teachers enrolled in a graduate-level, <u>online</u> Real Analysis course at a regional comprehensive University in the Southeastern United States.

2 out of 10 students had completed an undergraduate Real Analysis course prior to

TASKS & REFLECTIONS

Borrowed/modified tasks from Sellers et al. (2017) to better understand the teachers' attention to mathematical logic in addition to their conceptual understanding of the concepts of continuity and differentiability when interpreting alternative statements about the IVT and MVT.

They read Project ULTRA book and reflected on the relationship between their understanding of analysis and the high school mathematics that they teach.



First published by Springer Nature in 2023 in Wasserman, Buchbinder, and Buchholtz's article, "Making university mathematics matter for secondary teacher preparation", in ZDM–Mathematics Education, 55(4), pp. 719-736." *1, 2, and 3 added by authors.*

Proceedings

RESEARCH QUESTIONS

Our work adds to the current RUME literature by demonstrating a burgeoning relationship between <u>**in-service secondary teachers'**</u> understanding of continuity and differentiability in the context of a fully <u>**online**</u> Real Analysis course and their perception of the impact understanding these mathematical ideas has on their teaching.

1) What meanings for continuity and differentiability do in-service teachers construct in an online analysis course? How are these meanings related?

2) In what ways can the instructional recommendations of Project ULTRA be implemented in the context of an online course for in-service teachers?

DATA ANALYSIS

The teachers' responses to the IVT and MVT tasks were coded using Roh et al. (2010) codes in addition to emergent codes.

Teachers' reflection data was coded using open coding with an attention to their meanings for continuity, differentiability, quantifier order in the IVT and MVT statements, and perceptions of teaching or teacher change.

More than half of the pre-service secondary mathematics teachers' interpretations of De Villiers' (1990) roles of proof are often aligned on communication and explanation compared to other roles of proof.

Learner vs. Mathematical Perspectives: Pre-Service Secondary Mathematics Teachers' Interpretations of Roles of Proof

SCAN ME

Background

- Over the past decade, increased attention has been given to teaching and learning proof in school mathematics, as its central roles in mathematics include verification, explanation, discovery, systemization, and communication (e.g., De Villiers, 1990).
- In addition, proving and proof are fundamental to doing mathematics, communicating mathematical ideas, and developing mathematical knowledge (Stylianides, 2007).
- Given that pre-service secondary mathematics teachers (PSMTs) play a critical role in shaping their future students' experiences with proof and proving, we seek to better understand how PSMTs' interpretations of the verification, explanation, discovery, systemization, and communication roles of proof align or misalign with that of the discipline (as represented in De Villiers' (1990) seminal work).

Study

- This study involved 29 PSMTs in the transition-to-proof course titled "Discrete Mathematics" during two semesters (n = 11 in Fall 2020 and n = 18 in Fall 2021) at a Midwestern University in the United States.
- While gaining an appreciation of these five roles that proof can play in mathematics was one of the course goals, the instructor who is the first author did not explicitly name these five roles as a topic of study with students in class until the study week before final exams.
- The primary source of data for this study was PSMTs' written responses to the take-home portion of the final exam, where they were asked to read De Villiers's (1990) article and describe the five given roles of proof using their own words.
- The first author and one research assistant read all PSMTs' responses individually and coded each participant's self-description as not in alignment (N), **in partial alignment (P), or in alignment (Y)** with De Villiers's (1990) explanation.

De Villiers' Roles of Proof & Sample Responses

Verification Proof serves as a means to obtain conviction and establish the truth of a mathematical statement.	Y	*This role deals with the justification behind mathematical proofs. It reasons with the truth of the statements and is used as conviction to proof.*
	P	*To be able to verify a proof can be a difficult task. "Absolute certainty also does not exist in real mathematical research..." (18). This is not the only way verification could be used in fact most are taught to check the answer at the end of a problem. This form of verification can be extremely effective in easing the doubts of an incorrect conclusion.*
	N	*Verification can be used to show that something is incorrect or find mistakes in the problem.*
Explanation Proof serves as a means to promote understanding and illumination of why underlying mathematical concepts are true.	Y	*We must also say why something is true. Many believe the function of explanation is far more important than verification because it gives us an insight into the proof and in return makes us more intelligent.*
	P	*Explanations in proofs play the part of describing why a statement might be true. They are the validation of a proof's truthfulness. The explanation of a proof also helps strengthen the verification of the proof itself.*
	N	*Explanation doesn't necessarily aim to prove something true. It is more about giving reason or explanation as to why it is true.*
Systemization Proof serves as a means to structure unrelated definitions and previously-proven results to gain a global perspective of mathematical concepts.	Y	*Another function of a proof is as a means of systematization. Systematization helps show the logical relationships between statements. These statements are deductive systems such as theorems and definitions. Systematization makes it easier for all of the audience to understand how the proof is built.*
	P	*The systemization of a proof is the organizational process. This role helps simplify a proof and combine similar ideas into a more uniform one. Systemization can help strengthen a proof as well.*
	N	*Systematization is the organization of results. It can help identify errors within the work, connect similar ideas to promote understanding and simplifications, it provides a "global perspective" which I interpreted as a greater understanding within multiple views, and it can provide applications for many things.*
Discovery Proof as a means to expose unexpected results beyond the given mathematical scope or context	Y	*A proof that is written for the sake of discovery follows logical deductions to come to a conclusion that was not necessarily already known or thought to be true. This type of proof can also be used as a way to generalize something—if someone discovers the reasoning behind why a certain hypothesis is true while they are working through examples, that knowledge can then be used to construct a more general proof than before. Proofs of discovery do not always have to be done this way, however. They can also be done just by analyzing the properties of objects that are given.*
	P	*According to de Villiers, there is always a discovery of mathematical results when writing a proof. There are also many instances that new results are found for a proof. Many times, a mathematician has not gone and verified their theorems making their results different.*
	N	*The fourth role of a proof is discovery, in which some concepts and theories are actually discovered on accident through proof. This is not just for new theories to the world, but also new theories to the student. Students can stumble upon untaught theories through class work in proofs.*
Communication Proof serves as a means to expose unexpected results beyond the given mathematical scope or context.	Y	*The final role is communication, where the real value of proofs is seen through debates about the topic. Through debates, we learn new perspectives on topics that we would not have known otherwise and can implement these perspectives into our own work.*
	P	*The article by de Villiers points out that a proof is a way of communicating among people who are working on mathematics. The argument made in the proof is addressed to a human audience. We are trying to convince the audience our results are correct meaning in our explanations we need to use communication so they can understand it.*
	N	*Communication is key to any problem. This means explaining the reasoning good enough to communicate to the reader that it is a proof. It goes hand in hand with explanation. Being able to transcribe the meaning behind the proof to get the reasoning across.*

Preservice Teachers’ Knowledge and Understanding of Fraction Division

Kingsley Y. Adamoah
Middle Tennessee State University

Middle Tennessee State University

Keywords: Cognitive types, conceptions, content knowledge, content understanding

It is important for preservice teachers (PSTs) to have a deep and connected conceptual understanding of mathematical concepts they will teach in their future classrooms (Ball, 1990; Da Ponte & Chapman, 2015). For this reason, teacher education programs work to provide opportunities for preservice teachers' (PSTs’) to build understanding of the various ways students conceive of significant mathematical ideas and practices (e.g., Ball et al., 2008; Hill, 2010; Li, 2008; Li & Kulm, 2008; Lo & Luo, 2012; Tirosh, 2000). Therefore, it is important to investigate PSTs’ conceptions, connections, notions, and understandings of specific mathematics concepts so that results can be used to inform effective instruction in content courses for future teachers.

The goal of this comparative case study was to investigate PSTs’ *content knowledge* (Ball et al., 2008; Coskun et al., 2023) and *content understanding* (Bair & Rich, 2011; Hill et al., 2004, 2008) as the basis for measuring *cognitive types of teacher content knowledge* (Tchoshanov, 2011). The *cognitive types* include knowledge of facts and procedures (Type 1), knowledge of concepts and connections (Type 2), and knowledge of models and generalizations (Type 3). Our poster presentation will share results from the study for only *Type 2* with a content focus on fraction division. The research question for this portion of the study was: What are PSTs’ mathematical conceptions, connections, and notions of the fraction division concept?

We utilized a linear progression of constructs to guide the analysis of our data to answer the research question. That is, content knowledge □ cognitive types of teacher content knowledge □ specialized content knowledge (SCK) progression □ content understanding □ (conceptions, connections, and notions), with each construct rooted in the literature.

Data was collected from 18 preservice elementary teachers enrolled in mathematics content course at a public university in the Southeastern United States. The study analyzed both quantitative and qualitative data. For the quantitative data, a modified form of the Teacher Content Knowledge Surveys (TCKS) designed by Tchoshanov (2011) was used. For the qualitative data, pre- and post-term exit tickets were used. The SCK progression framework (Bair & Rich, 2011) informed the qualitative data analyzes.

Results also showed that Blair and Rich’s (2011) SCK progression framework was associated with levels of knowledge as measured by the TCKS. We found that 30% of PSTs with less than a numerical average value (< 0.5) of *Type 2* TCKS pre-post scores were those at Level 0 and Level 1 of SCK progression. Also, 40% of participants who were above average in TCKS scores were at Level 3 and Level 4 and the rest were at average. This study informed mathematics teacher educators and instructors of content mathematics courses for PSTs on the characterization of the kind and qualities of aspects of content knowledge and content understanding that PSTs possess and how to support them in specific mathematical concepts.

Mathematics and Science Education Doctor of Philosophy Program

Jeremy Strayer
Middle Tennessee State University

Introduction

It is important for preservice teachers (PSTs) to have a deep and connected conceptual understanding of mathematical concepts they will teach in their future classrooms (Ball, 1990; Da Ponte & Chapman, 2015). For this reason, teacher education programs work to provide opportunities for preservice teachers' (PSTs') to build understanding of the various ways students conceive of significant mathematical ideas and practices (e.g., Ball et al., 2008; Hill, 2010; Li & Kulm, 2008; Lo & Luo, 2012). The goal of this study was to investigate PSTs' *content knowledge* (Ball et al., 2008; Coskun et al., 2023) and *content understanding* (Bair & Rich, 2011; Hill et al., 2008) as the basis for measuring *cognitive types of teacher content knowledge* (Tchoshanov, 2011).

Theoretical Framework

The study utilized a linear progression of constructs to guide the analysis of our data to answer the research question. That is, content knowledge → cognitive types of teacher content knowledge → specialized content knowledge (SCK) progression → content understanding → (conceptions, connections, and notions), with each construct rooted in the literature.

Methodology

Participants

- ✓ A total of 18 elementary preservice teachers in a mathematics content course were involved.
- ✓ Ten of the participants were selected for further qualitative analysis. Those were the top 5 and lower 5 PSTs with Teacher Content Knowledge Surveys (TCKS) scores.

Data Source and Design

Written Exit Tickets. PSTs were provided with both pre-and post exit tickets modified from the TCKS (Tchoshanov, 2011) as the qualitative data.

Instruments, Tools, Constructs, and Data Coding

Instruments and Tools

Analyzed with the SCK Progression Framework (Blair & Rich, 2011)

Five-level SCK Progression Framework

Indicators: entry (Level 0), emerging (Level 1), developing (Level 2), maturing (Level 3), and deep and connected mathematical knowledge for teaching (Level 4).

Data Coding: Bair and Rich's framework to provide a fine-grained process for coding PSTs' *content understanding* using the five-level progression of indicators.

Research Question

What are PSTs' mathematical conceptions, connections, and notions of the fraction division concept?

Big Takeaways

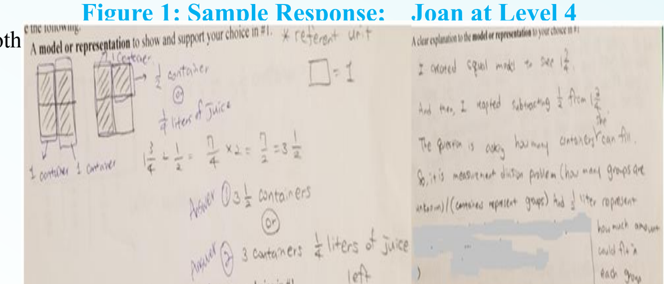
Content Knowledge

Blair and Rich's (2011) SCK Progression Framework **Levels** appear to be associated with the Cognitive Type of Teacher Content Knowledge as measured by the TCKS (Tchoshanov, 2011).

Content Understanding

PSTs with strong and explicit fraction division conceptions, connections, and notions were at Level 4 or Level 3 but getting nearer to Level 4.

Figure 1: Sample Response: Joan at Level 4



Joan: *"the question is asking how many ½ liters containers can be filled? So, it is a measurement division problem".* ***Fraction Division Conception***

Joan: "I created equal model to see $1\frac{3}{4}$ and then I *repeated subtracting* $\frac{1}{2}$ *from* $1\frac{3}{4}$".

Joan's model brings out (i) the problem structure, (ii) the action in the problem, (iii) appropriate representational connections to the problem situation and the context of solution, and (iv) the possible ways the solution can be expressed

Future Research

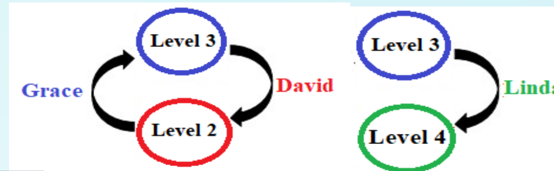
Investigating PSTs cognitive processes that interact with their conceptions, connections, and notions about specific mathematical concepts

Results

Level 0	Level 1	Level 2	Level 3	Level 4
Emily(**b**)	Sarah(**b**)	Kelly(**t**)	Linda(**t**)	Joan(**t**)
	Kate(**b**)	Grace(**b**)	David(**t**)	Lizz(**t**)
		Nina(**b**)		

PSTs with **"b"** against names are the **Bottom 5** for the TCKS scores

Those with **"t"** against them are the **Top 5** for the TCKS scores



Conclusion and Implication

The results of this study will inform instructors content mathematics courses for PSTs the need to integrate pedagogical strategies that will support the development of a deeper conceptual knowledge and understanding of any mathematical concept.

Creating Metaphors for Linear Algebra Concepts: Developing Cognitive, Behavioral, and Affective Domains

COLORADO STATE UNIVERSITY

Dr. Hortensia Soto
Colorado State University

Dr. Vladislav Kokushkin
Colorado State University

Dr. Jessi Lajos
Utah State University

Utah State University

Issues with Assessments Practices

Traditional Assessments:

- Privilege symbolism and formalism (Nemirovsky & Bunn, 2022)
- Characterize mathematics as mechanisms (Nemirovsky et al., 2023)
- Viewed as "easy" to implement, non-disruptive, and "real math" (Munter et al., 2014)
- Avoid mathematical aesthetics (Sinclair et al., 2006)

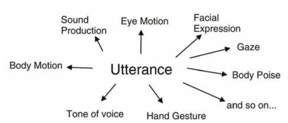
Current recommendations and ways forward:

Assessments should engage students: (Meta)Cognitively, Affectively, and Behaviourally (MAA Instructional Practices Guide).

Targeting Three Domains via Intentional Design of an Embodied Assessment

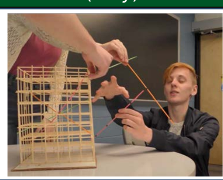
Embodied Cognition

Embodied design applied to "tools whose operatory function is **engineered** specifically so as to . . . **cultivate** . . . the development of particular **sensorimotor schemes** as a condition for masterful control of the environment in accord with **task demands**" and thereby "come to **ground mathematical concepts** we want these students to **learn**" (Abrahamson & Bakker, 2016, p.5, Piaget, 1954)



(Nemirovsky & Ferrara, 2009)

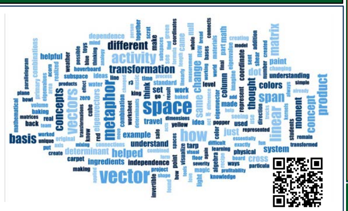
Formative Assessments (Play)



Summative Metaphor Creation

Two-part summative assessment:

1. **Written part:** Create and reflect on your own metaphors about various LA concept pairs (e.g., *Explain how you arrived at this metaphor and how it fits the formal concept.*
1. **Collaborative focus group:** Sharing and co-constructing new improved metaphors with peers.



Research Questions

1. What metaphors do students create for linear algebra concepts? How do they manifest?
2. What cognitive, behavioral, and affective behaviors emerge as students share their metaphors for linear algebra concepts?

Results: Students' Engagement During Summative Assessment

(Meta)Cognitive

Metaphor Resources:

- **Personal Experiences**
  - ***Hobbies***
  - ***Childhood experiences***
  - ***Professional Interests/Major:***
  - ***In-the-Moment***
- **Classroom Experiences**
- **Linguistics**

Evaluating the "Soundness" of Metaphors

A. **Incomplete model of real-world**
B. **Incomplete representation of linear algebra concept**

Extending Metaphor across Multiple LA Concepts: Popcorn Popper

kernels represent the **vectors**. Heat is the **matrix**, it's the one that's changing the vectors. The ones that pop and go into the bowl underneath the popcorn machine, those are in the **column space**, because they get **transformed** into a new location.	And the kernels that pop or just like fly out [throws hand over shoulder] of the machine and land on the floor, those are in the **null space**, because they get sent out of the system entirely.	Kernels that stay in the popcorn machine are like "**eigenvectors** because they didn't' really move" or "pop out".	The degree to which they [popcorn that don't move] got semi-popped is like the **eigenvalue** of the situation because it tells you how much it changed even though it's still like where it was before."

Affective

Behavioral

Slinky Metaphor for Invertible

You can actually ***see it*** *go back … repeats* gesture and then says *"to itself"*

In some of my science classes we used to … how ***sound moves***

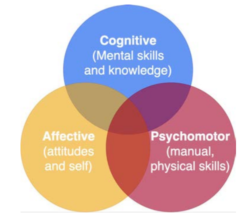
If we could physically see it (grab both ends with eyes focused on her slinky and Billy sweeps his hand)

It always goes back to itself *(brings hands together)*

Findings illustrate the notion that "***Learning – the creation of the new – comes about from situations that were previously unimagined, impossible, unusual, & unexpected … expressed through diagram/gesture [and verbiage] interplay"*** (de Freitas & Sinclair, 2014, p. 109).

Framework for Engagement

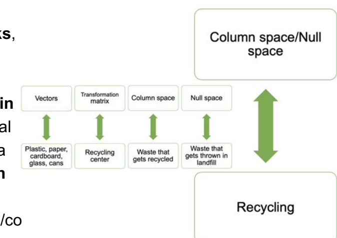
(Anderson & Krathwohl, 2016; Bloom et al., 1956)



The Knowledge Dimension	The Cognitive Dimension					
	Remembering	Understanding	Applying	Analyzing	Evaluating	Creating
Factual knowledge	Listing	Summarizing	Classifying	Ordering	Ranking	Combining
Conceptual Knowledge	Describing	Interpreting	Experimenting	Explaining	Assessing	Planning
Procedural Knowledge	Tabulating	Predicting	Calculating	Differentiating	Concluding	Composing
Meta-cognitive knowledge	Using Appropriately	Executing	Constructing	Achieving	Taking action	Actualizing

Conceptual Metaphors

Appear as **cognitive links**, or mappings, between a **source domain** (abstract/formal concept) and a **target domain** (real-world/physical/concrete).



(Lakoff & Núñez, 1997)

Discussion

1. **Embodiment espouses learning from concrete to abstract** (Tall, 2013)
   - This activity moves students from abstract back to concrete (make full circle)
   - Forced to think deeply about the abstract
2. **Metaphor Assessment Privileges**
   - Blending Creativity & Metacognitive
   - Togetherness
   - Aesthetics of Mathematics (surprise, joy, frustration)
3. **Learning is inventiveness** (de Freitas & Sinclair, 2014)

How Undergraduates Make Decisions When Co-Validating Mathematical Proofs

Jordan E. Kirby
Francis Marion University

Sarah K. Bleiler-Baxter
Middle Tennessee State University

Yi-Yin Ko
Indiana State University

Keywords: Proof, Introduction to Proof, Validation

Mathematical proof is central to the work of mathematicians (e.g., Weber, 2008), and is a center pointe of the undergraduate curriculum for mathematics majors (Stylianides, G., 2007). As undergraduates learn to prove, they need to learn various proving processes, not the least of which are construction and validation (e.g., Ko, & Rose, 2022; de Villiers, 1990; Segal, 2000). Construction and validation of proofs go hand-in-hand, yet they involve unique skills and processes (Kirsten & Greefrath, 2023; Selden & Selden, 2003)). Therefore, it is crucial to understand how undergraduates make decisions about proof construction and proof validation. In recent work, we explored how students in an inquiry-based Introduction-to-Proof (ITP) course make decisions when it comes to *co-constructing* proofs in small groups (Bleiler-Baxter et al., 2023). In this poster, we seek to extend the findings from that research by exploring situations where students are *co-validating* proofs in small groups. We ask: To what aspects of proof do students in an undergraduate inquiry-based ITP course attend when co-validating mathematical proofs within small groups?

This study involves students enrolled in an ITP course at a public university in the southeastern United States in the fall of 2023 taught by the second author. Students in this class were asked, at three separate time points during the semester (early, middle, late), to review sample arguments and to determine if those arguments should "count" as mathematical proof. They were given independent think-time to make their initial validations of the given arguments, and then they were tasked with coming to a consensus in their pre-assigned small-groups, as to whether each argument was or was not a proof and why. We explore the transcripts of audio data of small group discussions across these various points in the semester to investigate how students make decisions about validating proofs.

To analyze the small-group discussions, we use a three-part theoretical coding scheme informed by A. Stylianides' (2007) definition of proof: set of accepted statements, modes of argumentation, and modes of argument representation. We use this definition as a coding scheme to be able to discern what students prioritize when making decisions on what counts as proof. For example, students may focus on the way the definition of divisibility is used in an argument (i.e., set of accepted statements), the way proof by contradiction is employed (i.e., mode of argumentation), or the way a table is used to organize an argument (i.e., mode of argument representation).

Submitting as a poster will allow us to include various student excerpts from transcripts highlighting each of the codes we have used as well as how their frequency changes over the course of the semester. We hope to gain from attendees at the conference what questions they may have about our data and other data analysis methodologies to consider as we begin finalizing our data analysis in the spring.

Proofs Project Partners: Implementing Research-Based Instruction Across Institutions

Corinne Mitchell	V. Rani Satyam	David Duncan
Virginia Tech	Virginia Commonwealth	James Madison
Ahsan Chowdhury	Anderson Norton	Rachel Arnold
George Mason	Virginia Tech	Virginia Tech

Keywords: epistemological obstacles, logical reasoning, proof and proving

The Proofs Project is an NSF-funded research project investigating persistent challenges students experience in Introduction to Proofs courses. These challenges are framed in terms of epistemological obstacles (EOs) students and instructors experience during classroom interaction, even within research-based practice (Brousseau, 2002; Sierpińska, 1987). The project has generated video modules illustrating such obstacles and tasks that instructors can use to elicit and address them. Now, in the second year of the project, instructors at three different universities have begun using project materials in their Introduction to Proofs courses. These three instructors participated in a three-day Proofs Project workshop at Virginia Tech, during the Summer of 2023. Here, we report on their experiences implementing project materials to intentionally elicit and address EOs they have experienced in prior instruction. Data come from surveys conducted at the end of the summer workshop; at the start of the following Fall semester, as they taught their Introduction to Proofs course; and at the end of that semester. In addition to discussion of these findings, Authors 2, 3, and 4 will report on their individual experiences in implementing project materials to elicit and address students' experience of persistent challenges.

At the time of the workshop, one instructor had taught Introduction to Proofs more than five times; one was teaching the course for the fifth time; and one was "terrified" to be teaching the course for the first time. Following the summer workshop, all three instructors were eager to implement project materials and, indeed, had begun making instructional plans using those materials, during the workshop. They anticipated the materials—especially tasks and video clips—would help them address and elicit EOs related to students' treatment of logical implications, quantification, and particular methods for proving, such as proof by cases.

Each instructor elicited EOs that had been identified in prior research. One instructor noted, "For example, even after discussion, students will still take the negation of P implies Q as 'If P, then not Q' or 'If not P, then not Q,' when trying to negate a sentence written in everyday language." (cf., Dawkins & Hub, 2017; Epp, 2003). She found that when students became aware of such obstacles, they were able to begin addressing them on their own, or in discussion with peers. In reflecting on such an approach, another instructor shared the following:

> I think I am gaining an appreciation for the value of eliciting EOs. It's a lot easier to just let some of them fly under the radar, particularly in the classroom. I suppose in the past I had assumed/hoped that students were struggling with some of these concepts while engaging with the homework—that's how I remember experiencing many of them for the first time.

During the presentation, the three instructors will share, compare, and contrast such experiences.

Acknowledgments

This initiative was funded by 4-VA, a collaborative partnership for advancing the Commonwealth of Virginia.

Using Trees to See a Forest: Leveraging Machine Learning to Classify Student Thinking

Darryl Chamberlain Jr. Patrick McGuinness
Emily Faulconer Beverly Wood
Embry-Riddle Aeronautical University -- Worldwide

Keywords: Decision Trees, Qualitative Coding, Machine Learning

Introduction

ChatGPT has caught the world's attention and has researchers considering the ways artificial intelligence can be integrated into human endeavors (Kasneci et al., 2023). This methodological poster will present a systematic method to apply a particular machine learning classification model, Decision Tree (Song & Lu, 2015), to perform and extend the scale of qualitative analysis in mathematics education research.

Implementation of a Decision Tree

There are five general phases to the creation of a decision tree: data preparation, feature analysis, test label creation, decision tree coding, and parameter tuning.

1. Data Preparation: While the original data can take any form (verbal, student work, hand gestures, etc), it will need to be unitized in some way. The size of each unit of data will be affected by the theoretical framework employed and the attributes to be identified from the unit.

2. Feature Analysis: Each unit of data will then be coded for important attributes that are referred to as *features*. Features can be categorical or numeric, and do not need to be of just one type for a single decision tree. For example, features tied to a student's free response to a task could include [a] Presence of a response *(yes/no)*, [b] Presence/Absence of key words/phrases *(binary or number of occurrences)*, or [c] Use of a particular representation *(graphical, algebraic, tabular, etc)*. Identifying features is a critical human task in creating a decision tree, much like qualitatively coding according to a theoretical framework.

3. Test Labels Creation: We need to provide labeled data the decision tree algorithm can learn from. This is the second critical human researcher task that again mirrors a typical qualitative coding task where labels are determined by the theoretical framework employed.

4. Decision Tree Coding: Open source libraires such as Python's pandas library (Reschke, et al., 2020) contain the majority of the technical aspects of employing a machine learning model. After preparing the data, completing the feature analysis, and labeling the data, creating the decision tree is as easy as calling RandomForestClassifier().fit.

5. Parameter Tuning: Numerous parameters can be defined by the researcher to improve the accuracy of predictions as well as the amount of data that is used to train and test the data.

Discussion

We believe that incorporating machine learning can significantly benefit the qualitative coding process and is feasible for many mathematics education researchers. One major benefit to this implementation is the scale and speed at which data can be analyzed. Another major benefit was seen in our codebook. By carefully considering what features might be present and what labels they may correlate to, we have improved the replicability of our qualitative coding based on our extensive codebook. Finally, classification algorithms would provide an excellent engine for automating the analysis of student work based on qualitative coding of student responses. This would allow researchers to bridge the gap and provide practical uses of their esoteric work.

Analyzing Calculus Textbooks' Introduction of the Dynamic Derivative Using a Framework of Shape-Thinking and (Co)Variational Reasoning

Allison Olshefke
University of Delaware

Keywords: calculus, content analysis, covariational reasoning, shape thinking, textbook analysis

Research over the past few decades demonstrates that calculus students have difficulties making sense of the derivative conceptually, even if they can calculate derivatives fluently (e.g., Orton, 1983; Carlson et al., 2002; Thompson & Carlson, 2017; Epstein, 2013). In a review of literature on ideas foundational to calculus learning, Thompson and Harel (2021) argue that that the underdevelopment of covariational reasoning skills may be the missing link in students' ability to engage deeply with major calculus concepts including the derivative. Covariational reasoning, (i.e., reasoning about how quantities vary simultaneously and in relation to one another) is evident in the MAA's recommended conception of the derivative as dynamic (Bressoud, 2015). Recent work emphasizes the need to promote "derivative as instantaneous rate of change or as a measure of sensitivity of one variable to change in another," rather than the static conception of "derivative as slopes of tangent lines," which does not make explicit the relationship between quantities (Bressoud et al., 2015, p. 18).

A few recent studies suggest that calculus textbooks do not frequently provide opportunities for students to develop covariational reasoning skills with quantities related to the derivative. These studies used Carlson et al.'s (2002) five levels of (co)variational reasoning to compare the opportunities for covariational reasoning across international calculus textbooks (Chen, 2023) and between a regular and applied Calculus textbook (Mkhatshwa, 2022).

This study adds a different perspective on opportunities for reasoning covariationally in the context of the derivative by analyzing introductory material about the derivative in a two widely used calculus textbooks, one traditional (Larson & Edwards, 2018) and one reform (Hughes-Hallet et al., 2013) by applying a novel framework introduced by Tasova et al., 2018. Their framework for analyzing written curriculum, which they used to analyze precalculus content in calculus textbooks, merges Thompson & Carlson's (2017) (co)variational reasoning framework with Moore and Thompson's (2015) framework for static and emergent graphical shape thinking. This multi-layered approach allows for a more nuanced description of the opportunities for students to understand the derivative from a covariational perspective and for exploration of the alignment with a dynamic or static conception of the derivative.

In this poster, I present the results of my directed content analysis (Hsieh et al., 2005) to answer the following questions: *What opportunities does each textbook provide in its narrative and worked example sections for students to reason about quantities and variables related to the derivative as dynamic?* and *What are the similarities/differences between the textbooks in the nature and frequency of these opportunities?* Results are supplemented with an expanded presentation of Tasova et al.'s (2018) framework that includes examples illustrating the range of opportunities textbooks provide. Finally, I present suggestions for both research and practice that focus on supplementing textbook opportunities to foster a dynamic conception and the implications of these results for equity and inclusion in STEM.

Static and Dynamic: How Two Textbooks Introduce the Derivative

PRESENTER:
Allison Olshefke

MOTIVATION:

- Even when they can work with derivatives procedurally, students still struggle understanding the derivative conceptually.
- Covariational reasoning may help bridge this gap.
- How do textbooks promote conceptions of the derivative that are productive?

METHODS:

- I compared the intro chapter on derivatives from two commonly used calculus textbooks:
  - Larson's *Calculus*
  - Hughes Hallett et al.'s *Calculus: Single and Multivariable*
- I coded narrative sections of the textbooks using a framework that distinguishes between static and dynamic conceptions of the derivative.

MAIN RESULTS:

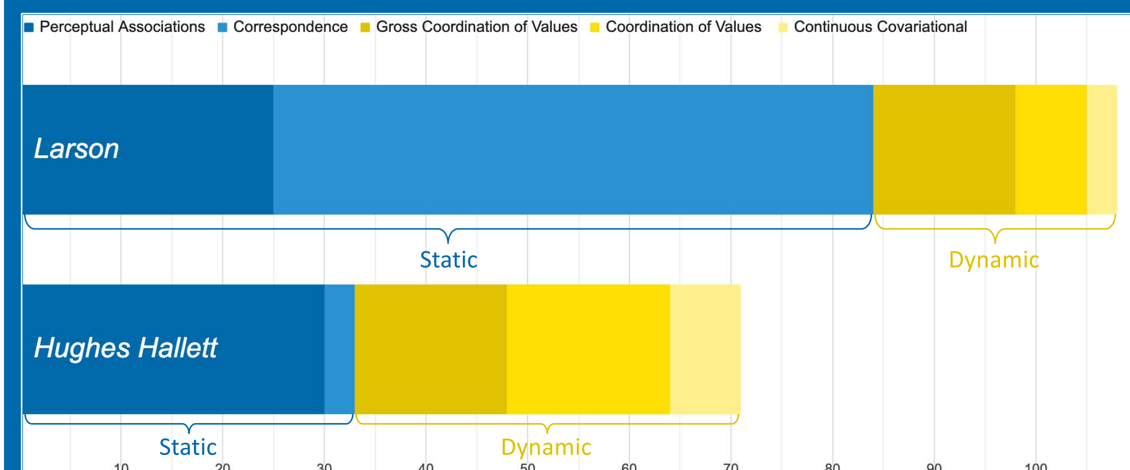
Frequency

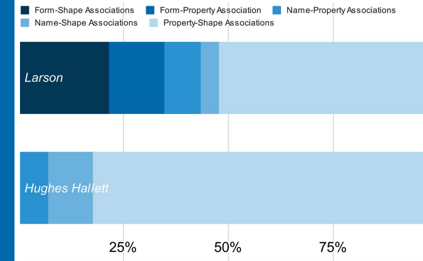
	Static	Dynamic	Total
Larson	76.4% (n = 84)	23.6% (n = 26)	110
Hughes Hallett	46.5% (n = 33)	53.5% (n = 38)	71

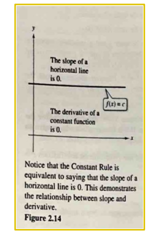
Scan for references & more info!

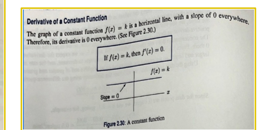
Created by cdesign933 from Noun Project

Calculus textbooks differ in the ways that they promote the **derivative** as static and dynamic.

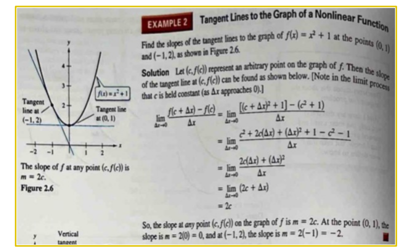








Property-Shape Association worked examples (*Larson* p. 110 & *Hughes Hallett* p. 94)



EXAMPLE 2 Tangent Lines to the Graph of a Nonlinear Function

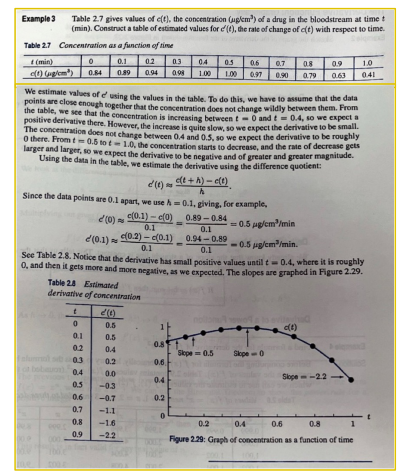
Find the slopes of the tangent lines to the graph of $f(x) = x^2 + 1$ at the points $(0, 1)$ and $(-1, 2)$, as shown in Figure 2.6.

Solution Let $(c, f(c))$ represent an arbitrary point on the graph of f. Then the slope of the tangent line at $(c, f(c))$ can be found as shown below. [Note in the limit process that c is held constant (as Δx approaches 0).]

$$\lim_{\Delta x \to 0} \frac{f(c+\Delta x) - f(c)}{\Delta x} = \lim_{\Delta x \to 0} \frac{[(c+\Delta x)^2 + 1] - (c^2 + 1)}{\Delta x}$$
$$= \lim_{\Delta x \to 0} \frac{c^2 + 2c(\Delta x) + (\Delta x)^2 + 1 - c^2 - 1}{\Delta x}$$
$$= \lim_{\Delta x \to 0} \frac{2c(\Delta x) + (\Delta x)^2}{\Delta x}$$
$$= \lim_{\Delta x \to 0} (2c + \Delta x)$$
$$= 2c$$

So, the slope at *any* point $(c, f(c))$ on the graph of f is $m = 2c$. At the point $(0, 1)$, the slope is $m = 2(0) = 0$, and at $(-1, 2)$, the slope is $m = 2(-1) = -2$.

Larson Correspondence worked example (p. 102)



Example 3 Table 2.7 gives values of $c(t)$, the concentration (μg/cm^3) of a drug in the bloodstream at time t (min). Construct a table of estimated values for $c'(t)$, the rate of change of $c(t)$ with respect to time.

Table 2.7 *Concentration as a function of time*

t (min)	0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
$c(t)$ (μg/cm^3)	0.84	0.89	0.94	0.98	1.00	1.00	0.97	0.90	0.79	0.63	0.41

We estimate values of c' using the values in the table. To do this, we have to assume that the data points are close enough together that the concentration does not change wildly between them. From the table, we see that the concentration is increasing between $t = 0$ and $t = 0.4$, so we expect a positive derivative there. However, the increase is quite slow, so we expect the derivative to be small. The concentration does not change between 0.4 and 0.5, so we expect the derivative to be roughly 0 there. From $t = 0.5$ to $t = 1.0$, the concentration starts to decrease, and the rate of decrease gets larger and larger, so we expect the derivative to be negative and of greater and greater magnitude.

Using the data in the table, we estimate the derivative using the difference quotient:

$$c'(t) \approx \frac{c(t+h) - c(t)}{h}.$$

Since the data points are 0.1 apart, we use $h = 0.1$, giving, for example,

$$c'(0) \approx \frac{c(0.1) - c(0)}{0.1} = \frac{0.89 - 0.84}{0.1} = 0.5\ \mu\text{g/cm}^3\text{/min}$$
$$c'(0.1) \approx \frac{c(0.2) - c(0.1)}{0.1} = \frac{0.94 - 0.89}{0.1} = 0.5\ \mu\text{g/cm}^3\text{/min}.$$

See Table 2.8. Notice that the derivative has small positive values until $t = 0.4$, where it is roughly 0, and then it gets more and more negative, as we expected. The slopes are graphed in Figure 2.29.

Table 2.8 *Estimated derivative of concentration*

t	$c'(t)$
0	0.5
0.1	0.5
0.2	0.4
0.3	0.2
0.4	0.0
0.5	−0.3
0.6	−0.7
0.7	−1.1
0.8	−1.6
0.9	−2.2

Figure 2.29: Graph of concentration as a function of time

Mississippi State University

Claudia Bertolone-Smith
California State University, Chico

Diana Moss
University of Nevada, Reno

Hortensia Soto
Colorado State University

Prior research highlights the critical importance of teachers' professional noticing skills (Jacobs et al., 2010; Sherin et al., 2011). Specifically, the concept of "embodied noticing," or the ability to interpret students' physical gestures and manipulations alongside their verbalizations, is gaining attention (Bondurant et al., 2023; Goldin et al., 2011; Walkoe et al., 2023). In this study, we investigated Pre-Service Teachers' (PTs) abilities to notice and evaluate students' embodied actions in mathematics (Bondurant et al., 2020; Bondurant et al., 2023). The aim of our study was twofold: to investigate PTs' skills in noticing students' embodied actions in math, and to determine how such noticing might contribute to more equitable classroom environments. We employed a sequential exploratory design, incorporating both qualitative and quantitative methods (Creswell & Plano Clark, 2017). Initial qualitative data were gathered from 20 PTs who participated in a 15-week online pedagogical course on elementary math education. PTs were asked to watch a video of a student engaged in a math task and to respond to a set of instructional activity prompts (Musser et al., 2013).

Our findings reveal that most PTs are still at the peripheral or transitional levels of noticing embodiment in all three stages: attending, interpreting, and deciding. In particular, they often overlook the embodied nuances and focus on evaluating the correctness of students' written and verbal responses using a deficit lens. This lack of attention to embodiment may be detrimental as it fails to consider the whole child's mathematical thinking and doing, possibly leading to an inequitable evaluation (Gutiérrez, 2008; 2009).

We recommend several interventions to improve PTs' embodied noticing skills:

1. Implement a mandatory multiple-viewing approach.
2. Utilize on-screen annotation tools for enhanced evaluation.
3. Initially, mute videos to emphasize embodiment, then enable sound for subsequent viewings.

Our study contributes to the field by offering refined instructional prompts, exemplars of embodied noticing, a framework for layering embodiment and noticing, and a rubric for evaluating embodiment in educational contexts. Future research should investigate the long-term impact of these interventions on PTs' noticing, teaching practices, and student outcomes.

Bridging Mathematics: To Care for an Abstraction

Sofía Abreu
Michigan State University

Anthony Dickson
Michigan State University

Keywords: philosophy, ontology of mathematics, stories, isomorphism

This theoretical poster engages with and presents dominant undergraduate mathematics topics as lively forces with rich potentialities for connection beyond disciplinary mathematics. More specifically, this poster offers both (a) a theoretical contribution to engage with undergraduate mathematics as situated, open, and lively (de Freitas & Sinclair, 2013; Mikulan & Sinclair, 2023); and (b) a potential bridge to resurface and generate connections between undergraduate mathematics and philosophical ideas that are often left out of mathematics classrooms. We invite our field to, as Mikulan and Sinclair (2023) write, *care* for an abstraction: "To care for an abstraction is to make sure you haven't extended it too far, forgotten the contingencies on which it depends, applied it flippantly or use it to foreclose thinking" (p. 70).

Doxiadis (2003), when inviting mathematicians to open up to other ways of sharing their work, suggested considering historical, philosophical, aesthetic, and other dimensions of mathematics to understand math differently. They propose to "[e]mbed mathematics in the soul…by embedding it in story" (p. 24). In resonance, this poster understands mathematics as embedded in worlds (rather than fixed, separated/separable from the 'real' world); always emergent, relational, and in transformation, carrying with it histories, desires, and possibilities that are neither predetermined/fixed nor confined within mathematics as a discipline. For example, the concept of *isomorphism* is often fixed to its algebraic definition and approached as the 'endpoint' of some learning trajectory (e.g., Larsen, 2013), narrowing down pedagogical conversations to metaphors of sameness or connections with homomorphisms (Rupnow, 2021). But what if instead we engaged with it as a *starting* point, as a spark? What stories can it awaken and how are they interconnected (or not) with(in) the world? Isomorphism then becomes a kaleidoscope of stories, awakening multiple wonderings: Why does isomorphism seek to preserve *these* specific structures (e.g., group operation), and what possibilities are foreclosed? Connecting isomorphism with notions of preserving a melody without, for example, consideration of an instrument's timbre could invite discussions of what might be left out when prioritizing certain structures at the expense of other dynamics. These stories, moreover, need not be reduced to auxiliary metaphors *towards* the definition of isomorphism and can invite other wonderings: Where does the persistent preoccupation for 'sameness of forms/structures' in dominant mathematics come from? This opens worlds of historical connections to follow, such as ties with coloniality and language (Barton & Frank, 2001; Gutiérrez, 2017) and often-ignored contingencies as well as connections between temporalities and abstractions (Mikulan & Sinclair, 2023), inviting us to trouble the belief that mathematics is 'universal' and 'objective.'

Understanding mathematics as open and entangled with lived/living histories has not only pedagogical implications but also political. The pervasive understanding of mathematics as abstract and thus objective is harmful in multiple ways, concerns that have been raised in K-12 literature (e.g., Fasheh, 2012; Martin, 2019) but are rare in undergraduate mathematics. Thus, we invite our field to open up to engage with mathematics as lively and situated, and question dominant narratives of undergraduate mathematics. As Wertheim (2019) writes, understanding mathematics as living "enables us to recalibrate our relationship with the subject, reframing it as a mode of engagement in which we can highlight its joyous potential for all people" (p. 70).

Dissolving Mathematics: To Care for an Abstraction
Sofía Abreu
Anthony Dickson
Michigan State University
Group
Def: A group is a set G with a binary operation (law of composition) written · (or + if commutative) satisfying:
(1) $a, b \in G \Rightarrow a \cdot b = ab \in G \quad \forall a, b \in G$
(2) $(a \cdot b) \cdot c = a \cdot (b \cdot c) \quad \forall a, b, c \in G$
(3) $\exists e \in G$ s.t. $ea = a = ae \quad \forall a \in G$
(4) $\forall a \in G \ \exists b \in G$ s.t. $ab = ba = e$
Homomorphism
Def: Let G and G' be groups. A homomorphism $\varphi : G \to G'$ is a map such that $\varphi(ab) = \varphi(a)\varphi(b) \quad \forall a, b \in G$.
isomorphism
Def: A homomorphism $\varphi : G \to G'$ is called isomorphism if $\exists$ a homomorphism $\psi : G' \to G$ s.t. $\varphi \circ \psi$ and $\psi \circ \varphi$ are the identity maps on G' and G respectively.
...carrying with it histories, desires, and possibilities...
Where does the persistent preoccupation for 'sameness of forms/structures' in dominant math come from?
How are they interconnected (or not) with/in the world?
What stories can it awaken?
Why does isomorphism seek to preserve these particular structures? (e.g., group operations)
Stories need not be reduced to auxiliary metaphors towards the definition of isomorphism
Dissolving mathematics "like salt in food, you can taste it but not see it" (Fasheh, 2012, p. 94)
What possibilities are foreclosed?

Keywords: equity, discrete mathematics, instructor professional growth

For many students, discrete mathematics is a first exposure to formal logical reasoning, proofs, and proving. Undergraduates entering discrete mathematics have much experience with procedural problem solving and many attribute the authority for mathematical sense-making to textbook, instructor, or software (Herbel-Eisenmann, 2007). Like calculus courses, discrete mathematics shares a history of enormous disparities in outcomes correlated to demographic variables. For example at one institution, grade point averages (GPAs) in discrete mathematics, disaggregated by demographic groups privileged in society's majority culture and those marginalized in it were, respectively, 2.28 and 1.72 (Hsu, 2020). Yet subsequent course-taking requires at least a C, 2.0 grade points or higher. The 1.72 is a disqualification for further study.

Research in undergraduate mathematics education, notably in calculus, has indicated that disparities can be addressed by changes in student materials and instruction methods (Bressoud & Rasmussen, 2015). Groupworthy learning opportunities for students, and faculty use of socio-culturally informed instructional approaches, build positive relationships among students, between students and institution, and create active engagement in and outside of class (Archie et al., 2022; Johnson et al., 2020; Laursen et al., 2014; Leyva et al., 2022). Decades of reform in calculus has generated rich curricula, client-discipline informed policy, and most recently, instructor preparation to address the disparity (Yoshinobu et al., 2023). Now, in calculus, the GPA for groups privileged in society is above 2.0 *and* the GPA for historically marginalized groups is near 2.0 (Voigt et al., 2023). For calculus it took several generations of scholarly work to transform the system of structures, values, policies, and people to eke out a less inequitable state. No similar reform effort has occurred for discrete mathematics. Yet.

This poster (Campisi et al., 2024) reports on a state-wide effort in California to transform curriculum and instruction in discrete mathematics. Project research examines student and faculty experience of team-worthy lessons (as substitutes for lecture) and scaffolds for use. Early results indicate increases in students' sense of access to, and engagement in, the intellectual work of discrete mathematics, growth in instructor knowledge of equity-supportive practices, and a reshaping of instructors' views of students' capabilities. Ultimately, the project will:

1. generate a collection of seven team-worthy discrete mathematics lessons,
2. create and refine an asynchronous short-course for faculty who teach with such lessons,
3. gather data from students and faculty to inform lesson and short-course revision,
4. examine implementation in a variety of 2-year and 4-year college settings, and
5. participate in the revision of state policy for the content and processes/practices in discrete mathematics and a similar course in computer science called discrete structures.

Decentering and Interconnecting as Key Practices for Change Agency Leadership in Teaching-focused Professional Development for College Mathematics Instructors

Shandy Hauk
San Francisco State University

Natasha Speer
The University of Maine

Keywords: teaching-focused professional development, leadership, decentering, interconnecting

Research in undergraduate mathematics education (RUME) continues to identify features of high quality learning opportunities for students and explore what instructors need to know and do to create those opportunities. RUME also has illustrated features of effective teaching-focused professional development (TPD) for college instructors, characterized the complexity of the system in which TPD occurs, and examined the practices used by providers of TPD in seminars about teaching (Akin et al., 2023; Deshler, et al., 2015; Smith et al., 2021; Yee et al., 2023). Additionally, recent work has explored how development of two skills, decentering and interconnecting, may support professional growth of instructors as future change agents (Hauk & Speer, 2023a,b). *Decentering* is, at its most basic, the act of seeing from someone else's point of view (Teucher et al., 2016). While decentering involves perspective-taking, *interconnecting* is meta-awareness linking across perspectives and contexts and is key in developing and nurturing coalitions, an essential component of local and systemic change (Kotter, 2012; Manville, 2016).

What does it look like if we leverage what is known from the literature to consider the questions: What do providers of TPD need to know and do to create desired types of learning opportunities (for instructors, about teaching) and, more broadly, what are the features of high quality leadership development *for providers to support their growth into facilitators* (who teach about *teaching about teaching*) and *stewards of the discipline* (Bass, 2006)? In addition to supporting faculty in their work to be effective providers of TPD for novice instructors (middle layer of Figure 1) leadership-focused development experiences (outer layers in Figure 1) can scaffold providers to take on roles as stewards and agents for change in the realm of TPD.

In this poster (Hauk & Speer, 2024), we illustrate how stewardship, a particular kind of leadership in the complex system of mathematics instructional development, requires decentering and interconnecting. This model for professional growth of faculty agents for change expands on Figure 1. Earlier work described how instructional practices used by TPD providers (for graduate students) could be beneficial both for learning high-powered teaching approaches for undergraduate mathematics and for building a foundation for future change-agent work. Here we extend the model, with analogous arguments for facilitators and stewards. Ensuring that faculty have capacity as facilitators and as stewards is essential. Such faculty will shape efforts over time, informed by developments in RUME and in response to other developments in the discipline.

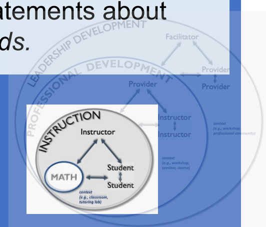
The text to the right describes acts of *decentering* and *interconnecting* done by instructors of mathematics. Use the words on green, blue, and yellow to transform these into statements about *providers, facilitators* and *stewards.*



Glossary

Decentering: the act of seeing from someone else's point of view [1,2].

Interconnecting: meta-awareness linking across perspectives and contexts response to other developments in the discipline [1,3,4].

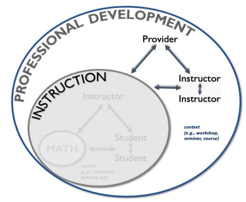
Student: learner of mathematics

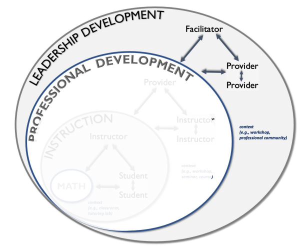
Instructor: person responsible for instruction in mathematics courses

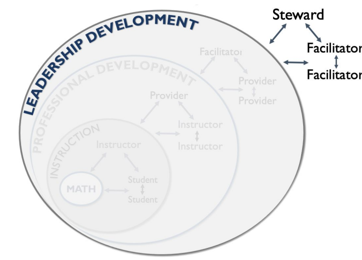
Provider: one who offers teaching-focused professional development to (often novice) instructors

Facilitator: one who offers professional learning for (sometimes novice) Providers.

Steward: one who shapes efforts over time to advance teaching-focused professional learning.







instructor | TPD | instructors | math/pedagogically

provider | facilitation | providers | math/pedagogically

colleague | stewardship | colleagues | professional change

Decentering

- learning to elicit <u>student</u> thinking
- learning how to shape <u>instruction</u> based on <u>student</u> thinking
- scaffolding <u>students</u> to contribute to <u>mathematically dense student</u>-to-<u>student</u> conversations
- being an expert participant rather than sole source of knowledge
- attention to <u>students</u> as (potentially) different from oneself

Interconnecting

- noticing how <u>student</u> conceptions may support or constrain how target <u>learning</u> progresses.
- knowing conceptions as well as the dynamics of communicating about them in a multi-contributor conversation
- selecting formats (e.g., group or pre-meeting activity) for <u>problem-solving about target learning</u>.
- connect across and prioritize <u>instructional / mathematical</u> and contextual factors, to decide what is professionally useful for <u>students</u>.

A Comparison of Tutors', Students', and Researchers' Perceptions of College Algebra Mistakes

Linda C. Burks
Santa Clara University

Mary E. Pilgrim
San Diego State University

Megan Ryals
University of Virginia

Experiences in first year mathematics classes predict persistence in a STEM major (Seymour & Weston, 2019). Retention becomes increasingly difficult when students need to develop foundational skills in prerequisite courses such as College Algebra. The development of study skills, including metacognitive skills, are often used to improve low success rates. As part of a study on the impact of metacognitive instruction for College Algebra students, we found that when reflecting on the reason for their errors, students often attributed exam errors to "simple mistakes." Researchers identified many of these mistakes as "not simple." Classifications of "simple" or "not simple" mistakes by undergraduate peer tutors, who provide support in campus learning centers, did not consistently align with either the views of students or researchers. We discuss student, tutor, and researcher views of mistakes and how they compare with each other.

Methods

For this IRB approved study, data was obtained from students in a College Algebra support course at a large, Western, public, Hispanic-Serving Institution. In semi-structured interviews, students classified recent errors on an exam as either simple or not simple and provided justification for their classifications. Transcripts of these interviews along with student work on the exams were analyzed to determine students' reasoning for classifying mistakes as "simple or "not simple." Data was later gathered from 11 undergraduate peer tutors at two institutions through an online questionnaire which presented five mistakes from the first college algebra exam. Iterative coding was used to analyze the tutors' reasoning for the mistakes.

Discussion and Conclusion

Researchers defined simple mistakes as ones that "could be made accidentally, would likely not be repeated, or violated a mathematical convention rather than a rule" (Authors, 2020b). Sometimes, tutors' classifications aligned with students' or researchers' classifications of simple and not simple; other times, the tutors were divided. Students sometimes distinguished between simple and not simple by the difficulty level of the problem or by how quickly they could see how to do the problem correctly when reviewing the exam. Student RG stated, "I think that a simple mistake is something that can be fixed without … a large amount of time" Tutors were similar to researchers in that they distinguished between simple and not simple mistakes by noticing if the student had demonstrated understanding previously. Different from both researchers and students, some tutors considered the amount of work it would take to correct the student's misconceptions. Tutor X stated, "A simple mistake is one that can be corrected (and the student would understand where they went wrong), with just a quick clarification. If the mistake requires a more in-depth discussion, then it is not simple." By comparing different views of mistakes between student, tutor, and teacher, we build a deeper understanding of how both tutors and instructors might better address student's misconceptions and misunderstandings.

A Comparison of Tutors', Students', and Researchers' Perceptions of College Algebra Mistakes

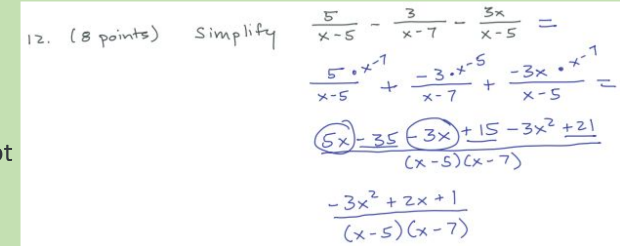
Linda C. Burks
Santa Clara University

Mary E. Pilgrim
San Diego State University

Megan Ryals
University of Virginia

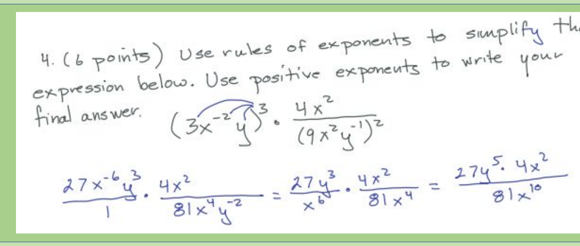
Mistake A

The student correctly began getting a common denominator for each term. The student did not correctly multiply the last numerator, which should have been $-3x^2+21x$.



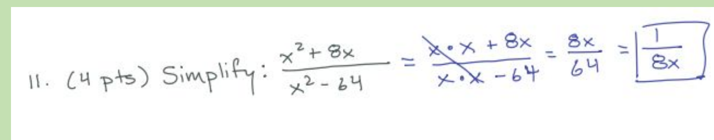
Mistake B

The student initially correctly combined exponents for the y-terms, but did not for the x-terms and the student did not reduce the coefficients.



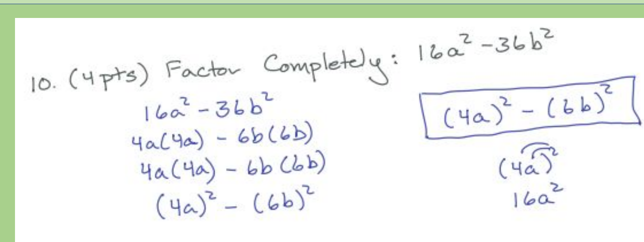
Mistake C

The student incorrectly canceled the x^2 terms in the numerator and denominator, which led to subsequent incorrect steps. Consider the first error of canceling the x^2 terms.



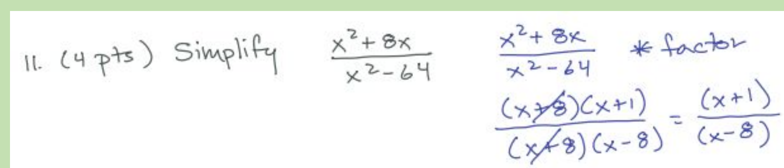
Mistake D

The student recognized the squared terms, but did not factor as a difference of squares to get (4a-6b)(4a+6b)



Mistake E

The student incorrectly factored the numerator as (x+8)(x+1). The student should have factored the numerator as x(x+8).



One Woman's Use of Learning Resources in Conjunction with Her Mathematical Identity

Brandi Rygaard Gaspard
Texas State University

Kristen Lew
Texas State University

Keywords: mathematical identity, learning resources, calculus

Calculus courses are critical turning points for university students. Reporting high Drop-Fail-Withdraw rates, retention in these courses is a problem (Voigt et al., 2017). Students, particularly calculus women, navigate decreasing attitudes towards mathematics (Good et al., 2012). For instance, Ellis et al. (2016) found that many women cited lacking confidence as their reasoning for not persisting after their calculus course.

Our study highlights how one woman employed learning resources in conjunction with her mathematical identity, where mathematical identity consists of her dynamic "self-understanding … in the context of doing mathematics" (Martin, 2006, p. 206). We aim to address the following research question: How does one woman calculus student use learning resources and how does her usage of those resources connect with her mathematical identity?

Methods

We conducted three semi-structured interviews with a university freshman, Becca, who was taking a calculus course designed for non-STEM majors at a large southern university. Interviews focused on Becca's perceptions towards her experiences in the course, how she viewed mathematics, and how she viewed herself in mathematical contexts. Analysis consisted of open coding to flag instances in which Becca described learning resources she felt supported her academic success or described a more stable sense of self in reference to mathematics – consistent with the definition of "core mathematical identity" (Cobb & Hodge, 2010).

Results

Becca's learning resources and mathematical identity were interrelated. She viewed herself as an organized mathematics learner focusing on step-by-step approaches, which led her to systematically use learning resources to process the concepts on her own. For example, Becca used apps that provided worked examples of her homework problems. Rather than copying answers, Becca focused on understanding and replicating these processes. We interpret Becca's intentional use of resources as influenced by her identity as an organized mathematics learner.

Becca's use of learning resources also impacted her mathematical identity. In particular, learning resources had a positive impact on her confidence related to mathematics. Reflecting on her instructor's open lab, in which she practiced solving problems, Becca explained, "[…] ***if I can do it now, then I can do it later*** […] when I went to the lab and I was like, so stuck on those problems then I, like, figured it out, it just like, like amazed me […]" *(author's emphasis)*. This quote suggests that the lab gave Becca confidence in her ability to solve problems.

While Becca's use of learning resources may appear to put her in danger of becoming dependent on them, we observe that she has found a way to transfer learning resources to her own knowledge in alignment with how she views mathematics, ultimately leveraging them to perceive herself as capable to persist mathematically.

Acknowledgment

We would like to thank Robert Sigley for their support in the design of this study.

Engaging Preservice Elementary Teachers in Statistical Investigations of Systemic Racism in School Discipline Data

Liza Bondurant, Mississippi State University
Anthony Fernandes, UNC Charlotte
Ksenija Simić-Muller, Pacific Lutheran University
Travis Weiland, University of Houston

In this poster, we share preservice elementary teachers' (PSTs') initial noticings during exploratory data analysis of materials focused on developing content knowledge of statistics as well as normalizing conversations of race in math class. The content covered is typically included in college-level introduction to statistics courses. We summarize PSTs' noticings and wonderings of an interactive data dashboard presenting racial disparities in school discipline.

Racial disparities in school discipline are a significant issue with lasting effects (Huang, 2018; ProPublica, 2023). To illustrate, Black students are suspended at a rate three times higher than their white counterparts (USDEOCR, 2014). These disparities are rooted in prevailing racial narratives that influence teachers' perceptions of Black, Indigenous, and People of Color (BIPOC) students and impact their math identities (Aguirre et al., 2013). Implicit biases may help explain these disciplinary disparities (Gilliam et al., 2016). Since about 80% of U.S. teachers are white, we must raise awareness of these disparities (NCES, 2023).

Inspired by Paulo Freire's critical pedagogy, we focused on critical thinking, empowerment, social justice, and collaborative dialogue to engage PSTs in addressing this issue (Freire, 2004). We developed instructional activities for secondary PSTs, combining statistical investigations with social justice concepts, contributing to the growing body of work on using data analysis to examine social justice issues (Bondurant et al., 2022; Casey et al., 2023). After implementing, we adapted it for elementary PSTs, emphasizing elementary math content and pedagogy, specifically operations with fractions, decimals, and percentages, and utilizing virtual manipulatives to teach math concepts (Suh & Roscioli, 2023).

This poster delves into elementary PSTs' initial observations of an interactive data dashboard focusing on racial disparities in school discipline. We aimed to answer the research question: When presented with such data, what aspects of racial disparities do PSTs notice? Using open coding, we identified themes in PSTs' responses, highlighted representative quotes, and determined frequencies for each theme (Corbin & Strauss, 2014). The findings revealed four key themes in PSTs' responses: "Personal connections" encompassed experiences as students or school employees; "Academics" focused on course offerings, graduation rates, and standardized test scores; and "Discipline" involved comments about behavior, classroom management, and suspension data. Surprisingly, only one PST mentioned discipline, and none discussed racial disparities. We employed nudges in the form of assessing and advancing questions to guide PSTs' attention toward racial disparities (e.g., "What do you notice about the suspension rates of Black and white students and why might this be?"). The impact of these nudges was not within the scope of this poster. Our findings suggest that PSTs may be uncomfortable discussing race and discipline or may not perceive them as relevant to their role as math teachers. These findings point to a need for math teacher educators (MTEs) to explicitly connect mathematics topics with social justice issues (Conway et al., 2022). Future research could explore the impact of different nudging techniques in this context.

Keywords: calculus, first-generation students, beliefs, problem-solving

The retention of college students in the Science, Technology, Engineering, and Mathematics (STEM) fields has been widely studied (e.g.; Rasmussen & Ellis, 2013; Sithole et al., 2017). Less research has focused on students traditionally underserved by the educational system (e.g., Carver et al., 2017). Understanding students' beliefs in mathematics can improve achievement and motivation (Muis, 2004), which has inspired research on the beliefs of several student populations (e.g.; Berkaliev & Kloosterman, 2009; Sangcap, 2010; Sintema & Jita, 2022; Yavus & Erbay, 2015). There is still a need to explore the beliefs of first-generation students, as little confidence in the ability to solve mathematics problems is related to lower academic performance (DeFreitas & Rinn, 2013). Since calculus is key for college STEM retention (Rasmussen & Ellis 2013), our study explores the beliefs that first-generation calculus students hold based on the Indiana Mathematics Beliefs Scale (IBMS) to inform on the retention of first-generation calculus students.

Methods

The study was conducted at a public, Ph.D.-degree granting institution in the midwestern United States implementing a quantitative research approach (Johnson & Christensen 2019). Demographic information such as gender and major was collected via a questionnaire. The IBMS (Fennema & Sherman, 1976; Kloosterman & Stage, 1992) contains 36 Likert-type scale questions measuring six beliefs about mathematical problem-solving, each including six questions that positively or negatively reflect it. The extensively used and validated (e.g.; Ayebo & Mrutu; Berkaliev & Kloosterman 2009) IBMS survey was distributed to 16 calculus classes with a total of 362 students. We collected 224 responses (61.9% response rate) and analyzed responses to identify students who self-identified as first-generation by reporting the highest degree achieved by one of their parents being less than a four-year degree in college. In the analysis, we assigned numerical values to the responses and adjusted for questions that had negative statements toward the beliefs. Then, we used descriptive statistics and an independent sample t-test on the average score of students by belief.

Results & Discussion

From the 94 first-generation students' responses to the demographic survey, we found that this was composed of 40 women, 53 men, and one non-binary student. We also found that within this subset of participants, 14 were black, 41 were Hispanic, and none were indigenous. Respondents most strongly believed that "understanding concepts are important in mathematics" and "mathematics is useful in daily life," but this is not the case for the belief that "there are word problems that cannot be solved with simple, step-by-step procedures." Using an independent samples t-test to compare the average score of each belief for both men and women, there were no significant differences seen ($p>0.05$).

Intro-to-Proof Students Discuss Logical Implication and Quantification: Themes from the Triangle Group

Alejandro Ortuno

Keywords: proofs, logical implication, quantification, epistemological obstacle

Research has shown that students in introduction-to-proof courses encounter epistemological obstacles (EOs, or persistent challenges; cf. Brousseau, 2002) in learning and reasoning about core concepts, even in the face of research-based instruction (e.g., Norton et al., 2022, 2023). Quantification and logical implication are two major course topics that are seen for the first time in the case of most students; consequently, they tend to experience challenges when working with mathematical statements, which are then reflected as specific EOs. In our ongoing research project, we investigate students' experiences in introduction-to-proof courses with particular attention to eliciting and addressing students' EOs. Data from our project include whole-class discussions, one-on-one interviews with students, and small group discussions. In this poster, we present findings from our analyses of the discussions of one small group.

Our methods included analyzing video data from a group of students (the "Triangle Group") working on mathematical tasks during an undergraduate introduction-to-proof course. Tasks were drawn from existing research on the teaching and learning of mathematical proofs (e.g., Hub & Dawkins, 2018; Shipman, 2016). During the completion of these tasks, students in the small group were able to discuss their strategies and any mathematical insights or challenges that they experienced. Consistent with basic qualitative data-analytic methods (Merriam & Tisdell, 2015), we analyzed students' discussions and found patterns in students' reasoning—patterns that constituted the themes shared in this poster.

Three major themes emerged from our analyses. The first major theme involves students establishing constraints on the universal set when reasoning about mathematical statements. For example, the group was asked to negate the statement, "for all nonnegative real numbers x, $\sqrt{x} \leq x$." They responded, "for all nonnegative real numbers less than 1, $\sqrt{x} > x$," constraining the truth set to the interval (0, 1). The second theme involves students providing a counterexample when asked to find the negation of a statement. Using the same statement as above, the Triangle Group said the negation would be given if they "define x and write the exact same thing, [the statement] will be false." Specifically, they said P(x) is false if $x = 0.01$, finding a counterexample to the given statement. Lastly, the third theme explores how small group discussions can help students address EOs. For instance, students in the course were asked to consider how the statement, "the matrix A is invertible," is an existence statement. We inferred that this task elicited hidden quantification (Shipman, 2016), which is the EO caused when quantifiers are not explicitly stated in a mathematical statement. However, the Triangle Group seemed to be able to address this EO through their small-group discussion about the task.

Motivation

- ***Epistemological obstacle (EO)****:* a persistent challenge in one's learning, even in the fact of best instruction (Brousseau, 2002; Norton et al., 2023)
- Research shows students encounter specific EOs related to core concepts about proof and proving (Arnold et al., in press; Norton et al., 2022, 2023; Shipman, 2016)
- The Proofs Project aims to identify EOs and design instructional strategies for supporting students by eliciting and addressing EOs directly

Methods

- The Proofs Project collected data from whole-class discussions, small-group discussions, and clinical interviews with students
- Tasks designed by The Proofs Project or adapted from published research (e.g., Dawkins & Roh, 2020; Hub & Dawkins, 2018; Vroom, 2020)
- Regular opportunities for discussion provided in class for students to share ideas, strategies, and challenges
- Analyzed video data from small groups of students working on tasks during an intro-to-proofs class
- Focus of this presentation on the "Triangle Group"
- Identified regularities in qualitative findings from our analysis of small-group discussions, constituting the themes shared here (Merriam & Tisdell, 2016)

Theme 1

Students place constraints on the universal set when reasoning about mathematical statements.

Task 1

Determine if the following statement is true or false. "Suppose a, b, and c are integers. If $|a-b|<5$ and $|b-c|<5$, then $|a-c|<5$."

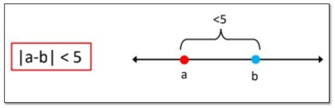

Fig. 1: Visual representation for Task 1

"Since it's an absolute value, we know at least one of them [a or b] has to be <u>over 5</u>. Or... I don't know. There's some sort of <u>constraint</u> about a and b, like <u>over 5 or under 5</u>, or something like that."

Task 2

Negate the statement. "For all nonnegative real numbers x, $\sqrt{x} \leq x$."

"For all nonnegative real numbers <u>less than 1</u>, $P(x)$ is false."

Constrained the universal set to the interval (0,1).

Theme 2

Students provide a counterexamples when asked to find the negation of a statement.

On Task 2, Triangle Group initially found a counterexample to the statement.

"Don't we just need to find a value of x where the square root of that number is greater than? ... $P(.01)$ is false"

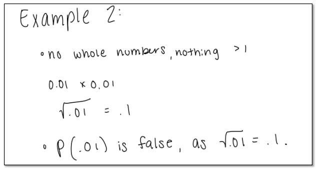

Fig. 2: Group's work on Task 2

Progressing from identifying a counter-example to writing a negation of the statement posed a challenge.

- **S1: So then the whole statement is false. Therefore, $P(x)$ is false.**
- **S2: So, in order to make this statement true—**
- **S3: Well, $P(x)$ is the open statement. So, all of $P(x)$ isn't false. 'Cause, $P(x)$ is true for like 2 or 3. So I think we can just say that, um, just statement P of .01 is false.**

Theme 3

Small group discussions can help students elicit EOs and work together to begin addressing EOs.

Task 3

Explain how the statement "Matrix A is invertible" *is an existence statement.*

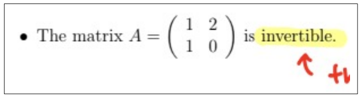

Fig. 3: Statement for Task 3

Task designed to elicit the EO of hidden quantification (Shipman, 2016).

"It's kind of like saying, *there exists* a matrix such that [A] is invertible."

Group member unveils the hidden quantifier, reframing the statement as an existence statement.

Task 4

Prove or disprove the statement.

"If x > 0, then $x + \frac{1}{x} \geq 2$."

Statement contains a hidden universal quantification. Through working together, the group was able to unveil the universal quantifier and work together to negate the statement.

"...the way you would negate it would be 'there exists', right?"

Purpose

To share themes from qualitative analysis of one small group's discussions about research-based tasks during class

Keywords: Department change, introductory math, student voice, equity

The proposed poster describes information collected from a case study of a DEI initiative in the math department at Kappa University (KU). In Spring 2023, a Networked Improvement Community (NIC) of faculty members and administrators began meeting monthly to discuss DEI in introductory math at KU. After one semester, in recognition of the need to better attend to Gutiérrez' critical axis of equity (2002), the NIC leaders solicited applications from undergraduate and graduate students. Applicants were asked "Why are you interested in joining the KU Networked Improvement Community (NIC)?" We use the 117 application responses as data to answer the question: *What motivates students at KU to get involved in DEI work in the mathematics department? How do students bring their identities into these motivations?* We conceptualize students' desired engagement in the NIC as involving "joint action for a common good," within the "voluntary organizational activity" of NIC participation (Ansala et al., 2016, p. 151). Ansala and colleagues detail five emergent themes which motivated students' engagement with activism: *social* motives of engaging collaboratively, motives of *influence* related to a desire to have a positive impact, motives emphasizing the *benefits* of engaging in activism, motives related to activism as a *lifestyle*, and motives of pure *coincidence.* We utilized the former four themes as first-level *a priori* codes. We also found a need to attend to student identities, framed with a critical sociocultural lens (Esmonde et al., 2009), which articulates both *social identities* and *practice-based* components of a person's identity. The social components are the socially constructed aspects of one's identity, that are both imposed on people by society and that we impose on ourselves. The practice-based identities are developed through our participation in cultural practices. This perspective on identity encourages attention to how social identities interact with and inform practice-based identities. Here, we explore how students evoke their identities in their expressions on wanting to join the DEI work in the mathematics department.

Our preliminary analysis shows that of the 117 applicants, 50 referenced a component of their social identity as salient to their application. The social identities they cite include race, gender, sexual orientation, being a first generation student, being an international student, being low income or rural, and disparate access to calculus before college. Among these students, 27 also reference either having previous positive experience with math, a very strong math identity, or referenced mathematical struggles. Additionally, 104 out of 117 cited a desire to have influence as a component of their motivation for their participation in the NIC, often in the context of making the mathematics program or its associated classes a more positive experience for other students. This often included reference to their own identities; a student remarked, "*as a Latina woman, I usually find myself pretty isolated in the fields of STEM…I would love to be a part of transforming the world of mathematics, especially at KU, into one that is accepting and transformative for people like me.*" In the poster, we highlight student voices behind the motivations and patterns of how students motivate their participation in an equity-oriented NIC.

Self-reported Student Motivations to Participate in DEI Service Work

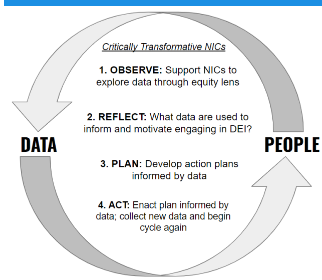
Shira Viel[1], Victoria Akin[1], Jessica Ellis Hagman[2], Rachel Tremaine[2], Kaylee Fantin-Hardesty[2], and Nancy Kress[3]

[1]Duke University, [2]Colorado State University, [3]University of Colorado, Boulder

Background

Existing structures in college math departments that don't attend to students' varied identities may compound feelings of exclusion in introductory courses [5]. Thus, there is a need to interrogate and challenge the systems currently in place, particularly at the level of college calculus. Students, as experts in their own experience, play an important role in such DEI initiatives. As D'Ignacio and Klien assert in Data Feminism, leveraging experience and emotion as sources of data has the potential to inspire systemic change [2].

Kappa Networked Improvement Community (NIC)



NIC Improvement Cycle

In 2022, a team of faculty members at Kappa University (Kappa), as part of a multi-institution collaboration, began work toward critically transforming their introductory math courses. They assembled a "Networked Improvement Community" (NIC) of faculty, staff, and administrators who met monthly to discuss potential changes in the Calculus sequence at Kappa. After one semester of work, NIC leaders recognized the need to better attend to Gutiérrez' critical axis of equity [4] in understanding and addressing student experiences in Calculus at Kappa and the intersection of these experiences with student identities and backgrounds. Thus, it became essential to not just gather data on student experiences but to incorporate students into the NIC itself. In Summer 2023, the NIC leaders solicited applications from graduate and undergraduate students to join the NIC. As a case study, we analyze responses to the single application question, "Why are you interested in joining the Kappa NIC?"

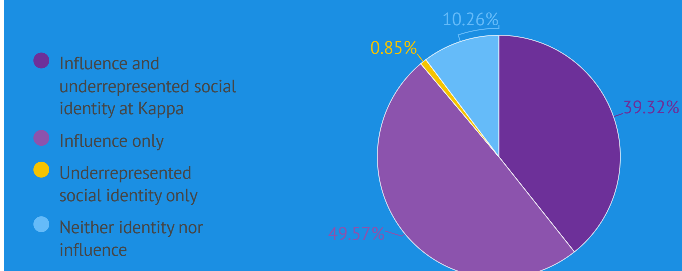
Research Question 1: Motivations

What motivates Kappa students to get involved in math department DEI work?

We conceptualize students' desired engagement in the NIC as involving "joint action for a common good," within the "voluntary organizational activity" of NIC participation [1], and thereby used Ansala et al.'s four themes as *a priori* codes:

- **Influence (89%)** → Desire to participate in decision-making, ensure values are represented, and/or influence change.
- **Benefit (35%)** → Desire to learn more, gain skills and/or apply skills in a way that complements university studies.
- **Social (18%)** → Desire to collaborate and/or make friends. May describe being drawn to DEI through friendship.
- **Lifestyle (16%)** → View activism as part of their identity. May cite prior experiences with activism as motive.

Students cite desire for influence and social identities as motivations to join DEI-focused intro math Networked Improvement Community.



Self-reported applicant motivations, n=117

Student Voices

Influence **Social identity**

As a Latina woman, I usually find myself pretty isolated in the fields of STEM, rarely coming across professors or other students who look like me. I would love to be a part of transforming the world of mathematics, especially at [Kappa], into one that is accepting and transformative for people like me.

Benefit

I am interested because it seems like a good opportunity to help [with] on going research at [Kappa]. I want to get better at interviews which will be beneficial to me.

Social Motivation

What excites me most is the chance to collaborate with a diverse group including faculty, instructors, and fellow students. I am enthusiastic about participating in data collection, analysis, and collaborative efforts within the [Kappa] NIC that accommodate different learning styles and backgrounds.

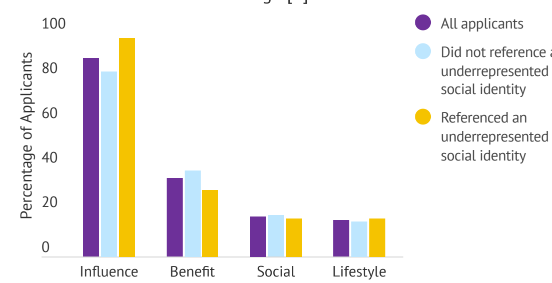
Lifestyle

As a lifelong activist, I have always fought for change and equity as much as is possible in the environments I inhabit. Nowhere is this more relevant than in the courses that I take, where I do not see the diversity of students that I would expect to find at a diverse institution. I want to join the NIC so that I can help make math courses, nationwide, a more welcoming place for all, so that all students are comfortable in the math classroom and all can forget about its looks to focus instead on expanding our knowledge in the field.

Research Question 2: Intersection with identity

How do Kappa students bring their identities into these motivations?

47 of the 117 applicants referenced a component of their social identity [3] that is underrepresented in math at Kappa as salient to their application. Underrepresented identities that were referenced by students related to race (13.7%), gender (8.5%), sexual orientation (3.4%), high school math preparation (4.3%) being a low income or rural student (11.1%), being a first generation student (6%), and being an international student (6%). **Students who referenced an underrepresented identity were significantly more likely than those who did not to also express a desire for influence as a component of their motivation for participation.** This was often in the context of making mathematics courses at Kappa a more positive experience for other students, resonating with Gutiérrez' critical axis of equity and a desire for structural change [4].



Self-reported applicant motivations, n=117

An Integrated Teaching Model for Post-Covid Graduate Teaching Assistants Professional Development

John Sevier
Appalachian State University

Keywords: GTA Professional Development, Teacher Preparation, Online Instruction

The roles and expectations for many of the GTAs vary across higher education, from assisting instruction through grading and tutoring on a small scale to teaching entire mathematics courses. Graduate teaching assistants (GTAs) are indispensable assets in many undergraduate learning programs in higher education (Di Bendetti et al., 2022; Lang et al., 2020; Mutambuki & Schwartz, 2018). Higher Education has responded to the growing demand for teaching staff by utilizing GTAs in many gateway courses, including entry-level mathematics courses. It is assumed that if GTAs have a background or a degree in mathematics, they can support and teach mathematics. Unfortunately, many of these GTAs have little to no prior teaching experience (Choate et al., 2021; Di Bendetti et al., 2022; Jonnalagadda et al., 2022; Lang et al., 2020; Mutambuki & Schwartz, 2018). This issue only intensified after many educational programs and clinical practice (student teaching) experiences were altered, shortened, or eliminated outright in March 2020 due to COVID-19 (Choate et al., 2021; Flores & Swennen, 2020). Many students now have a perceived gap (K-12 and post-secondary) in content understanding due to the sudden shift to online learning. This gap is especially impactful on mathematics students and pre-service educators (Choate et al., 2021; Flores & Swennen, 2020; König et al., 2020). Many GTAs entering graduate mathematics programs during this time were expected to support students in the gateway mathematics courses with little to no training or professional development. Many higher education institutions provide some professional development, including one-day workshops, one-credit courses, observation/shadowing opportunities, mentoring, and microinstruction, but few provide any extensive, effective teacher training (Di Bendetti et al., 2022; König et al., 2020; Lang et al., 2020). Even so, many GTAs still are underprepared for future teaching beyond graduation (Choate et al., 2021; Lang et al., 2020). However, with the sudden shift to online learning, there needs to be a new emphasis on GTA professional development and effective teaching training to help engage students affected by the changes in mathematical instruction.

This poster will present the development and implementation of a comprehensive GTA effective teacher training and professional development model created to tackle and address the need for a more conducive and thorough professional development framework for teaching and assisting mathematics GTAs in the post-Covid era and the sudden shift to online instruction. This model is divided into three phases and covers a four-term (two-year) graduate program that incorporates clinical teaching (in-person and online), a mentoring program, micro sessions of professional development, peer and student feedback reflections. This poster will review the model with collected GTA insight from the past three years (Fall 2020- Fall 2023) on the impact of their experiences within this model. Specific highlights will focus on areas GTAs felt most prepared in content understanding, pedagogical preparedness, and beliefs about entering the mathematics classroom. The aim is to provide other mentors insight to better support the educational growth of GTAs and other preservice mathematics teachers.

Stakeholders' Perspectives on a Coordinated Developmental Mathematics Course

Introduction

From my own experience as a graduate student and adjunct instructor of developmental mathematics courses (DMCs), I was interested in contributing to the field of developmental mathematics (DM) research by conducting an exploratory, qualitative study documenting the perspective of educator stakeholders involved with College Algebra, a second-level DMC. The participants, informed by their experiences and values as educators, demonstrated a strong commitment to their students, expressing hope for students' mathematics future and a desire to improve their practice.

Research Questions

1. How do stakeholders describe the purpose, goals, and outcomes of College Algebra?
2. What kind of professional development (PD) do DMC instructors receive and what PD would they like to receive?

Methods

I interviewed five stakeholders involved with College Algebra, the math department's second level DMC.

- John (he/him), adjunct instructor
- Diane (she/her), non-tenure track instructor
- Nancy (she/her), course coordinator
- Sarah (she/her), coordinator of developmental math
- Rae (she/her), leadership in math department

For the past several years, the math department has undertaken efforts to redesign its DMCs in response to the needs of the growing DM student population. These efforts were mentioned by nearly all the participants and meaningfully shaped our conversations.

Big Ideas

Stakeholders unanimously stated the goal of College Algebra as **preparing students for pre-calculus and beyond**.

The stakeholders valued **gaining pedagogical content knowledge** through the **experience of teaching**.

For more details on my study, scan the QR code or email me at katherine.j.burke@temple.edu, I'd love to continue our conversation!

Results

Participants described the development of students' academic maturity as another necessary purpose of this entry level course; they expressed a willingness and desire to help their students make the transition from high school to college. Overall, the participants viewed College Algebra as successfully achieving its preparatory purposes, especially since the DM redesign. Similarly, though PD had not been a requirement for DM instructors in the past, with the concerted attention paid to DMCs going forward, upper-level stakeholders described the creation of PD attuned to the needs of DM instructors; a new grading PD session was well-received and appreciated by a participant of this study.

Discussion and Future Work

The participants of this study provided insight into the systemic operation of developmental mathematics, as well as perceptions of this system and the DM student population. With recent DM redesign efforts, the participants depicted an increasingly cohesive and comprehensive program that works to serve and support both its instructors and students. That said, the means through which the branches of this DM system achieve its aims warrant further study. I am interested in pursuing the following lines of inquiry:

- Building on this study with a larger population of instructional stakeholders, namely adjunct and graduate student instructors
- Repeating this study with first-level DMC educator stakeholders
- Investigating how DMC instructors support their students in practice
- Understanding how DMC instructors' enacted practices are perceived by students

Tracking Graduate Teaching Assistants' Responses through Sustained Professional Development

V. Rani Satyam Virginia Commonwealth University	Franklin Yu Virginia Commonwealth University	Rebecca Segal Virginia Commonwealth University
Mary E. Pilgrim San Diego State University	Mary Beisiegel Oregon State University	ELITE PD Research Group EHR #2013590, 2013563, and 2013422

Keywords: graduate teaching assistants, professional development, active learning

There is a strong need to support mathematics graduate teaching assistants (MGTAs) in leveraging active learning techniques in ways that are inclusive and equitable (Beisiegel et al., 2019). Mathematics graduate students make up a large section of the workforce involved in teaching introductory mathematics courses at Ph.D. granting universities (Selinski & Milbourne, 2015). Professional development geared specifically towards MGTAs would provide support and guidance (Kuechle, 2022). In this poster we examine: How do MGTAs' responses about teaching with active learning shift through a year of sustained professional development? We track three MGTAs' responses over time and describe their individual trajectories.

This is part of a large multi-site project focused on designing and implementing a multi-year professional development program for MGTAs. We report on data from one of the three sites, a public Southeastern university. Participants are graduate students who were teaching assistants for mathematics courses and took part in a teaching seminar in the fall and then an Introduction to Active Learning course in spring. Each of these professional development structures involved readings and activities in and out of class. These included reading Su (2016)'s *The Secret Mathematical Menu* and sessions on facilitating group work, examining the meaning of equity, considering majority versus marginalized identities, and reflecting on problematic assumptions in teaching. Data consisted of exit tickets and reflections to the aforementioned activities and the overall course from graduate students who consented to the research.

Preliminary analysis of MGTAs' discourse reveals (1) increased sophistication in articulating their thoughts regarding teaching, (2) centering of students, and (3) intellectual need for learning more about issues of diversity, equity, and inclusion in teaching. For example, one participant wrote, "The course has given me more specific examples of what equity and inclusion look like specifically in classroom settings and ideas on how to implement them." Another participant wrote in her exit ticket at the end of the course, "I have learned new ways to be more inclusive" and included what she would still like to learn: "More about changing our own biases." This last finding corroborates MGTAs' readiness for the next phase of the professional development and research: to design and implement a more advanced course around issues of equity, where they can gain deeper awareness and tools to be prepared for teaching. In the poster, we will provide quotes and trajectories for three MGTAs who consistently shared, for how their thoughts shifted through the various professional development activities.

The Effect of Small Group Interactions on Opportunities for Student Learning

Lauren Surratt
Rhodes College

Erika David Parr
Rhodes College

Keywords: Group Work, Student Interaction, Calculus

Mathematics instructors frequently incorporate group work as a pedagogical tool to enrich students' comprehension and engagement. This approach promotes social interaction and encourages student autonomy, potentially leading to deeper student learning (e.g., Amit & Fried, 2005; Smith & Confrey, 1991). Our research investigates the intricate relationship between group dynamics and mathematical learning, specifically focusing on students' comprehension of graphs and distances within the Cartesian coordinate system. Understanding the impact of group dynamics on mathematical learning provides insights into how students collaboratively approach mathematical concepts, which can significantly influence their individual learning outcomes. Accordingly, we center our research around the following question: How do social interactions among undergraduate math students completing a graphing activity influence individual opportunities for mathematical learning?

Data for this study was collected from four sections of a Calculus II course at a small, private college in 2022 and 2023. The primary data source includes student work and 23 video recordings of small groups of 2-3 students working on an "Interpreting Graphs for Calculus Activity" during one 50-minute class period. This activity required students to write algebraic expressions to represent distances in one- and two-dimensional graphs. Data was also collected from students completing a pretest item before the activity, two questions on their third exam, and questions on their final exam, all assessing skills relevant to the graphing activity.

We draw on a preliminary analytical framework (Parr et al., 2023) to develop knowledge-based questions (e.g., who is being sought for knowledge?) and five questions related to social dynamics (e.g., who directs the group's activity?) to guide our video data analysis. Throughout video analysis, the first author created content logs, documenting key elements of students' behavior and interactions within the group work. Additionally, the first author documented emerging themes and patterns across group videos. Thus far, analysis has been conducted on ten videos, with plans to continue to analyze additional videos and work from the larger dataset.

Our analysis revealed a diverse spectrum of group interactions among students during the completion of the graphing activity. While some students demonstrated a high level of collaboration, others adopted a more independent approach, primarily cross-checking their answers and communicating only when uncertainties arose. Two prominent themes emerged across groups in the interactions, which impacted their responses to the tasks. First, the role of pattern recognition emerged, in which students validated solutions through pattern identification from previous tasks in the activity, valuing consistency. Second, the extent to which students were willing to correct their peers, reflecting variations in students' perceived comfort levels with correcting their group members, emerged as a significant distinction in varied opportunities for mathematical learning across groups.

The diverse group dynamics observed during students' group completion of the graphing activity highlights the need to comprehend the complex interplay between social interactions and mathematical learning. As our research progresses, we intend to use position codes to analyze selected episodes more closely from the videos that are expected to yield intriguing results.

Undergraduate Students' Mathematics Efficacy Change through Collaborative Projects in General Education Mathematics Course

Jinsook Park
University of Hartford

Keywords: Collaborative learning, General education mathematics, Mathematics efficacy

Some challenges of teaching General Education Mathematics Courses (GEMC) motivated us to investigate how doing collaborative projects affects undergraduate students' self-efficacy in mathematics. The problems we see in the GEMC include students' low self-efficacy in mathematics, low engagement, and negative attitudes toward mathematics. Many students in GEMC described mathematics as a challenging subject area and a mixture of formulas and intense calculation, not recognizing the close connection with real-life. The need to improve the student success rate in GEMC is pervasive (Aycaster, 2001; Harrington et al., 2016; Thiel et al., 2008). These issues led us to questions about changing these low and negatives to higher and positive. In addition to achieving the specific student learning outcomes, three main goals in our teaching include 1) promoting student self-efficacy, 2) boosting student engagement in mathematics, and 3) fostering students' recognition of the relevance of mathematics in the real world. Several research studies have presented that project-based approaches worked positively for students' academic achievement and interest (Han et al., 2015; Jacques, 2017; Larmer & Mergendoller & Boss, 2015; Lou et al., 2012; Remijan, 2017; Rice & Shannon, 2016; Tseng et al., 2013). We added two collaborative projects in Math 1004 (pseudonym), one of the GEMC, to get students more engaged and constructing their meaning in learning.

Five elements were considered in implementing the collaborative projects in Math 1004: 1) own team decision, 2) own topic decision, 3) online shared documentation, 4) presentation together, and 5) peer evaluation. Students could learn technical competency, communication, presentation skills, and mathematical content knowledge throughout this process. Students could develop competency in identifying the problems in the real world and how to present the issues related to the problem and demonstrate techniques.

To explore any change in students' mathematics self-efficacy and recognition of mathematics relevance in real life, the pre-and post-surveys were given in the two sections of the Math 1004 course in the fall of 2021. There were 22 participants in both the pre-survey and the post-survey. In the survey forms, students were asked to mark one of the Likert scales: Strong Disagree, Disagree, Not Sure, Agree, Strongly Agree.

In summary, the results of this pre-survey and post-survey presented a positive change in the participants' self-efficacy in applying mathematical knowledge, problem-solving and explanation quantitatively, mathematical interpretation, and writing ideas quantitively. The findings through these students' positive changes include the following: 1) The participants anticipated the relevance of mathematics in real life through collaborative projects in the GEMC. 2) The participants showed positive change related to efficacy in mathematics after completing the collaborative projects in GEMC.

It is necessary to understand better how collaborative learning approaches work related to students' efficacy in mathematics. Knowing more about what students value in their experiences of learning mathematics through a collaborative learning approach is essential for instructors to develop instructional strategies for positive outcomes in learning.

Undergraduate Students' Mathematics Efficacy Change through Collaborative Projects in General Education Mathematics Course

Jinsook Park, Department of Mathematics, University of Hartford

UNIVERSITY OF HARTFORD

Introduction

General Education Mathematics (GEM)

- Quantitative Literacy (Association of American Colleges and Universities, 2005; Bennett et al, 2008; Steen, 2004)
- Students Failing in GEM (Aycaster, 2001; Harrington et al., 2016; Thiel et al., 2008)
- Students are less confident in mathematics (Ellis et al., 2016; Hall & Ponton, 2005; Hill et al., 2010; Sadler & Sonnert, 2017).
- Mathematics is frustrating (Hoyles, 2016; Riegel, 2021).

Motivation

Issues Noticed in My Teaching Experiences

- Low self-efficacy in doing mathematics
- Low engagement
- Low interaction
- Difficulty in developing written communication summaries after/during their verbal discussion.
- Difficulty making the task align with other elements such as context and purposes.

Change in My Teaching

- Provide more meaningful learning opportunities for students to have a more positive orientation towards mathematics.
- Collaborative Projects in GEM

Elements Considered in the Implementation of Collaborative Projects

- Students' own team decision
- Students' own topic decision
- Online shared documentation to progress-check
- Presentation together
- Peer evaluation

Method

Ontological Assumptions

- "Realities are multiple, constructed, and holistic" (Lincoln & Guba, 1985, p. 35).
- Each student's experience constructs their reality, which is related to their learning.
- "Knowledge is constructed by learners as they attempt to make sense of their experiences" (Driscoll, 2000, p. 376).

Research Question

- How do students change in efficacy in mathematics through collaborative projects in the General Education Mathematics course?

Data Collection

- We added two collaborative projects in Math 1004 (pseudonym), one of the GMC.
- Pre-survey and post-survey were given in two sections of the Math 1004 courses in the fall of 2001.
- There were 22 participants in both the pre-survey and the post survey.
- In the Survey forms, students were asked to mark one of the Likert scales: Strongly Disagree, Disagree, Not Sure, Agree, Strongly Agree.

Results

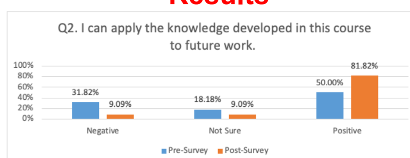

Figure 1: Students' self-efficacy change in applying mathematical knowledge in pre-survey and post-survey.

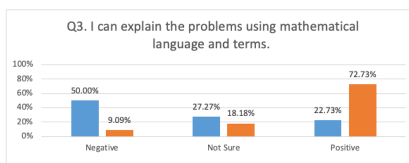

Figure 2: Students' self-efficacy change in problem-solving and explanation mathematically.

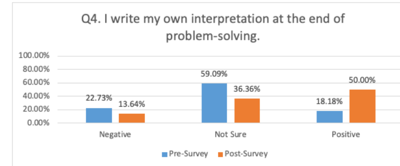

Figure 3: Students' self-efficacy changes in interpretation after mathematical problem-solving.

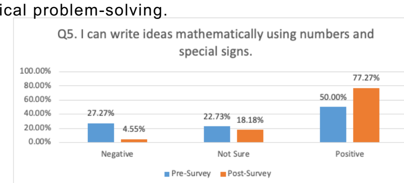

Figure 4: Students' self-efficacy changes in writing ideas mathematically.

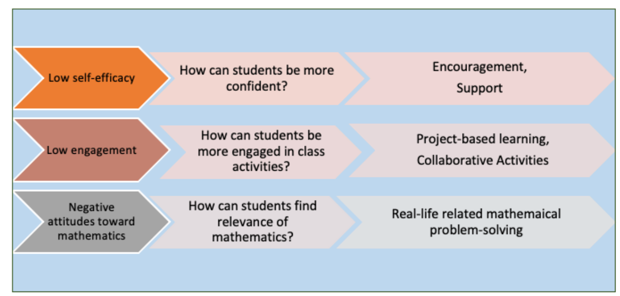
The participants showed positive change related to efficacy in mathematics after completing the collaborative projects in GEM.

Discussions

- The participants anticipated the relevance of mathematics in real life through collaborative projects in the GEM.
- The students interacted more actively and constructively during class and outside class.



- Knowing more about what students value in their experiences of learning mathematics through a collaborative learning approach is essential for instructors to develop instructional strategies for positive outcomes in learning.

Acknowledgments: This research was supported by a Davis Fellows Grant from the University of Hartford. The views expressed here are those of the author and do not necessarily reflect those of the University of Hartford.

Project Adelante: An Anti-deficit Professional Development Program for University Mathematics Instructors

Aditya P. Adiredja
The University of Arizona

Marta Civil
The University of Arizona

Becca Jarnutowski
The University of Arizona

Keywords: antideficit perspective, professional development, community engagement

In this report, we share the design of a year-long professional development program for university math instructors that we developed and refined as the Anti-deficit Learning and Teaching Project (Adelante). The program is a community learning project wherein minoritized students, STEM peer mentors, and math instructors (graduate students and instructional faculty) build relationships as they share their knowledge and experiences with race, gender, and mathematics. *Culturally relevant pedagogy* (Ladson-Billing, 1995) frames the goals of the community learning in terms of deep mathematical knowledge, cultural knowledge, and sociopolitical consciousness. The program activities are inspired by the *Funds of Knowledge for Teaching* project (Moll et al., 1992) wherein teachers are offered opportunities to build meaningful relationships with students and their communities.

An anti-deficit perspective (Adiredja et al., 2020) guides the learning experience for all participants. Not only are minoritized students assumed to have cultural and intellectual assets for learning, but the project also aims to dismantle *deficit master narratives* (Solórzano & Yosso, 2002) about these students and their capacity to learn. Instructors worked on explicitly challenging deficit narratives about their students as they engaged in the program's activities. The project also takes an anti-deficit approach to instructor development, focusing on their individual growth and agency, joy in teaching, and mental health. We also position ourselves as learners to the experience and wisdom of the staff and students at the university cultural centers.

The core activities for the PD engage teachers to: (a) participate in five PD meetings on anti-deficit teaching and Inquiry Based Learning (IBL) teaching method; (b) lead a five-day math summer bridge workshop in Pre-Calculus, Calculus I, II, Vector Calculus, or Linear Algebra immediately following the meetings; (c) participate in critical conversations about race and gender in STEM with students at the cultural centers; (d) conduct a semi-structure interview with one of their students from the summer workshop about their STEM experience; and (e) participate in group reflection meetings debriefing their experience in the activities.

Preliminary analysis of two of the three cohorts of participants found that most instructors developed a more humanizing approach to their teaching and their students (Gutiérrez, 2018). IBL helped instructors to explicitly challenge deficit narratives about minoritized students in the classroom, wherein most observed their students engaging in deep mathematical reasoning. Interviewing one of their students also shifted deficit narratives that developed in the classroom for some instructors. The workshop served as a space to try out previously learned teaching ideas (student centered teaching) without constraints from curriculum and assessments. Doing so reinvigorated many instructors' passion for teaching, especially those who are more experienced.

From Conflict to Unity: Leveraging Incoherence in Student Thinking to Improve Understanding

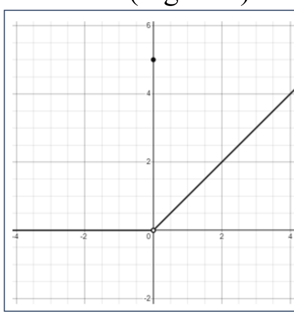
Steven Ruiz
Arizona State University
slruiz3@asu.edu

Keywords: schemes, coherence, teaching experiment, proof-texts, continuity, differentiability

Many methodological approaches, such as clinical interviews (Clement, 2000) and teaching experiments (Steffe & Thompson, 2000) are well-equipped for investigating the schemes and constructed knowledge of individuals (Glasersfeld, 1988). Sellers (2020) extended the teaching experiment to the exploratory teaching interview for when the researcher aims to influence student thinking but is not testing a pre-determined hypothesis. Numerous researchers have tasked subjects with reading proofs to probe their thinking (e.g., Dawkins & Zazkis, 2021). I used proof-texts during a teaching experiment which modeled a subject's thinking. This approach was profoundly effective in revealing inconsistencies to the subject in her thinking.

Incoherence as a Basis for Task Design

The lone participant in the study, Rachel, sat for a series of six interviews designed to probe her understanding of the chain rule of differentiation and its underlying ideas, such as continuity, differentiability, and function composition. On several occasions, she evidenced conceptions relevant to the tasks which I conjectured would result in her acknowledging a conflict if presented properly. For example, during the first interview, Rachel stated that a function f was continuous at a if a was in the domain of f. Later in the interview, she said that f was continuous at a if $\lim_{x\to a} f(x)$ existed, regardless of whether a was in the domain of f. Though she did not initially indicate that she found her thinking inconsistent, presenting her with proof-texts which imitated her thinking was effective in helping her recognize conflicts in her thinking and the need to reconcile them (Figure 1).



Claim: f is continuous at $x = 0$.
Proof:
- $\lim_{x\to 0^+} f(x) = 0$
- $\lim_{x\to 0^-} f(x) = 0$
- Since the one-sided limits agree, $\lim_{x\to 0} f(x) = 0$.
- Therefore, f is continuous at $x = 0$.

Claim: f is continuous at $x = 0$.
Proof:
- From the graph, we see that $f(0) = 5$.
- Since f is defined at $x = 0$, f is continuous at $x = 0$.

Figure 1: Graph of Function and Accompanying Proof-Texts

Discussion and Future Steps

The interventions in the teaching experiment were designed only to focus on sources of incoherence (Thompson, 2008). As such, my only desired learning outcome for the experiment was to perturb Rachel's schemes (Glasersfeld, 1988) and observe how she assimilated the new stimuli. Resolving conflicts allowed Rachel to cultivate a much deeper understanding of the target concepts. As such, the methodological combination of exploratory teaching interviews (Sellers, 2020) and proof-texts which imitate the subject's thinking warrants further implementation and investigation.

Argument-Mirroring Proofs:
A Methodological Approach for Helping Students Recognize Incoherence in Their Thinking

Steven Ruiz, Arizona State University

Theoretical Backing

- Radical Constructivism (Glasersfeld, 1988)
  - *Scheme* – a discrete unit of knowledge possessed by an individual
  - *Perturbation* – when expectation associated with a scheme is different from what occurs
  - *Accommodation* – action taken by an individual to account for a perturbation
    - E.g., adjustment of scope of schemes, rejection of schemes, rejecting perturbation as anomaly
  - *Coherence* – the extent to which a thinker's schemes are consistent with one another (Thompson, 2008).

Glossary of New Constructs

- Extensions to tenets of radical constructivism
  - *Disjoint activated schemes* – schemes evoked by individual in response to specific stimuli
    - "Disjoint" refers to notion that individual's schemes may not be related or that individual may not recognize relationships between them
  - *Schemes targeted for conflict* – disjoint activated schemes which an outside observer conjectures represent lack of coherence in subject's thinking
  - *Perceived conflict* – Explicit recognition by the subject that their thinking was indeed incoherent
- ***Argument-Mirroring Proofs*** – texts which use subject's previously exhibited thinking to form and justify a claim, particularly in effort to perturb their schemes

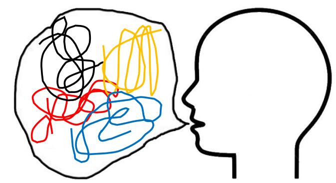
Overview of Case Study

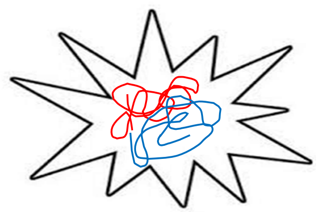
- Participant was an undergraduate student of mathematics education
- Teaching experiment (Steffe & Thompson, 2000)
  - Consisted of clinical interviews (Clement, 2000) and exploratory teaching interviews (Sellers, 2020)
- Task-based interviews focused on continuity, differentiability, and the derivative of composite functions

Argument-Mirroring Proofs, Illustrated

1) Characterize subject's schemes

- Conduct task-based clinical interviews to gather evidence about how student understands mathematical ideas at hand



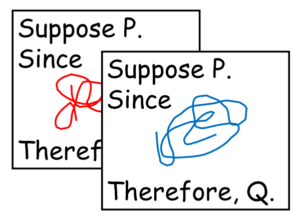


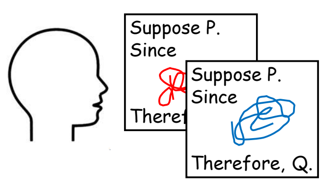
2) Target schemes for conflict

- Code clinical interview data to identify segments of subject's thinking which represent lack of coherence or internal inconsistency

3) Write argument-mirroring proofs

- Construct proof-like texts for use in exploratory teaching interview which model the thinking indicated by the student in the schemes targeted for conflict.



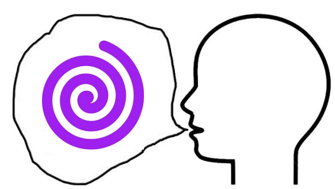


4) Present argument-mirroring proofs

- In an exploratory teaching interview, task the subject with examining the validity of the claims and reasoning in the proof-texts.

5) Characterize subject's schemes

- Code exploratory teaching interview data to gather evidence about how student understanding of mathematical ideas has **changed.**



Interview Tasks

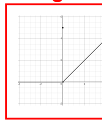
- Clinical interviews
  - Consider where $f(x) = \sqrt{k - 1 - x^2}$ is continuous (resp. differentiable) under various conditions
  - Purpose is to model subject's understanding of the mathematical ideas relevant to the task and target schemes for conflict
- Exploratory teaching interviews
  - Confirm that researcher's model is representative of subject's thinking
  - Present subject with **argument-mirroring proofs** in efforts to perturb their schemes

Illustrative Episode from Study

- Schemes Targeted for Conflict from First Interview

a) If f is defined at a, f is continuous at a.
b) If $\lim_{x\to a^+} f(x) = \lim_{x\to a^-} f(x)$, then f is continuous at a.
c) Although f is not defined where $x = a$, if $\lim_{x\to a} f(x)$ exists, f is continuous at a.

- **Argument-Mirroring Proofs** from Second Interview



Claim: f is continuous at $x = 0$.
Proof:
- $\lim_{x\to 0^+} f(x) = 0$
- $\lim_{x\to 0^-} f(x) = 0$
- Since the one-sided limits agree, $\lim_{x\to 0} f(x) = 0$.
- Therefore, f is continuous at $x = 0$.

Claim: f is continuous at $x = 0$.
Proof:
- From the graph, we see that $f(0) = 5$.
- Since f is defined at $x = 0$, f is continuous at $x = 0$.

- Schemes Targeted for Conflict after Accommodation

a) If f is defined at a, f is continuous at a.
b) If $\lim_{x\to a^+} f(x) = \lim_{x\to a^-} f(x)$, then f is continuous at a.
c) ~~Although f is not defined where $x = a$, if $\lim_{x\to a} f(x)$ exists, f is continuous at a.~~

→ If f is defined at a, $\lim_{x\to a^+} f(x) = \lim_{x\to a^-} f(x)$, and $\lim_{x\to a^+} f(x) = \lim_{x\to a^-} f(x) = f(a)$ then f is continuous at a.

Discussion and Next Steps

- Key Findings
  - **Argument-mirroring proofs** were unanimously effective in revealing incoherence to subject
  - Subject's thinking became more coherent in response to **argument-mirroring proofs**
- Future Research
  - Conduct similar investigations with students of various mathematical backgrounds
  - Explore other mathematical content areas

Student Perceptions on Collaborative Class Projects in Gateway College Calculus Courses

Melo-Jean Yap
Johns Hopkins University

Emily Braley
Johns Hopkins University

Keywords: Gateway Calculus, Group work, STEM writing, Real-world applications, peers

Working in small groups can be a daunting activity for students, yet also provide an opportunity to promote peer interactions and build an inclusive community (Tanner, 2013). In this focus group study, we present how students (n = 43) perceive collaborative class projects in Calculus I at Johns Hopkins University, a predominantly-White, “very high research” university in an urban metropolitan area in the Northeastern United States. 51.16% identified as women and 48.84% as men. The most represented majors were Computer Science (23.26%), Mechanical Engineering (16.28%), and Pre-Major (16.28%).

Prior to the focus group, participants filled out a questionnaire that gathered their demographic information (major, gender identity, racial/ethnic identities), first-generation student status, limited-income status, etc.). The questionnaire also asked students to rank these course assessments from most helpful to least helpful to their learning: homework, quizzes, group projects, final portfolio, midterm, and final exam. While homework ranked as the most helpful and tests (final and midterm) as the least helpful, group projects have the highest variability in helpfulness. Hence, in the focus group, Dr. Yap explored this trend by eliciting elaboration on students’ group work experience. Responses were analyzed by qualitative coding of themes (Saldana, 2021) that emerged from the focus groups.

Findings show that participants who highly favored group projects saw these collaborative activities as opportunities: (1) to meet students who can be their friends outside of class, (2) to practice Calculus in a different way, such as being a teacher to a groupmate to explain a concept, and (3) to apply Calculus in practical ways. Meanwhile, other participants disliked group projects because of (1) group dynamics, (2) logistical limitations, and (3) resistance to new ways of learning Math. Examples of group dynamics include dealing with absent or uncooperative groupmates and feeling left out if groupmates are either too far ahead or behind in understanding the class topic. Logistical limitations consist of receiving limited instructions about the group project, including rubrics not being given in advance; however, instructions and rubrics were posted in the syllabus and learning management system. Finally, students complained that the group work was “busy work” forcing them to work with others, was not directly helpful in exams, was too demanding in writing in non-technical ways, was unclear how it was connected to the lessons, and too practical and connected to the real world.

These findings inform the next iteration of Calculus I group projects at Johns Hopkins University. The curriculum team will improve collaborative projects by (1) providing multiple reminders of the already existing pointed instructions and rubrics in multiple modalities, (2) providing best practices in group communication, in regards to norms for participation, work distribution, etc., and (3) providing clear connection to lessons for genuine buy-in from resistant students.

In conclusion, collaborative group projects provide opportunities for improving peer social cohesion and practical knowledge of Calculus but need targeted improvements in implementation and genuine buy-in from potentially resistant students.

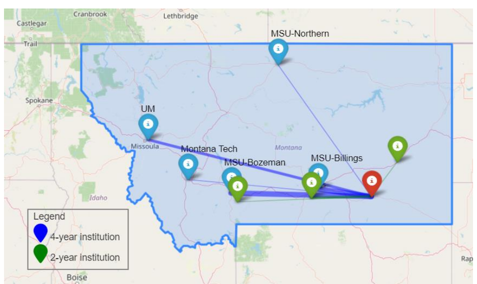
STEM Course Taking Patterns of Transferred Students from Tribal College

Authors: Shurong Li*, Jeff Hooker**, Gary Ramsey**, Aaron Thomas*, Ke Wu*

* University of Montana, ** Chief Dull Knife College

The purpose of this study is to examine the academic outcomes and performance patterns of students transferring from a tribal college to four-year institutions in the Montana University System(MUS).

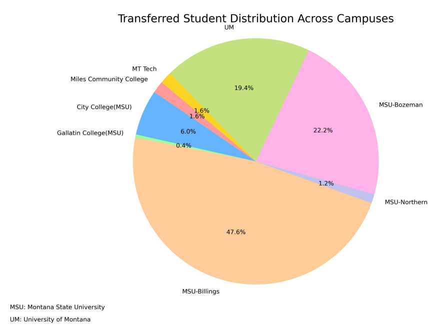


Data source: Merged data between a tribal college and OCHE for 2001 to 2019

Data Variables Overview:

- Transferred student counts by year and term
- Transferred student counts by year and institution
- Student demographic: Ethnicity and Gender
- Transfer destinations within MUS
- Major distribution across institutions
- Enrollment duration in terms of semesters
- Initial status at 4-year institutions
- First-term GPA
- Credit hours completed per term
- Graduation after 4-year MUS enrollment
- STEM courses of identified successful students

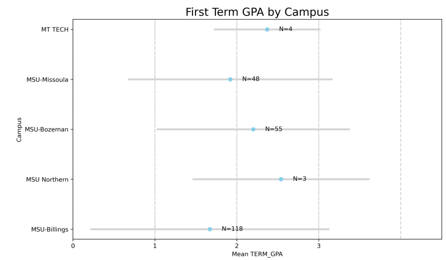
Gillborn, D., Warmington, P., & Demack, S. (2018). QuantCrit: Education, policy,'Big Data'and principles for a critical race theory of statistics. *Race ethnicity and education*, *21*(2), 158-179.



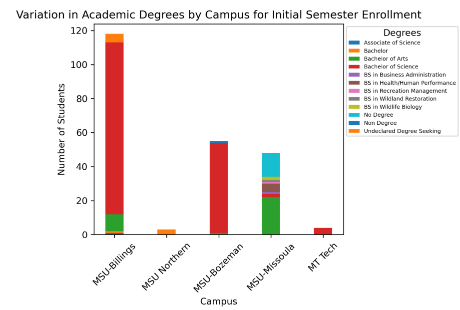
Transferred Students General Demographics

Ethnicity	Frequency	%
Hispanic	4	1.6
Indian	**208**	**83.9**
Missing	4	1.6
Other	1	.4
White	31	12.5
Total	248	100.0

Gender	Frequency	%
Female	165	66.5
Male	83	33.5
Total	248	100



More than 56% of Students Achieved Good Standing in the First Term.



Patterns of Successful Students:

- **"Success" is identified as tribal college students who transferred to a 4-year public institution and earned a STEM degree.**
- **A majority of these successful Native American students are female.**
- **Successful transfer students often return to CDKC for summer science courses.**

Discussion:

- Western success measures, such as degree completion times, may not align with tribal college experiences.
- The role of tribal colleges extends beyond transfer, supporting students through their 4-year institution journey.
- The notable success of Native women in STEM highlights the need to explore the participation of other Native demographics.

Postsecondary Mathematics Teaching Methods and Practices: A National Study

Molly C. Bowen
Baylor University

Introduction

Many students find themselves struggling in college-level coursework despite previous successful secondary academic experiences and acceptable college entrance exam scores (Complete College America, 2015; Woods et al., 2018). There have been few studies that specifically address college mathematics faculty knowledge and utilization of best teaching methods and practices and their effectiveness (Benken et al., 2015; Cox, 2007). Recent research has shown that teachers have the greatest impact on student achievement above any other factor of schooling (Chemosit & Rugutt, 2020; Schriver & Harr Kulynych, 2021). Therefore, the researcher explored teaching methods and practices utilized by faculty in the U.S.

Literature Review

Many faculty heavily rely on lecturing and/or direct instruction for most to all of the course and may not know about other teaching methods and/or practices (Blair et al., 2018; Mathematical Association of America, 2017; Mesa et al., 2014; Ngo, 2020; Oleson & Hora, 2014). Unlike PK-12 teachers, faculty are not required to obtain teaching certifications, licenses, or participate in internships or mentorships; they are only required to have an advanced degree (Blair et al., 2018; Chiu & Corrigan, 2019; Gilmore et al., 2014; U.S. Bureau of Labor Statistics, 2016). Inexperience and lack of support may contribute to the heavy use of lecture and/or direct instruction (Fong & Zientek, 2019; Purnomo et al., 2018).

Methodology

This sequential explanatory mixed methods study took place in postsecondary institutions in the U.S. Cluster-random sampling was used to select institutions. Mathematics department chairs were sent a survey containing the TPI (*Teaching Practices Inventory*), ATI (*Approaches to Teaching Inventory*), and demographic questions to forward to faculty (full-time, part-time, tenure-track, and non-tenure track) (Trigwell & Prosser, 2004; Wieman & Gilbert, 2014). It was hypothesized that demographic groups would reveal statistically significant differences in TPI scores, ATI classifications (information-transmission/teacher-focused (ITTF) and conceptual change/student-focused (CCSF)), and between the TPI and ATI. The research questions (RQ): (1) Are there statistically significant differences in the TPI score performance between faculty demographic groups, methods, or practices? (2) What similarities and differences can be found in the ATI classification between faculty demographic groups, methods, or practices?

Results

There were 113 participants from 37 states. For the first RQ, the significant demographic group was membership. The testing revealed that faculty who were members were more likely to utilize more methods and practices that focus on their students. For the second RQ, demographic groups did not reveal significant findings, but individual methods and practices were significant. Faculty who reported utilizing the inquiry, problem-based learning and cooperative learning teaching methods were more likely to be classified by the ATI as CCSF. Also, faculty who utilized more than three methods were more likely to be classified as CCSF. Qualitative and mixed method results are still in progress.

Postsecondary Mathematics Teaching Methods and Practices: A National Study

Molly C. Bowen, Ph.D. Candidate
RUME Conference, Omaha, NE, Feb. 22-24

CURRICULUM & INSTRUCTION GRADUATE PROGRAM

Background

Many students find themselves struggling in college-level mathematics courses (Complete College America, 2017; Woods et al., 2018).

- Teachers have the greatest impact on student achievement (Chemosit & Rugutt, 2020; Schriver & Harr Kulynych, 2021).
- There have been few studies that specifically address college mathematics faculty knowledge (Benken et al., 2015; Cox, 2007).

Therefore, the researcher explored teaching methods and practices utilized by faculty in the U.S.

Quantitative Research Questions

1. Are there statistically significant differences in the TPI score performance between faculty demographic groups, methods, or practices?

2. What similarities and differences exist in the ATI classifications Conceptual Change/Student-Focused (CCSF) or Information Transfer/Teacher-Focused (ITTF) between faculty demographic groups, methods, or practices?

Methods

This study was conducted using sequential explanatory mixed methods.

- **Quantitative Participant Selection Process:**

Institution Selection
Chose institution by type (2-year, 4-year, university) and geographic location

→

Targeted Participants
Department chairs were notified and forwarded the survey to the participants

- **Items in Survey to Participants:**

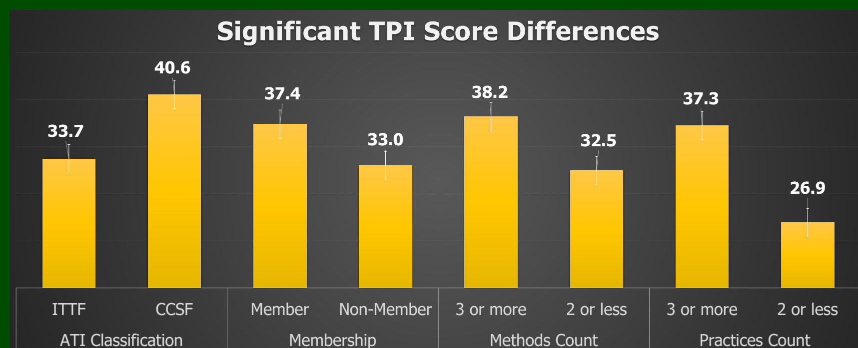
TPI
Results in a score for practices (Wieman & Gilbert, 2014)

ATI
Results in a classification of either conceptual-change/student-focused (CCSF) or information transfer/teacher-focused (ITTF) (Trigwell & Prosser, 2005)

Teaching methods are defined by Kilbane and Milman (2014)

Teaching practices are defined by NCTM (2014).

Faculty who were **student-focused** were **more likely** to **utilize more practices and methods** in their classrooms than those who were teacher-focused. **Membership** in professional organizations also correlated with the use of **more practices**.



CCSF Classification Significant Results

Group	Chi-Squared Value	Probability
Lecture (M)	4.36	0.0368
Inquiry (M)	5.39	0.0203
Problem-Based Learning (M)	5.07	0.0243
Cooperative Learning (M)	5.84	0.0157
Goals (P)	4.06	0.0440
Build Procedural Fluency from Conceptual Understanding (P)	4.59	0.0322
Method Count (3 or more)	9.03	0.0027

Note: M=Method, P=Practice

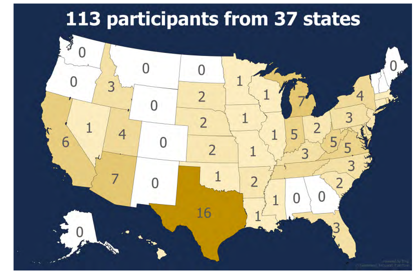
ITTF Classification Significant Results

Group	Chi-Squared Value	Probability
Lecture (M)	8.27	0.0040
Inquiry (M)	8.55	0.0035
Problem-Based Learning (M)	7.56	0.0060
Cooperative Learning (M)	8.41	0.0037
Goals (P)	4.42	0.0354
Methods Count (3 or more)	11.01	0.0009

Note: M=Method, P=Practice

Scan me for the full paper!

Results



Most Frequent Methods and Practices

- Direct Method: n=85 (75.2%)
- Lecture Method: n=45 (39.8%)
- Problem-Based Learning Method: n=35 (31.0%)
- Implementing Tasks Practice: n=65 (57.5%)
- Mathematical Representations and Connections Practice: n=56 (49.6%)
- Productive Struggle Practice: n=52 (46.0%)

Chi-squared testing revealed that these variables were significant for the ATI classifications. Phi coefficients were calculated to determine an association, which is similar to a regression score.

Positive Association with CCSF (phi > 0.2)	• Inquiry, Problem-based learning, and Cooperative learning methods • Use of 3 or more teaching methods
Positive Association with ITTF (phi > 0.2)	• Lecture • Procedural Knowledge from Conceptual Understanding
Negligible Association (0< phi < 0.2)	• Setting Goals

Discussion

- Faculty who were members of a professional organization had statistically significantly higher TPI scores, which means more practices are being utilized in their classrooms.
- Faculty who reported utilizing the inquiry, problem-based learning, and cooperative learning teaching methods or a combination of multiple methods were more likely to be classified as CCSF (conceptual-change/student-focused) than faculty using other methods.
- Qualitative themes emerged and include faculty experiences as students, professional development, teaching experience, and personal connections.
- Integration of results is in progress.

Keywords: Critical reforms, Students as Partners, Student voice, Power dynamics

A growing body of research points to the transformative potential of engaging students as partners with faculty to humanize math education (Cook-Sather et al., 2023). Successful partnerships follow a principle of reciprocity, in which students and faculty are both positioned as having expertise which can be leveraged to improve education (Mercer-Mapstone et al., 2017). A larger research study was developed to investigate how the use of Networked Improvement Communities (NIC) composed of key mathematics stakeholders could work to address issues of Diversity, Equity, and Inclusion (DEI) within introductory mathematics courses through critically transformative participatory action research. A unique single case-study emerged from a NIC that recruited students in addition to the faculty as NIC members. We address the following research questions: (a) In what ways was **student voice** prioritized in the NIC? (b) How does the integration of students impact the **power dynamics** within the NIC?

This single case study (Yin, 2009) draws from data collected as part of the ACT UP Math project which is examining the formation of NICs addressing inequities in introductory math courses. Alpha University's NIC presented a unique case study because of their intentional recruitment of students. Out of the eight NIC members, three are students. The NIC met every other week for two hours from January-May 2023 and created two action plans informed by data: (1) dismantling the placement system for introductory mathematics courses and (2) creating programming that connects students to the uses of mathematics.

We conducted a thematic analysis of structured observational field notes of the NIC meetings, semi-structured interviews of NIC members conducted in May 2023, and four reflexive journal entries completed by each NIC member. This process generated cross-cutting themes relevant to the NIC's inclusion of student voice and perceptions of power. These themes are: (1) the intentions of the NIC to prioritize student voice, (2) the inclusion of students as partners (or not) in NIC activities, and (3) reflections on power dynamics by NIC members.

Findings from this study suggest that although the structure of the NIC was intended to uplift student voices and create a space where students and faculty were *equal partners*, outside power structures prevented students from fully viewing themselves as partners with faculty members. For example, NIC student members described how having colleagues in the NIC who were also course instructors outside of the NIC influenced the ways in which they interacted with each other. However, the NIC has made strides mitigating power dynamics over the semester and demonstrating the value of student voice.

This research is funded in part by a grant from the National Science Foundation (EDU 2201486). All findings and opinions are those of the researchers, not necessarily those of the funding agency.

Exploring Undergraduate Students' Experiences with Standards-Based Grading

Russ F. deForest, Pennsylvania State University
Debbie Gaydos, Pennsylvania State University
Neil J. Hatfield, Pennsylvania State University
Eric Hudson, Pennsylvania State University
Joseph D. Houck, Pennsylvania State University
Louis Leblond, Pennsylvania State University
Jennelle Malcos, Pennsylvania State University
Michael Steward, Pennsylvania State University

Keywords: Standards-Based Grading, Specifications Grading, Student Perceptions, Grounded Theory

Specifications or Standards-based grading (SBG) is a set of grading approaches that focus on evaluating students' proficiency of learning objectives (Campbell et al., 2020). Over the academic year of 2022-2023, seven Pennsylvania State University faculty from the departments of chemistry, math, physics, and statistics, have implemented SBG in a dozen classes, ranging from introductory to upper division and small (<25 students) to large (~500 students). We present preliminary results of an investigation on students' experience with SBG in these settings. There have been only a few such investigations in higher education (e.g., see Buckmiller et al., 2017).

Our retrospective qualitative study includes student interviews and focus groups. We selected participants from initial survey responses paying attention to diversity among demographics, courses, and expressed opinions about SBG. At the time of this submission, 186 students have completed the survey, and we have conducted interviews with seven students and two focus groups covering seven additional students. While most of the students' comments in the survey describe positive experiences with SBG, we made sure to interview students who described negative or particularly unusual experiences. All authors participate in constant comparative coding, focused coding, and memo writing (Olson et al., 2016).

As we work towards building a grounded theory of students' experiences with SBG, we have identified several preliminary emergent themes. First, many participants feel that SBG leads to deeper learning compared to traditional grading system. Second, students often highlighted the flexibility of SBG systems, particularly the common retake policy on proficiency checks or quizzes. Some students discussed using this flexibility to have more control over their learning, setting up the pace of their study, increasing motivation and reducing stress. One student mentioned difficulties that arose from such flexibility as they had to manage procrastination and work-avoidance behaviors. One focus group discussed the stress they felt related to the slow pace of progress and/or exhaustion from the large number of quizzes. Almost all participants reported some level of initial confusion with how SBG worked. Finally, some participants expressed mistrust towards the attribution of grades in traditional grading systems. These students conveyed that SBG grades felt more reflective of their actual understanding of the material.

Russ deForest, Debbie Gaydos, Neil Hatfield, Joe Houck, Eric Hudson, Louis Leblond, Jennelle Malcos, Michael Steward

Specifications or Standards-based grading (SBG) is a set of grading approaches that focus on evaluating students' proficiency of learning objectives. Often graded on pass/fail or proficient/progressing with multiple opportunities for retakes.

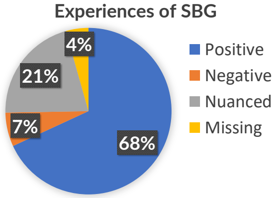
Research Question: What are the experiences of undergraduate students in science and mathematics courses that use Standards-Based/Specifications Grading?

Courses	N	Main Assessment
Intro Calculus	238	Learning Target Quizzes with retakes
Statistics	132	Homework/Projects
Chemistry	739	Learning Target Quizzes with retakes
Physics	90	Learning Target Quizzes with retakes

METHODS

1. Retrospective Survey data (91 respondents).
2. Individual and focus group interviews (24 students to date).
3. Focused coding, memos.
4. Work on the grounded theory in progress.

Experiences of SBG



Students perceive that the control and flexibility of standards-based grading increases motivation and reduces stress but some report procrastination and test-reset behaviors.

[...] and just gather knowledge at your own pace, you know, at your own time, and stress-free.

You were able to just breathe and really understand the work that you were doing

You really had full control over what grade you were going to get.

This Research Is

Proficient	Progressing ✅

Early Findings

SBG = Standards-Based grading
TG = Traditional Grading

Grades as source of motivation
- Trade-offs between minimizing effort and maximizing grade
- Striving to reach mastery in SBG, not just satisfactory
- Low grades are not damning (SBG)
- SBG grades only increase; TG is opposite

Understanding material/content
- Test/reset phenomenon, chunking
  - Felt in both grading systems
  - TG incentivizes short-term learning
  - Some students saw chunking as a positive that helped them learn
- SBG provided deeper learning
  - Better at recall in SBG

Flexibility of SBG
- Both positive and negative
- Student controls learning in SBG
  - Can lead to procrastination
  - Can lower stress

Stress of grading systems (both)
- Many items tested together TG
- Initial unfamiliarity with SBG

Exploring Summer Bridge Program Participants' Sense of Belonging in Mathematics

Skylyn Irby
The University of Alabama

Keywords: sense of belonging; identity; self-efficacy; diversity; bridge programs

Students often leave STEM majors after taking math courses within the first two years of college (e.g., Chen et al., 2013), and historically underrepresented college students are less likely to persist in STEM areas compared to their peers (e.g., Alkhasawneh & Hobson, 2011). A sense of belonging in math may improve students' desire to persist in STEM (Good et al. 2012), so programs that support the development of a math sense of belonging could be a critical component of STEM retention. Summer bridge programs contribute to retention efforts of underrepresented STEM students through diverse representation, community, mentorship, and tutoring. However, little is known about how these programs influence math sense of belonging. This project explores the development of participants' sense of belonging, confidence, and identity in math while involved in a summer bridge program. In particular, I ask: (1) How does the math sense of belonging of bridge program participants change or differ throughout their participation in a bridge program?, and (2) What aspects of bridge programs do participants value and why? How do these valued aspects relate to their sense of belonging in math?

Theoretical Framework

This work is grounded in the academic and social integration components of Tinto's Conceptual Schema for Dropout from College (1975), which identifies academic and social systems as contributors to one's dropout decision. This theoretical framework has been widely adapted for researching retention in STEM.

Methods

Data were collected using surveys and semi-structured interviews. The survey instrument included the 30-item Good et al. (2012) sense of belonging in math scale, the six-item Lubienski et al. (2021) math confidence scale, and short answer questions about students' identity and sense of belonging in math. A coding scheme for belonging explanations, adapted from Rainey et al. (2018), was used for initial content analysis and coding reasons such as math identity, interpersonal relationships, personal interest, or competence. I used qualitative analysis methods and descriptive statistics to produce results.

Results and Conclusions

Participants' feelings of membership and acceptance as measured by the Good et al. (2012) sense of belonging in mathematics scale, declined between the start and end of the summer bridge program. However, this decrease may be attributed to the intensive nature of summer courses. Despite these challenges, students valued the mentoring and program components.

Interviews with one participant revealed confidence in their sense of belonging in math with the reasoning being personal interest and competence, often feeling reassured by peers and mentors in the program. Initial findings indicate a decline in students' overall sense of belonging in math after their first college summer math course. Yet, the positive experiences with the bridge program suggest that continued participation may lead to an improvement in their sense of belonging over time.

Exploring Summer Bridge Program Participants' Sense of Belonging in Mathematics

Skylyn Irby, The University of Alabama, Department of Mathematics

THE UNIVERSITY OF ALABAMA | College of Arts & Sciences

PURPOSE & MOTIVATION

- Attrition in STEM
- Less than half of American students who enroll in STEM undergraduate programs go on to earn a STEM degree (Wilson et al., 2012).
- Historically underrepresented students are less likely to persist in STEM areas in comparison to their counterparts at the postsecondary level (Alkasawneh & Hobson, 2011; Riegle-Crumb et al., 2019)
- Students often leave STEM majors after taking mathematics courses within the first two years of college (Chen et al., 2013; Seymour & Hunter, 2019)
- Research has revealed that the first year of college is a critical period for attrition in STEM (Chen, 2013), particularly as the transition to college involves students negotiating both academic and personal stressors (Ruble & Seidman, 1996).
- Sense of Belonging (Strayhorn, 2012), Identity (Estrada et al., 2018), and Self-efficacy/Confidence (Rincón, 2018) are some variables that often impact one's ability to successfully academically and socially integrate in STEM.

RESEARCH QUESTIONS

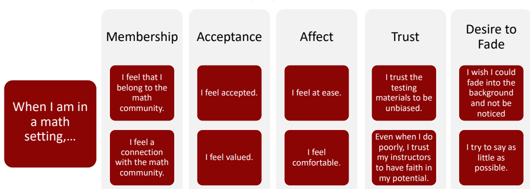
1. How does the math sense of belonging of bridge program participants change or differ throughout their participation in a bridge program?
2. What aspects of bridge programs do participants value and why? How do these valued aspects relate to their sense of belonging in math?

THEORETICAL FRAMEWORK

STEM retention programs are dynamic environments for integrating academic and social systems. This work is grounded in the academic and social integration components of Tinto's Conceptual Schema for Dropout from College (1975), which identifies academic and social systems as contributors to one's dropout decision. This theoretical framework has been widely adapted for researching retention in STEM.

METHODS

Mathematics Sense of Belonging Scale (Good et al., 2012)

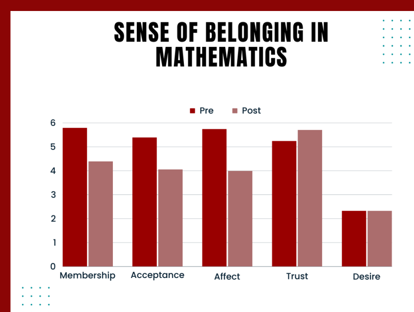


Coding Scheme for Belonging Explanations (Rainey et al., 2018)

Code	Reason for belonging	Reason for not belonging
Interpersonal relationships	Feels socially connected with peers and/or faculty members. May share common interest with peers.	Lacks a social connection with peers. Feels socially different, does not fit in.
Math Identity	Math is a part of their identity as a person.	Lacks a personal connection to the major or material
Personal Interest	Expresses personal interest in course subject or major.	Explicit lack of interest. May find the material boring or unrelated to their reason for choosing their major.
Competence	Feels like they understand major-related material or receives good grades in major-related courses.	Feels like they do not understand major-related material well or receives poor grades in major-related courses.

MAIN FINDINGS

Initial findings indicate a **decline** in **underrepresented STEM bridge** program participants' overall **sense of belonging** in **math** after their first **college summer math course**.

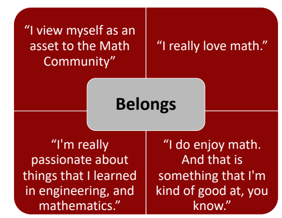


SITE & SAMPLE

- Large, graduate degree-granting, research-intensive PWI, Southeastern part of the United States
  - Louis Stokes Alliance for Minority Participation (LSAMP)
    - 4-week Summer Bridge Program
    - 16 Underrepresented incoming freshmen in STEM

RESULTS

Excerpts of a Student's Responses



"…making sure that I had that foundation…, really contributed to my sense of belonging, because when I would get the problems, it would make me feel like, oh, wow, I can really do the math. You know, this is something I enjoy. It's something I love."

Reasons for Belonging

"…my love for that logical and straightforward process really contributed to my belonging in math."

"And I wanted to continue in something during my undergraduate that has something to do with math. And engineering was the one that appeals most to me because the careers that it will lead to."

"…people would tell me, oh the way that she thought about that and went to explain that, it sounds like you're an engineer, and I'm really passionate about things that I learned in engineering and mathematics. So overall, it was just a combination of things that I'm passionate about, things that I enjoy doing."

Competence | Personal Interest

CONCLUSION

- Participants' feelings of membership and acceptance as measured by the Good et al. (2012) sense of belonging in mathematics scale, declined between the start and end of the summer bridge program.
- Interviews with one participant revealed confidence in their sense of belonging in math with the reasoning being personal interest and competence, often feeling reassured by peers and mentors in the program.
- Initial findings indicate a decline in students' overall sense of belonging in math after their first college summer math course. Yet, positive experiences with the bridge program suggest that continued participation in LSAMP may lead to an improvement in their sense of belonging over time.

FUTURE WORK

- More rounds of coding to draw conclusions from interview data and open-ended survey questions
- Connections among students' sense of belonging in mathematics, mathematics identity, and mathematics confidence
- Longitudinally follow up with participants as they persist through their first year of mathematics courses

Student's Understanding of the Time Series and State Space Trajectory of the Solution of a Differential Equation

Steve Bennoun
UCLA

Keywords: differential equations, mathematical modeling, teaching mathematics

Over the last decades the study of dynamical systems has become an increasingly important area in biology and the life sciences. High profile national documents call for the reform the mathematics instruction for biology and life sciences students in order to focus on modeling and dynamical systems (e.g., National Research Council, 2003). Related to these calls are time series and trajectories in the state space. The representations are central to the solutions of the differential equations describing a dynamical system as they provide important and complementary information about a system's behavior. It is a critical skill to be able to construct the trajectory associated with a given time series, and vice versa.

In this exploratory study, I analyze to what extent students who have taken an undergraduate course focusing on modeling have developed the skill of navigating between these two types of representations. I conducted think-aloud interviews with eight students who had completed the course. Students were given a time series and asked to construct the associated trajectory. They were then asked to do the opposite task. I conducted a thematic analysis (Braun & Clarke, 2006) of the interviews focusing on what level of covariational reasoning (Thompson & Carlson, 2017) the students exhibited when constructing these graphs. Covariational reasoning has been shown to be a core competency to understand functions and engage in mathematical reasoning.

The analysis of the interviews reveals that students showed a variety of levels of covariational reasoning when sketching these graphs. For example, when given a time series, Stan picked points by "going in units of 5 to make it easy". He then plotted the points for his trajectory and connected them with straight lines, exhibiting what Thompson and Carlson (2017) call chunky continuous covariation. When probed about the precision of his trajectory, Stan said that to make it more precise "you would go in units of one". He then indicated that he would pick more points and still connected them with line segments. In other words, he would use the same process but with a smaller time step, further showing chunky continuous covariational reasoning. When asked how confident he was of his answer he said: "Oh, I am definitely very confident on how to do it". In contrast, Carly picked points where the time series "kind of just change[s] direction in general or […] hit[s] a maximum" denoting that she used important features of the functions to pick her points rather than simply choosing points at regular intervals. She then graphed her trajectory using smooth curves, clearly denoting smooth covariational reasoning.

Both students also completed the "opposite task" consisting in starting with a trajectory and sketching an associated time series. While it could be reasonable to expect students to show the same level of covariational reasoning for this new task, the opposite was actually observed. Stan continued to pick points at regular intervals but this time he connected them with smooth curves, which would suggest smooth covariational reasoning. As for Carly, she picked points at regular interval (not based on the shape of the trajectory) and connected them with line segments, showing chunky continuous covariational reasoning. These results suggest that students do not consistently exhibit the same level of covariational reasoning even if the tasks are related. On the poster, I will share additional results and discuss implications for practice.

This work is supported by the National Science Foundation grant DUE-2225258.

An Exploration of Precalculus Students' Reasoning about Exponential Functions

Spirit Karcher
Florida State University

Susana Brewer Castano
Florida State University

Keywords: Exponential Functions, Quantitative and Covariational Reasoning, Precalculus

In recent years both the teaching and learning of introductory mathematics courses, such as Precalculus, have made immense strides to improve students' understanding of foundational skills such as covariational reasoning (e.g., Thompson & Carlson, 2017). Despite the emphasis being placed on teaching from a covariational lens, exponential functions continue to be taught from a correspondence lens (Ellis et al., 2016). In other words, the focus is on solving an algebraic expression that defines a static relationship between two variables instead of the underlying covariational relationship between two quantities. This work is a subset of a larger project to support students' covariational reasoning and specifically focuses on exponential functions. We are guided by the following questions: What type of covariational reasoning is present in students' responses on exponential growth/decay questions? How do the students' responses align (or not) with the mathematical goals of each lab?

Methods

This study is situated at a large R1 university in the American Southeast. In Summer 2022, the project began by developing five precalculus lab units based on the findings of small-scale teaching studies and other relevant literature on student thinking (e.g., Cobb et al., 2003; Ellis et al., 2017; Oehrtman et al., 2008). Each lab consists of a brief pre-lab assignment, a lab activity, and an exit ticket. The purpose of this presentation is to detail the ongoing development of two labs which were designed to support students' conceptualization of exponential functions from a covariational reasoning lens. Students' anonymized written work from the two focal labs were used as the primary source of data analyzed for this study. There were approximately 480 students across twenty classes from Fall 2022 and Spring 2023 included in the data set. Data analysis began by identifying which questions from each lab most closely aligned with the learning goals of the corresponding lab. An a priori codebook was created based on the Exponential Growth Learning Trajectory (EGLT) (Ellis et al., 2016). Student responses were coded for correctness and salient reasoning in several iterative rounds (Miles et al., 2020).

Findings and Discussion

One learning goal which we focused on was based on the ninth covariational reasoning ability from Ellis et al.'s (2016) EGLT which states that "any constant change in x results in a proportional multiplicative constant change in y" (p. 160). The main finding was that the majority of students were able to correctly answer questions despite their reasoning not always accurately reflecting the exponential relationships. For example, students agreed that halving the x value does not halve the y value; however, their explanations did not reference proportional multiplicative changes in the y value. Instead, students tended to rely on linear reasoning (i.e., additive changes in both x and y values. The misalignment between students' reasoning and their ability to get a "correct" answer implies that there is a disconnect between how the labs are currently designed and their intended learning goals.

An Exploration of Precalculus Students' Reasoning about Exponential Functions

Spirit Karcher and Susana Brewer Castano
Florida State University

Background

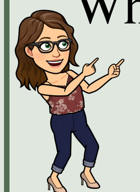
Alice Shrinking is the first of two 50-minute lessons that were designed using the work of **Ellis et al.'s (2016) Exponential Growth Learning trajectory (EGLT)** as a guide. The two labs are designed to support a key shift in student reasoning from **coordinating constant ratios for x-value changes larger than 1 to constant rations for fractional changes** (Ellis et al., 2016).

This poster highlights the findings from an analysis of Desmos responses from **120 students across 5 classes** during a lesson on exponential functions from **Fall 2022** titled **Alice Shrinking**. Student responses were assigned codes deductively based on the salient reasoning in the students' response using the categorizations from **Ellis et al.'s (2016) EGLT** as an a priori codebook.

Research Question

What types of covariational reasoning are salient in undergraduate precalculus students' responses to an exponential decay question with successive changes of an x-value that are greater than 1?

Scan to read our proposal!



When presented with successive additive and multiplicative changes in an exponential decay context, most students reasoned using repeated multiplication or exponentiation of the scale factor.

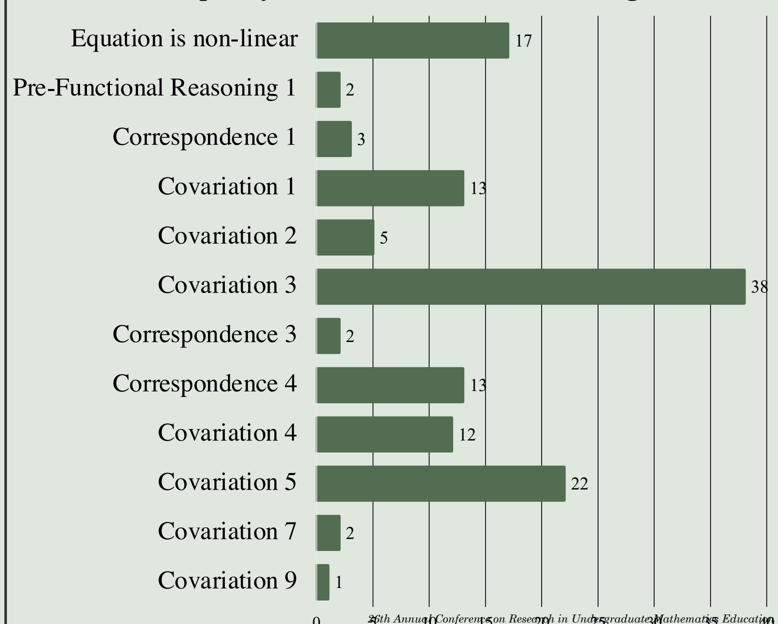
Drink Me: After each sip of potion, the drinker shall shrink to 2/3 their current size. (1 sip = 0.5 oz.)

Your roommate claims that if Alice drinks 1 oz., she would shrink twice as much as if she'd only drank 0.5 oz.

Do you agree or disagree?

Scan for current lesson on Desmos

Frequency of Codes for Student Reasoning



Examples of Most Common Student Reasoning
(Explicit Coordination for Multiple-Unit Changes)

Covariation 3: Repeated Multiplication defined as "coordinating the change in y-values for multiple–unit changes in x-values, but [the student's] mental imagery is grounded in the actions of repeated multiplication" (Ellis et al., 2016, p. 164).	**Covariation 5: Exponentiation Imagery** defined as the "coordination of the ratio of y-values for any Δx > 1; students no longer rely on repeated multiplication imagery" (Ellis et al., 2016, p. 169).
"After drinking 1 ounce of potion Alice would shrink 0.44 times her current height because .5 oz = 2/3 h (height). meaning 1 oz = 2/3 * 2/3 h, equaling 4/9."	"After drinking 1 ounce of potion Alice would shrink to 0.44 times her current height because she would be taking 2 sips; Therefore, she would shrink by (2/3)^2."

Active Assessment for Active Learning

Simone Sisneros-Thiry
California State University, East Bay

Keywords: Active Assessment, Community of Practice, Active Learning

What does it mean for assessment to be aligned with the values of *active learning*? What are the potential benefits and challenges of identifying and defining approaches to assessment consonant with active learning (i.e., *active assessment*)? In the last several years, there has been a surge in interest in developing more flexible assessment structures, with a great deal of momentum for this movement coming from COVID-19 pandemic equity considerations (Kadakia & Bradshaw, 2020; Kim, 2020). Conversations about equity and active learning (Theobald et. al, 2020) and about equity and formative assessment (Kalinec-Craig, 2017) have opened the door to the consolidation of ideas into a framing of "active assessment". This poster focuses on perceived challenges and benefits for defining and designing active assessment. For example, how active assessments may be more or less equitable than timed, independent, written exams. This work takes place at an institution with a variety of supports available, and individual instructors' consideration and implementation of *active assessment* occurs within the ongoing process of professional and pedagogical growth.

This poster presents preliminary results from a qualitative study of exploration of this question in a professional learning community (the Assessment Community of Practice, or ACoP). Pulling ideas from discussions of active learning, formative assessment, and alternative assessment, and from reflections on our own practice, members of the ACoP collaboratively produced two drafts of a definition of *active assessment* in Summer 2023. Both drafts of the definition will be included in the poster. Our goal in developing a shared definition of *active assessment* is to support our implementation of assessment strategies that align with the values and practices of active learning. Throughout the academic year 2023-2024, ACoP members are implementing a variety of active assessment strategies, including variations on standards-based grading, group projects and portfolios, in a broad range of courses, from first-year general education courses through upper division electives for mathematics majors. We continue to engage in discussion about how the strategies do or don't align with our current, working definition. The poster presents preliminary themes that have appeared in these discussions.

Active learning has been defined broadly as instructional activities involving students in doing things and thinking about what they are doing (Bonwell & Eison, 1991). Our consideration of active learning includes Laursen and Rasmussen's four pillars of inquiry-based mathematics education (2019). The ACoP development of a working definition for active assessment also included ideas from Black and Wiliam's (2009) five key aspects of formative assessment and themes presented in the PRIMUS Curated Collection on Assessment (Katz, 2022).

This poster aims to share the motivation, and initial thoughts on the implementation of *active assessment* and present some challenges and questions that have arisen. The conversations generated through the poster session will inform the ongoing research into the development of the definition and practice of active assessment.

Active Assessment for Active Learning

Simone Sisneros-Thiry
simone.sisnerosthiry@csueastbay.edu

Institutional Context
Regional, public 4-year university, primarily undergraduate-serving
- Faculty invested in active learning
- STEM Pathway Community of Practice
- Coordination of materials and topics for multi-section courses

Motivation
Create Assessment Community of Practice for connecting across context, focused on **active assessment.**

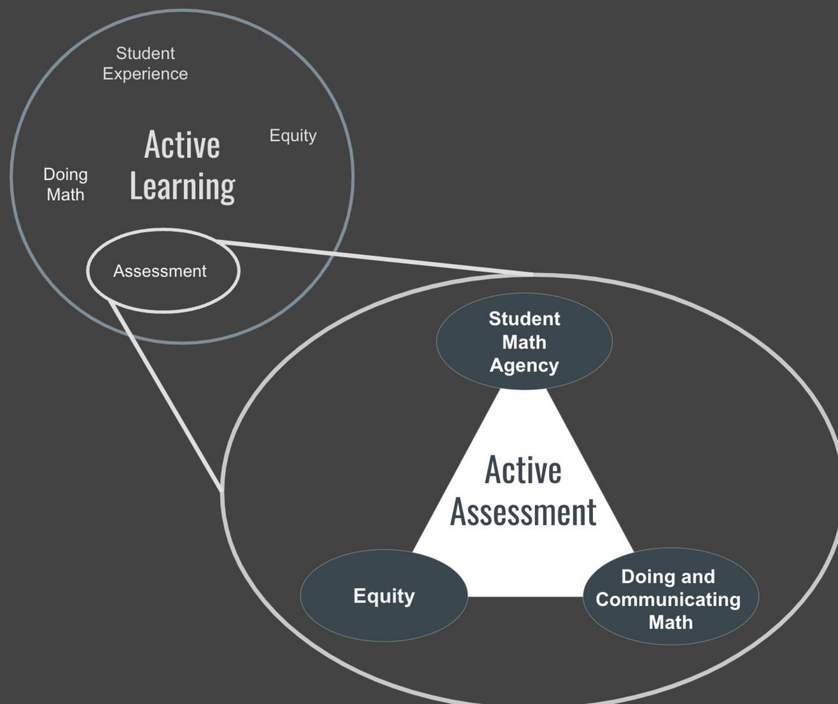
Evolving Definition of Active Assessment

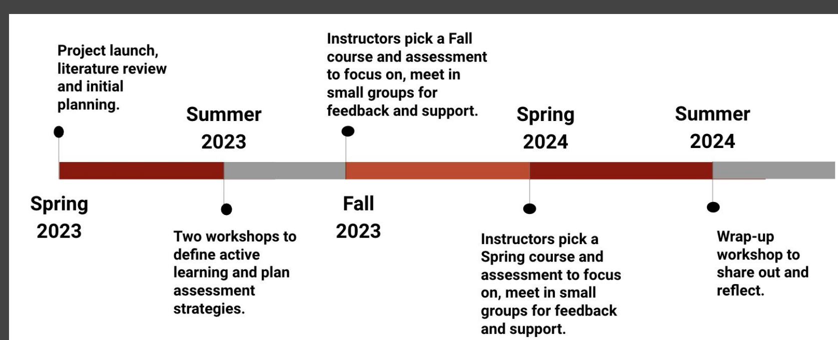
Draft #1 (5/19/2023)
A type of assessment that is rooted in
- *engaging student understanding equitably,*
- *reinforcing communication, reflection, collaboration, and mathematically rich tasks,*
- *valuing diversity in expression while being asset-minded,*
- *and transferring power to students and community*

And captures student progress and facilitates growth in the journey through mathematics.

Draft #2 (7/14/2023)
Active assessment captures student progress and facilitates growth in the journey through mathematics. Active assessment is rooted in
- *engaging student understanding equitably,*
- *reinforcing communication, reflection, collaboration, through mathematically rich tasks,*
- *valuing diversity in expression while being asset-minded, and*
- *giving students the opportunity to share, learn, and expand on ideas as a community.*

Yes, we're starting to understand ***active learning***, so what does ***active assessment*** look like?





2023-2024 Assessment Community of Practice
- Includes lecturer, pre-tenure faculty, and tenured faculty
- Wide range of courses and assessment strategies represented, including:
  - Group Projects and Presentations in upper division Diff. Eq.
  - Final Portfolios in Math for the Arts & Humanities
  - Standards-Based Grading in Precalculus with Algebra

CHALLENGES & NEXT STEPS
- How are current practices opportunities for active assessment development?
  - Standards-based grading.
  - Multiple drafts with collaboration.
  - Summative assessment for the course as formative assessment for students
- How do we operationalize the definition?
  - What does the instructor do?
  - What do the students do?

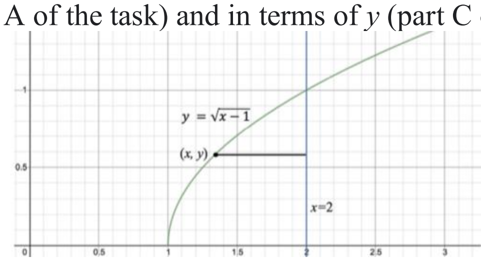
Keywords: Cartesian connection, difference expressions, magnitude interpretation, graphs of functions, survey study

The purpose of this poster presentation is to highlight the variations in student thinking when working with difference expressions in the Cartesian plane — a fundamental skill crucial for grasping numerous Calculus concepts illustrated graphically, such as area, volume, and difference quotients. Previous research has shown students often struggle to conceptualize and express distances in the Cartesian plane (Parr et al., 2021). We view two key understandings, a magnitude interpretation, and the Cartesian connection, as prerequisites to this ability. By magnitude interpretation, we mean interpreting a difference expression as the magnitude of the distance between two corresponding positions in a single dimension (Parr, 2023). The Cartesian connection is the connection between pairs of values of *x* and *y* that satisfy an equation and the ordered pairs of points on the graph of that equation (Moschkovich et al., 1993).

The goal of this study was to investigate the prevalence and nature of challenges that students face when engaging in tasks to represent distances in the Cartesian plane. To investigate this question, we surveyed *n*=169 undergraduate math students at a private liberal arts college located in the southern United States between spring 2022 and fall 2023. On the survey, students were asked to represent distances within the Cartesian plane using expressions in terms of *x* (part A of the task) and in terms of *y* (part C of the task).



a. Represent the horizontal segment's length in terms of *x* (Your expression should have "x" in it).

b. In a sentence or two, explain how you came up with your expression.

c. Represent the horizontal segment's length in terms of *y* (Your expression should have "y" in it).

d. In a sentence or two, explain how you came up with your expression.

Figure 1. Survey item to represent the length of the segment in black in terms of x and in terms of y.

We found that only 16 students (9.47%) correctly responded to both A and C, 22 students (13.02%) correctly answered A but not C, five students (2.96%) correctly answered C but not A, and the remaining 126 students (74.56%) answered both questions incorrectly. We further analyzed the structure of student responses to see if they contained a difference expression, which could indicate the use of a magnitude interpretation. We also analyzed responses for evidence of issues related to the Cartesian connection, including when and how to manipulate the given equation. Our findings highlight a need for instruction on the skills foundational to understanding distances in the Cartesian plane within Calculus education.

The manifestation of graph-theoretic methods in mathematics education research: A metasummary of intercontinental conference proceedings

Haile Gilroy
Auburn University

In this poster, I present a metasummary of articles employing graph-theoretic methods (i.e., Graphs, Network Analysis, Maps, etc.) published in proceedings from North American (SIGMAA-RUME) and European (CERME) mathematics education conferences from 2015 to 2022. I use the results of this metasummary to describe international trends in the choice of method and prominent research topic themes in mathematics education research amongst conference proceedings articles employing graph-theoretic methods.

Keywords: meta-analysis, graph theory, research methods, mathematics education research

Leveraging the mathematical definition of a graph (Chartrand et al., 2016), I define a *graph-theoretic method* as a research method that makes use of a set of objects and the relationships between them. In this poster presentation, I answer the following research questions: (RQ1) *What are the graph-theoretic methods present in mathematics education research (i.e., Graph Theory, Social Networks, Mapping, etc.)?* and (RQ2) *What topics in mathematics education research are studied using graph-theoretic methods?*

To answer these questions, I conducted a metasummary, a type of qualitative meta-analysis that relies on descriptions of broad research trends rather than a typical interpretive synthesis (Timulak, 2014), of prominent intercontinental mathematics education conference proceedings published in the past eight years. For an article to be included in this analysis, it must (1) be published in a SIGMAA-RUME or CERME Conference proceeding from 2015 to 2022, a collection of 3,940 articles, and (2) employ a graph-theoretic method, narrowing the analysis to 80 articles (26 from RUME proceedings and 54 from CERME proceedings). The articles analyzed represent a diverse, international perspective of 21 countries spanning 5 continents. A full list of articles analyzed is available at https://aub.ie/1lKIDG.

Open coding (Thornberg & Charmaz, 2014) was used to determine graph-theoretic methods, while a combination of open coding, thematic analysis (Thornberg & Charmaz, 2014), and social network analysis (specifically degree centrality) (yEd – graph editor, 3.23.2) was used to extract prominent research themes. Results of the analysis indicate the existence of 6 graph-theoretic methods: Network Analysis (Hannula & Moreno-Esteva, 2017), Graphs (Johns et. al., 2016), Maps (Andrews-Larson & McCrackin, 2018), Grids (Watson & Jones, 2015), Flowcharts (Anwar & Goedhart, 2020), and Data Visualization (Van Steenbrugge, 2022), which are distributed differently between RUME and CERME articles. The results also indicate that graph-theoretic methods are employed in a wide variety of topics across mathematics education research, whose prominent themes include Teachers (Horsman, 2022), Students (Kanwar & Mesa, 2022), Mathematics Education Research (Hannula & Moreno-Esteva, 2017), Learning (Lyublinskaya & Du, 2022), Setting (Funk et. al., 2022), Pedagogy (Andrews-Larson & McCrackin, 2018), Curriculum (Henriksen, 2022), and Hot Topics (Kim & Andrews-Larson, 2022). The articles cited here exemplify each type of method and research theme.

Mathematics Engagement in College Precalculus: Understanding Students' Experiences Through a Graphing Elicitation Tool

Aida Alibek
University of Georgia

Keywords: mathematics engagement, Precalculus, qualitative methods, phenomenology

In recent years, we have witnessed great efforts to improve college-level mathematics courses by shifting to student-centered instruction and providing better supports for all learners (e.g., Apkarian et al., 2021; Rasmussen et al., 2019). The implementation of pedagogies like active learning, inquiry-based learning, or flipped classroom instruction in gateway mathematics courses highlights the importance of student engagement in improving learning outcomes (Uhing et al., 2021). To increase student engagement, it is critically important that we understand how students experience this phenomenon.

Despite its importance in learning, educational researchers have not come to a clear consensus on a conceptualization of student engagement (e.g., Appleton et al., 2008; Wong & Liem, 2022). Our colleagues in K-12 mathematics education have been inquiring into students' mathematics engagement since the 1990's (Middleton et al., 2017) and a commonly adopted conceptualization comes from Fredricks et al. (2004) of engagement as a multi-dimensional meta-construct capturing students' affect, behavior, and cognition (Middleton et al., 2017).

This poster proposal aims to highlight a part of the methods of a larger study exploring undergraduate students' experiences of mathematics engagement in a college Precalculus course. This study considers students' mathematics engagement holistically, drawing on engagement research in K-12 mathematics education for its conceptual framework and acknowledging that the various dimensions of engagement are interwoven with each other and are extremely dynamic. The overarching research question is: "What is the story of college students' mathematical engagement in Precalculus?" The theoretico-methodological framework of the study is foundationally based in the socio-cultural tradition (Vygotsky, 1978) and built with hermeneutic phenomenology (van Manen, 2014), which means that the experience of the phenomenon of engagement is studied against the backdrop of socio-cultural learning theory.

The focus of the proposed poster is on the use of a graphing elicitation tool as part of the research design, wherein study participants will be asked to sketch a graph of their engagement in their Precalculus course across the semester over the course of 4 interviews. The sketches drawn by the participants will provide the participant and interviewer a common representation to discuss during the conversation and can allow the researcher's questions to be more specific, eliciting rich descriptions of the students' experiences of engagement. In fact, detailed lived experience descriptions are the main goal of phenomenological interviewing (van Manen, 2014).

During the poster presentation, conference attendees will be able to learn about the methodology, see examples of student-produced sketches, and discuss the affordances of the elicitation tool for understanding college students' engagement in the mathematics classroom. Affect graphing is not new in mathematics education research (Riske et al., 2021; Satyam et al., 2022), and pairing the tool with phenomenological interviewing practices can allow us to gain insight into students' experiences, grasp aspects of students' mathematics engagement that are hard to capture through traditional interviewing methods, and study it as the complex dynamic multi-dimensional construct that it is.

Mary Frances Early College of Education
UNIVERSITY OF GEORGIA

Aida Alibek, PhD Candidate

Background

Using graphs as elicitation tools to understand students' affect is not new for mathematics education research (Riske et al., 2021; Satyam et al., 2022). This study is using the graphing engagement tool to solicit students' self-described experiences of mathematics engagement in their college Precalculus course.

Engagement is a multi-dimensional meta-construct (Fredricks et al., 2004; Middleton et al., 2017). The key dimensions of engagement in education research are the *affective*, *behavioral*, and *cognitive* dimensions (Appleton et al., 2008; Fredricks et al., 2004; Wong & Liem, 2022).

Stay for a chat if you want to:

- learn how the participants in this study were prompted to share their lived experiences of engagement through graphs,
- view select examples of student-produced graphs with highlighted quotes from interviews,
- discuss the affordances of the elicitation tool for understanding undergraduate students' engagement in the college Precalculus classroom,
- learn about the phenomenological underpinnings of the study design and the graphing prompts.

Methods of the overall study

- 12 participants enrolled in Precalculus
- 8 distinct sections taught by 4 instructors
  - 2 lecture-based sections
  - 6 flipped classroom sections
- partially coordinated Precalculus course

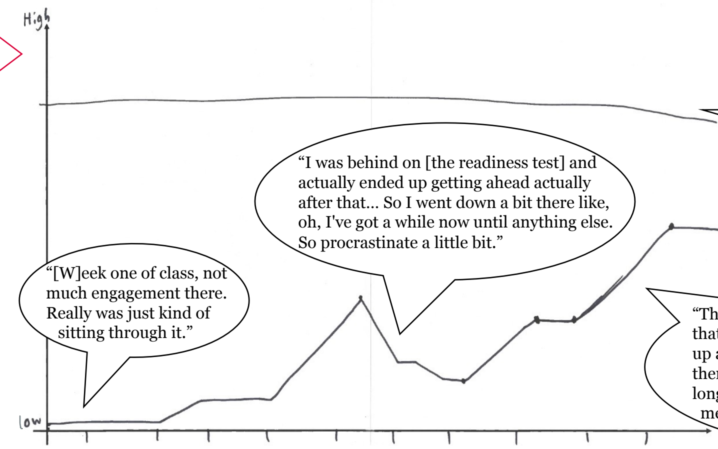
- 4 phenomenological interviews over the course of one semester
- during each interview participants sketch a segment of their engagement graph

For more information please scan the QR code, email me at aida.alibek@uga.edu, or visit: https://bit.ly/AlibekRUME24

Asking students to graph how their engagement in Precalculus shifts throughout the semester is a powerful way to elicit rich qualitative data.

David (he/him)

- Freshman at UGA
- Intended major: Finance
- In a lecture-based classroom

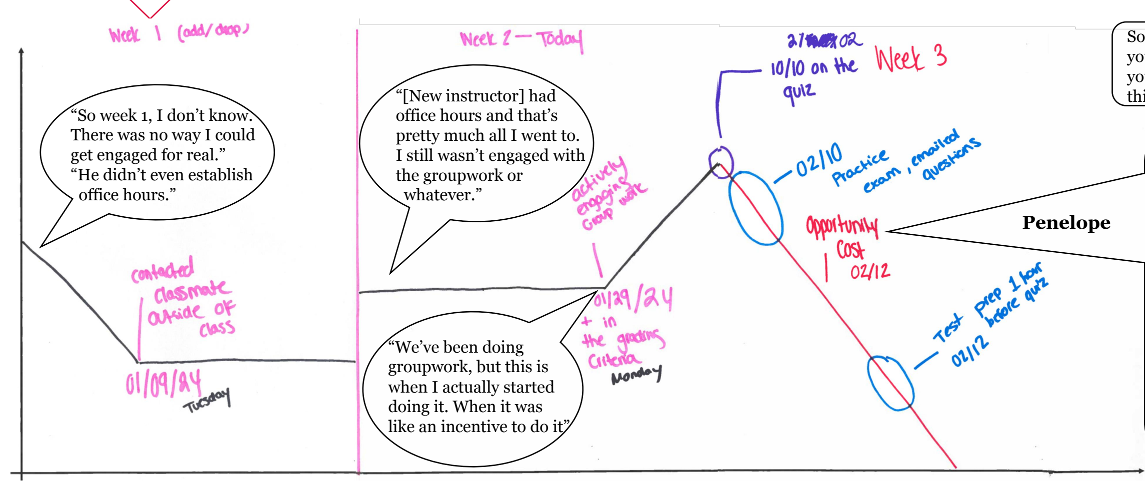


Aida: Is there a limit for you in terms of **engagement** in this class?

David: "Maybe around **here**. Because I got four classes. [M]aybe a B in this class and getting A's in other classes is just better than getting an A in this class and two B's or something like that. ... Two other classes are also [business school] requirements."

Penelope (she/her)

- Freshman at UGA
- Intended major: Accounting
- Switched Precalculus sections after 1 week of classes
- In a flipped classroom



Aida: So what are some ways you have **engaged** in your Precalculus course this past week?

Penelope: "I usually go to office hours, but this week I didn't, because I had a lot of more stuff to do ... [Precalc] is more demanding, so I'm like, okay. It is kinda like an **opportunity cost**. Like I'm giving up time for another class. I made time for this class. It's just, I don't know, I can't find that balance right now."
"I had my RA interview today... I don't have nowhere to live on campus next semester, for real. I'm still a kid. I just turned 19... So it's either I go ahead and prep for my RA interview... or I'm gonna have to sit and study for my test. ... I chose the housing."

Participant and Designer Competing Goals, Resources, and Orientations for Professional Development of Faculty Teaching Mathematics to Future K-8 Teachers

Billy Jackson
University of Illinois, Chicago

Jenq Jong Tsay
University of Texas Rio Grande Valley

Shandy Hauk
San Francisco State

Keywords: faculty professional development, prospective elementary teacher, provider

There is a documented need for professional learning opportunities to support mathematics faculty in working with prospective elementary school teachers (Ping et al., 2018). Recent efforts by the authors and others have generated frameworks for mathematics-faculty-specific, teaching-focused professional development (TPD) (Jackson et al., 2020; Schoenfeld, 2007). In particular, the *Professional Resources and Inquiry into Mathematics Education for K-8 Teacher Education (PRIMED)* project created and implemented a series of online modules for faculty new to teaching mathematics courses for future elementary school teachers. The modules constitute a 15-hour "short-course" for faculty. PRIMED designers had the role of “TPD Providers” (Yee et al., 2023) whose presence was implicit in the asynchronous short-course.

The theory of change informing the work was based on humanizing mathematics instruction for future teachers (MacArthur, 2022; Su, 2020). In the short-course setting, attention to student voices occurred at three levels: children in the future classes of pre-service teachers, the undergraduate pre-service teachers, and the faculty as learners. Providers of the short-course were the implicit instructors in the asynchronous online TPD. The framework for examining designer and faculty views used the **resources** at the disposal of each (knowledge and material resources), their **orientations** (beliefs, preferences, values, etc.), and their **goals** (which exist at multiple levels and change dynamically according to evolving events; Schoenfeld, 2023).

In this poster, we explore short-course design and revision spurred by the distinctions in goals, resources, and orientations of participating novice instructors and Provider-designers. The poster focuses on how the distinctions shaped redesign of the short-course after the initial pilot. The data were designer memos, faculty surveys, and faculty interviews to address the questions:

1. Promise: How does the short-course support faculty learning of target content?
2. Feasibility: Are module materials accessible and useful to faculty?
3. Fidelity: What are the supports needed for participation-as-intended by designers?

Previous findings from research on the use of the short-course included the students of participating faculty demonstrating greater gains in knowledge for teaching mathematics than is common in courses for pre-service K-8 teachers (Hauk et al., 2023). Also, though faculty-participants sought the resource of ready-made materials, research suggested that faculty needed more opportunities to develop the specialized content knowledge used in teaching grades K-8 in addition to knowledge needed for selecting and orchestrating use of course materials).

The work reported in the poster will contribute to the literature because, to date, studies have rarely differentiated among what constitute the professional skills needed as an instructor and professional skills as a teacher-educator, the role of teacher-educator skills in being consumers and selectors of activities (rather than producers or designers of them), and the still understudied forms of motivation behind the work of faculty new to being teacher-educators.

Fostering Set-Based Reasoning for Mathematical Proofs: Student Interaction and Challenges in an Inquiry-Oriented, Transition-to-Proof Course

Kyeong Hah Roh
Arizona State University
Norman Contreras
Arizona State University
Olivia Bruner
Arizona State University
Paul C. Dawkins
Texas State University

Keywords: transition-to-proof course, inquiry-oriented classroom, representations for mathematical logic, set-based reasoning

This poster aims to provide salient insights into an inquiry-oriented transition-to-proof course designed to cultivate undergraduate students' set-based reasoning for mathematical proofs. By set-based reasoning, we refer to a person's reasoning with predicates and relationships between predicates and their truth-sets (Dawkins, 2017). The course emphasized learning fundamental logical principles – such as non-contradiction, contrapositive equivalence, and converse independence – via set-based reasoning. Opportunities were given to students to actively engage with their peers and the instructor team, including the primary instructor for whole-class discussions and research assistants responsible for facilitating small-group discussions. These interactions occurred in the physical classroom and extended to virtual discussion forums.

We examined several aspects of student engagement: peer-to-peer interaction, interaction with the instructor team, assignments and exams, and online discussion forum posts. Our focus was on four key areas: (1) students' participation in building the learning community's acknowledgment of mathematical logic, (2) instructional deliveries in the utilization of set operations and set relationships, (3) formative assessment for students' main takeaways from classroom activities, and (4) student challenges.

Our analysis reveals that (1) students' active participation in sharing their reasoning and reflection on their learning with their peers contributed to developing their collective understanding of logic for mathematical statements and proofs. In addition, (2) the incorporation of mathematical representations (e.g., Euler diagram) and analogies from everyday language (e.g., an empty Hermès Bag for an empty set, fried eggs for proper subset relationships, and Mastercard for non-disjoint relationships) served as a valuable pedagogical tool. These aids fostered student engagement in set-based reasoning for logic. Furthermore, (3) encouraging students to share their main takeaways with their peers in the last five minutes of class and through online discussion forums emerged as an effective formative assessment strategy in gauging students' comprehension and progress. We attended to (4) the challenges faced by students when conveying their reasoning using set-builder notation and Euler diagram, especially those who had prior experience with truth tables for logic and resisted using these new tools introduced in the course for set-based reasoning. Addressing these challenges is an ongoing focus as we refine the course and support student learning in the inquiry-oriented transition-to-proof course.

Fostering Set-Based Reasoning for Mathematical Proofs: Student Interaction and Challenges in an Inquiry-Oriented, Transition-to-Proof Course

Kyeong Hah Roh[1], Norman Contreras[1], Olivia Bruner[1], Paul C. Dawkins[2]
[1]Arizona State University [2]Texas State University

Gotta run? **Scan here** for a copy of our poster!

Objective

We provide salient insights into an **inquiry-oriented** transition-to-proof (**TTP**) course designed to cultivate undergraduate students' **set-based reasoning** for mathematical proofs.

Aspects of Student Engagement

- ♦Peer-to-peer interaction
- ♦Interaction with the instructor team
- ♦Assignments and exams
- ♦Online discussion forum posts

Curriculum Implementation

Our curriculum was implemented in an in-person TTP course in an inquiry-oriented classroom during the Fall 2023 semester at a large public southwestern university in the United States.

- ♦Unit 1: To cultivate students' set-based reasoning about logic for mathematical proofs (Dawkins, 2017)
- ♦Unit 2: To cultivate proof reading comprehension through apprenticeship
- ♦Unit 3: To humanize mathematics through engaging with proof authors' stories

Analytic Foci

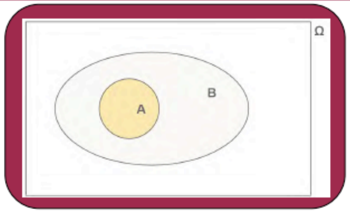
A(1) Students' participation in building the learning community's acknowledgment of mathematical logic

A(2) Instructional deliveries in the utilization of set operations and set relationships

A(3) Formative assessment for students' main takeaways from classroom activities

A(4) Student challenges

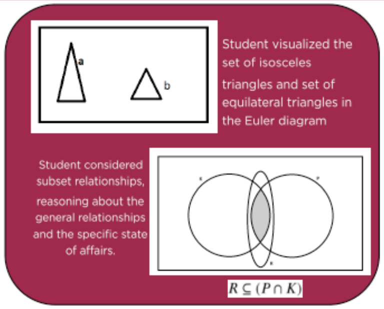
Normative Set Visualizations



Refer to A as the "yolk" of a **fried egg** and B as the "egg white".

Instructor used this description and students adopted these analogies in their verbal and written peer discussions.

Nonnormative Adoption of Set Visualizations



Multimodal **peer interactions, set-based reasoning** tools, and active **reflections** help students make meaning in **transition to proof classroom.**

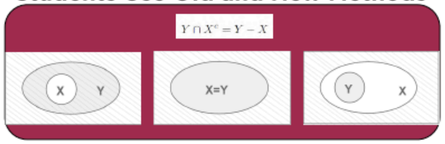
Student Reflections

"Truth sets which equal the empty set have complements that are the universal set and that set can show what proves the original statement!"

"I've found myself using set notation, structure, and different proof approaches in my *linear algebra* class. It's been very helpful using a structured argument rather than winging it!"

"I see sets all the time in my linear algebra class...subsets also come up a lot when talking about vector spaces."

Students Use Old and New Methods



Student used the Euler visualizations, guided by instructional assistant, **to verify a tautology** using set-based reasoning

Some students resisted the use of set-based reasoning, instead using previously acquired tools such as truth tables to evaluate claims about sets throughout the course.

P	Q	P->Q	Q ∩ ¬P
T	T	T	F
T	F	F	T
F	T	T	F
F	F	T	F

All images are researcher generated reproductions of observed student work and are not authentic student generations

Conclusions

C(1) Students' **active participation** in sharing their reasoning and reflection on their learning with their peers.

C(2) Incorporation of **mathematical representations** (e.g., Euler diagram) and **analogies** from everyday language (e.g., fried eggs for proper subset relationships) served as a valuable **pedagogical tool**.

C(3) **Students shared their reflections** in class and in the online discussion forum, **revealing their understanding** of key ideas and application of these tools to other contexts.

C(4) Initial **student challenges** included using new tools in a nonnormative manner or using old tools such as truth tables.

Overall, students exhibited progress and gained ownership in adopting the set-based reasoning tools normatively across various contexts.

Sense of Belonging of Minoritized Female STEM Students in Introductory Mathematics Classes: A Mixed Methods Study

Sarah H. Park
University of Georgia

Keywords: Sense of Belonging, Minoritized Female Students

Higher education institutions are becoming increasingly diverse in their undergraduate populations, but minoritized female students, especially Black and Latina women, continue to be underrepresented in almost all STEM fields (Hatfield, 2022; Ong et al., 2016). Although minoritized female students often begin college with a strong interest in STEM, they are more likely to leave the STEM major due to an absence of belonging in their introductory courses (Rainey et al., 2016). Researchers argue that sense of belonging at the classroom level, is a key factor in supporting minoritized student persistence, and it may even improve participation and academic performance (Strayhorn, 2019). Understanding female minoritized students' sense of belonging in the introductory mathematics classroom context, therefore, is crucial in better understanding their academic experiences, and by extension, understanding how to better support their persistence and achievement in STEM (Museus et al., 2017).

The following research aim will guide this study: How do their identities as female minoritized students play a role in their sense of belonging in gateway mathematics classrooms at a racially and ethnically diverse open access institution? Specifically, 1. How do Black and Latina female students' sense of belonging in the college algebra and precalculus classrooms compare to students in other racial and gender groups? 2. Does Black and Latina female students' sense of belonging in college algebra and precalculus change from the beginning to the end of the semester? 3. How do Black and Latina female students describe their college algebra and precalculus learning environment, experiences, participation, persistence, support systems and challenges as it relates to their sense of belonging?

Theoretical Perspectives – I frame my study using three conceptual frameworks: (a) sense of belonging (Strayhorn, 2019); (b) intersectionality (Crenshaw, 1991); and (c) authorizing student perspectives (Cook-Sather, 2006).

Research methodology – I use a sequential, explanatory mixed methods design (Creswell, 2015) to conduct quantitative methods using a sense of belonging scale at the beginning and end of the semester. I will then follow with qualitative methods (a math autobiography and semi-structured interviews). Participants in the quantitative phase are students (n=1162) enrolled in college algebra and precalculus during the Fall 2023 semester, at a diverse minority-serving open-access public college in the Southeast with a student population of about 11,000. For the qualitative phase, participants are 12 Black and Latina female students.

Results – At the current date of submission, I have analyzed the beginning semester sense of belonging scale data. These results indicate no statistically significant difference between the mean belonging scores based on students' race or gender, but there is a statistically significant difference in students' mean belonging scores based on their affinity for mathematics. By the date of the poster presentation, I will have also analyzed the end of semester belonging scale data and will present findings on how students' sense of belonging changes throughout the semester based on their racial and gender identities. Understanding how sense of belonging changes over time in introductory mathematics classes is important, as classroom-level belonging has been shown to be a critical element of students' motivation, participation, aspirations, and success.

A General Education Data Literacy and Visualization Course Using Service Learning

Betty Love
University of Nebraska at Omaha

Michelle Friend
University of Nebraska at Omaha

Andrew Swift
University of Nebraska at Omaha

Becky Brusky
University of Nebraska at Omaha

Keywords: general education, data literacy, data visualization, service learning

We report on a new course, Data Literacy and Visualization, that fulfills the university general education requirement for quantitative literacy and engages students through service learning. Students learn valuable data skills in an authentic context similar to those they would encounter in the workplace. Specifically, students work with local non-profit organizations who typically have data but lack the in-house expertise to derive value from it.

Motivation

At many institutions of higher education across the country, introductory undergraduate mathematics courses tend to have high failure rates and present a barrier to success for many students (Holm and Saxe 2016). In recent years many institutions have created alternative pathways to prepare students with quantitative literacy, and more recently, data literacy, skills (Dana Center 2020, Heinzman 2022). Data is ubiquitous in all types of organizations today, and individuals who have knowledge and skill in working with data, coupled with discipline-specific expertise, are increasingly valuable assets. Service learning is a method of experiential education that combines classroom instruction with meaningful, community-identified service. This form of engaged teaching and learning emphasizes critical thinking by using reflection to connect course context with real-world experiences (Bringle and Hatcher 1996).

Course Information

The course begins with an introduction to data and visualizations. Then students learn basic statistics including how to compute summary statistics by hand, create histograms, and identify normally-distributed data, then explore the concepts of correlation and regression. They then do these calculations and generate graphs in Excel. The next four weeks are devoted to learning about visualizations in general, including characteristics of good visualizations as well as how they can be misleading, and how to use Tableau, the software used for the projects. The final third of the semester is devoted to with the community partners.

Results

Students leave the course with much more confidence in their mathematical ability than they had at the beginning of the semester. They report enjoying the class and finding it more interesting than other math courses they've taken. In their comments about the course, many students specifically state their appreciation for being able to apply the math they've learned in a real-world context.

Digital Task Design to Support Students' Developing Graphing Meanings

Claudine Margolis, University of Michigan
Teo Paoletti, University of Delaware
Allison Olshefke, University of Delaware

Keywords: graphs, covariational reasoning, task design

The ability to construct and interpret graphs is critical for students as learners across STEM fields (e.g., Paoletti et al., 2020; Potgieter et al., 2008). However, from algebra through calculus, there are well documented difficulties that students experience with graphs and graphing (e.g., Glazer, 2011; Thompson et al., 2017). A small but growing body of literature addresses ways to support students' development of graphing meanings by utilizing digital tasks (Ellis et al., 2015; Liang & Moore, 2021; Paoletti & Moore, 2017). We describe an emerging digital task design principle: That enabling interaction with theoretically salient aspects of a representation directs students' attention there. We use Paoletti et al.'s (2023) framework to determine which aspects of the representation are theoretically salient and to analyze students' activity.

Building on the research on students' covariational reasoning and graphing meanings (Carlson et al., 2002; Moore, 2021; Moore & Thompson, 2015; Thompson, 2011), Paoletti et al. (2023) argue that providing students with repeated opportunities to bridge their meanings for quantities in situations and the graphical representations of those quantities is productive for developing graphing meanings. This entails constructing quantities from a situation and representing the "amount-ness" (Stevens & Moore, 2017) of the quantity as a magnitude bar. A different part of the process entails conceiving of a coordinate point as a multiplicative object which simultaneously represents the length of magnitude bars along orthogonal axes.

In this poster, we address the question: *How does Paoletti et al.'s (2023) framework inform the iterative design of digital tasks intended to support students' developing graphing meanings?* We use data collected during a two-year design experiment (Cobb et al., 2003) consisting of multiple teaching experiments (Steffe & Thompson, 2000). We describe how Paoletti et al.'s (2023) framework supported iterative cycles of task design, fine-grained analysis of students' activity, and task revision. We draw on examples in which our task design resulted in students' activity that we did not intend. We describe 1) how we use the framework to determine where students' attention could be directed to better elicit the intended activity, and 2) how we applied this emerging digital task design principle to direct students' attention in those ways.

For example, we designed a task to support students' conceiving of a coordinate point as a multiplicative object. We first prompted students to drag dots along the vertical axis to represent increases in one quantity for equal increases in the other. Later in the task, we prompt them to do this again, but also show the related coordinate point in the plane. We intended for students to notice the coordinate points' movement as they manipulated the dots along the vertical axis, but their attention was not drawn to the coordinate point. When revising, we wanted students to attend to the relationship between the coordinate point and the length of the related magnitude bar along the vertical axis. We prompted them to accomplish a familiar goal (arrange dots along the vertical axis to represent a changing situational quantity) through a new type of interaction with the graphical representation (dragging a coordinate point in the plane). We provide implications for teachers and researchers as they adapt or design digital graphing tasks.

EMERGING PRINCIPLES OF DIGITAL TASK DESIGN

Digital Task Design to Support Students' Developing Graphing Meanings

EDUCATION
Claudine Margolis
Teo Paoletti
Allison Olshefke

Study Goal: Develop an instructional sequence that supports 6th graders (11-12 years old) in developing emergent graphical shape thinking (Moore & Thompson, 2015).

Methodological Context: Design-based research study (Cobb et al., 2003) with multiple rounds of small-group teaching experiments (Steffe & Thompson, 2000).

Framework: Provide repeated opportunities to develop meanings for situations (MS), develop meanings for graphical representations (MR), and bridge those meanings (MS ←→ MR).

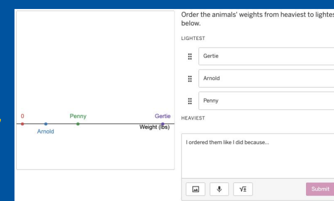
Partial LIT for EGST (Paoletti et al., 2023)

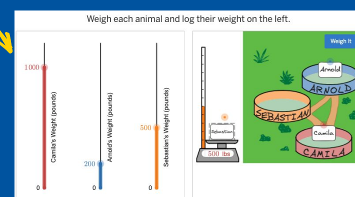
M.S. - Situational quantitative and covariational reasoning	**M.R. - Reasoning with graphical representations of covarying quantities**
M.S.1 - Construct quantities in a contextualized or decontextualized situation.	M.R.1 - Consider a varying segment length as representing a quantity's magnitude.
M.S.2 - Coordinate how two quantities change in relation to each other.	M.R.2 - Consider variations in two orthogonal segment lengths on axes in a coordinate system in relation to two covarying quantities.
M.S.3 - Develop an operative image of covariation that entails a multiplicative object.	M.R.3 - Conceive of or anticipate a point as a multiplicative object in the coordinate system simultaneously representing the two segments' magnitudes.

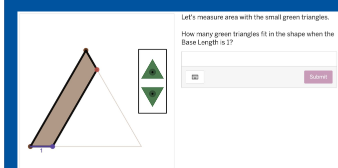
Direct students' attention to theoretically salient aspects of a representation by making it interactable.

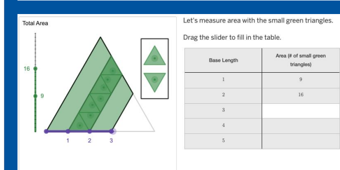
Goal: MS1

New Interactions:
- Measure weight of mystery animals
- Construct magnitude bar representations by dragging







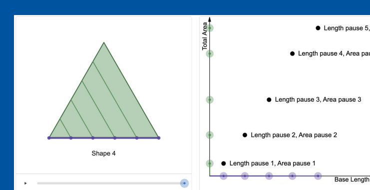


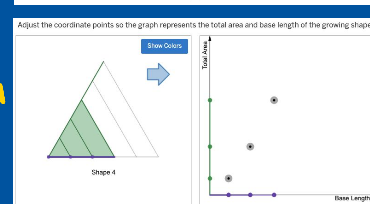
Goal: MS2

New Interactions:
- Drag Base Length
- Construct a table to coordinate values

Goal: MS3←→MR3

New Interaction:
- Drag coordinate point to arrange orthogonal magnitude bars

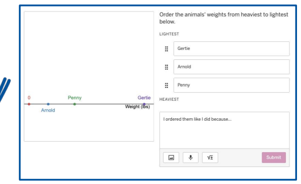


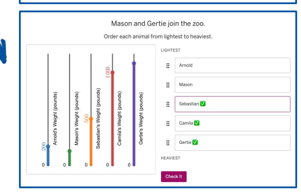


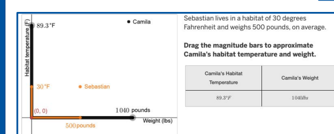
Use visual feedback to represent intended ways of thinking.

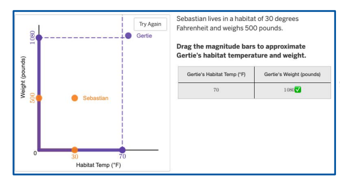
Visual Feedback: visual information provided automatically in response to student actions with potential for mathematical meaning (Margolis & Boyce, in press).

Feedback Design: Click "Check It." Magnitude bars reorder to reflect the student's selection.



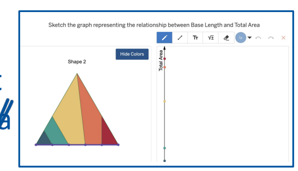


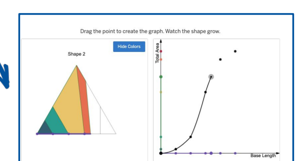




Feedback Design: Drag mag. bars to estimate amts. Press "Check It" and see dotted lines extend toward point.

Feedback Design: Drag coordinate point to create the graph via dynamic trace. See mag. bars on the axes follow the motion of the point.





Speaking into the silence: Using multilingual students' own words through poetic transcription to tell their stories within introductory college mathematics education

Jocelyn Rios
Colorado State University

Jessica Ellis Hagman
Colorado State University

Rachel Tremaine
Colorado State University

Kaylee Fantin-Hardesty
Colorado State University

Sarah Lutz
Colorado State University

Kimberly Espinoza
Colorado State University

Keywords: Multilingualism, student voice, equity, introductory mathematics

As universities continue to become more multicultural, a growing body of literature recognizes the important role that language plays in students' undergraduate mathematics educational experiences (Hwang et al., 2021; Rios, 2023). For example, language mediates how students think, learn, make sense of the world, and socialize (Barwell, 2015). In addition, language, as it intersects with other social identities, positions people within social power hierarchies (Rios, 2023). Driven by these motivations, and within the context of a larger study examining 28 multilingual students' experiences in introductory mathematics, we explore the question: *What are the stories of multilingual students in introductory mathematics?*

We use poetic transcription (Glesne, 1997; Prendergast, 2009; Tremaine, 2022) to showcase the stories of multilingual students of color within these courses. Poetic transcription is an arts-based methodological tool that re-presents interviewees' words in the form of a poem; this allows the interviewee's own words to be used to tell their story while also bringing in space for the researcher's interpretation and analysis, which are used to decide how to present the interviewee's words. In this analysis, our focus is on how experiences of "silence" show up within these experiences, both of being silenced by others and how students use silence as a response for navigating the sociopolitical contexts of the classroom (Mills, 2006). Our results come in the form of poems from each of the six interviews involved in this analysis, chosen because of their discussion of silence. Here, we present an excerpt of one poem to illustrate the power of this methodology. This poem comes from Qamar (she/her), a Syrian refugee living in Saudi Arabia while enrolled as an international student at a large US university, and illustrates her experience of being silenced by multiple calculus instructors at various times.

When I asked that question
She muted me.
She asked, "Does anyone have any other questions?"
Yeah, I have my question,
but you muted me.
You just don't want to speak to me
You're muting me.
I'll stay silent.

On our poster, we will present all six poems in full, and highlight the ways in which silence acts as a navigational response and form of resistance for these multilingual students in undergraduate introductory math courses.

Speaking into silence:

Using multilingual students' own words through poetic transcription to tell their stories within introductory college mathematics education

Intro

- As universities become more multicultural, language plays an increasingly important role in students' undergraduate mathematics educational experiences (Hwang et al., 2021; Rios, 2023)
- Language is both a resource that supports learning of mathematics, and is tied to power, how social interactions unfold, and who has access to speak and have their voices heard (Planas & Civil, 2013)

Methods

- Poetic transcription (Glesne, 1997) allowed us to use the students' own words to describe their experiences of silence in college math (Mills, 2006)
- Within the context of a larger study examining 28 multilingual students' experiences in introductory mathematics, we explore: *What are the stories of multilingual students in introductory mathematics?*

Discussion

- The theme of silence and being silenced was a salient part of how multilingual students of color described experiencing their introductory math courses
- Students described using silence in various ways to **navigate** their undergraduate mathematics classrooms, including navigating:
    - feeling uncomfortable speaking, feeling like their contributions were not listened to or valued, and feeling like they were treated differently than peers
- Students used silence as a form of **resistance** to empower their own voices, and discussed their **aspirations** related to using their voices
- These poems highlight the importance, from an instructor standpoint, of recognizing the role silence plays in navigating the classroom, along with the need to make the mathematics classroom more inclusive for multilingual students

Multilingual students of color experienced **being silenced** and **using silence** in ways that are interwoven with their linguistic, navigational, resistance, and aspirational capital (Yosso, 2005)

PODER Promoting Opportunities in Diversity & Equity Research

Nader

(he/him) is an international student from Iran. He is one of few international students at this school who started in Precalculus instead of Calculus.

I'm a silent person
most of the time.
I prefer to work myself.
Nader, do you have any questions?
Ask it,
don't be shy.
No,
I'm okay.
I can work on it–
I can figure it out myself.
It's really hard for me to start talking so much in the group.

I don't feel good when I ask a lot.
The students
-don't like-
when a student asks lots of questions.
When I want to explain complicated things,
people couldn't understand.
My English is not perfect.
I was talking to my classmates
I just said something very weird in Farsi.
No, no I mean, nah, sorry–
I just said nah–
it was no in Farsi–
She was just like,
What?
I said nothing.
It's hard to speak another language.

…Some part of it was bad
Some part of it was good…

When you talk to teacher
and you feel that teachers
-likes-
to communicate with you in class.
She let us to do whatever we want,
how we are comfortable to do things.
I have good communication with my teacher.
I think that makes it much easier.

My friends, they say,
Yeah, we were like you for the first year.
And we get through it.
I was able to get through it.
At the middle of the semester, I feel much better,
I feel more comfortable.
I've been working on it;
I think I might be ready by fall to talk with people
and communicate.

Proportional Reasoning as a Tool to Understand Structural Racism in a Senior Capstone Course

Molly Robinson
Portland State University

Eva Thanheiser
Portland State University

Keywords: Social Justice, Instructional Activities and Practices

Teaching mathematics in exclusively de-contextualized ways sends students the message that mathematics is not a tool that people can use to make sense of or change the world (Aguirre et al., 2019; Stephan et al., 2021). Lord (2020) found that the perception that mathematics is not useful in making the world better is one reason that some girls who achieved high levels of mathematical success choose not to pursue mathematics in college. Students of Color have shared that the ways mathematics can be used to impact their lives was missing from their secondary mathematics experiences, and that they wanted to use mathematics to promote social justice (Jett, 2019; Rodriguez et al., 2020; Varley Gutierrez, 2009). Adult undergraduate learners have lower levels of math self-efficacy than more "traditional" college students in mathematics content that is perceived as academic, but similar levels when math is seen as useful (Jameson & Fusco, 2014). So, learning about how mathematics can be used in social justice contexts can support students in choosing to continue their mathematics education.

Mathematics is a tool that humans have developed for specific purposes as the needs and wants of their communities have changed over time (Joseph, 2011), including making sense of social justice issues. Proportional reasoning in particular is the foundation of most arguments about equitable treatment and outcomes in politics, media, and education (e.g. Crenshaw, 1989). But students may understand concepts like percentages and ratios procedurally without being able to apply them in social justice contexts (Simic-Muller, 2015). Given the primacy of this content in understanding (in)justice, we wanted to study how a group of college students in a course titled "The Mathematics of Racism" made sense of ratios *and* racism together. We developed a lesson in which students explored claims in newspaper articles about the election of Indigenous Congresspeople through making sense of proportions. Our research question is: To what extent do students see mathematics as connected to social justice issues after the lesson?

Methods and Preliminary Results

The lesson was developed for a synchronous online senior capstone course at a public university in the Pacific Northwest in the Spring of 2023. The data were all 10 participating students' recorded video reflections on the lesson captured in FlipGrid in response to three questions: What did you learn about mathematics? What did you learn about racism? What do you want to know more about? We analyzed the data by identifying which features of Gutstein's (2006) teaching mathematics for social justice framework and Kokka's (2020) critical mathematics consciousness were indicated by students' video reflections.

Students did connect their mathematical learning to social justice by helping them see how mathematics can help them make sense of the world and advocate for change. Every student referred to at least one issue of the representation of Indigenous people in Congress that they thought was unfair or wrong, and all but one student shared that mathematics helped them make sense of the (un)fairness they saw. This is an example of what Gutstein (2006) describes as reading the world with mathematics. Also, 7 students expressed a desire to have things change or to be part of the change themselves, suggesting that students developed their sense of being agents for social change as described by Kokka (2020).

Cafecito con Matemática: A bilingual mathematics outreach event that centers family, culture, and community

Jocelyn Rios
Colorado State University

Elizabeth G. Arnold
Colorado State University

Kimberly Espinoza
Colorado State University

Keywords: Outreach, Bilingual mathematics education, Hispanic/Latino communities, Design principles

With the growing emphasis on supporting and celebrating diversity in mathematics, it is important for mathematics departments to build responsible partnerships with local communities and schools. In the context of the Southwest, extant research has documented how outreach initiatives can create bridges between families, school, and universities, helping to facilitate the mathematical participation of students and parents from Hispanic/Latino communities (Civil et al., 2005) and mathematics pre-service teacher professional development (Stoehr et al., 2022). Moreover, research demonstrates the importance of using culturally responsive practices and creating bilingual spaces that affirm Spanish as a valid language for teaching and learning mathematics (Civil, 2007; Civil & Andrade, 2002; Turner et al., 2013).

In this poster, we present *Cafecito con Matemática* (CM), a bilingual mathematics outreach event run by Colorado State University. This event is hosted at a local bilingual elementary school that serves predominantly Hispanic/Latino communities. Occurring monthly during the evenings, CM first provides students and their families with dinner and then engages everyone in fun, culturally relevant mathematics games and activities which are facilitated by school teachers and university members (including mathematics graduate students and pre-service teachers who gain valuable experience interacting with students and their families). All materials for CM are provided in English and Spanish to create accessibility and promote bilingualism. Ultimately, CM creates a space which validates and leverages families' language and mathematical knowledge, while also providing them with resources to help their children develop their learning of, excitement for, and curiosity within mathematics.

Additionally, CM creates a space that celebrates the home languages of our Spanish-speaking mathematics pre-service teachers and graduate students. By intentionally recruiting Spanish speakers to be involved in CM, we are positioning their home language as a valuable resource that strengthens their ability to teach and mentor diverse communities. Through this event these pre-service teachers and graduate students represent the department in a teaching role, serve as role models to the community, and have a space to interact with school students in their home language, and celebrate their culture alongside community members.

In this poster, we further describe the guiding features and implementation of CM in an effort to support others interested in developing similar outreach events within their local communities. We blend a mathematical approach that focuses on hands-on learning experiences with a culturally responsive approach that features mathematics games and activities that draw inspiration from Hispano cultures, communities, and traditions (e.g., Lotería and traditional games from Latin America). We conclude with initial findings from an examination of the benefits of implementing such an event. We focus on multiple perspectives, providing excerpts from students and their families, from the teachers and administration within the schools, and from the mathematics pre-service teachers and graduate students who serve as teaching assistants for CM. We have found that this event is meaningful in many ways for those involved and serves as a way to celebrate culture and diversity in mathematics education.

Beginning Teacher's Trajectory in the Figured Worlds of Reform and Traditional Instruction

Naama Ben-Dor & Orly Buchbinder
University of New Hampshire

NSF Improving Undergraduate STEM Education: Education and Human Resources (IUSE: HER) # 1941720

Rationale

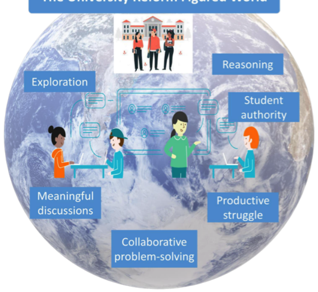
- Beginning teachers transition from the world of reformed teaching of their teacher preparation program to the more traditional world of school teaching (Bjerke & Nolan, 2023; Gainsburg, 2012; NCTM, 2014).
- This transition involves **developing identities** and teaching practices that allow novice teachers to **reconcile the two worlds** (Horn et al., 2008; Ma & Singer-Gabella, 2011).
- Not enough is known about beginning teachers' long-term process of identity formation during the reconciliation of the two worlds.
- We can learn about identity formation by considering beginning teachers' **narratives** about their **current** pedagogical actions and **desired** actions (Heyd-Metzuyanim, 2013; Horn et al., 2008).

We follow the identity formation of one teacher, Olive, by examining her narratives about her current pedagogical actions and her desired ones, as she transitions from being a pre-service teacher (PST) to being an intern (INT) in a mentor teacher classroom, to becoming a new teacher (NT).

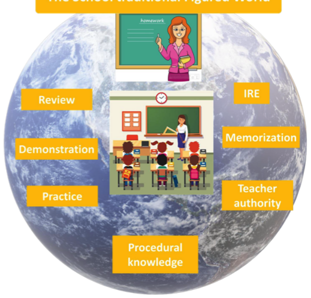
Conceptualization

Drawing on Holland and colleagues (1998), we conceptualize two *figured worlds*, each populated with their own specific actors, pedagogical valued actions, and valued outcomes.

The University Reform Figured World



The School traditional Figured World



Research Question: What was the trajectory of Olive's narratives about her current and desired pedagogical actions in relation to their alignment with the traditional and reform pedagogical actions?

Data collection

Pre-Service Teacher (PST)
- 4 Written reflections on 4 lessons Olive taught during a capstone course on reasoning and proof

Intern (INT)
- 2 interviews on 2 lessons Olive taught as intern in her cooperating teacher's (CT's) classroom.

New Teacher (NT)
- 4 interviews on 4 lessons Olive taught as a new teacher in her own classroom and 2 PLC meetings for new teachers

Findings

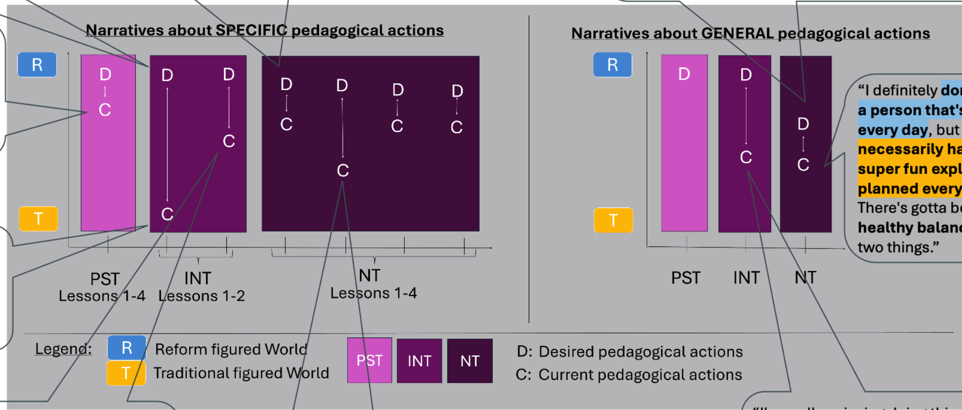
"**I wanna** just go along with what they're saying [...]. [As if saying to them,] "**let's just play with the rules** for the day and" [...], show them [the students] **why** it doesn't make sense."

"I guess my hesitation [...] I'm playing devil's advocate in the situation, if I went and tried to go off on a conceptual tangent with each kid, I think that they would tune it out immediately [...] with so many kids [...] **to try to circulate that room and have a deep conceptual conversation with each of those 28, I don't even think I'd have time** in the block to do that."

"**[In] undergrad and even as an intern** [I] made some lesson plans that were just **absolutely ridiculous** in terms of what I expected the students to understand at a rate or pace that was absolutely **unrealistic** for the children [...] I've definitely become more, I like to consider it, realistic [...] **sometimes I feel bad about it and sometimes I feel guilty about it**. [...] I try to maintain high expectations, but I think I, **I'm a little bit more realistic.**"

"Together [with the students] we defined a **conditional statement** and **discussed how they occur in a variety of settings.** I also asked for students to **provide their own examples.**"

"I would feel accomplished if they [the students] understood **how to combine like terms** on two sides of the equation, **moving chunks with the variable.**"



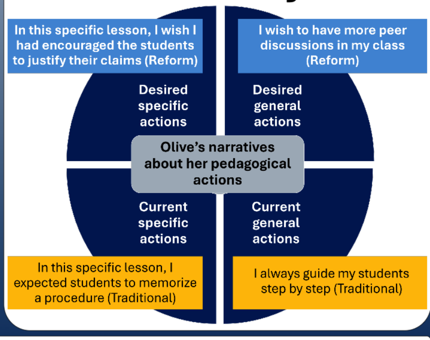
"I definitely **don't wanna be a person that's lecturing every day**, but I also **don't necessarily have some super fun exploration planned every day either.** There's gotta be like a **healthy balance** of those two things."

"I had decided to do that little, what I called an **exploration in the beginning** [of the lesson]. [...] I kind of pushed to do that [...] I wanted them to see it for themselves and to understand, using numbers, **why that was the case.**"

"I liked that some of it [the lesson] felt **exploratory**, but then some of it definitely felt like a **very telling way of teaching**, like just kind of giving them the information as opposed to letting them figure it out."

"I'm really enjoying doing this project because **I have been doing a lot of boring, I feel like, lecture-style things**. And so, **this is like an opportunity for me to stop talking, which is really wonderful.**"

Data Analysis



Discussion

Current Traditional | MIND THE GAP | Desired Reform

- Olive's case revealed two main **critical junctures** along her trajectory of navigating between the university reform figured world and the school traditional figured world:

1. Internship – the opening of a gap between her narratives about her current traditional actions and her desired reform actions; attempting the **close the gap by modifying current actions to align more with desired reform ones.**

2. NT period – "lowering the bar", attempting to close the gap between current and desired actions by modifying the desired actions to be more "realistic" and include more traditional ones.

- Practically, it may be important for teacher educators to anticipate the possibility of a gap opening between current traditional and desired reform pedagogical actions during the internship period.
- It is important to provide continued support to beginning teachers and help them cope with the gap, to address their justifications for the gap, and to find ways to help keep the view of reform teaching "realistic" and desired.

Statistical Literacy of College Students in a Simulation-Based Introductory Statistics Course

Samuel Waters
University of Northern Colorado

Keywords: Statistical Literacy, Statistics Education, Simulation-Based Curriculum

The news media is the primary source of information about social and scientific issues for most adults (Bissonnette et al., 2021). Statistical and mathematical products in the news take on many forms, requiring multiple inter-related skills to appropriately comprehend and evaluate (Gal & Geiger, 2022). Additionally, messages in the news are often shaped by political, commercial, or other agendas contributing to inaccurate, misleading, or intentionally manipulative messages (Mehta & Guzmán, 2018). As such, increasing emphasis exists in the literature regarding the need to develop students' critical capabilities in understanding how mathematics and statistics are used (Gal & Geiger, 2022). Hence, this qualitative pilot study investigated the question: what, if any, statistical concepts do students in an introductory statistics course utilizing a simulation-based curriculum apply when critiquing statistics in the news media?

Current trends in statistics education include the use of technology to provide students with dynamic, interactive simulations and the importance of attending to risk, critical literacy, and communication in contexts such as the media (Burrill & Pfannkuch, 2023). Previous studies have utilized media-based tasks to investigate student statistical literacy (e.g., Kaplan & Thorpe, 2010). Other studies found simulation-based curricula improve student outcomes on topics such as confidence intervals, significance testing, and data collection (e.g., Chance et al., 2022). This study extends existing research by investigating how a simulation-based curriculum prepares students to use critical questioning when engaging with news media.

The conceptual framework of this study draws from Watson and Callingham's (2003) six-level construct of statistical literacy. Gal's (2002) characterization of critical questioning, and Gal and Geiger's (2022) nine categories of statistical and mathematical products in the news informed the development of tasks. Five participants, who were enrolled in an introductory statistics course at a mid-sized university, completed task-based interviews during which they commented on three mock news headlines and accompanying articles. Interviews took place after the simulation-based inference topics were covered in class. Participant responses will be coded, after transcription, for the six levels of statistical literacy and how statistical concepts were utilized throughout the task.

Current analysis includes identification of themes in students' responses. Initial findings indicate participants mentioned sampling, study design, and hypothesis tests with additional themes including wanting more information, relying on non-statistical arguments, and struggling to connect statistical ideas to critical questions. During the poster session, further results of the pilot study will be shared and ideas for future directions and adjustments to tasks will be discussed.

Conceptualizing and Representing the Cartesian Connection in Calculus

Shayla Garrison
Rhodes College

Erika David Parr
Rhodes College

Keywords: Cartesian Connection, Graphical Representations, Conceptual Analysis, Theoretical Sampling

Calculus concepts require students to express and interpret distances in the Cartesian plane. Yet previous research shows that many students are not easily able to do so (Parr et al., 2021). To effectively represent distances, students must be able to understand and apply the Cartesian connection, that a point is on graph A if and only if its coordinates (x, y) satisfy the equation of A (Moschkovich et al., 1993). This connection requires students to draw on algebraic and graphical concepts to conceive of coordinate points as pairs of distances rather than simply a location on a graph (Parr et al., 2021). Students should also be able to flexibly move between using a graph and its equation to represent distances both in terms of x and y or determine if points lie on a line (Knuth, 2000). We are interested in why some student may not display this flexibility and what underlying issues are preventing students from making the Cartesian Connection.

In this poster, we explore the following research question: What types of reasoning, successes, and challenges arise when undergraduate students engage in tasks meant to develop their ability to make the Cartesian Connection to represent distances? To answer this question, we presented surveys to 169 undergraduate students at a small private college to assess their ability to represent distance in the Cartesian plane both in terms of x and in terms of y. We selected 9 students who did not correctly complete the tasks to conduct exploratory teaching interviews. During the interviews, students worked through a series of tasks to represent distance in the Cartesian plane while thinking out loud and explaining their thought process and reasoning. We analyzed the students' interviews using theoretical sampling (Corbin & Strauss, 2014). Our results highlighted that whether students can make the Cartesian Connection is not a yes or no question, but rather better represented by a spectrum of student thinking. We broke up the Cartesian Connection into 3 components: (1) the definition, (2) the underlying algebraic meanings, (3) the underlying graphical meanings. As part of our results, we offer a conceptual analysis (Thompson, 2008) identifying the mental operations needed to make the Cartesian Connection in this context.

Many different types of student reasoning emerged, yet we found similar obstacles that students encountered when representing distances in the Cartesian plane. Some common obstacles were students having difficulty understanding the phrase "in terms of" as well as students having difficulty associating distance in terms of y for a horizontal segment. We analyzed students' responses according to two dimensions: 1) categories encapsulating all the mental processes needed to make the Cartesian Connection to represent distances and 2) the extent to which students were reliant on either algebraic expressions or graphical representations. This poster will give an overview of the spectrum of student thinking that highlights the complexity and nuance of the Cartesian Connection. We will also describe the implications of our findings for teaching and research.

Holding on to Reasoning and Proving While Navigating Professional Obligations: Secondary Teachers' Transition from University to Schools

Sophia Brisard
University of New Hampshire

Rebecca Butler
University of New Hampshire

Orly Buchbinder
University of New Hampshire

Keywords: Reasoning and Proof, Beginning Teachers, Teacher Obligations, Teacher Education

Transitioning between university teacher preparation programs and secondary schools is a complex process, fraught with many challenges for beginning mathematics teachers (Klein, 1932/2016). During this transition, many of the ambitious teaching practices experienced in teacher preparation programs may be absent (e.g., Stokking et al., 2003), but some may reemerge later (Grossman et al., 2000). Herbst and Chazan's (2003) theory of *practical rationality* allows for conceptualizing this transitioning process as the socialization of beginning teachers into the profession, as they adopt a decision-making framework rooted in norms and four professional obligations. These obligations are to the *discipline* of mathematics, to students as *individuals* with unique needs, *interpersonal* obligations to the entire class, and obligations to follow the *institutional* policies, curricula, and practices of schools.

To explore how beginning teachers negotiate between their formal education and the realities of classroom practice, specifically, how they integrate reasoning and proving into their teaching, we followed three beginning teachers: Nancy, Olive, and Diane for three years. First, as PSTs in the capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020), then as interns (INTs), and then as novice teachers (NTs) in their own classrooms. For each teacher, we collected observations, lesson plans, and interviews (3-4 in each setting) and analyzed them in terms of four professional obligations (Chazan et al., 2016) and personal beliefs. Here, we report in aggregate the observed percentages of coded utterances.

As INTs, the participants' discourse was dominated by *institutional* obligation (39%) evident in the expressed need to adhere to the school rules, curriculum, and the cooperating teacher's traditional practices (e.g., "she [the CT] has a system that tends to work for her. So that's what I've been doing"). *Disciplinary* obligation is only expressed in visionary terms – a wish to have students do more explorations. As INTs gained more experience their focus on *institutional* obligation decreased to 17.7% in favor of exposing students to *disciplinary* practices (percent increase of 19) like exploring, conjecturing, and justifying. Having their own classrooms as NTs was characterized by renewed increased *interpersonal* obligation for the classroom (percent increase of 21.5). Despite the added responsibilities, the NTs continued to incorporate reasoning and proof, for example, by including discovery activities. By the end of year 1 the *disciplinary* and *individual* obligations were most prominent, about 30% each. These findings shed light on the process of reconciling various professional obligations while maintaining some focus on reasoning and proof. The findings have implications for those who work to support beginning teachers in their effort to create more reasoning and proof-oriented classrooms.

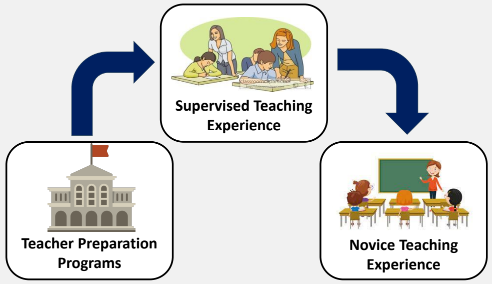
Holding on to Reasoning and Proving While Navigating Professional Obligations: Secondary Teachers' Transition from University to Schools

Sophia Brisard, Rebecca Butler, & Orly Buchbinder
University of New Hampshire

NSF No. # 1941720 The opinions expressed herein are those of the authors and do not necessarily reflect the views of the National Science Foundation

Background



- Transitioning between university teacher preparation programs and secondary schools is a *complex process*, fraught with many challenges for beginning mathematics teachers (Klein, 1932/2016; Smagorinsky et al., 2004).
- Challenges emerge in *balancing commitments* to the university, the cooperation teacher, while developing one's own teaching identity (Bieda et al., 2015).
- The process of socializing in teaching profession involves developing a decision-making framework that takes into account four professional *obligations*: to the discipline of mathematics, to individual students, to students as a class and to the institution of schooling (Herbst & Chazan, 2003).

Goal: To explore how beginning teachers negotiate the four professional obligations as they transition from university to classroom practice; specifically, how they uphold disciplinary obligation by integrating reasoning and proving into their teaching.

The Study

Participants: Three beginning teachers: Olive, Nancy, & Diane

Setting: The study is part of a *longitudinal* project that investigates beginning teachers' expertise to teach mathematics via reasoning and proving.

- Each participant took a capstone course *Mathematical Reasoning and Proving for Secondary Teachers* (Buchbinder & McCrone, 2020) in their teacher preparation program.

Data sources for each participant:

- Lesson plans and observations
- Lesson debrief interviews (3-4 for each participant).

Supervised Student Teaching → Solo Student Teaching → First Year of Teaching own class

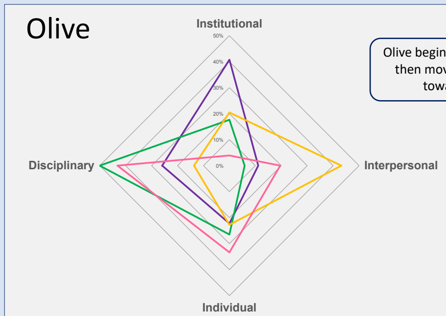
Data analysis:

- Transcribed interviews were coded by three researchers for instances of the four professional obligations.
- For each participant and for each lesson, we aggregated the codes into a single score on each obligation.
- Percentages were calculated to identify trends across lessons and participants.

Theoretical Framework

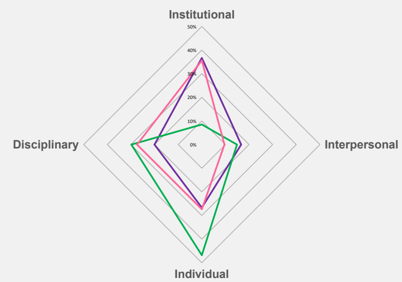
Results

Olive



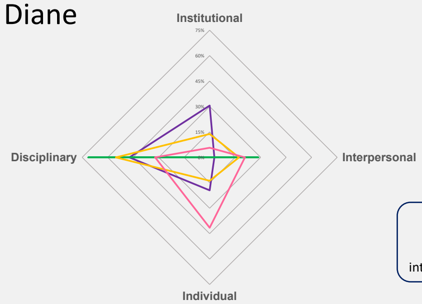
Olive begins by focusing on institutional obligation, then moves toward individual, and finally shifts toward disciplinary and interpersonal

Nancy



Nancy begins by focusing on institutional obligation, then moves toward individual, and then shifts back to institutional followed by disciplinary

Diane



Diane begins by focusing on disciplinary and institutional obligation, then moves toward disciplinary, and in the follow-up interview mostly focuses on individual obligation

Lesson Key: Intern Lesson 1 | Intern Solo Week | Novice Teacher Lesson 1 | Year 1 Follow-up

Conclusions

As interns, the participant's discourse was dominated by ***institutional*** obligation evident in the expressed need to adhere to the school rules, curriculum, and the cooperating teachers' traditional practices. The interns have a desire to implement more exploratory activities.

> In my head, [students] are doing explorations all the time.

> [The CT] has a system that tends to work for her. So that's what I've been doing.

With more experience, the interns started to focus less on *Institutional* obligations and more on ***disciplinary*** obligations (exploring, conjecturing, and justifying).

> I pushed to do an [exploration activity] because in the original lesson plan that [CT] had written like for years prior the idea of flipping the inequality sign is not really explored at all…I wanted [students] to see it for themselves and to understand why that was the case.

As novice teachers, they concentrated more on their ***interpersonal*** obligation to the classroom while still having a strong desire to implement reasoning and proof activities.

> Classroom management pieces were overwhelming in the beginning….But [students] have been really patient with me.

> I want to do more like group activities in the class, and less like direct instruction…and I'd like to do more exploratory stuff

By the end of their first year of teaching, the ***disciplinary*** and ***individual*** obligations were more prominent.

> The advanced group of kids, I like to confuse them because I like for them to unconfuse themselves because I find that's when they really understand something.

> The set of notes I had was this long, dreary like list of properties. So, I'm going to let them do this [exploration] activity instead.

AI-Facilitated Cross-Cultural Problem-Solving in Calculus

Tuto Lopez-Gonzalez — San Francisco State University
Michael Todd Edwards — Miami University (Ohio)
Zheng Yang — SCUPI

Keywords: Artificial Intelligence, Cross-Cultural Collaboration, Calculus

Artificial Intelligence agents are used by undergraduates to support their doing of mathematics (D'Mello et al., 2023; Isgandarli, 2022; Khazanchi et al., 2023). For example, ChatGPT is increasingly used by undergraduates and their professors (Davies et al. 2021; Li et al., 2023). How can this reality be leveraged to improve the mathematical learning experiences of students in the U.S. and globally? (Almoubayyed et al., 2023).

The authors report preliminary findings of a research project that explored Large Language Models (LLM) as tools for facilitating cross-cultural discussions about the "big ideas" of calculus. The following question guided the study: (Q1) *What impact do LLMs have on the collaboration and mathematical problem-solving of calculus and precalculus students in an international context?*

In the study, two precalculus students from a state university in the United States (SFSU) and two calculus students from a state university in China (SCUPI) worked collaboratively to solve rich mathematics tasks. Four students participated, two from each university. Across three 90 minute sessions, the students met online (via ZOOM) and engaged in three types of collaborative mathematics tasks---namely, (1) a computational task, (2) an applied problem, and (3) a conceptually-oriented question. At the end of each session, students completed a short exit survey consisting of Likert-style and open-ended prompts that asked about the nature and quality of their interactions with each other and AI as well as their mathematical learning. An AI assistant facilitated the meetings in a student breakout room, with human instructors available as needed (in the main ZOOM room). The online meetings were recorded for further analysis.

In addition to the students' written work on tasks, responses on exit surveys, and ZOOM recordings, the authors report participant responses on a recruitment survey. These four data sources comprise all of the data sources for the study. The research team at SCUPI followed the ethical guidelines and standards established by SFSU.

Data analysis is ongoing at the time of this writing and will include thematic coding of student activities during the meetings, and a discussion analysis using Techno-Mathematical Discourse (TMD) framework, focusing on the AI assistant's role in facilitating discussions including the nature and depth of the mathematical and cultural conversations. The authors compare and contrast interactions of students with each other and AI both within and across cultures as they consider the research question (Q1).

The poster will include illustrations of the AI assistant-in-use, further details of the research protocol, and QR code for accessing the research study AI agent directly. Poster-side conversation will focus on the design of the study, lessons learned about cross-cultural aspects from the first use of the protocol, and advice for revising the protocol.

AI-Facilitated Cross Cultural Problem Solving in Calculus

PRESENTERS
Tuto LopezGonzalez
Todd Edwards
Zheng Yang

PROJECT OVERVIEW

We engaged in a **case study** with four undergraduates--two from San Francisco State University (USA) and two from Sichuan University (China) who worked (via ZOOM) on collaborative calculus tasks assisted by an AI agent embedded into the sessions. The study explored the impact that the **AI-based agent** had on students' understanding of **foundational ideas of calculus**.

THE TASK

In particular, three types of collaborative mathematics tasks were explored in the sessions: (1) a computational task, (2) an applied problem, and (3) a conceptually-oriented question. At the end of each session, students completed a short exit survey about their interactions and their mathematical learning.

THE AGENT

The Agent has a focus on mathematical guidance and cultural insight. It has three functions: (1) leads math discussions, (2) engages in discussions embodying historical mathematicians, and (3) helps create examples. The adaptive and inclusive approach aims to provide a friendly learning experience.

The agent is programmed using **prompt engineering** techniques such as algorithm of thoughts (AoT) (Bilgehan et al., 2023), program simulation (Scalamogna), and chain-of-thought (CoT).
The result is a single prompt that starts the agent when entered to a large language model (LLM) to initiate the assistant. *Note: An LLM is a mathematical construct employing transformer-based neural networks to model probability distributions over sequences of words.*

DATA COLLECTED

Zoom recordings, Students' work on tasks, Conversation with AI assistant, Responses on surveys

AI has potential as a supportive educational tool. Students used the AI agent to assist in understanding and solving calculus problems.

Open tasks provide better contexts for AI learning agents to assists students.

“We ask the AI to help us understand and see ways to solve open problems"

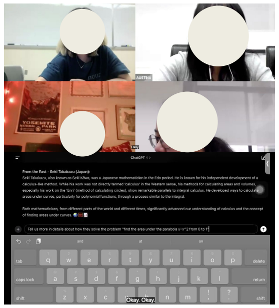
Scan the code to access the agent through GPT-4

MEETING SUMMARIES

First meeting: Meeting each other
The focus was to meet each other, explain the objectives of the study, and provide context on technology setup. Students completed 2 ice-breaker tasks and explored the agent.

Second meeting: Derivative - Optimization
Students explored the notion of derivative and collaboratively solved the Fenced Vegetable Garden task (Find dimensions would maximize the area of the vegetable garden). We used knowledge gained in this session to inform the revision of our AI-based agent for our final meeting.

Third meeting: Integral - Area
Students engaged mathematically and culturally through a study of Eastern and Western contributions to calculus. Students calculated areas under curves, comparing methods used by 16-17th century mathematicians. Students constructed an example "where the value of the area under the graph of a function may not be found" and explain why.



FINDINGS

The Agent Matters: Sometimes the AI leaves out important steps in the calculations. For example, the agent described how Isaac Newton would have calculated the area under f(x) not explaining the evaluation of the anti-derivative at the limits of integration. “if we think, his approach is not very clear. Shall we ask the agent to explain more about that?”

IMPACT

The combination of the AI-agent and tasks designed to engage students' vocational aspirations strengthened student understanding of calculus and culture in ways not always possible with more traditional methods. This highlights the relevance of culturally responsive teaching.

Discourse Between Learning Assistants and Calculus Students on Implicit Differentiation

Rebecca Butler
University of New Hampshire

Orly Buchbinder
University of New Hampshire

Keywords: Learning Assistants, Near-Peer Tutors, Calculus, Implicit Differentiation

Learning assistants (LAs) are undergraduate near-peer tutors who, having previously been successful in some course, aid in the instruction of that course, typically by interacting with individual students or groups (Otero et al., 2010). It has been shown that LAs' presence in classrooms is associated with positive student outcomes (Barrasso & Spilios, 2021), but there is little understanding of how LAs contribute to such outcomes. While there are some action-focused categorizations of LA practices, e.g., providing feedback and increasing discussion time (Knight et al., 2015; Thompson et al., 2020) they are not tied to specific content areas. This study contributes a subject-specific perspective on LA classroom practice by examining discourse between LAs and students on the topic of implicit differentiation in a Calculus I course.

LAs were incorporated into the course as one part of a cross-departmental effort to transform introductory STEM courses at a large, public, northeastern university. This Calculus I course consisted of a lecture (~160 students) taught by a faculty member and recitations (~20 students) taught by a graduate teaching assistant. LAs were present only in recitations, and their role was to facilitate small group discussions during work on conceptually oriented activities. This study is focused on one recitation lesson on implicit differentiation. Data consists of 360-video recordings of small groups and students' written work on the activity. Video clips were selected for analysis based upon the presence of the LA with the small group and conversation focus on implicit differentiation. Through this process, 19 clips (~25 minutes of video data) were identified for five LAs across two semesters. LA and student speech were transcribed and analyzed at the turn of talk level for mathematical content and discursive actions. Mathematical content was analyzed using components of a hypothetical learning trajectory (HLT) for implicit differentiation (Buchbinder & Allen, 2024). Discursive actions of LAs were analyzed using Thompson et al.'s (2020) Action Taxonomy for Learning Assistants while those of students were coded using an open process under the constant comparative method (Strauss & Corbin, 1998).

Initial analysis indicates that LAs aid students in learning this topic by coordinating across multiple components of the HLT and integrating previous calculus content knowledge into these components. For example, one LA shared their conceptualization of implicit differentiation as the chain rule, rewriting y as y(x), while another LA described the implicit differentiation procedures as the "normal" derivative then "multiplying by dy/dx". While students tended to ask LAs questions about algebraic procedures, LAs reoriented these questions toward sensemaking across graphical and symbolic representations of implicit equations.

This analysis of LA-student interactions around implicit differentiation sheds light on the nuances of how LAs support student mathematical learning of that content. The study has the potential to bolster our understanding of student learning of the topic of implicit differentiation and gain insight into LAs' instructional moves as they interact with students.

Discourse Between Learning Assistants and Calculus Students on Implicit Differentiation

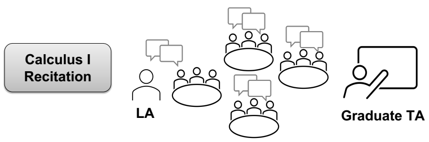
Rebecca Butler & Orly Buchbinder
University of New Hampshire

NSF Award No. 2013427. The opinions expressed herein are those of the authors and do not necessarily reflect the views of the National Science Foundation.

Background

The Learning Assistant (LA) Model
(Otero et al., 2010)

Learning Assistant: A current undergraduate student who has passed some course and who aids in the instruction of that course.
- **Practice:** LAs help teach students in Calculus I recitations
- **Content:** Weekly meeting with course instructor to refresh course content
- **Pedagogy:** Weekly meetings with a mentor to discuss educational topics (e.g., metacognition)



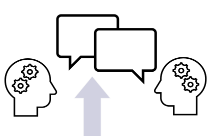
Motivation: Students in LA-supported courses show more *positive content-related outcomes* compared to students without LA support (Barrasso & Spilios, 2021), but little is known about *how* LAs facilitate positive student outcomes. Students *struggle with implicit differentiation* (Martin, 2000; Chu, 2019) offering opportunities for LAs to authentically aid student learning.

Research Question
What mathematical aspects of implicit differentiation do students and LAs discuss during their interactions in Calculus I recitations and ***how*** do they discuss them?

The Study

Setting: Part of a multi-disciplinary project for reforming introductory STEM courses at a large, public, northeastern university.
LAs teach in Calculus I recitations (~20 students each), facilitating small group discussions about conceptually rich activities.
Participants: 5 LAs and 7 different small groups of students; 3-4 students per group.
Data sources: 22 different 360°-video recordings of LA-student conversations on the topic of implicit differentiation
~25 mins of video data across two semesters.

Theoretical Framework

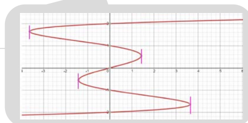


Vygotsky's (1978) Sociocultural Theory
Learning is fundamentally social and mediated by language use

Critical Discourse Analysis (Gee, 2014)		
	Saying (Information)	Utterances coded for *topic* of implicit differentiation discussed (Buchbinder & Allen, 2024)
	Doing (Action)	Utterances coded for *student actions* (open coding) and *LA actions* via ATLA (Thompson et al., 2019)
	Being (Identity)	Speech interpreted within the context of near-peer tutoring in Calculus 1

ID Topics (N=250)

Graphical 37% | Symbolic 26% | Algebra 24% | Calculus 13%



$$x = y^5 - 5y^3 + 4y$$
$$\frac{dy}{dx} = \frac{1}{5y^4 - 15y^2 + 4}$$

"How do you draw the *tangent line*?"
"At each point of *inflection*…"
"So, what is the meaning of *dy/dx*?"

Trend: Conversations focus on prior knowledge and symbolic representations, graphs discussed in connection to computations.

LAs' Actions (N=140)

Directed facilitation 52% | Feedback 33% | Guided facilitation 13% | Advice 2%

"So, if you solve this plugging in one for all the y's, you'll get it."
"You can use the quadratic equation to solve for y squared"

"Yeah, um, I think you just forgot to add the powers at the end, right?"
"Yeah, that's what you did there. Oh, so yes, this is correct."

"Do you see any other points that look like they behave the same way?"
"So, how would you draw the tangent line there?"

Trend: LAs tend to explain concepts and give feedback (e.g., correcting, confirming) on students' work.

Students' Actions (N= 110)

Ask for directions or reassurance 44% | Following LA Instruction 32% | Explaining work or thinking 24%

"Is this right? Like am I on the right track?"
"How do you draw the tangent line?"

"That would make a lot more sense!"
"Oh, my gosh. You're so right."

"So, I said the derivative of y in terms of x the x derivative."
"Okay, I did the (0,-1), but didn't get the same."

Trend: Students seek out LAs to ask questions about next steps. They follow LAs' explanations, but also explain their thinking.

Example of Discourse

ID Topic | Student Actions | LA Actions

Symbolic Evaluation
Ask for directions → Examine student work

Are there other points on the graph, where the slope of the tangent line is the same as you found at (0,1)? Respond using the graph, and then verify algebraically.

Graphic Coordination
Examine student work → Explain next step → Explain thinking → Point out incorrectness → Elicit student thinking → Checking work → Confirm correctness → Explain next step

Significance
The student begins at the symbolic level, but the ***LA engages with graphical representations in complex ways***, before returning to the pragmatic matter of symbols

Symbolic Evaluation
Explain next step → Confirm correctness

Responding to the Research Question

- LA-Student discourse is often *pragmatic*, focusing on correctness of mathematical *procedures* and connections to *previous knowledge*.
- *Implicit differentiation* topics: graphs in connection to computations.
- Students ask LAs questions about next steps, follow LAs' explanations, but also explain their thinking.

Results of Analysis Using the Social Justice Syllabus Design Tool

Jonathan Balagot, Jordan Guillory, Shandy Hauk
Thomas Kunze, Rebeca Hernandez, Sandra Torres
San Francisco State University

Keywords: syllabus, social justice, equity

The re-humanizing of mathematics calls for a variety of classroom-level changes (Su, 2020). Supporting faculty to transform their views of self, students, and authority can begin with the course syllabus (Palmer et al., 2016). This report gives results of the authors' analysis of 39 mathematics class syllabi, from 27 instructors, based on the Social Justice Syllabus Design Tool (Taylor et al., 2019). The tool has 25 questions, each aligned with at least one of three categories: *community, process, relationships*. In using the tool to design a syllabus, one answers reflection questions and makes adjustments to bring the syllabus into greater alignment with recommended practices (i.e., an answer of "Yes"). For this analysis, reviewers answered each of the tool's questions with Yes (1) or No (0) and had the option of offering notes about their selection (e.g., statements from the syllabus that prompted a "Yes" or "No").

On the tool were 10 questions aligned with the community category so 10 opportunities on each syllabus for a "1" in community, 4 opportunities in process, and 11 in the relationship category. Some questions were reverse-coded (i.e., where "No" indicated the *presence* of justice-supportive language). Thus, there were 10+4+11=25 "points" possible for each syllabus.

As an example of poster content, across the 19 syllabi that were for 100-level courses, there were 25*19=475 points possible. The leftmost chart in Figure 1 indicates the proportion of points, out of all 475 possible, aligned with each of the three categories (the gray area indicates the remaining proportion of potential points---social justice foci not present). Similar analysis of nine 200-level course syllabi led to the rightmost chart in Figure 1.

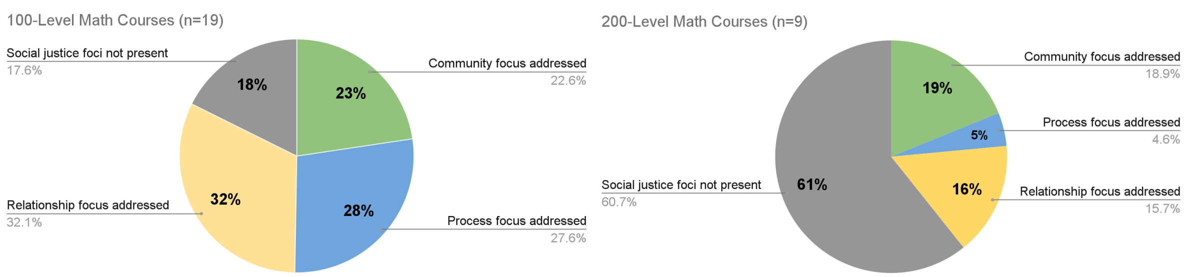

Figure 1. Charts for 100-level and 200-level courses.

In addition to other visuals and comparisons, the poster shares wording. For example, the following illustrate justice-aligned wording (coded with the answer "No" on the reverse-scored question "Does the syllabus read like a legal contract?"):

> This course aims to offer a joyful, meaningful, and empowering experience to every participant.
>
> We (you, your classmates and I) will experience many different class relationships and mathematical ideas this semester. This syllabus documents significant goals and expectations for our class and is a resource for the development of our particular Statistics learning community.

Results of Analysis Using the Social Justice Syllabus Design Tool

San Francisco State University

Jonathan Balagot, Jordan Guillory, Shandy Hauk, Rebeca Hernandez, Thomas Kunze, Sandra Torres

Background

Poster Purpose: Offer and collect ideas for making sense of (and making sense with) justice as an essential component in syllabus design.

Abstract: Supporting faculty to transform their views of self, students, and authority can begin with the course syllabus. This poster gives results of analysis of 39 mathematics syllabi written by 27 different instructors in a single department. Analysis used Taylor et al. (2019) *Social Justice Syllabus Design Tool.*

Theoretical Perspective

Relationship: *Emphasizes the messages that students receive from a syllabus about the type of relationship that is expected to occur between faculty and student* (p. 147).

- Roles are implicit in "relationships"
- Clear outline for desired student-instructor relationship in their syllabi.

Community: *Highlights the way a syllabus either promotes or inhibits a collaborative and inclusive environment* (p. 150).

- Inherently tied to inclusivity.
- Can establish with collaborative language.

Process: *Draws attention to…how learning can and will occur…how faculty regulate emotions … [and] judgements about student behaviors, and grading outcomes* (p. 153).

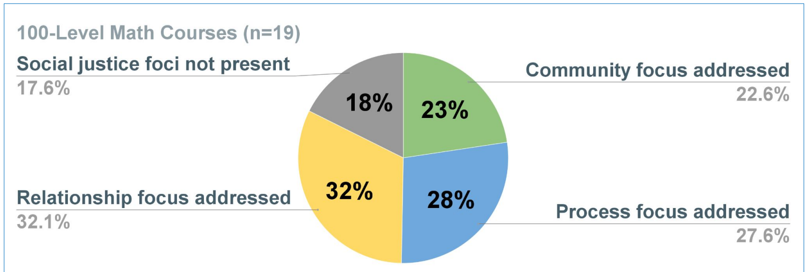
- Grading, practicing, risk-taking
- Success-oriented language (e.g., productive struggle is valuable)

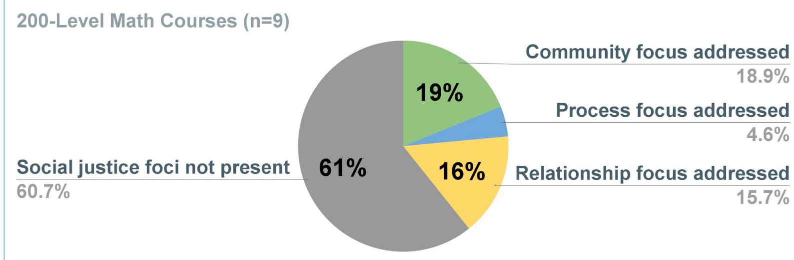
In what ways does a syllabus acknowledge, act, and hold us accountable for increasing justice? What is the evidence of it, for you?

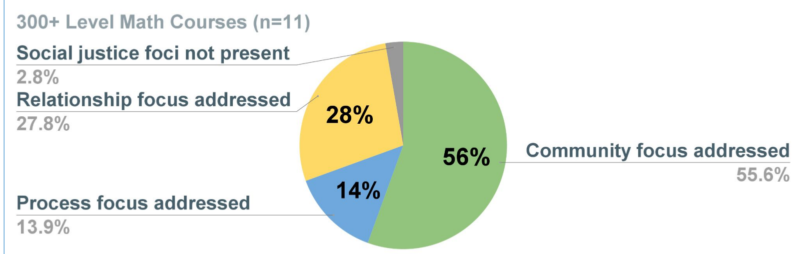
Reference

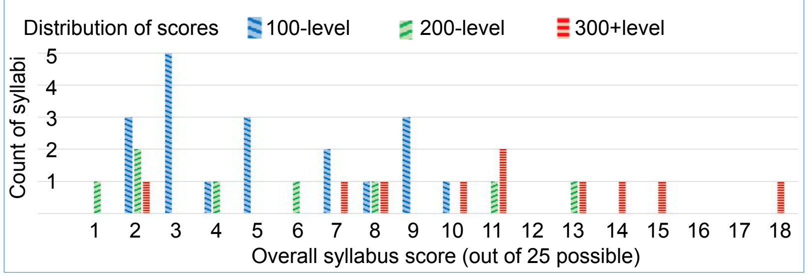
Taylor et al. (2019). The social justice syllabus design tool: A first step in doing social justice pedagogy. *Journal Committed to Social Change on Race and Ethnicity*, *5*(2), 133–166.

Comparisons









Examples

Learning mathematics is all about practice, which means: struggling through confusion, making mistakes, receiving feedback, and having an opportunity for growth. (Process)

We all go through difficult times that can affect our academic life. If you feel this way, regardless of the reason, please do not hesitate to talk to me and ask for extra time or resources. Your well-being is most important. (Relationship)

Please offer and ask (your classmates and me) for help with the material and assignments. Mathematics is often best learned with others, even if that can be a bit uncomfortable sometimes. Start your work early. Come to student hours. Form study groups. (Community)

We (you, your classmates and I) will experience many different class relationships and mathematical ideas this semester. This syllabus documents significant goals and expectations for our class. This syllabus is a resource about the structure, content, and processes for the development of our particular class community. (Community)

What More? What Next?

- Implications for Practice
  - revisit and revise syllabus each term
- Implications for Teaching-focused Professional Development
  - practice with exemplars to support syllabus refinement
- Implications for Research
  - include syllabus score as a covariate
  - explore undergraduate response to syllabi with various score profiles

International and Non-International Students' Experiences in Chavrusa-Style Mathematics Courses

Baldwin Mei
Columbia University

Mine Cekin
Columbia University

Keywords: Chavrusa, International Students, Collaborative Learning

A significant group within increasingly diverse U.S. classrooms is international students, whose learning success involves social elements such as ensuring feelings of belonging, respect for one's knowledge, and creative, effective, and confident participation in one's learning environment (Ryan and Viete, 2009). Collaborative learning methods are effective pedagogical techniques to address these needs as they allow learners to interact with each other and build a sense of belonging while exposing each other to varied socio-cultural perspectives (Huijser et al., 2008; Barkley & Cross, 2014). Chavrusa-style learning, modeled after Jewish Talmudic instruction, is a pedagogical technique where students are paired long term and asked to construct understanding from learning materials through debate (Pace, 1992; Kent, 2010). Research by Flint & Mei (2020) indicated that when implemented in mathematics courses, students felt chavrusa-style learning (MathChavrusa) broke down classroom barriers and improved the overall course experience. Due to the heavily social nature of MathChavrusa, it was hypothesized that this method may impact international and non-international students differently. Thus, the purpose of this research was to understand the experiences of international and non-international students in chavrusa-style mathematics courses.

Method

Participants consisted of a total of six international (3) and non-international (3) students who had taken graduate mathematics courses using chavrusa-style learning in the Fall 2021 semester. Data collection consisted of one online semi-structured interview for each participant and eight optional in-person classroom observations. The interview covered participant's impressions of MathChavrusa and perceptions of how it impacted their learning and socialization experiences. Classroom observations focused on partner interactions and were recorded using field notes. Data analysis consisted of coding interview transcripts and field notes using provisional and in vivo coding to develop themes of participants' learning and socialization experiences.

Findings and Future Research

International and non-international students perceived MathChavrusa to be beneficial when developing their mathematical understanding as it provided students with easily accessible sources of support when grappling with new material. Social and schedule compatibility of MathChavrusa partners were issues raised by all participants. The former was influenced by the mode in which MathChavrusa was implemented (i.e., in-person, hybrid, and online learning), with participants noting hybrid learning particularly undermined collaboration and socialization. A benefit noted exclusively by international student participants was that the long-term nature of partnerships allowed them to more easily build relationships that extended beyond the classroom and course. The poster will provide more granular descriptions and discussions of participants' experiences, including the impact of modes of instruction, participant pairings, and individual preferences. In the future, we hope to examine differences in MathChavrusa when used in specific modes of instruction.

A Growing Need for Asian (American) Perspectives in Math Education

Matt Furuta Park
Virginia Tech

Inyoung Lee
Arizona State University

Undergraduate mathematics features a significant presence of Asian[1] students, whether international or American (NCES). These students naturally bring their views on learning mathematics from their cultural experiences. However, researchers often adopt theories of learning and teaching that may not fully incorporate the students' viewpoints when developing instructional materials and analyzing student reasoning. This proposal aims to foreground Asian scholarship by reviewing existing literature in this regard and intends to open a venue for discussing ways the RUME community could begin addressing this issue.

Keywords: Asian perspectives, Cultural differences, Dispositions, Equity

Despite the prominence of Asian (American) students in STEM classrooms, and Leung's (2001) declaration that an awareness of Asian scholarship "should contribute in a more meaningful way to a sharing of best practices with other cultural traditions," studies rarely reflect the nuanced views they bring when learning mathematics. To address this issue, we focus on two aspects: 1) dispositions - exploring instances where Asian (American) students may uniquely experience mathematics, and 2) the Asian Classroom Paradox - examining the perspectives of math education researchers that render their common frameworks inadequate.

Dispositions.

We explore instances that may be interpreted differently among students. When teaching undergraduate students in the US classroom, we often encounter concerns expressed by those who struggle in mathematics, such as 'math is not my thing.' (Nisbett, 2003; Whang, 1994) The researchers observed that Asian students facing challenges in mathematics tend to perceive it as requiring additional effort, while others may view it as a lack of inherent mathematical ability. Such differences also extend to classroom behavior. (Ing & Victorino, 2016; Kim, 2002) We found literature that may help locate the roots of these dispositions among Asian (American) students, emphasizing memorization, practice, and a perception of education rooted in Confucian dialectics instead of Socratic dialectics. (Fan et al., 2021; Kitayama et al., 2003; Marton et. al, 2005; Wang & Cai, 2007)

Asian Classroom Paradox.

Next, we draw particular attention to studies concerning student-teacher dynamics in Asian mathematics classrooms. This paradox involves a disconnect between assumptions regarding Asian classroom environments and their associated mathematical performance. Western researchers have viewed the Asian classroom as less autonomous than the US classroom pointing out the prevalence of directive lectures from teachers as the primary mode of learning. However, recent studies (Zhou et al., 2012) claim that such a finding is only paradoxical because cultural differences are not accounted for. These studies found that a Confucian framework describes such lectures as student-centered and better discerns the relationship that Asian students have with authority figures like teachers. (Jiang et al., 2021; Li, 2016; Chan et al., 2017)

[1] Asian students include students from Southeast Asia (Philippines, Singapore, Malaysia etc…), South Asia (India, Pakistan, Nepal, etc…), and East Asia (Korea, Japan, China etc…). Due to the positionality of the authors, this proposal is mainly focused on East Asian scholarship.

The Need for Asian Perspectives in RUME

Matt Furuta Park
Inyoung Lee

Introduction

"There exists an East Asian identity in mathematics education, and an awareness of that identity should contribute in a more meaningful way to a sharing of best practices with other cultural traditions" -Leung (2001)

Examples

These papers are examples of those which touch on their given construct, yet lack solid epistemological foundations by Western standards.

- Mimicry/Imitation (Zhou, J., Guo, W. (2016). Imitation in Undergraduate Teaching and Learning. Journal of Effective Teaching, 16(3), 5-27.)
- Practice (Wang, T., Cai, J. (2007). Chinese (Mainland) teachers' views of effective mathematics teaching and learning. ZDM, 39, 287-300.)
- Memorization (Marton, F., Wen, Q., Wong, K. C. (2005). 'Read a hundred times and the meaning will appear...'Changes in Chinese University students' views of the temporal structure of learning. Higher Education, 49, 291-318.)

Conclusion

The RUME community should incorporate more non-Western philosophy to enrich our learning theories.

Math education research from the West touches upon constructs or phenomena that is not well represented in the literature. Ideas from Asia can help fill in such theoretical gaps. Please join our working group if you are interested in such work.

Additional Information

Take our survey

- What are some things in math education that you feel are important but underrepresented in how math education research is done in the West?
- Briefly describe American cultural practices or attitudes regarding teaching and learning that initially surprised you.

Working Group Goals

- Host a Working Group at the next RUME.
- Get a talk submitted to PMENA and RUME.
- Draft at least two papers integrating the constructs on the left into existing, popular epistemological frameworks.

Argument Mapping for Proof Comprehension

Andrew Baas
Texas State University

Keywords: argument mapping; proofs; proof comprehension

Proof comprehension has long been recognized as a critical skill for mathematics students (Conradie & Frith, 2000; Cowen, 1991). Cowen specifically states that, while most students will not be proving theorems after graduation, many will need to be able to read and understand mathematical writing. While undergraduate proof comprehension has historically received little attention from researchers (Mejía-Ramos & Inglis, 2009), this has begun to change in the last decade due to theoretical-methodological advancements like the assessment model developed by Mejía-Ramos et al. (2012). These models have overcome challenges inherent to measuring students' proof comprehension, enabling researchers to evaluate efficacy of methods developed to improve students' proof comprehension. For example, two empirical studies have shown that proof presentations which have been assumed to improve proof comprehension (Alcock & Inglis, 2008; Rowland, 2002) actually fail to improve student proof comprehension compared to traditional proof presentations (Lew et al., 2020; Roy et al., 2017).

Borrowing from research in philosophy education, I present argument mapping as a promising instructional technique for improving students' proof comprehension. Argument mapping (also called argument diagramming) is the practice of converting a written argument into a graph-like representation which depicts the logical relationships among statements within the argument. One form of argument mapping, Toulmin diagrams, has been extensively studied both as an analytic tool to investigate proof production (e.g. Aberdein, 2006; Corneli et al., 2019; Pease et al., 2009) and as structured representation to facilitate collaborative argumentation (Wagner et al., 2014; Zambak & Magiera, 2020). Researchers in philosophy education have investigated how argument mapping techniques can improve students' critical thinking (Harrell, 2012; Twardy, 2004). Twardy (2004) demonstrated that first year philosophy students who were taught argument mapping had significantly higher gains on the California Critical Thinking Skills Test (CCTST) than those taught traditionally. Similarly, Harrell (2012) showed that students taking an introduction to philosophy course which taught argument mapping had significantly higher gains on a critical thinking-focused pre/post-test than those who had traditional instruction. While critical thinking in philosophy is not identical to proof comprehension, the skills measured by the CCTST and by Harrell's critical thinking test seem to align with some of the dimensions of proof comprehension laid out by Mejia-Ramos et al. (2012). For example, one goal of Harrell's test was to test whether students were able to "determine how the premises are supposed to support the conclusion" (2012, p. 34), which aligns with the dimension of comprehension "justification of claims" (Mejía-Ramos et al., 2012, p. 9).

Based on this research in the field of philosophy education, argument mapping has the potential to improve student comprehension of proofs. For this poster, I will report a literature review of the current use of argument diagramming in mathematics education and in adjacent fields (like philosophy and logic) and present a study design which seeks to address the question: how does diagramming the argument of a proof impact a student's comprehension of that proof?

Distributed Leadership in Action: The PAC-Math NIC

Jack Bookman
Duke University

Emily Braley
Johns Hopkins University

Jeneva Clark
University of Tennessee, Knoxville

Erica Slate
Appalachian State University.

Keywords: Distributed Leadership, Networked Improvement Communities

Distributed leadership (DL) abandons the heroism of an individual leader, and instead, capitalizes on participants' expertise by creating structures that encourage collaboration among an overlapping web of leaders and followers. Our prior work presented a new way of framing DL as 'flipping the spider' of traditional organizational hierarchy (Clark et al., 2022). Our previous research explored how DL-informed workshops can motivate faculty development (Clark et al., 2022) and teacher education (Miller & Braley, 2021). In our current project, we build on this and expand the work to explore how DL works within a Networked Improvement Community (NIC) (Bryk et al., 2015). NICs are described by four key characteristics: (1) the community aims to accomplish a clearly defined outcome, (2) members have a deep understanding of the common challenges of the community and are poised to adapt and create to make progress towards addressing needs, (3) the community action is informed by improvement science and strives for continuous inquiry and learning, and (4) members are coordinated to maximize effort towards addressing complex problems (LaMahieu, 2015). The DL structure provides opportunities for members to step into leadership roles according to their self-identified strengths and curiosities, while a core group of organizers and facilitators provide infrastructure and support.

In October 2023, the Program Assessment Conference for Mathematics (PAC-Math) (NSF award #2306211) brought together mathematics professional development practitioners, evaluation professionals, and higher education administrators to develop a flexible protocol for mathematics departments to use for self-evaluations of their Professional Development for Teaching (PDT) programs for graduate student teaching assistants (GTAs). By replicating the DL model in this NIC context, we aim to provide more nuanced descriptions of the DL anatomy. PAC-Math will advance the frontiers of knowledge about how DL supports NICs.

In this poster, we will review research about DL and describe how DL principles were applied in the planning of the PAC-Math conference by involving all participants. We will highlight how the DL model capitalized on the diversity of voices and shared expertise of participants. We will present some of the outcomes of the conference, conclusions of the external conference evaluation, and how the results of the conference will inform how DL might interplay differently in a NIC than in faculty development. We look forward to hearing from the RUME community about their insights into and experiences with DL and working in NICs.

Assessing Graduate Student Professional Development for Teaching:
Needs and Progress With PAC-Math

Jack Bookman, Duke University
Emily Braley, Johns Hopkins University
Jeneva Clark, U. of Tennessee Knoxville

The Program Assessment Conference in Mathematics (PAC-Math, DUE# 2036211) was hosted in October 2023 at the University of Tennessee Knoxville. The conference produced key components to build a protocol for mathematics departments to self-assess their professional development for teaching provided to graduate students in mathematics. We describe previously presented results of a census survey of mathematics PhD programs conducted in Fall 2021 that reinforces the need in higher-ed mathematics for tools to do this assessment work, confirming results from a similar survey conducted in 2015. In this poster we outline the protocol, departmental resources needed to undertake this assessment work and questions of interest for the RUME community.

Keywords: Graduate Student Teaching Assistants, Professional Development, Program Assessment

Most PhD-granting mathematics departments provide Professional Development for Teaching (PDT) to Graduate student Teaching Assistants (GTAs) (Braley et al., 2023; Rasmussen et al., 2019). To sustain and improve these programs, departments and administrators need to be able to assess program effectiveness and establish assessment cycles that inform continuous improvement. From surveys conducted in 2015, in partnership between the CoMInDs project (NSF#1432381) and Progress Through Calculus project (NSF#1430540), and in 2021 by the CoMInDS project, we know that evaluation of GTA PDT has been extremely limited. For example, despite reservations of their validity, student evaluations of teaching are used as a primary evidence source to assess ongoing teacher training efforts (Braley et al., 2023; Speer et al., 2017). Survey respondents also indicated that tools for evaluation would be the one of the most valuable resources to help improve PDT programs.

The PAC-Math (Program Assessment Conference in Mathematics, DUE# 2036211) project aims to improve program assessment practices for PDT programs for GTAs in mathematics. PAC-Math convened a diverse group of experts and oriented them to (1) the current landscape of GTA PDT in PhD granting mathematics departments and (2) the need and desire in the mathematics community to assess PDT. In October 2023 PAC-Math participants met in-person to draft a flexible assessment protocol for self-assessment of PDT programs.

This poster will describe the background and evidence supporting the mathematics community's need for GTA PDT assessment tools or guides. It will provide an outline of the draft protocol developed through the work of the PAC-Math participants with a focus on stakeholders roles and needs, as well as the differing needs at various institutions. We invite the RUME community to scrutinize our results and make suggestions for improving the PAC-Math Protocol. We hope to recruit partners for future work in this area.

PAC MATH

Ready!

ONCE UPON A TIME

- What preparation would Math Departments do before evaluating their GTA PDT programs?
- How would they identify goals?
- What tools, such as logic models or key performance indicators, could help the evaluation planning process?
- Would it help to describe the history of and current state of the program?

THE PLOT

- What data could be collected?
- What are pros and cons for types of data collection?
- Who are the stakeholders and what would each of the stakeholders consider as evidence of success?
- How does data collection reflect the voices and interests of stakeholders?
- What analyses can be done?

PAC MATH

MORAL OF THE STORY

- What form should results take?
- How are results communicated?
- How should stakeholders' responses to results be reflected in reporting?
- How do stakeholders provide feedback to drive continuous improvement and positive change?
- How can the assessment cycle be continued and connected to the broader missions?

Mathematics Motivation in Students Enrolled in an Introductory Biology Course

Sophia Brisard
University of New Hampshire

Melissa Aikens
University of New Hampshire

Keywords: Mathematics Student Motivation, Quantitative Biology, Task Value, Self-Efficacy

Over the last two decades, the field of biology has become increasingly more quantitative leading to more mathematics being integrated into biology education curriculum (Brewer & Smith, 2011). However, students enrolled in biology courses often report having negative feelings towards mathematics, resulting in them being resistant to learning course material (Thompson et al., 2013). To understand these negative feelings, this study focuses on identifying patterns of mathematics motivation among undergraduate students enrolled in a gateway biology course. To do this, the study utilizes Expectancy Value Theory (EVT; Eccles et al., 1983), which proposes that an individual's expectancy for success and their subjective task values are predictors of academic choice, persistence, and performance. Subcomponents of values are (1) utility value, or how useful the task is for future goals, (2) interest value, or the intrinsic interest of a task, (3) attainment value, or the importance of doing well, and (4) cost, or the accumulated negative aspects of engaging in the task. This study looks at two dimensions of cost: emotional cost and effort required to complete the task (Wigfield & Eccles, 2000).

Participants include 538 students in an introductory biology course at a large research-intensive university. At the start of the course, students completed a 7-point Likert Scale survey that examined six variables including self-efficacy, emotional cost, effort cost, intrinsic value, mathematics attainment value, and utility value. Self-efficacy was measured as an indicator of expectancy of success (Eccles & Wigfield, 1995). Each subscale was taken or modified from previously validated surveys (Andrews et al., 2017; Flake et al., 2015; Gaspard et al., 2015; Glynn et al., 2011). The study used Confirmatory Factor Analysis, with "lavaan" R package (Rosseel, 2012) with maximum likelihood robust estimation (Knekta et al., 2019) to verify the factor structure of the variables. All fit indices (CFI, TLI, RMSEA, SRMR) were within suggested cutoff values as suggested by Hu & Bentler (1999) and Steiger (2007).

This study used hierarchical cluster analysis (Wards method and Euclidean distance), to find students with similar motivation characteristics based on task values (mathematics attainment, utility, and intrinsic value), cost (emotional and effort) and self-efficacy (expectancy of success). Using the "NbClust" package (Charrad et al., 2014), we found three different patterns of mathematics motivation within the data: low, moderate and high. The low group includes 45 students that place low value on mathematics (range of task value means: 1.76 - 3.91) and do not feel confident to complete the mathematics required in the course (self-efficacy mean: 2.93). Also, low motivation students felt that mathematics had high costs (emotional and effort cost means > 5.55). In contrast, the high group (164 students) place high value on mathematics and are more confident in the subject (task values and self-efficacy means > 5.60). In addition, students believe mathematics in the course has low costs (means < 2.50). The final group, moderate, is composed of 319 students who are moderately motivated to do mathematics. In this group, mathematics attainment value and utility value had higher means of 5.42 and 5.18, respectively. All other variable means were relatively close to 4. The findings show that students in the introductory biology course can be clustered into three groups (low, moderate, and high), with over half in the moderate cluster. For future analysis, we plan to further examine each cluster, with more of a focus on the moderate cluster.

Mathematics Motivation in Students Enrolled in an Introductory Biology Course

Sophia Brisard & Melissa Aikens
Department of Biological Sciences, University of New Hampshire, Durham, NH 03824

Introduction

- Over the last two decades, the field of biology has become increasingly more quantitative leading to more mathematics being integrated into the biology curriculum (Brewer & Smith, 2011).
- However, students enrolled in biology courses often report having negative feelings towards mathematics, resulting in them not fully engaging in quantitative tasks (Thompson et al., 2013).

Research Questions:

1. What are the mathematics motivational patterns among undergraduate students who are enrolled in a gateway biology course?
2. To what extent is gender and pre-professional status related to these motivational patterns?

Data

Setting and Participants

- Course: Introductory biology course
  - Six sections over 2 years
- Data consists of 473 student survey responses who were life-science majors enrolled in the course.
  - Gender: Male = 121 & Female = 352
  - Pre-Professional Status: Pre-Professional = 211 & Non-Pre-Professional = 262
  - Highest math class taken in High School: Algebra, Geometry or Trigonometry = 70, Pre-Calculus = 202, & Calculus = 201

Instrument & Variables Measured

- The survey is made up of 28 7-point Likert-type items taken or modified from previously published surveys (Andrews et al., 2017; Flake et al., 2015; Gaspard et al., 2015; Glynn et al., 2011).
- The instrument contains items that relate to six constructs:

Construct 1: *Intrinsic value* - interest in using mathematics to understand biology

Construct 2: *Utility value* of mathematics for a career in life science

Construct 3: *Attainment value* – importance of doing the mathematics well

Construct 4: *Emotional Cost* of using mathematics in the biology course

Construct 5: *Effort* required to do mathematics in the biology course

Construct 6: *Expectations for success* in using mathematics in biology courses - measured by self-efficacy (Eccles & Wigfield, 1995)

- Confirmatory Factor Analysis with maximum likelihood robust estimation (Knekta et al., 2019) verified that all fit indices (CFI, TLI, RMSEA, SRMR) were within suggested cutoff values as suggested by Hu & Bentler (1999) and Steiger (2007).

Expectancy Value Theory (Eccles et al., 1983; Wigfield & Eccles, 2000)

Task Values

- Intrinsic Value
- Utility Value
- Attainment Value
- Emotional Cost
- Effort Cost

Expectancy of Success

- Self-Efficacy

Achievement Motivation & Task Completion

Data Analysis

What are the mathematics motivational patterns among undergraduate students who are enrolled in a gateway biology course?	Agglomerative Hierarchical Clustering using Wards method as the algorithm and Euclidean distance as the distance measure. Bootstrapping was used to determine the optimal number of clusters.
To what extent is gender and pre-professional status related to these patterns?	Multinominal Logistic Regression Analysis Outcome Variable: Cluster Independent Variables: Gender (male or female) and Pre-Professional Status (pre-professional or non-pre-professional) Control Variable: Highest Mathematics Course Taken in High School (Algebra/Geometry/Trigonometry, Pre-Calculus, or Calculus)

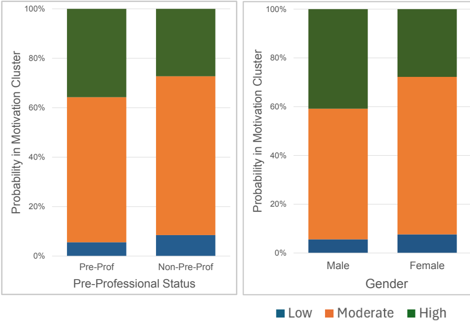
Cluster Analysis Results

Table 1: Means and Standard Deviations of the six affective variables in each motivation cluster.

Variable \ Cluster	Low Motivation N = 45	Moderate Motivation N = 319	High Motivation N = 164
Intrinsic Value	1.76 (± 0.65)	3.56 (± 1.23)	5.62 (± 0.77)
Utility Value	3.76 (± 1.23)	5.42 (± 0.99)	6.20 (± 0.81)
Mathematics Attainment Value	3.91 (± 1.07)	5.18 (± 1.02)	6.13 (± 0.77)
Emotional Cost	6.11 (± 0.60)	4.32 (± 1.05)	2.33 (± 0.91)
Effort Cost	5.55 (± 0.76)	3.74 (± 0.98)	2.10 (± 0.72)
Self-Efficacy	2.93 (± 1.17)	4.72 (± 1.05)	5.98 (± 0.84)

Multinominal Logistic Regression Results

Figure 1: Percent chance each predictor variable category is in low, moderate and high motivation cluster.



Conclusions

- Students in the introductory biology course can be clustered into three groups of motivation (low, moderate, and high), with over half in the moderate cluster.
- Gender and pre-professional status were not statistically significant in predicting motivational patterns.
- Controlling for highest mathematics course taken in High School, the probability that a female will be in the high motivation cluster is 27.8%. In comparison, the probability that a male will be in the high motivation cluster is 40.9%.
- Pre-Professional majors have a 35.7% chance of being in the high motivation cluster while non-pre-professional majors have a 27.3% of being in the high motivation cluster while controlling for highest mathematics course taken in High School.
- Next Steps: Investigate whether students' motivational patterns change as they complete the biology course?

The Journey of Quantitative Literacy Development: Insights from Physics Majors

Qirui Guo, Charlotte Zimmerman, and Suzanne White Brahmia (University of Washington)

INTRODUCTION

What is ……

★**Quantitative Literacy (QL)**: the ability to understand, interpret, and apply numerical and mathematical information across various contexts.

★**Physics Quantitative Literacy (PQL)**: the blending of conceptual and procedural mathematics to generate and apply quantitative models of physical phenomena.

★**Physics Inventory for Quantitative Literacy (PIQL)**: a multiple-choice test designed to assess PQL in everyday and abstract contexts.

METHOD

★Where: University of Washington

★When: between 2020 - 2023

★Who: Matched groups of physics majors (anonymized by code) from 3 levels of courses

✳ Number of people in each matched set:

100 - 200 Level: 198

200 - 300 Level: 60

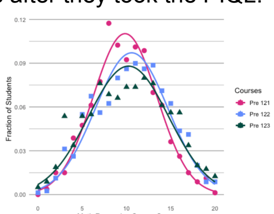
All Three Levels: 42

★How:

✳ Quantitative: We group students by thirds according to their pretest scores and use the same breakdown for posttest.

✳ Qualitative: Free response survey collected from 102 students after they took the PIQL.

What they saw →



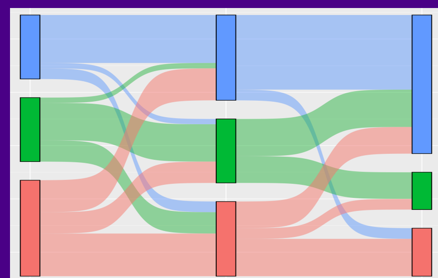
Physics majors develop *algebraic reasoning* **but** they <u>don't</u> perceive it as *"doing physics"*

Students' **transitions** between low, medium, and high scoring groups.

28.6% (15 - 20)

28.6% (11 - 14)

42.9% (2 - 10)



100 → 200 → 300 Level

61.9% (15 - 20)

16.7% (11 - 14)

21.4% (2 - 10)

Percentage of students (Score Range)

Max score = 20

Are physics majors <u>surprised</u> that students **don't** typically reason math better after taking introductory physics?

High (15 - 20)	12	16.3	**28.6**	16	16.6	**38.1**	26	17.1	**61.9**

Max score = 20

Why do they think so?

✳ "…in my experience <u>UW physics does not teach math reasoning skills</u>"

✳ "…the intro physics courses are <u>more about learning the details of the physics rather than broader math reasoning skills</u>"

✳ "…intro physics is too dense with memorizing equations, <u>it does not introduce mathematical creativity very much</u> for better or worse"

✳ "…the intro series of physics courses is also <u>pretty poor at building up mathematical reasoning skills</u>, …, with the math consistently being the most difficult part as well as <u>the most glossed over part</u> of these courses"

DISCUSSION

What are we doing next:

★ Collect more data and look more closely into students who change their groups and who stay in the same groups

★ Compare students' PIQL scores with their course grade and see if there is a connection

Proof Writing and Comprehension in Topology

Caleb Judkins
The University of Oklahoma

Sepideh Stewart
The University of Oklahoma

Keywords: Topology, mathematics communication, APOS, Tall's worlds of mathematical thinking, proof

The pedagogy of proof has been a topic of research interest in mathematics education literature (e.g., Melhuish et al., 2022). While proof writing is a formal and abstract topic for many students, topology proofs typically demand a level of visual comprehension as well, which places topology in a spot of particular interest. Many argue that learning topology relies on spatial reasoning, yet others have noted that students' shortcomings are typically in the formal, proof-based aspects of problems (e.g., Narli, 2010). Various researchers have sought to understand how we can teach topology by studying how learning takes place (e.g., Cook et al., 2017; Wilkerson-Jerde & Wilensky, 2011), what methods of teaching can support this learning (e.g., Griffiths, 1971; Deogratias, 2022; Estabrooks & McArdle, 2022; Stewart, 2000), and what concepts students typically understand (e.g., Aksu, Gedik, & Konyalioglu, 2021; Cheshire, 2017; Gallager & Infante, 2019). However, there is a lack of research into how students perceive their own experiences in learning topology.

We seek to build a model based on Tall's (2008; 2013) framework of mathematical thinking and APOS theory in order to gain insights into the cognition of topology. In addition, we will examine how students communicate their experiences and think about topology. Tall's three worlds suggests that modes of thinking can be described as three different "worlds" of thought: the embodied, symbolic, and formal worlds (Tall, 2008; 2013). The embodied world refers to aspects of thought informed by perception, the symbolic world contains the thinkable concepts as generalized objects, and the formal, axiomatic world derives meaning from definitions and formal constructions. APOS theory refers to the depth of understanding that learners may demonstrate as they come to understand a topic (Dubinsky & McDonald, 2001). Using the three worlds of mathematical thinking and the action, process, and object levels from APOS, we will create a table synthesizing both ideas inside a grid (APOS on the first column, three worlds on the top row). Networking these theories gives language to what behaviors are exhibited in proof as the writer transitions across various types of thinking and levels of complexity. Changes throughout a proof would be characterized as transitions of thought, demonstrating how various ideas are handled, transformed, or ignored. We will demonstrate this model with a particular example from topology and elaborate on the mathematics behind it in order to develop it.

This three worlds-APOS model can be employed as novice graduate students complete work in topology. Students may understand concepts as actions, then generalized processes, then complete objects, and have a schema to allow them to transition between all three worlds of mathematical thinking. This research study is sought to determine students' struggles and experiences with topology using the model. We seek to answer the following questions: How can this model be used to examine the level of understanding of topology? What improvements can be made to this model? What topics in topology does this model reveal that are typically neglected on the formal level? What topics in topology are transitioned into spatial reasoning? What topics in topology are kept on the formal level of understanding?

Proof Writing and Comprehension in Topology

Caleb Judkins & Sepideh Stewart
University of Oklahoma

INTRODUCTION

The pedagogy of proof has been a topic of research interest in mathematics education literature (e.g., Melhuish et al., 2022). While proof writing is a formal and abstract topic for many students, topology proofs typically demand a level of visual comprehension as well, which places topology in a spot of particular interest. Many argue that learning topology relies on spatial reasoning, yet others have noted that students' shortcomings are typically in the formal, proof-based aspects of problems (e.g., Narli, 2010). A portion of the literature can be summarized with the following:

What do students struggle with?	What methods of teaching can help students?	How do students develop understanding?	How can we reinvent how topology is taught?
Countable unions/intersections Non-metrizable spaces Escaping the usual topologies Applying topology to geometry	Topology can be taught motivated from analysis General topologies are abstractions of metric spaces Physical objects can be helpful, though sometimes confusing	Students reinvent and adapt their own axiomatic systems Students reconcile misconceptions Experts learn well from proofs	Classes based around students discovering the concepts do incredibly well Motivations for topology exist in games/art
e.g., Deogratias 2022; Aksu et al. 2021; Cheshire 2017; Gallagher 2019; Narli 2010	e.g., Shipman & Stephenson 2022; Helmstutler et al. 2012; Griffiths 1971	e.g., Cheshire 2017; Wilkerson-Jerde, Michelle, & Wilensky 2011	e.g., Estabrooks & Mcardle 2022; Cook et al. 2017; Stewart 2000; Poggi 1985

Still, there is a lack of research into how students navigate transitions from the spatial concepts to formal logic and how they perceive their own actions in topology.

THEORETICAL BACKGROUND

Tall's Three Worlds of Mathematical Thinking suggests that modes of thinking can be described as three different "worlds" of thought: the embodied, symbolic, and formal worlds (Tall, 2008; 2013). The embodied world refers to aspects of thought informed by perception, the symbolic world contains the thinkable concepts as generalized objects, and the formal, axiomatic world derives meaning from definitions and formal constructions.
APOS theory refers to the depth of understanding that learners may demonstrate as they come to understand a topic (Dubinsky & McDonald, 2001). First, there are actions taken. Processes are actions that are repeated and reflected upon, which then are encapsulated into objects that can be acted on. The schema is the collection of all of these.

DESIGN OF THE MODEL AND RESEARCH QUESTIONS

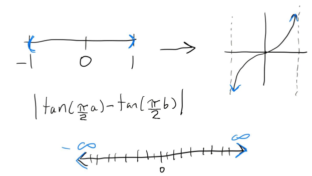
Seeking to gain insight into how students perceive their own actions in their topology proof writing, we network Tall's Three Worlds and APOS Theory together to develop a model. Putting these together gives a holistic perspective of the learner's thoughts and actions. We perform this networking by combining both theories into a single table with APOS columns and Tall's Three Worlds rows. With this model in mind, we seek to answer the following **research questions**:
How can this model be used to examine students' understanding of topology? What topics in topology does this model reveal that are typically neglected on the formal level? What topics in topology are transitioned into spatial reasoning? What topics in topology are kept on the formal level of understanding? What are the limitations of this model and what improvements can be made?

APPLYING THE MODEL: TASK AND SAMPLE SOLUTION

To help identify when transitions are made, the order of the items are numbered with superscripts.

Question 1: Give a metric on the set (-1,1) that induces the usual topology and is complete.

	Action	Process	Object
Embodied	$-1\to-\infty$, $1\to\infty$ [6]	$(-1,1)\to\mathbb{R}$ sends points to infinity [4]	Graph of Tan is infinite 1-manifold [1.5]
Symbolic	Compose distance with Tan [9]	$d(a,b)=\lvert a-b\rvert$ [8]	$\mathbb{R}\cong(a,b)$ [1] Metric has 2 inputs [7]
Formal		$f(x)=\tan(x*\pi/2)$ [5]	Reals are complete [2] $(-1,1)$ doesn't have its limits [3]

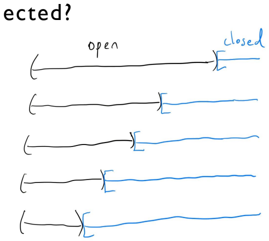


- Why are there no formal actions?
- The world with the most behavior is the symbolic, the stage most referenced is object. Does the performance on this question support this?
- When do transitions from worlds/stages happen?

What is the usual topology on this interval? It's the same as the reals, as is any basic open interval (via some variation on tangent). I must come up with a *metric* that induces the usual topology but is complete as a metric space, so I ask if the space is usually complete. The reals are complete with the usual metric, but clearly, as is the concept of the question, the interval given is not complete with the same metric. So, comparing the two spaces, how are they different from a metric standpoint: While the interval is finite in length, the reals are infinite, so we just need to identify how the interval is sent to the reals via tangent, then combine that with the usual metric on the reals.

Question 2: Is the topology given by $T=\{(0,a) \leq \mathbb{R}^+ \mid 0 < a\}$ path connected?

	Action	Process	Object
Embodied		Path-Connectedness is embedding lines throughout the space [2]	
Symbolic	Compliment of (0,a) is $[a,\infty)$ [5]		Closed sets of R [6]
Formal	Courser topologies are not always subset topologies [1]		Definitions: Topology as a set-family [1.5], path-connected [3], continuous function [4]



- Why was this mostly a symbolic and object oriented proof?
- Does the lack of varying concepts reflect a lack of understanding or completion?

While being a subset of the reals, this is not given the subspace topology, so I need to be mindful of that distinction as I think of this space. My usual intuition for path-connectedness fails since this is not the usual topology. I fall back on the definition of path-connected, and, wanting to make a path between any two points, I realize I'm not sure what a continuous function into this space should look like. The definition of continuous is the preimage of closed sets are closed, so I need to know what sets are closed in this topology. Since these are just compliments of the open sets given to me, they all look the same as $[a,\infty)$. These sets are already closed in the usual topology, so the usual paths are already continuous here, so any straight-line path is a path from any two points of the space, thus the space is path-connected.

REFLECTION

Although the model is adequate at showing how students think about concepts in topology in terms of complexity and form, as the examples above show a lack of formal actions, it needs more research directed towards questions demanding those behaviors.

Keywords: Active Assessment, Community of Practice, Active Learning

Recently, there has been a surge in interest in developing more flexible assessment structures, with a great deal of momentum for this movement from COVID-19 pandemic equity considerations (Kadakia & Bradshaw, 2020; Kim, 2020). Active-learning-based instructional practices are now established in undergraduate education (Laursen & Rasmussen, 2019). Yet, how to align assessment with those practices is still developing. The ideas presented are part of a larger project that explores instructor and student perspectives on *active assessment*, assessment strategies grounded in the values and practices of active learning, including attention to equity. The authors are participants in the project. This poster will focus on challenges and benefits that have appeared in the first year for the authors, as a community of practice (CoP), designing and implementing active assessment.

Members of the CoP are mathematics instructors in a variety of career stages and positions, teaching courses from introductory-level courses with co-requisite support, through upper division electives for math majors. This work takes place at an institution with a variety of supports available, and individual instructors' consideration and implementation of *active assessment* occurs within the ongoing process of CoP professional and pedagogical growth.

This poster will share stories about our motivation as well as initial and in-progress thoughts on implementation. It will include details on class sizes and examples of active assessments as well as notes on how they are administered. The stories generated some questions related to equity and the challenges and benefits of *active assessment*:

- We have noticed a challenge in structuring projects as a form of active assessment. Thus, a focal question for the group is: How do we balance promoting group projects and offering individual options for projects in response to the needs and preferences of students?
- Using assessments involving short- and long-answer responses, we noticed students gave short, surface-level responses. This led to another question for the CoP to address: How can we leverage assessment strategies and give qualitative feedback that supports students in engaging with written assignments in a meaningful way?
- Peer feedback on assessments can help students plan their learning and identify strengths and areas for growth. How can we evoke critical peer feedback that encourages students to reflect more deeply on the quality of their work?

In all of these questions, we aim to center equity and access to rich mathematical experiences. A goal of this poster is to generate critical conversations that will inform our ongoing research and practice.

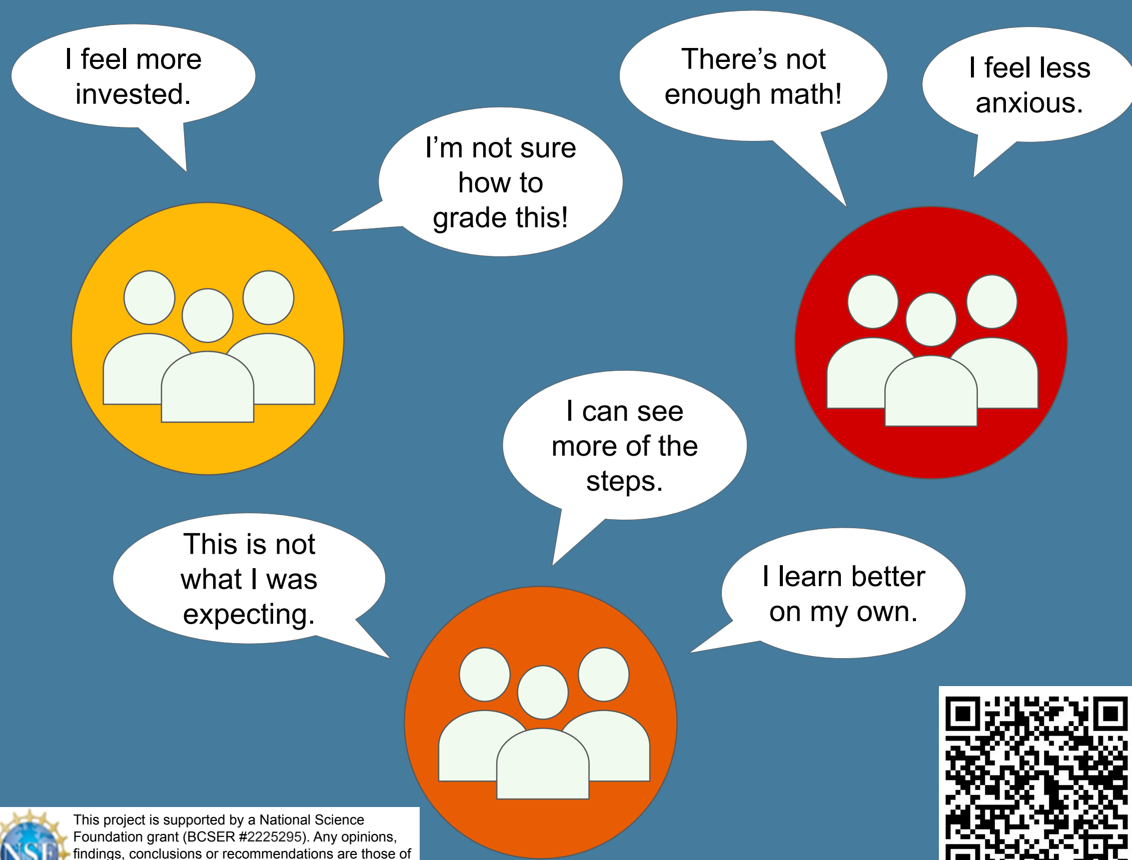
Implementing Active Assessment:
Stories from an Instructor Learning Community

2023-2024 Assessment Community of Practice

- Includes lecturer, pre-tenure, and tenured faculty.
- Wide range of courses and assessment strategies represented.
- Focus on **active assessment** across different contexts.

By using **assessment strategies** aligned with **active learning**, we uncover more about **students' learning process**.



Projects:
Finite Math for Business
Business Majors, 35 students
Students chose to either use real data from a company that produces and sells items or to estimate data from an imaginary future business. Groups built models of business functions and used platforms such as Desmos to make a presentation that explains important points in the model and provide the best consulting solution for the business by mathematics.

- Reducing stress compared to a traditional test.
- Challenging if students cannot work in groups for any reason.
- How flexible we can be if students can't work in project for any reason?

Written Responses:
Math for the Arts and Humanities
Non-STEM majors, 35 students
Students compiled portfolios of their work. As part of the portfolio, students had to write summaries of mathematical content from topics covered in class.

- Writing summaries helps students reinforce content and encourages students to write mathematical ideas in their own words.
- Students typically gave surface level responses and had a difficult time synthesizing material.
- How can we prepare students in a math class to engage in writing at a deeper level?

Peer Feedback:
Intro to differential Equations
STEM Majors, 20 students
Students created mini lessons to teach each other techniques for solving ODEs. They were required to give feedback on their classmates' mini lessons, and use feedback they received to revise their work.

- Student presentations provided insight into their thinking and how they approached each problem.
- Peer feedback did not promote deeper reflection or increase progress toward the learning objectives for either learner.
- How can we evoke critical peer feedback that encourages students to reflect more deeply on the quality of their work?

Is There an Interrelation Between Graduate Students' Teaching of Undergraduate Courses and Their Own Learning of Advanced Mathematics?

Anna Mikulo
University of Oklahoma

Sepideh Stewart
University of Oklahoma

Keywords: mathematics graduate students, teaching, leaning, ROG, PCK

The academic role of mathematics graduate students is complex, as it entails being simultaneously a student, a teacher, and a researcher. The three roles are inseparable from the graduate school experience and shape graduate students' professional identity (Colbeck, 2008). Some studies (e.g., Lai et al., 2016; Speer & Hald, 2008; Schoenfeld, 2015) suggest a deeper consideration of the connection between teaching, research, and learning among graduate students. Furthermore, Beisiegel (2019) believes that some mathematics graduate students perceive teaching and research as contrasting and contradicting roles.

The purpose of this poster is to build and discuss a model of "Interrelation Between Teaching and Learning Mathematics of Graduate Students", based on Schoenfeld's (2015) "Resources, Orientations, and Goals" model along with Ball et al.'s (2008) "Pedagogical Content Knowledge" theoretical framework. As a teacher and researcher, being a student is an inseparable part of graduate students' professional identity (Colbeck, 2008); hence, constant learning is inevitably a part of graduate students' lives, resulting in the accumulation of mathematical knowledge. The framework of "Resources, Orientation, Goals, and Decision-Making" (ROGs) was developed to predict and map one's professional behavior (Schoenfeld, 2015). Schoenfeld's framework made knowledge to be the resource in focus, which, in the presented model, graduate students rely on the most. According to Schoenfeld, "an individual enters into a particular context with a specific body of resources, goals, and orientations" (p. 347), they observe and orient the situation, establish or re-establish goals, and make decisions as a result of this internal analysis (Schoenfeld, 2015). In teaching undergraduate courses, graduate students' decisions and choices are impacted by their previously acquired knowledge. The choice of lecture style, problems solved, examples, and explanations given are based on graduate students' mathematical knowledge acquired through their prior learning. For example, upon completing Real Analysis, graduate students' teaching of limits and integrals may be enhanced by their theory encountered in the class. In addition to mathematical knowledge, teachers have a pedagogical content knowledge acquired through teaching (Ball et al., 2008). As teachers, graduate students have a developed intuition about problems and concepts that are challenging for students and are "able to hear and interpret students' emerging and incomplete thinking" (p. 401) (Ball et al., 2008). The knowledge of the origin of common mistakes and misconceptions among students allows teachers to reliably identify students' thought processes behind solving math problems. The awareness of multiple ways to approach solving a problem, the knowledge behind made choices, and recognition of different strategies applied in the solution are a product of pedagogical content knowledge (PCK). Such gained skill set is expected to help graduate students with answering challenging homework problems in their classes by revealing alternative approaches. In light of the proposed model, our research questions to guide this study are: Does the pedagogical content knowledge gained from teaching undergraduate courses affect graduate students' learning of advanced mathematics? Does the knowledge acquired while studying for graduate courses impact the graduate students' teaching?

Interrelation Between Teaching and Learning Mathematics of Graduate Students

Anna Mikulo & Sepideh Stewart

INTRODUCTION

The academic role of mathematics graduate students is complex, as it entails being simultaneously a student, a teacher, and a researcher. The three roles are inseparable from the graduate school experience and shape graduate students' professional identity (Colbeck, 2008). A study by Beisiegel (2019) reveal mathematics graduate students' view of the relation between teaching and research, where studied participants perceived two roles being "totally different" (p. 494). This perception could lead to research and teaching requiring separately invested time and energy, leaving graduate students with no choice but under-commit to one of the roles. The purpose of this poster is to build and discuss a model of "Interrelation Between Teaching and Learning Mathematics of Graduate Students", based on Schoenfeld's (2015) ROGs model along with Ball et al.'s (2008) PCK theoretical framework.

RESEARCH QUESTIONS

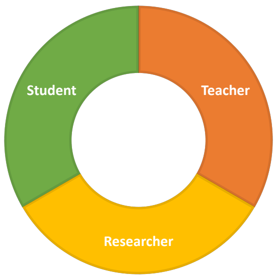
- Does the pedagogical content knowledge gained from teaching undergraduate courses affect graduate students' learning of advanced mathematics?
- Does the knowledge acquired while studying for graduate courses impact the graduate students' teaching?

DESCRIPTION OF THE MODEL

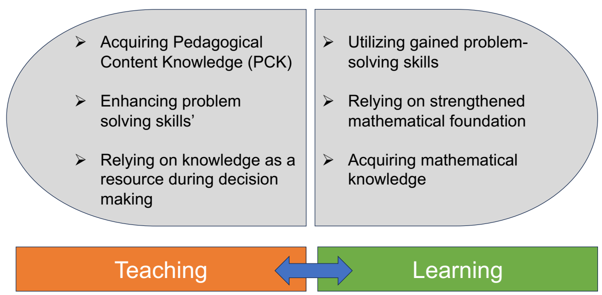
This model relies on two theoretical frameworks: PCK (Ball et al., 2008) and ROGs (Schoenfeld, 2015). During teaching, graduate students acquire pedagogical content knowledge, which enhances their understanding of the material taught and introduces them to different solution approaches undergraduate students take. With wider exposure to problem-solving techniques, we conjecture that producing proofs may become clearer for graduate students. On the other hand, while learning advanced mathematical content, graduate students expand their knowledge, which is the primary resource of their reliance. With knowledge as a resource, according to ROGs, graduate students' decisions in teaching change correspondingly to the resource. Hence, graduate courses students take influence their choices of material presentation, solution approaches, and variety of examples provided.

The model aims to track and establish the existence of a relation between teaching and learning, which would help to understand graduate students' experience as teachers and students and help them witness the influence of this interrelation.

PROFESSIONAL IDENTITY



THE MODEL: INTERRELATION BETWEEN TEACHING AND LEARNING MATHEMATICS OF GRADUATE STUDENTS



THEORETICAL BACKGROUND

The framework of ROGs was developed to predict and map one's professional behavior (Schoenfeld, 2015). Schoenfeld's framework made knowledge to be the resource in focus, which, in the presented model, graduate students rely on the most. According to Schoenfeld, "an individual enters into a particular context" (p. 347), they observe the situation, establish goals, and make decisions as a result of this internal analysis (Schoenfeld, 2015). In teaching undergraduate courses, graduate students' decisions and choices are impacted by their previously acquired knowledge.

As teachers, graduate students have a developed intuition about problems and concepts that are challenging for students and are "able to hear and interpret students' emerging and incomplete thinking" (p. 401) (Ball et al., 2008). The awareness of multiple ways to approach solving a problem, the knowledge behind made choices, and recognition of different strategies applied in the solution are a product of PCK. Such gained skill set is expected to help graduate students with answering challenging homework problems in their classes by revealing alternative approaches.

Graduate students observe norms of social interactions in their professional environment, interpret them based on their personal experience, and adapt such norms according to how they see themselves fit in that professional environment. Adapting Colbeck's definition (2008), the identity is "'what it means to be who one is'" (p. 10) and "individuals' identities are often associated with labels for social positions or roles" (p. 10) (Colbeck, 2008). So, having a professional identity as a *graduate student* entails having teacher, student, researcher, mathematician, tutor, grader, and TA as part of their professional identities.

FUTURE STUDY

To test the developing model, the future research may be a case study using a qualitative research approach and it may be carried out in two phases. The fist phase will investigate the relation between teaching and graduate students' learning where the participants will be University of Oklahoma mathematics graduate students two have taken Real Analysis sequence, have no prior experience teaching Calculus, and are assigned to teach Calculus I or Calculus II. Before the semester of teaching, graduate students will be asked to answer a list of Real Analysis questions that relate to Calculus topics other advanced Real Analysis questions. At the end of the semester, graduate students will be asked a set of similar questions to gage any enhancement of understanding of Real Analysis concepts.

REAL ANALYSIS TEST

1. Find an increasing function f such that $f' = 0$ a.e. but f is not constant on any open interval (p. 129) (Bass, 2013).
2. If f is real-valued and differentiable at each point of $[0, 1]$, is f necessarily absolutely continuous on $[0, 1]$? If not, find a counterexample (p. 129) (Bass, 2013).
3. Prove or disprove: If $F \subseteq \mathbb{R}$ is such that every bounded continuous function from F to $\mathbb{R}$ can be extended to a continuous function from $\mathbb{R}$ to $\mathbb{R}$, then F is a closed subset of $\mathbb{R}$ (p. 72) (Axler, 2020).
4. Prove or disprove: If $A \subseteq \mathbb{R}$ a d $f_1, f_2, \ldots$ is a sequence of uniformly continuous functions from A to $\mathbb{R}$ that converges uniformly to a function $f : A \to \mathbb{R}$, then f is uniformly continuous on A. (p. 71) (Axler, 2020).
5. Suppose $f, g : [a, b] \to \mathbb{R}$ are Riemann integrable. Prove that $f + g$ is Riemann integrable on $[a, b]$ and $\int_a^b (f + g) = \int_a^b f + \int_a^b g$ (p. 7) (Axler, 2020).
6. Suppose $f : [a, b] \to \mathbb{R}$ is a bounded function. Prove that f is a Riemann integrable if and only if for each $\epsilon > 0$, there exists a partition P on $[a, b]$ such that $U(f, P, [a, b]) - \mathcal{L}(f, P, [a, b]) < \epsilon$ (p. 7) (Axler, 2020).
7. Suppose μ is a signed measure on $(\mathcal{X}, \mathcal{A})$. Prove that if $A \in \mathcal{A}$, then $\mu^+ = sup\{\mu(B) \mid B \in B, B \subset A\}$ and $\mu^- = -inf\{\mu(B) \mid B \in B, B \subset A\}$. (p. 98) (Bass, 2013).

The second phase will consist of exploring ways studying advanced mathematics may influence teaching undergraduate courses. The participants will be mathematics graduate students who have not taken Real Analysis sequence and they will be interviewed before and after the sequence. The interview questions will target graduate students' approach to teaching Calculus I or II related topics. The Interviews will be conducted and after before taking Real Analysis sequence.

INTERVIEW QUESTIONS RELATED TO TEACHING

1. Describe your teaching approach of derivatives.
2. Give three examples of continuous functions and justify your choice.
3. Please explain the relation between continuity and differentiability.

Keywords: quantitative literacy, assessment, physics

The Physics Inventory of Quantitative Literacy (PIQL) is a 20-item multiple-choice test designed to measure the development of students' physics quantitative literacy (PQL) across multiple physics courses (Olsho et al., 2023; Smith et al., 2020; White Brahmia et al., 2021). Repeated testing, coupled with requiring up to 40 minutes for students to complete the test, could lead to testing fatigue and unreliable results. We seek to create two shorter versions of the PIQL (a.k.a. piqlets) that are statistically equivalent to each other in terms of student performance on three facets of PQL (ratios and proportions, covariation, and signs and negativity).

Han et al. (2015) used a large data set of student responses to a 30-item conceptual physics test to identify combinations of items that produced testlets with the most similar average student scores. They demonstrated the equivalence of the testlets using item response theory (IRT) and correlating individual students' scores across versions. We follow their example by creating 12-item piqlets that each contain four overlapping anchor items (to facilitate comparisons between versions) and eight distinct items. Our work was guided by these research questions:

1) Which combination of items produces piqlets with the smallest score differences?
2) How does the reliability of these piqlets compare to each other and to the PIQL?
3) How similar are the psychometric parameters for the anchor items across piqlets?

Data were collected using the full PIQL in three introductory physics courses at a large public university in the western US (2100–3200 students in each data set). We considered 240 combinations of items for the piqlet versions, subject to constraints that both the content and the format of items were equivalent across the two versions. We calculated a total test score for each piqlet based on the average percentage of items answered correctly, as well as subscores for the three facets of PQL. For each of our three data sets we determined the average score difference between the piqlets, calculated Cronbach's α for each piqlet, and applied IRT analyses to each.

The combinations of items that we identified as being the most similar had overall average score differences from 0.6–1.3%. Cronbach's α values ranged from 0.67 to 0.75, with differences less than 0.01 between versions. We see strong correlations between individual student scores on the two piqlets, with $0.79 \leq r \leq 0.85$. The IRT parameters support the statistical equivalence of the piqlets with parameters of overlapping items agreeing to within 0.1. These preliminary results suggest a strong potential for identifying piqlets that are statistically equivalent for the broader population of mathematics and physics students based on a larger, more diverse, data set.

Introduction

- Improving students' physics quantitative literacy (PQL) is a goal for many physics instructors.
- PQL is the blended relationship between students' general mathematical reasoning and conceptual understanding of physics.
- The **P**hysics **I**nventory of **Q**uantitative **L**iteracy (PIQL) is a 20-item multiple-choice test designed to measure PQL across three facets (Olsho et al., 2023; Smith et al., 2020; White Brahmia et al., 2021).
- PIQL used in multiple physics courses to track student growth
- Some items are multiple-choice-multiple-response (MCMR)
- **Known Problems:**
  - The PIQL takes a long time to complete (40 minutes on average)
  - Repeated testing risks memorization and reduced efficacy
- **GOAL: Create two shorter versions of the PIQL (a.k.a. PIQLets) that are statistically and psychometrically equivalent**

Research Questions

1. Which combination of items produces PIQLets with the smallest score differences? (Figure 1, central Venn diagram)
2. How does the reliability of these PIQLets compare to each other and to the PIQL? (Table 1)
3. How similar are the psychometric parameters for the anchor items across PIQLets? (Table 3)

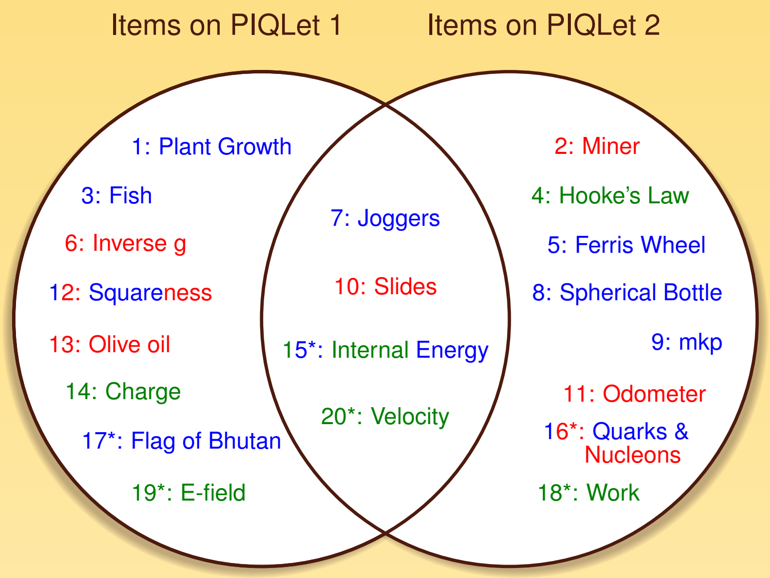
Constraints and Criteria

- Constraints: each pair of PIQLets must have:
  - 12 items on each PIQLet: 4 anchor items in common, 8 unique items
  - the same number of items (anchor and unique) testing each PQL facet
  - the same number of items in each format (single response or MCMR)
- Criteria: the best pair of PIQLets should have:
  - similar total average scores for all three data sets
  - similar average subscores for all three facets
  - good test reliability (Cronbach's α)
  - similar item response theory (IRT) parameters for anchor items

Methods

- Followed example of Han et al. (2015)
- Full 20-item PIQL administered 3 times during introductory physics course sequence at a public university in the Western US
  - Before mechanics (PreMech, $N = 3206$)
  - After mechanics, before electricity & magnetism (PostMech, $N = 2580$)
  - After electricity & magnetism (PostEM, $N = 2136$)
- Each item categorized based on content and format
- Identified 5 candidates for anchor items based on prior analyses
- Identified all combinations of items based on constraints (240 total)
- For each combination of items:
  - Split the full data set into two parts
  - Calculated the differences in the mean total score and mean subscores for each facet for each data set (total of 12 average score differences)
  - Calculate the mean $\langle\Delta\rangle$ and the root-mean-squared Δ_{rms} of the 12 score differences as measures of the total difference between the PIQLets
- Identified a handful of combinations that had the lowest Δ_{rms} and $\langle\Delta\rangle$ close to zero.
  - Calculated Cronbach's α for each PIQLet for each data set
  - Identified the combination with the most similar α values
- For the single most similar PIQLet pair:
  - Applied a three-parameter logistic (3PL) model to calculate IRT item parameters
  - Compared parameters for anchor items between the two PIQLets
- All analyses performed using the `r` computing environment (R Core Team, 2019), specifically using the `mirt` and `tidyverse` packages

Certain combinations of PIQL test items create statistically equivalent testlets



Ratios and Proportions
Covariation
Signed Quantities and Negativity
*MCMR Items

Scores

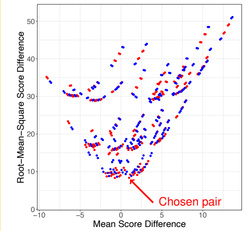

Figure 1. Mean percentage score difference $\langle\Delta\rangle$ and root-mean-square score difference Δ_{rms} for all PIQLet item combinations. Red points have anchor items 7, 10, 15, and 20; blue points have anchor items 1, 10, 15, and 20.

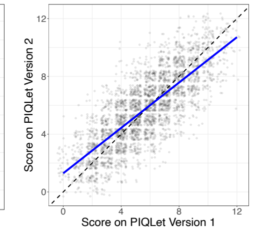

Figure 2. Comparison of PreMech students' scores on the PIQLets. The blue line shows the relationship between the scores on the two versions. The black dashed line represents equal scores on the two versions.

For the chosen pair of PIQLets: the mean total score difference for PreMech data is 1.6%, the mean difference for PostMech data is 1.1%, and the mean difference for PostEM data is 1.3%. In all three data sets PIQLet 2 has the higher mean score.

Statistical Comparisons

Test	PreMech	PostMech	PostEM
PIQL	0.76	0.80	0.82
PIQLet 1	0.68	0.73	0.75
PIQLet 2	0.67	0.72	0.75

Table 1. Cronbach's α for the full PIQL and the closest combination of PIQLets.

Comparison	PreMech	PostMech	PostEM
PIQLet 1 v. P2	0.79	0.82	0.84
PIQL v. P1	0.94	0.94	0.95
PIQL v. P2	0.93	0.94	0.95

Table 2. Pearson's r correlation between scores on the two PIQLet versions, as well as between each PIQLet and the full PIQL.

IRT Parameters

$$\text{3PL Model:} \qquad P_{i,j}(1|\theta_i) = c_j + \frac{1 - c_j}{1 + e^{-1.7a_j(\theta_i - b_j)}}$$

The probability that student i answers item j correctly, given their overall ability and understanding θ_i (i.e., PQL). Each item has three estimated parameters: discrimination a_j, difficulty b_j, and guessing c_j.

	Discrimination a_j			Difficulty b_j			Guessing c_j		
Item	PIQL	P1	P2	PIQL	P1	P2	PIQL	P1	P2
7	0.72	0.73	0.75	-0.27	-0.28	-0.22	0.01	0.00	0.03
10	1.10	1.14	1.09	-0.78	-0.77	-0.79	0.00	0.00	0.00
15	0.93	0.99	0.89	0.40	0.43	0.40	0.01	0.03	0.01
20	1.02	1.08	1.06	0.01	0.03	0.00	0.00	0.01	0.00

Table 3. 3PL IRT parameters for anchor items for the full PIQL and each PIQLet version for our chosen combination.

Summary

- Categorizing testlet similarity by mean scores yielded a pair of PIQLets with very small differences in mean scores, but these differences vary greatly across item combinations (Figure 1).
- Scores are less similar for students at the high and low ends (Figure 2).
- Cronbach's α is very similar across the chosen pair of PIQLets, but slightly smaller than the total PIQL (Table 1). This is expected, given the smaller number of items (Streiner, 2003).
- Student scores across PIQLet versions are strongly correlated (Table 2).
- IRTparameter values for the anchor items are very similar across the two chosen PIQLet versions: a_j differs by 0.1 or less, b_j by 0.06 or less, and c_j by 0.03 or less (Table 3).

Next Steps

- Define difference between PIQLets based on more than mean scores
- Use IRT analyses to compare other PIQLet items based on IRT parameters for anchors items and overall distribution of parameters
- Apply the Stocking-Lord method to define transformations between PIQLets, looking for combinations that require the smallest adjustments

Keywords: Professional development, online workshops, teaching

Introduction

Professional development (PD) workshops on teaching have been shown to effectively increase undergraduate math instructors' use of research-based instructional strategies (Archie et al., 2022). However, face-to-face PD is not accessible for all math instructors, including those with young families, those at under-resourced institutions, and those concerned about the environmental impacts of travel. In response to these constraints, the Mathematical Association of America (MAA) sponsored a series of nine online PD workshops in summer 2022. The MAA solicited proposals and selected teams to lead workshops on a variety of mathematics teaching topics. These teams participated in planning sessions in winter 2022 to prepare their workshops and implement best practices in workshop design (Daly et al., 2021). The workshops served 25 participants each over 24-27 contact hours, conducted via Zoom in two formats: a one-week intensive model and a mini-course format spread over three weeks. The purpose of this preliminary research was to explore the outcomes of the 2022 workshops.

Methods

Participants completed surveys about one month before their workshop (pre), immediately after (post), and 12 months later (follow-up). Survey measures probed instructors' current capacities (knowledge, skill, attitude, and motivation) related to the workshop topic (pre, post), perceptions of workshop quality (post), planned implementation (post) and implementation at one year, and what workshop features helped them learn (post). 119 instructors responded to all three surveys, out of 203 instructors who completed workshops.

Results and Discussion

Overall, participants rated the workshops favorably and reported strong gains in knowledge and skills related to the workshop topic. Most (83%) indicated they would likely implement what they learned in the workshop. Indeed, at the one-year follow-up, 84% of respondents reported some degree of implementation, which is comparable to implementation after face-to-face workshops (Archie et al., 2022). When survey non-responders are included in the total, the self-reported implementation rate drops to 50%. As a group, participants identified the atmosphere, their interactions with others, practical examples, facilitator modeling, and working and connecting with other participants as workshop features that helped them learn the most. Together, these findings suggest that well-designed online professional development can help instructors implement what they learned at the workshops.

Acknowledgments

This work was funded by the National Science Foundation: award DUE- 2111273.

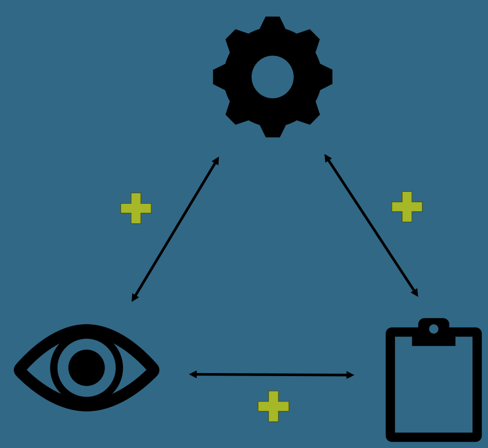
Participants implement what they learned from online professional development

Jenny Valadez Fraire, Tim Archie, Sandra Laursen & Kyra Gallion



Observations and surveys show that online workshops support implementation

Need

Professional development (PD) workshops have been found to effectively increase undergraduate math instructors use of research-based instructional strategies[1].

Benefits of online PD
- Under-resourced institutions
- Instructors with young families
- Environmental impact of travel

Workshops

During the Summer of 2022, the Mathematical Association of America (MAA) sponsored a set of eight virtual PD workshops to address these needs.

Workshop Features
- Facilitators participated in Winter trainings based on PD best practices http://tinyurl.com/2p83ayry
- Conducted via Zoom in two formats: one week intensive model & mini course spread over three weeks
- 25 participants / workshops through 24-27 contact hours

Method

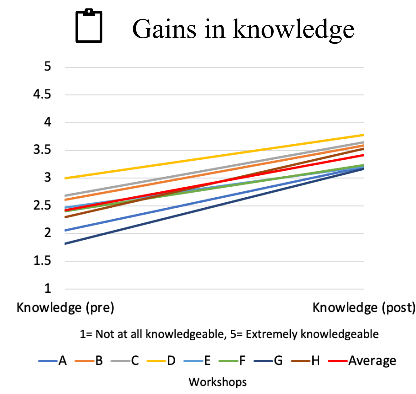
Pre survey and Post Survey
Instructors' current capacities (knowledge, skill, attitude and motivation) related to the workshop topic

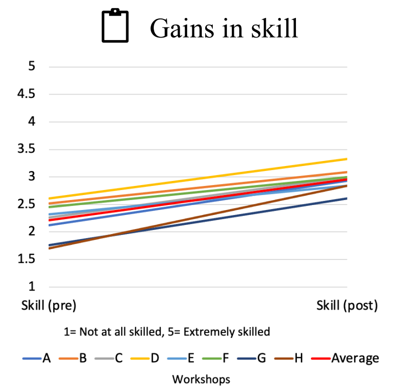
Online Professional Development Observational Checklist (OPDOC)
19 item rubric that assesses workshop features and provides a quantitative score (https://tinyurl.com/27tcrhe6)

119 out of 203 instructors who completed workshops responded to all three surveys

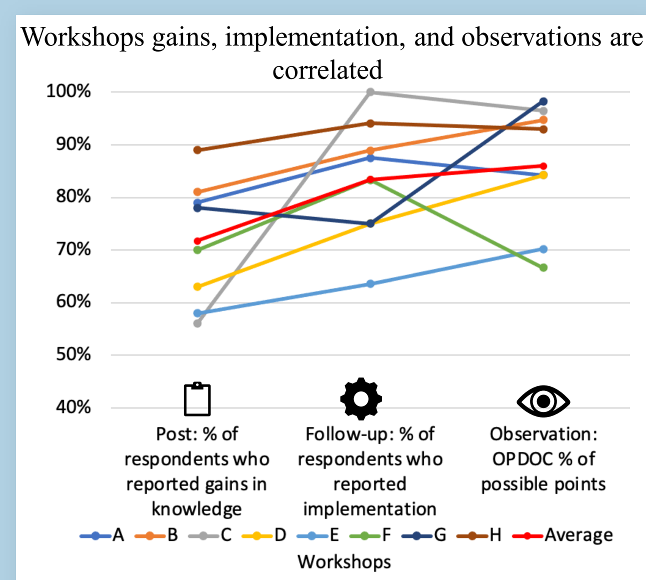
Follow Up Survey
Implementation at one year

Workshop Participant Gains





Results & Discussion



Takeaways

Overall, participants rated the workshops favorably and reported strong gains in knowledge and skills related to the workshop topic.
- Most helpful workshop features included: supportive atmosphere, interactions with others, practical examples, facilitator modeling and collaborating (working & connecting) with other participants
- 83% indicated they would likely implement what they learned in the workshop.
- 84% of respondents reported some degree of implementation at the one-year follow up.
- The high degree of implementation reported by participants is comparable to implementation after face-to-face workshops (Archie et al., 2022), helping to indicate that high quality online PD can be a more accessible form of PD.

Novice Statistics Students' Forms of Reasoning When Reasoning About and With Sampling Distributions

Claire Miller
University of Georgia

Keywords: statistics education, sampling distribution, deductive reasoning, inductive reasoning, abductive reasoning

Understanding ideas of sampling, sampling distributions, and statistical inference are important for improving students' statistical literacy and productive citizenship, particularly given calls for students to become "critical consumers of statistically-based results reported in populator media" (GAISE College Report ASA Revision Committee, 2016, p. 8). Despite the importance of understanding statistical inference and sampling distributions, research suggests that students struggle with these ideas (Sotos et al., 2007). One reason for this difficulty stems from the complex and abstract concept of sampling distribution, which requires the coordination of multiple statistical ideas, including distribution, the relationship between sample and population, sampling variability, randomness, and probability (Chance et al., 2004; Saldanha & Thompson, 2002; Noll & Shaughnessy, 2012). I hypothesize that another reason students experience difficulty understanding sampling distributions and statistical inference is because these ideas require students to reason with uncertainty, a kind of reasoning that differs greatly from the forms of reasoning that are expected and highlighted in mathematics, such as deductive and inductive reasoning.

Deduction, induction, and abduction are three classic forms of reasoning that can be modeled with a triadic structure involving a case, rule, and result. (Peirce, 1878; Reid & Knipping, 2010). A case is a specific observation that a condition holds. A condition describes an attribute of something, or a relation between things. A rule is a general proposition that states that if one condition occurs then another one will also occur. A result is a specific observation, similar to a case, but referring to a condition that depends on another one linked to it by a rule. The order in which one links a case, rule, and result determines the kind of inference—deduction, induction, or abduction—needed to gain more knowledge about the situation.

Using this triadic structure, I examined the forms of reasoning—deductive, inductive, and abductive—that novice statistics employed when reasoning about and with sampling distributions. The data come from two clinical interviews, each 60-75 minutes in length, with undergraduate students who recently completed an introductory statistics course. Participants were asked to work through a series of statistical tasks related to sampling distributions. I identified reasoning excerpts—instances in which participants provided justification or an explanation for a claim—from the interview transcripts. Within each reasoning excerpt, I identified case, rule, and result, then examined how the participant linked them, which provided evidence for the form of reasoning they employed.

Preliminary results indicate that participants used all three forms of reasoning when reasoning about and with sampling distributions, though not all three forms were productive ways of reasoning. However, abductive reasoning was powerful for some participants when making inferences from sample data to an unknown population of interest. In this poster presentation, I will provide examples of reasoning excerpts from a small subset of the participants and discuss possible implications for this work.

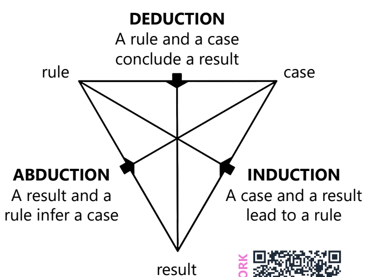
PAPER

Background

Data are everywhere. Being able to make sense of data collected from samples is important for improving students' statistical literacy and their ability to critically evaluate data-based claims.

Forms of Reasoning



FRAMEWORK

Methods

PARTICIPANTS
Undergraduate students, with varying majors, who recently completed an introductory statistics course

→

CLINICAL INTERVIEWS
Two task-based clinical interviews designed to examine participants' existing ways of reasoning about sampling distributions

→

PEIRCE'S (1878) FORMS OF INFERENTIAL REASONING
Identified case, rule, and result in each reasoning excerpt and examined how the participant linked them to infer the form of reasoning (deductive, inductive, or abductive) they employed

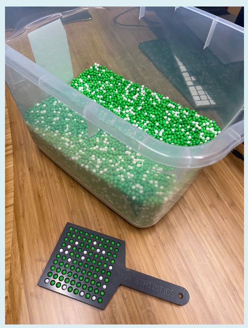
Results

Inductive reasoning is useful when estimating sampling variability, and abductive reasoning is powerful when estimating an unknown population parameter.

Department of Mathematics, Science, and Social Studies Education
Mary Frances Early College of Education
UNIVERSITY OF GEORGIA

Abductive reasoning is powerful when making inferences from sample data.

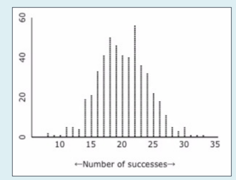
Lyla **induced** a range for a single sample outcome from observing a pattern in multiple sample outcomes.

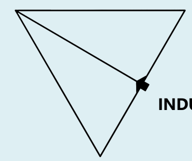


"I would say between 10 and 30. And really just from the samples we've taken so far, we've taken a lot, we haven't seen many go above 30. I don't know if we've seen one. I've seen we've reached 30, but I don't think we've gone above 30 and we haven't really gone below 10 besides these two in 500 [samples]."

I expect that any one single random sample of 100 undergraduates drawn from this population will produce between 10 and 30 business majors

Many random samples drawn from a population of undergraduates with 20% business majors





INDUCTION

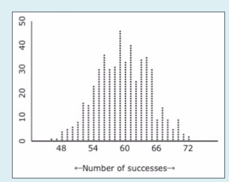
Very few samples produced a number of business majors that was less than 10 or greater than 30

Lorraine **abduced** that her sample could have come from a population with a parameter of 60%.

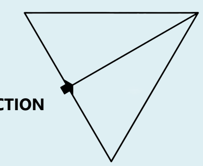
"It looks like [my sample outcome of] 52 would be reasonable. There's a pretty significant number of results that are 52. And then past that is where [the distribution] tends to kind of taper out. So maybe if the true proportion were 60, the lower bound would be like 48 or so."

A population with 60% business majors produced several sample outcomes of 52

The sample I drew could have come from a population with 60% business majors



ABDUCTION



A random sample drawn from a population with an unknown proportion of business majors produced a sample outcome of 52 business majors

Participatory Meta-Research: Opportunities for Engaging Pre-Service Teachers in Educational Research

Keywords: Meta-Analysis, Meta-Synthesis, Pre-service Teachers, Algebra

As the body of research in the RUME community grows, synthesizing data across these studies becomes more important. This goal can be accomplished through *meta-research,* a method for aggregating studies in a field of research involving both meta-analysis and meta-synthesis. A *meta-analysis* consists of a systematic search, data extraction, and aggregation of quantitative data to explain phenomena in greater detail than individual studies alone (Cooper, 2017). *Meta-synthesis* is the qualitative partner to meta-analysis, and involves a "deliberate process of selecting studies with an emphasis on synthesizing, analyzing, and interpreting across the selected studies" (Thunder & Berry, 2016). Qualitative data is then extracted from the articles, appraised for quality, and then analyzed using any of the traditional qualitative techniques. The results of a meta-synthesis can highlight gaps in a given field, look for themes across studies, and condense swaths of research, making it more useful for practitioners (Erwin et al., 2011).

Participatory synthesis (Wimpenny & Savin-Baden, 2012) takes the perspective that by engaging various participants in the process of meta-research, a study can "ensure all voices are heard", present the "possibility of reciprocal learning", and "progress knowledge within a field" (p.697). For educational research, this presents a great opportunity for pre-service teachers. By participating in meta-research, a pre-service teacher can be exposed to research and interventions that might be relevant to their future classrooms. At the same time, the results of the research can be made richer by incorporating their viewpoints into topics they view as relevant and knowledge they consider useful for the classroom. In addition, if the team is diverse, it presents the opportunity to make the work more equitable by incorporating decisions from a diverse range of viewpoints.

This poster has two purposes. First, we will describe some of the latest techniques of meta-analysis and meta-synthesis through the lens of a current project (Sharpe et al., in prep) looking at algebraic teaching interventions for grades K-12. This includes illustrating the use of cutting-edge software for conducting a meta-synthesis such as Covidence and Raayan and looking at a new technique for extracting qualitative data from an article using artificial intelligence. Second, we will describe some of the challenges and opportunities that have resulted from this process to highlight how pre-service teachers and researchers could benefit. This includes discussions about the definition of an algebraic teaching intervention for screening, a look at some of the interventions that were discovered during search/screening that might be applicable for teaching, and a discussion about what information from an article would be useful for a practicing educator. Our hope is that this poster and the resulting discussion will encourage others to engage in meta-research and consider pre-service teachers as undergraduate researchers for such projects.

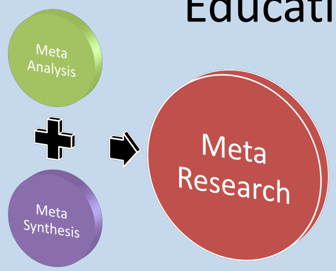
Participatory Meta-Research: Opportunities for Engaging Pre-Service Teachers in Educational Research

What is Meta-Research?

A "**meta-analysis** uses a statistical procedure that aggregates and condenses a body of Quantitative research studies to a common standard metric, such as a mean effect size" (Finlayson & Dixon, 2008; Thunder & Berry, 2016, p.319).

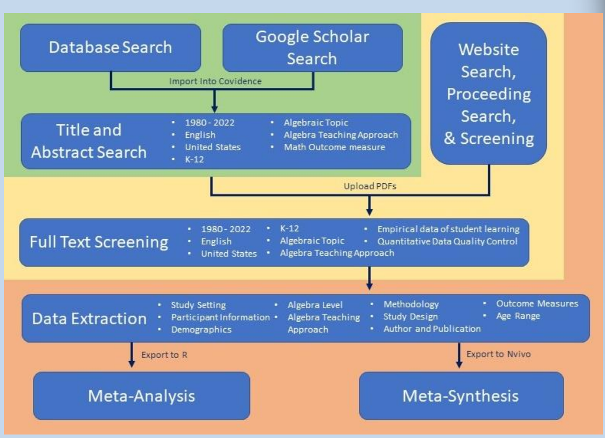


A **qualitative meta-synthesis** uses a "deliberate process of selecting [qualitative research] studies with an emphasis on synthesizing, analyzing, and interpreting findings across the selected studies" (Thunder & Berry, 2016, p.319).

Matthew Mauntel
Sheree Sharpe
Rebecca Butler
Maryam Aswad & Jerome Amedu
Bitna Choi

Participatory Meta-Research can provide a **rich research experience** for undergraduate pre-service teachers/mathematics students while incorporating valuable perspectives into the research synthesis process.

Meta-Research Process



Participatory Meta-Research

Participatory synthesis (Wimpenny & Savin-Baden, 2012) takes the perspective that by engaging various participants in the process of meta-research (p.697), a study can

- "ensure all voices are heard."
- present the "possibility of reciprocal learning."
- "progress knowledge within a field."

For **Pre-Service teachers** this might mean:

- Exposure to research and interventions for the classroom.
- The ability to influence the direction of research.
- Engage with under-represented perspectives and provide their own perspective.

Tasks for Exploring Fraction Understandings of Undergraduate Developmental Mathematics Students

Lucinda Ford
Texas State University

Keywords: fraction understandings, student thinking, undergraduate developmental mathematics

Many students experience difficulties with fractions (Mesa et al., 2014; Ngo, 2019). Thus, it is unsurprising that fractions act as a gatekeeper for college-level mathematics courses (Ngo, 2019). Research on how undergraduate developmental mathematics students understand fractions is scarce (Alexander, 2013; Mesa et al., 2014). Moreover, existing studies in this area seem to take a deficit perspective, focusing more on what students in this demographic do not understand about fractions rather than reporting what is productive in their thinking (Alexander, 2013; Baker et al., 2012; Doyle et al., 2015).

In this poster, I will report on tasks that I developed to examine the fraction thinking that undergraduate developmental mathematics students can utilize. I implemented these tasks during clinical interviews (Ginsberg, 1997), which come from a larger dissertation study that was designed to (a) examine how undergraduate developmental mathematics students understand fractions and (b) explore pathways to support fraction understandings that will help the student to be successful in future mathematics courses. In designing the tasks, I drew from existing K–12 fraction literature, including Lamon's (2020) fraction understandings and Steffe & Olive's (2010) fraction schemes, which I will explain in the poster. In short, Lamon's fraction understandings include part-whole, operators, quotients, measures, and ratio understandings. Fraction schemes I attend to include part-whole, partitive, and iterative fraction schemes (Steffe & Olive, 2010).

Twelve fraction tasks are spread over two 45-minute sessions for this clinical interview (Ginsberg, 1997). The interview tasks were designed to help me answer the following research question: How do undergraduate developmental mathematics students understand fractions? Specifically, (a) which of the five fraction understandings outlined by Lamon (2020) do the students operate with, and how do they support their fraction understandings; and (b) which of the fraction schemes outlined by Steffe & Olive (2010) do the students operate with and how do they support their fraction understandings?

In this poster, first, I will present an overview of Lamon's (2020) five fraction understandings, three of Steffe & Olive's (2010) fraction schemes, and how I correlated these views of fractions. Second, I will present examples of the tasks that I developed. I will identify which of Lamon's fraction understandings or Steffe & Olive's fraction schemes were intended to be elicited from each task. I will also provide the goals and design principles, as well as follow-up questions for these tasks. Finally, I will discuss some of the affordances and limitations of each task after implementing them in three clinical interviews (Ginsberg, 1997). For example, I designed a number line task that targets the measure understanding of fractions (Lamon, 2020). This task provides insight into the participants' fraction thinking beyond measures. However, due to the complexity of the measure understanding, the task may not reveal enough information to definitively say that the participant has constructed the measure fraction understanding (Lamon, 2020). I hope to provide examples of productive mathematical thinking that undergraduate developmental mathematics students have about fractions. This study aims to counter the deficit narrative prevalent in developmental mathematics.

Tasks for Fraction Understandings of Undergraduate Developmental Mathematics Students

Lucinda Ford
Department of Mathematics, College of Science and Engineering, Graduate College, Texas State University

Background and Goals

- Many students experience difficulties with fractions (Mesa et al., 2014; Ngo, 2019).
- Fractions act as a gatekeeper for college-level mathematics courses (Ngo, 2019).
- Research on the way that undergraduate developmental mathematics students understand fractions is scarce (Alexander, 2013; Mesa et al., 2014).
- Existing studies in this area focus more on what these students do not understand about fractions (Alexander, 2013; Baker et al., 2012; Doyle et al., 2015).
- Goals: (1) Build models of developmental math students' fraction understandings (Lamon, 2020; Steffe & Olive, 2010). (2) Explore pathways to support fraction understandings that help the student to be successful in future mathematics courses.

Research Questions

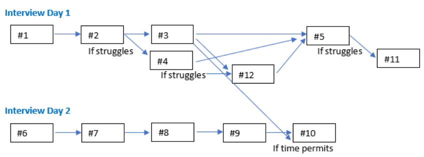
1. How do undergraduate developmental mathematics students understand fractions?
   a. Specifically, which of the five fraction understandings outlined by Lamon (2020) do the students operate with and how do they support their fraction understandings?
   b. Which of the fraction schemes outlined by Steffe & Olive (2010) do the students operate with and how do they support their fraction understandings?
2. What ways of fraction thinking are present (from RQ1) that could specifically help to further the participant's measure fraction understanding?

Task Design Overview

Methods

- Clinical interviews (Ginsberg, 1997)
- 12 questions over two 45-minute sessions
- Video recorded from multiple angles
- 8-12 participants
- Ongoing and retrospective analysis (Steffe & Thompson, 2000)

Potential Paths According to Students' Responses



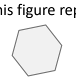
Analysis Framework

Lamon's Five Understandings	Steffe & Olive's Fraction Schemes
Part-Whole: Relating the number of equal parts of a unit to the unit	**Part-Whole Fraction Scheme: Simultaneously partitioning the whole into equal distant, connected, lengths**
Partitioning: Splitting the unit into equal parts **Iterating: Creating copies of the unit fraction**	**Partitive Fraction Scheme: The first true fraction scheme involves comparing the part to the whole. Note: The part-whole fraction scheme is a pre-requisite for the partitive fraction scheme.**
Partitioning and Iterating Beyond the Whole: Creating copies of the unit fraction beyond what is necessary to construct a figure that is equivalent to the whole	**Iterative Fraction Scheme (beyond the whole): Taking a unit fraction or a complex unit and iterating it to create a composite unit. Note 1: The partitive fraction scheme is a pre-requisite for the iterative fraction scheme. Note 2: This generally requires coordinating 3 levels of units.**
Operator: Viewing a fraction as a calculation(s) to be done (e.g., $\frac{a}{b} \cdot k$ means $a \cdot k \div b$)	
Quotient: Not only viewing a fraction as a set of instructions for calculation but assigning meaning to the result	
Measure: This is a geometric meaning of a fraction that involves magnitudes, or lengths, of intervals. **Magnitude recognition: Recognizing that relative size needs to be taken into account when working with the fraction**	Note: the above fraction schemes are part of measurement thinking (Steffe & Olive, 2010, p. 121).
Ratio: This fraction meaning can be comparative of the numerator and denominator as ordered pairs. Note: Not all ratios are fractions.	

This table shows how I correlate Lamon's (2020) fraction understandings with Steffe & Olive's (2010) fraction schemes.

Iterating Beyond the Whole

This figure represents a whole. Draw [   ]



[Goal] To examine whether the student has a partitive unit fraction scheme with a whole greater than one.

a. If student has difficulty, with #2, start with 4/6.
b. **Can you show me 1/6 in your figure?**
c. Round 2: **Let's try another one. Our figure still represents a whole. Draw 15/6**.

- Affordance: Fractions beyond the whole in action
- Limitation: 15/6 may not provide further information if the participant is still constructing an understanding of improper fractions.

Opening Tasks

What does 2/3 mean to you?

[Goal] To examine students' initial immediate response regarding their fraction conception without further prompting that targets specific fraction understandings, as in the following tasks. The student is being asked to read the task prompt to gather more information about how they read/write a fraction.

a. **Can you draw me a picture to show me the 2/3?** (Make sure to follow the student's language.)
b. ***Are there any other ways you can think about this fraction (2/3)?***
c. **Keep going until you exhaust this line of thinking.**

What does 7/3 mean to you?

[Goal] To examine whether they iterate the 1/3 beyond the whole. How they would make sense of an improper fraction in relation to their fraction conception.

a. ***Can you draw a picture of 7/3*** (if not done already-use their language)**?**
b. ***How do you know that's 7/3 and not 7/9?***

- Affordance: Initial reaction before targeted tasks
- Limitation: Not a full story of their understanding

Quotient

Jade shared 5 candies (cherry, chocolate, cinnamon, lime, and peppermint) among 3 friends. What amount of candy did each friend get?

[Goal] To examine whether the student has a quotient understanding of fractions.

a. Have index cards labeled with the candy flavors for the participant to demonstrate the sharing process.
b. If student can do the mental calculations and say that each person gets 5/3 candies each, ask student to use the index cards to show their thinking.
c. If student struggles, ask **Can you show me how to share these candies using the index cards?**

- Affordances:
  - Fair sharing (whole number not divisible by the number of people).
  - Partitioning an object into thirds.
  - Operator vs. quotient understanding
- Limitation: Consideration of number choices

Measure

Directions: Give the participant four index cards marked with 1/2, 2/3, 3/8, and 7/6, respectively.

Without using decimals, put these fractions in order from least to greatest.

[Goal] To examine whether the student has a measurement understanding of fractions.

a. If student indicates they do not know how to do this without fractions, ask the student to give me their best guess.
b. **What were you thinking as you ordered the fractions?**
c. Give the participant a piece of aper with a line across it lengthwise. **If this is a number line, where would you place the fractions as accurately as you can?**
d. *Offer sticky flags for placing numbers (they are moveable).*
e. Pay attention to whether the participant marks 0, 1, etc. and/or benchmarks on the number line.

- Affordances: Operator understanding, commensurate fractions, percentage thinking, and benchmarks
- Limitations: May need further questioning due to the complexities of the measurement understanding

Comparing Calculus Students' Use of Problem-Solving Strategies on Related Rates of Change Problems in a Traditional versus Online Homework Format

Tyson C. Bailey
The University of Texas at Arlington

James A. M. Álvarez
The University of Texas at Arlington

Keywords: problem-solving, related rates, calculus, online-homework

With the advent of many online platforms for assigning and grading homework, more and more of the homework in calculus no longer entails paper-and-pencil homework (Dorko, 2020). As such, with the prevalence of associated scaffolding embedded in these platforms, more needs to be understood about whether this tends to over-proceduralize topics, such as related rates of change (RRC), and undermine roles these topics may have in further developing students' capacity in mathematical problem solving or mathematical reasoning. Engelke (2008) maintains that to successfully solve RRC problems, students require well-developed mathematical problem-solving skills. However, Mkhatshwa (2020) asserts that few studies have explored students' reasoning on solving RRC problems. The purpose of this investigation is to explore how problem-solving strategies (PSS) may differ when solving RRC problems presented in a traditional paper-and-pencil format versus RRC problems presented in an online platform which includes typical options for scaffolding help as well as "view an example" features. In this poster, we address the following research questions: (1) How do students' PSS when working online homework on RRC problems compare with their PSS when working paper-and-pencil homework RRC problems? (2) What influence does the 'view an example' feature in online homework have on a student's PSS when working an online RRC homework problem?

This study takes place at a large, urban research university located in the southwestern United States during a 15-week first-semester calculus course which incorporated the use of an online platform for homework. After scoring 318 participants' written work on a free response RRC common midterm exam problem for the extent to which their work exhibited processes for productive problem solving of RRC problems (Engelke, 2008), participants were invited for task-based interviews using a scheme aimed at ensuring that participants from different score ranges would be included in the interviews. Fourteen participated in task-based interviews. Because we were interested in comparing PSS when working paper-and-pencil versus online homework problems, the task-based interviews included four RRC problems, two sets of paired tasks of a paper-and-pencil format problem and a similar problem on the online platform. Qualitative data analysis software was used to code the data using a priori codes from Álvarez et al. (2019) and Carlson and Bloom (2005). Common themes were identified using thematic analysis (Braun and Clark, 2016).

Data analysis reveals more instances of PSS from the exemplary group (top quartile scorers on midterm RRC problem) when compared to the other groups. In addition, participants used more PSS when solving paper-and-pencil RRC problems than when solving online RRC problems. Further, participant's use of PSS decreased when using the 'view an example' feature in the online format. Three categories emerged on participant use of the 'view an example' feature (1) those who mimic the example (ME), (2) those who use the example to learn the process (LP), and (3) those who refuse to use the feature (RF). Participants using this feature for ME used fewer PSS than those whose use was classified as LP or RF. Findings suggest that the format of and resources for online homework RRC problems may need to change to ensure that students engage in using PSS in a manner comparable to traditional paper-and-pencil homework.

Comparing Calculus Students’ Use of Problem-Solving Strategies on Related Rates of Change Problems in a Traditional versus Online Homework Format

Tyson C. Bailey
James A. M. Álvarez

THE UNIVERSITY OF TEXAS AT ARLINGTON

Introduction

With the advent of many online platforms for assigning and grading homework, more and more of the homework in calculus no longer entails paper-and-pencil homework (Dorko, 2020). As such, with the prevalence of associated scaffolding embedded in these platforms, more needs to be understood about whether this tends to over-proceduralize topics, such as related rates of change (RRC), and undermine roles these topics may have in further developing students’ capacity in mathematical problem solving or mathematical reasoning. Engelke (2008) maintains that to successfully solve RRC problems, students require well-developed mathematical problem-solving skills. However, Mkhatshwa (2020) asserts that few studies have explored students’ reasoning on solving RRC problems.

The purpose of this investigation is to explore how mathematical problem-solving strategies (MPSS) may differ when solving RRC problems presented in a traditional paper-and-pencil format versus RRC problems presented in an online platform which includes typical options for scaffolding help as well as “view an example” features.

Research Questions

(1) How do students’ mathematical problem-solving strategies when working an online homework related-rates of change problems compare with their mathematical problem-solving strategies when working paper-and-pencil related-rates of change homework problems?

(2) What influence does the ‘view an example’ feature in online homework have on a student’s mathematical problem-solving strategies when working an online related-rates of change homework problem?

Phase 1: Textbook Problem to Online Problem

Frequency of Problem-Solving Strategies Utilized in Phase 1

23. Time-lagged flights An airliner passes over an airport at noon traveling 500 mi/hr due west. At 1:00 P.M., another airliner passes over the same airport at the same elevation traveling due north at 550 mi/hr. Assuming both airliners maintain their (equal) elevations, how fast is the distance between them changing at 2:30 P.M.?

ates | Question 8, 3.11.23 Part 3 of 3 | HW Score: 0%, 0 of 14 points | Points: 0 of 1 | Save

An airliner passes over an airport at noon traveling 530 mi/hr due west. At 1:00 p.m., another airliner passes over the same airport at the same elevation traveling due north at 580 mi/hr. Assuming both airliners maintain their (equal) elevations, how fast is the distance between them changing at 2:00 p.m.?

The equation relating the horizontal distance between the first airliner and the airport, a, the horizontal distance between the second airliner and the airport, b, and the horizontal distance between the two airliners, c is $a^2+b^2=c^2$.

Differentiate both sides of the equation with respect to t.

$$(2a)\frac{da}{dt}+(2b)\frac{db}{dt}=(2c)\frac{dc}{dt}$$

(Do not simplify.)

At 2:00 p.m., the distance between the airliners is changing at a rate of about 743.4 mi/hr.
(Round to the nearest tenth as needed.)

Phase 2: Online Problem to Textbook Problem

Frequency of Problem-Solving Strategies Utilized in Phase 2

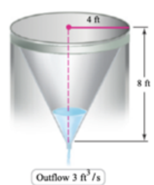
ates | Question 11, 3.11.36 Part 3 of 3 | HW Score: 0%, 0 of 14 points | Points: 0 of 1 | Save

An inverted conical water tank with a height of 8 ft and a radius of 4 ft is drained through a hole in the vertex at a rate of 3 ft^3/s (see figure). What is the rate of change of the water depth when the water depth is 4 ft? (*Hint*: Use similar triangles.)



Let V be the volume of water in the tank and let h be the depth of the water. Write an equation that relates V and h.

$$V=\frac{\pi}{12}h^3$$

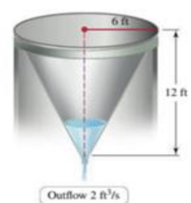
(Type an exact answer, using π as needed.)

Differentiate both sides of the equation with respect to t.

$$\frac{dV}{dt}=\left(\frac{\pi}{4}h^2\right)\frac{dh}{dt}$$

When the water depth is 4 ft, the rate of change of the water depth is about −0.24 ft/s.
(Round to the nearest hundredth as needed.)

36. Draining a tank An inverted conical water tank with a height of 12 ft and a radius of 6 ft is drained through a hole in the vertex at a rate of 2 ft^3/s (see figure). What is the rate of change of the water depth when the water depth is 3 ft? (*Hint:* Use similar triangles.)



http://tinyurl.com/4f9s57cc

Methods

We used student (n=338) departmental midterm performance levels on RRC problems to select participants for task-based interviews. Participants were drawn from three groups, based upon their performance and problem-solving score quartile on the midterm RRC problems.

Of the 14 participants consenting into the study, six came from the fourth quartile, six came from the third quartile, and two came from the second quartile. The task-based interviews entailed solving two pairs of RRC problems (textbook-to-online, online-to-textbook).

Transcripts were coded using thematic analysis techniques (Braun & Clarke, 2006) with a priori codes from Alvarez et al. (2019) and Carlson and Bloom (2005) and also examined for emergent codes.

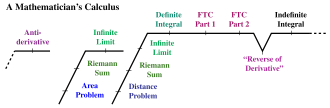
- The problem-solving codes used included orienting/sense-making, planning, representing and connecting, executing, reviewing, justifying, checking.
- Emergent codes included the use of *view an example* for *process*, to *mimic*, or for *sense-making*.

Findings

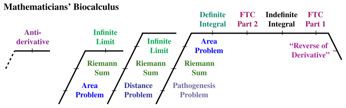
Participants appear to use MPS strategies more frequently when solving the traditional paper and pencil-related rates of change of problems.

The findings suggest that students may be using features of online homework platforms on RRC problems in a manner that circumvents the use of MPSS. That is, ‘view an example’ feature in online homework may be scaffolding the problem-solving process in a manner that leads to students missing opportunities to further develop their MPSS.

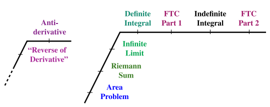
A Mathematician's Calculus



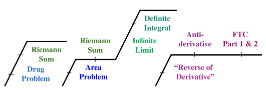
Mathematicians' Biocalculus



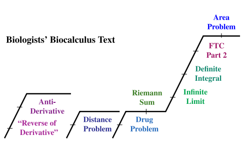
Biomathematicians' Biocalculus Text (Example 1)



Biomathematicians' Biocalculus Text (Example 2)



Biologists' Biocalculus Text



Biologists and Mathematicians tell very different **stories** of the **definite integral**.

On Narratives of the Definite Integral in Biocalculus

Melinda Lanius, Auburn University

Goal: Explore variation in the presentation of the definite integral in calculus texts written by mathematicians and those written by biologists.

Corpus: (biology-oriented texts are classified by authorship teams + preface materials).

- **[Mathematician's Calculus.]** James Stewart. (2016). *Calculus: Early transcendentals* (8th Ed.). Cengage Learning.
- **[Mathematicians' Biocalculus.]** James Stewart & Troy Day. (2015). *Biocalculus: Calculus for Life Sciences.* Cengage Learning.
- **[Biomathematicians' Biocalculus (Example 1).]** Claudia Neuhauser & Marcus L. Roper. (2018). *Calculus for biology and medicine.* Upper Saddle River: Pearson.
- **[Biomathematicians' Biocalculus (Example 2).]** Erin N. Bodine, Suzanne Lenhart, & Louis J. Gross. (2014). *Mathematics for the life sciences.* Princeton University Press.
- **[Biologists' Biocalculus.]** Alan Garfinkel, Jane Shevtsov, & Yina Guo. (2017). *Modeling life: the mathematics of biological systems.* Springer International Publishing AG.

Framework: Analysis via literary tradition of narrative.

- Established use in studying mathematics curriculum (e.g. see Dietiker, 2013; Dietiker, 2015; and Miežys 2023).
- I'm following Netz (2005) - mathematics texts tell a story:
  "*Some passages - descriptive - add detail to the fictional world, constructing its underpinning of reality; other passages - narrative - unfold the plot that takes place in that fictional world*" (2005, p. 262).
- Final product of analysis - a set of chronological diagrams that position the mathematical concepts (descriptions) along a story arc to convey how narrative relates these topics.

How to interpret diagrams:

General features.

- Upward slope (rising action) indicates a concept building on another concept.
- Horizontal lines (a climax or false-climax) are concepts that were separated from the general text as important (e.g. by a box.)
- Downward slope (denouement) indicates a closing thought.

Notable combinations of general features.

- A horizontal line that ends without a decent immediately following it indicates a split narrative, where the reader is to keep this train of ideas in mind, but we start again at height zero to build up another sequence of concepts.
- A horizontal line appearing at a height greater than zero without an upward sloping line preceding it indicates a *deus ex machina*, or the abrupt introduction of a concept in a climactic role without narrative connection to proceeding concepts:

(Surprising) Finding 1:
No narratives used a *deus ex machina* to reach the definite integral.

Note. The *deus ex machina* is a popular narrative device in stories of the derivative, e.g., to introduce the derivative function in Biomathematicians' Biocalculus (Example 1).

(Surprising) Finding 2:
In some narratives, the definite integral was not a climax.

Future Directions.

[1] Explore the scope and rigidity of student's structural expectations and how this impacts learning.

[2] Explore other fruitful constructs from literature, e.g., the analytic tool of implied reader inspired implied student (Ulriksen; 2009).

Using a Rubric from Pedagogical Partnership to Improve the Accessibility and Usability of Desmos Activities for Students in Calculus 1

Tabitha Mingus
Western Michigan University

Melinda Koelling
Western Michigan University

Elisha Hall
Western Michigan University

Jessyca Olvera
Western Michigan University

Yaronn James Arciaga
Western Michigan University

Keywords: Desmos, Pedagogy, Interactive

There was a successful departmental effort to improve the calculus DFWI rates at a midwestern university (Mingus & Koelling, 2021). To maintain this change during the pandemic, instructors developed Desmos-based activities to encourage student engagement and active learning. This platform allows students to interact with tools on activities designed by their instructors. Since the implementation, instructors sought feedback from the students on the digital experience. This study focuses on a partnership between the students and the instructors to develop a rubric to evaluate Desmos activities for the Calculus course.

Our goal is to understand how students interact with digital platforms to further improve students' learning experience. To accomplish this, a pedagogical partnership with undergraduate students was created with the intent to co-develop a rubric to evaluate activities. Pedagogical research with students provides benefits to both the students and instructors. The students gain a greater understanding of course content, learning, teaching, and improved agency. The instructor gains a greater understanding of student thinking and feedback on how to meet student needs. (Bovill et al., 2011, Cook-Sather & Motz-Storey, 2016, Partridge & Sandover, 2010)

An initial rubric was created as a result after the first focus group interview. The rubric consists of three categories: Overall, Between the Slides, and On Each Slide. The Overall category addresses the content in the whole Desmos activity. The Between the Slides category addresses the transitions of the content within the Desmos activity. The On Each Slide category addresses the content within the individual slide.

The poster will consist of the rubric and slides from an activity before and after the application of the rubric. It will be discussed how the team has used the rubric to modify Desmos activities to improve their accessibility and usability for students.

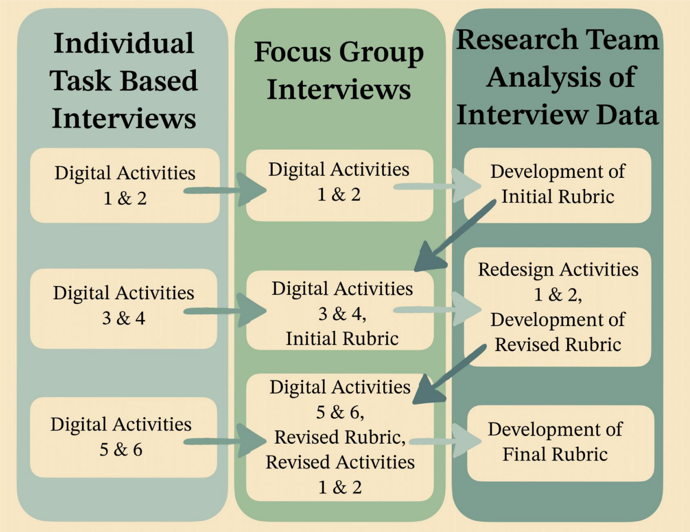
Using a Rubric from Pedagogical Partnership to Improve the Accessibility and Usability of Desmos Activities for Students in Calculus 1

Tabitha Mingus, Melinda Koelling,
Elisha Hall, Jessyca Olvera, Yaronn James Arciaga
Western Michigan University

Introduction

- DFWI rates decreased after previous course redesign [3]. Success of the course redesign motivated implementation of Desmos activities.
- Student response to the implementation of activities motivated pedagogical partnership.
- Goal was to create a rubric which instructors could use to evaluate the effectiveness of Desmos activities.

Study Design



- Students were selected from calculus courses taught the semester prior
- Interviews, rubric creation, and slide edits were conducted outside of the classroom

Rubric

Purpose: Evaluate the Desmos Activities to improve students' learning

Breakdown:

- Overall
- Between Slides
- On each Slide

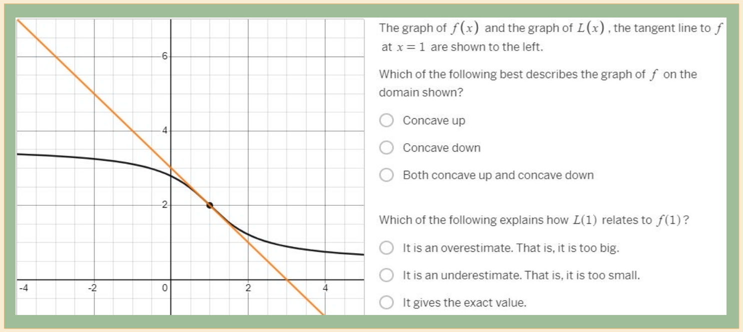
Scan for References & Supplemental Materials

![WMU logo] Western Michigan University

Data Sample

Slide from Desmos Activity 5

Students below are discussing the slide shown during a focus group session after the creation of the initial rubric.



Student A: "I guess if you're able to zoom in, you get more clear understanding of graph. Sometimes, I probably would fall into that route to keep going in and out. If I got bored or distracted in class."

Student B: "Well, I guess it's just a give and take. I feel like it would be a distraction, but it's the kind of distraction that could be learned from…"

Discussion

- Student discussions underscored the necessity for equitable learning material
- Using students as an authority to their experience in the classroom helps us build better curriculum materials.
- The study had to adapt to real-life constraints including availability, student interest, and fluctuations in student turnover.

Transformations in the Plane: Towards Interpretations and Proofs of Linearity

Anairis de la Cruz Benito
Florida State University

Christine Andrews-Larson
Florida State University

Keywords: linear algebra, linear transformations, proof

In recent years, student reasoning in linear algebra has been a rich area of research, but relatively few studies have focused on linearity and proof in this area (Stewart et al., 2019). In this study, our research questions are: (1) What are students' evoked concept images of linear transformations in the context of a Desmos module focused on transformations in the plane? (2) What do students report finding helpful in this module?

Existing literature has examined how students conceive of linear transformations in relation to their interpretations of functions in prior coursework, and how students shift from local to global views of linear transformations (Zandieh et al., 2017; Andrews-Larson et al., 2017), but there is limited work on how students make sense of the properties of linearity, particularly in relation to their proof activity. For our analysis, we draw on the notion of concept image from Tall and Vinner (1981) who described a person's concept image for a particular concept as "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (Tall & Vinner, 1981, p. 152).

The data for this report comes from Desmos activity completed by 54 U.S. undergraduate linear algebra students at the end of a unit on linear transformations. The goals of this activity were to help students identify and prove whether or not given transformations in the plane were linear. We analyzed our data by first developing data-driven codes (deCuir-Gunby et al., 2011) for students' responses to the questions "Explain in your own words what it means for a transformation to be linear and why it matters whether a transformation is linear," and "Which of the examples or slides in this Desmos activity did you find most helpful for your learning and why?" We aim to develop theory-driven codes to relate our findings to those of Zandieh et al. (2017), particularly identifying aspects of students' concept images of linear transformations in terms of: computations, properties, and clusters of metaphorical expressions.

We identified three broad categories of responses regarding the meaning of linear transformations that relate to students' concept images: references to the formal definition, preservation of straightness and parallelism of lines, and references to uniformity in how an image is transformed (e.g. points affected equally, retaining proportional changes in position and magnitude, reversibility, and preservation of orientation). We identified four primary aspects of the Desmos activity that students reported finding helpful: features that helped students develop intuition for linear transformation (e.g. via visualization and distinguishing examples from non-examples), features that helped students relate algebraic to geometric interpretations of linear transformations, and features that helped students make sense of the formal definition and proof methods (e.g., separating out interpretations of the two properties of linear transformations; providing examples of correct proofs and prompts to write a proof). In our poster, we will examine relationships among the meanings students ascribe to linear transformations, what students found helpful, and existing literature.

Transformations in the Plane: Towards Interpretations and Proofs of Linearity

Anairis de la Cruz Benito ad19cc@fsu.edu
Christine Andrews-Larson

NSF grant #1914793

MOTIVATION

In recent years, student reasoning in linear algebra has been a rich area of research, but relatively few studies have focused on linearity and proof in this area (Stewart et al., 2019).

RESEARCH QUESTIONS

(1) What are students' evoked concept images of linear transformations in the context of a Desmos module focused on transformations in the plane?

(2) What do students report finding helpful in this module?

PARTICIPANTS

53 undergraduate linear algebra students.

METHODS

We analyzed developed data-driven codes (deCuir-Gunby et al., 2011) for students' responses to prompts in the Desmos module.

Take a picture to access the Desmos unit on Linear Transformations

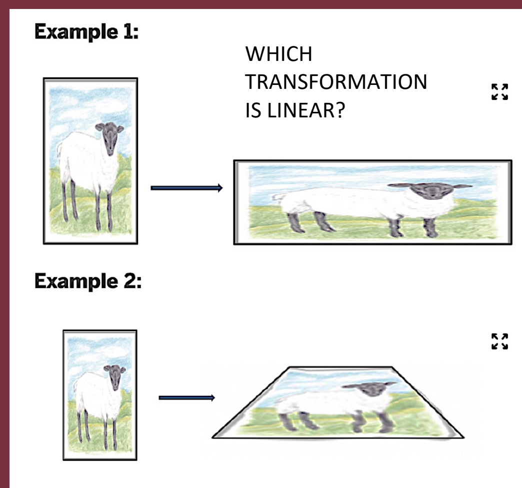
WHAT DOES IT MEAN FOR A TRANSFORMATION TO BE LINEAR?

P005: This means that the order of operations of T(V1) + T(V2), and T(V1 +V2) does not matter. You can transform then add or add then transform. Also applies to scaling with constant c. Scale before the transformation or after, it should be the same in a linear transformation.

P009: For a transformation to be linear, it has to be able to be written linearly in an algebraic form. This is made evident in the formal definition.

P0028. A linear transformation is a transformation that keeps the origin the same, straight lines remain straight, and parallel lines remain parallel. It also follows the properties T(V1+V2) = T(V1)+T(V2) and cT(u)= T(cu). It matter whether a transformation is linear because it helps us understand the nature of transformation and it does not completely change the original thing.

P0018. A transformation is linear when a vector's position relative to other vectors is the same from before the transformation to after, both additively and multiplicatively. It matters because it means the transformation is reversible, and that the relationships between vectors are maintained from before to after the transformation.



Visualization can help students make sense of the formal definition of linear transformations; students take away a variety of interpretations from visualization activities.

RESULTS

We identified three categories of responses that relate to students' concept images based on:

- references to the formal definition,
- preservation of straightness and parallelism of lines, and
- references to uniformity in how an image is transformed (e.g. points affected equally, retaining proportional changes in position and magnitude, reversibility, and preservation of orientation).

Based on student reports, useful features of the module were those that helped students:

- develop intuition for linear transformations (e.g. via visualization; distinguishing examples from non-examples),
- relate algebraic to geometric interpretations of linear transformations, and
- make sense of the formal definition
- model appropriate proof methods (e.g., separating interpretations of two properties of linear transformations; providing examples of correct proofs)

Exploring Mathematical Intuition and its Role in Physics Problem-Solving

Ella Henry
University of Washington

Charlotte Zimmerman
University of Washington

John Goldak
University of Washington

Suzanne White Brahmia
University of Washington

A large body of work in both mathematics and physics education research has explored mathematical reasoning in physics contexts (Redish & Kuo, 2015; Van den Eynde et al., 2020; Serbin & Wawro, 2022; Zimmerman et al. 2023b). Studies show that expert reasoning in physics problem-solving is not purely physical or mathematical, but a blended way of thinking (Redish & Kuo, 2015; Schermerhorn & Thompson, 2023). In this study, we build on the recent work of Zimmerman et al. who observed that one way physics experts reason while modeling is by “mathematical riffing”–manipulating familiar physical models, having a feel for when one might be useful, and quickly rejecting those that are not (Zimmerman et al., 2023a). Just as jazz might seem random and unpredictable to the untrained ear, mathematical riffing is hard to pinpoint and practice for physicists-in-training, even at the graduate level. There is no direct instruction to develop this kind of mathematical intuition on which experts rely to propel their thinking.

While the physics community values mathematical intuition as a mark of expertise, little work has been done to understand what it looks like, or what role it plays in generating quantitative physics models. To better understand mathematical intuition and its role in physics problem-solving, we conducted a pilot study in which we interviewed three physics graduate students after completion of their first year PhD coursework. We asked the interviewees to think aloud while solving unfamiliar graduate-level physics problems that relied on familiar mathematics. The data were coded using a grounded theory approach (Glaser & Strauss, 1967). This poster describes the study and its preliminary findings.

We identified three ways that mathematical ideas drive physics reasoning that, collectively, we call *mathematical impetus*. We see mathematical impetus as part of the set of behaviors associated with riffing. Each feature relies on *interactions with symbols* and is associated with having an *expectation of an outcome* without feeling the need to prove it mathematically. We also developed a description of a few distinct ways that graduate students act on mathematical impetus in tandem with other problem-solving skills. These findings help characterize problem-solving approaches that are typical in graduate classrooms, and can help inform instruction, making expert mathematical intuition more transparent to the learner.

Exploring “Mathematical Intuition” and its Role in Physics Problem-Solving

Ella Henry, Charlotte Zimmerman, John Goldak, Suzanne White Brahmia | University of Washington, Department of Physics

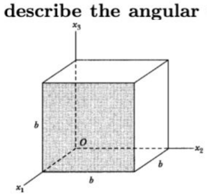
Background

- **This study:** We explore the *“mathematical intuition”* experts rely on to *propel their thinking,* and the role it plays in *generating quantitative physics models.*
- **Analysis framework:** Zimmerman et al. physics expert way of reasoning–*“mathematical riffing”*
  - manipulate familiar physical models, recognize when one might be useful, and quickly reject those that are not [1].
  - analogous to jazz: seems random and unpredictable to physicists-in-training

Methodology

- Interviewed 3 first year graduate students at University of Washington in July 2023.
- Think-aloud interviews that included solving the following classical mechanics problem [2]:

> You wish to study this object’s angular momentum as it rotates with the origin fixed, given its moment of inertia tensor, the equation of motion for rigid body rotations, and the initial conditions
>
> - $\theta_1(0) = \theta_2(0) = \theta_3(0) = 0$
> - $\omega_1(0) = \omega_2(0) = 0\ ,\quad \omega_3(0) = \omega_0,\ \omega_0 > 0$
>
> **What would you do next to describe the angular velocity of this cube?**
>
> $$I_{ij} = mb^2 \begin{pmatrix} \frac{2}{3} & -\frac{1}{4} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{2}{3} & -\frac{1}{4} \\ -\frac{1}{4} & -\frac{1}{4} & \frac{2}{3} \end{pmatrix}$$
>
> $$0 = \frac{d\boldsymbol{L}}{dt} = \frac{dL_i}{dt}\boldsymbol{e}_i + L_i\boldsymbol{\omega} \times \boldsymbol{e}_i$$



- Unfamiliar physics topic that relied on familiar mathematical tools.
- Data coded using a grounded theory; results are emergent from the data.

Some Emergent Ways of Symbolic Reasoning

Defining quantities	providing a working definition or understanding of what a symbol represents
Analogous symbols	using familiar quantities to understand new or unfamiliar ones
Symbols-guided math doing	doing algebraic manipulations, guided by symbols' meanings, interpretations, implications
Symbols-motivated process choosing	choosing a process to move forward in problem solving, cued by symbols' meanings, interpretations, implications
Extracting physical meaning	coming up with a physical interpretation for a mathematical result
Expected outcome	having an expectation for the mathematical/physics implications based on symbols

Mathematical Impetus (bracketing: Symbols-motivated process choosing; Extracting physical meaning; Expected outcome)

Examples of “mathematical impetus” from the transcripts

Symbols-motivated process choosing	Extracting physical meaning	Expected outcome
"But then usually, when I encounter [...] a differential equation like this, [...], where I'm like, fairly certain that there's no closed form solution--- um, we should just linearize? I think?"	"And then we know that DL dt is going to be zero. So this is going to be, um, constant in time."	"yes, that like decouples the set of equations very nicely. Like with this, you get, instead of the nasty i j omega j within the, um, in the differenti---in the differential equations I got, I'll just get a bunch of like [...]decoupled equations."

Preliminary Results

- 3 emergent ways of symbolic reasoning drive physics reasoning; we call this driver ***mathematical impetus***:
  - associated with mathematical riffing.
  - ***interactions with symbols*** with an ***expectation of an outcome*** without feeling the need to prove it mathematically.
- We are embarking on a case study analysis of the individual graduate students to characterize their ***unique ways*** of blending mathematical impetus with other problem-solving skills.

Further Work

- “Mathematical intuition” as a way of knowing is poorly understood and extremely important in physics. There is *no direct instruction to develop it in our classrooms.*
- Toward a characterization of mathematical impetus we will:
  1. continue the analysis of the transcripts to uncover the diverse ways that graduate students use mathematical impetus when solving new physics.
  2. use the codebook developed in this project to study how experts engage with mathematical impetus in generating new physics.

Pirates, Wobbly Jelly, and Bunnies … Analyzing Applets and Video Games from the Perspective of RME

Matthew Mauntel, University of New Hampshire
Michelle Zandieh, Arizona State University
David Plaxco, Clayton State University

Keywords: Linear Algebra, Technology, Realistic Mathematics Education, Game-based Learning, Dynamic Geometry Software

Realistic Mathematics Education (RME) is a curricular design theory that involves designing materials with realistic starting points and guiding students through four levels of activity: situational, referential, general, and formal (Gravemeijer, 2020, 1999). This theory has been used to develop a multitude of curricular materials including ones that incorporate technology. This poster investigates the design of three different technologies (video games, GeoGebra, and applets) designed to elicit different forms of activity in an RME sequence. Each technology has a 2D and a 3D version and was either could be used or was designed to be used in a linear algebra classroom. This poster will present the design heuristics of each type of technology that lend themselves to a particular type of activity to be evoked with the goal of providing insight into designing technology for use in an RME-type sequence.

The first technology we analyze is a 2D video game called *Vector Unknown* which was designed to convey a realistic starting part for situational activity. *Vector Unknown* was designed to mimic the first task from the Inquiry-Oriented Linear Algebra (IOLA) Magic Carpet Ride Sequence (Wawro et al., 2013). Mauntel et al. (2021) explored the student strategies from the game. *Vector Unknown* gave rise to a new 3D video game called *Vector Unknown: Echelon Seas* (Plaxco et al., 2023). The video game added a new dimension to gameplay and a different design and environment. This new design generated different strategies including the need to adjust the viewpoint in 3D environments.

Mauntel (2023) built upon the foundations of the game Vector Unknown and used an open GeoGebra environment for students to analyze and refer (referential activity) to the game. GeoGebra was intended to be a tool that would help students analyze the game and explore linear combinations more extensively. One issue with this implementation was that students experienced the technology differently as GeoGebra presented linear combinations to students differently depending upon how they entered them into GeoGebra which created some conflicts with how the game presented linear combinations. We investigate this issue, as it is important to consider when technology supplements an already existing phenomenon as opposed to becoming a new phenomenon itself. In this case, for some students, the GeoGebra open environment became a new realistic starting point as opposed to a tool for referring to the video game.

The final context was the use of GeoGebra applets for a sequence on determinants (Wawro et al., 2023) which were used at the end of an RME sequence to promote generalizations. In this case, there were two applets that were explored, 2D and 3D. This allowed students to make generalizations within a context and between contexts. This poster will look at all three technologies and discuss design choices made in each concerning their alignment along an RME sequence and its relation to student activity.

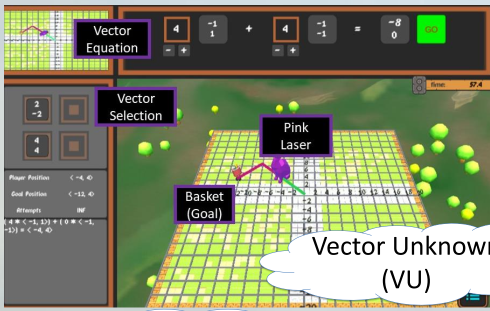
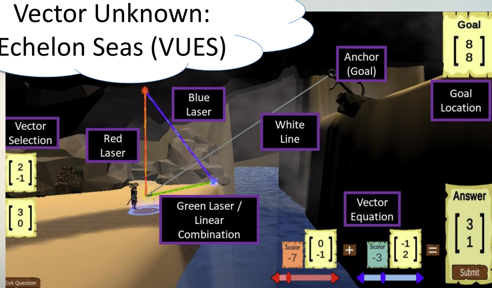
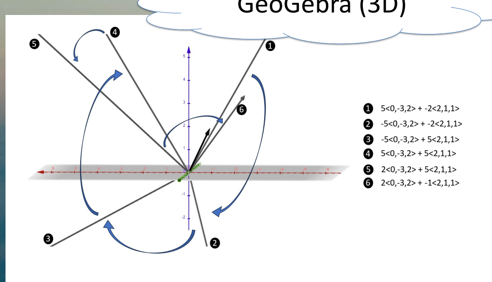
David Plaxco

Comparing Contexts

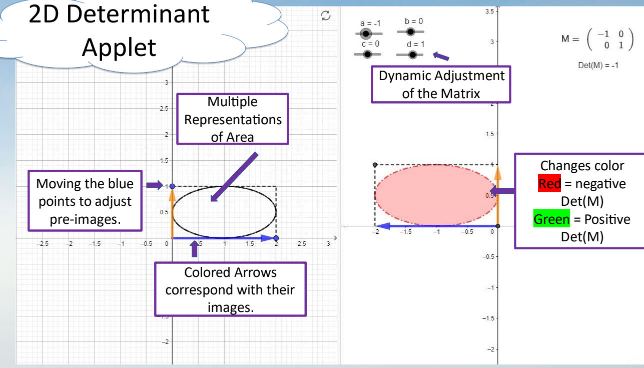
1. Some student strategies between VU and VUES differed because of the presence of the green laser and **white line**. Some students tried to move the green laser onto the **white line**.
2. After playing VU, a student explored linear combinations with GeoGebra 3D. They found they could rotate the result of a linear combination by changing the scalars. This had implications for how they thought about **all possible linear combinations.**







Carefully designed digital environments can serve as realistic starting points for student exploration and promote generalizing activity.



Connections

1. In the 2D and 3D applets we build connections between the matrix, determinant, and associated images using colors and **dynamic color change** associated with the **sign of the determinant**.
2. The **Movable Green Points** were designed to allow students to create biconditional generalizations. We noticed that without the ability to change the images, most generalizations originated with the matrix.
3. Having the option to **switch rows/columns** hints at the importance of **row/column operations**.

Observations Related to RME

1. **Applets and video games** can be great **realistic starting points for RME activities**. If multiple digital environments are used, it is important to consider the connections between design. For example, the student who played VU and then used the GeoGebra applet considered the contexts different and built-up separate strategies.
2. **Randomization** can be a great tool for **generating examples** for generalization and for **designers to scaffold learning**. VU has a difficulty setting (easy) with 0 as an entry because we observed student play and choosing vectors with 0s.

Exploring The Role of Undergraduate and Graduate Real Analysis Experiences in the Mathematical Trajectories of Women Mathematicians from Historically Disenfranchised Groups: The Cases of Anna and Sasha

Te'a S. Riley
The University of Texas at Arlington

James A. M. Álvarez
The University of Texas at Arlington

Keywords: real analysis, classroom practices, equity, mathematical identity

As the population of the United States becomes increasingly diverse, more attention to efforts aimed at understanding ways in which colleges and universities can achieve equity in science, technology, engineering, and mathematics (STEM) education is needed to maintain global competitiveness in STEM (Henthorne, 2023; Office of Science and Technology Policy, 2022). As such, since courses in real analysis (undergraduate and graduate or similar courses)—typically required in the undergraduate and graduate mathematics programs in the US—often pose significant challenges to progressing in mathematics (Lew et al., 2016; Weber, 2004), we explore the cases of Anna and Sasha, part of a larger research study exploring the experiences of women mathematicians who come from groups historically disenfranchised in STEM (HDG), with a focus on undergraduate and graduate real analysis.

To investigate the mathematicians' experiences in real analysis, participants completed a 90-minute interview which included questions about their undergraduate and graduate classroom environments, their recollections of important concepts, and the role of their experiences in the development of their mathematical identity. This poster focuses on the following research questions: (1) What belief structures about how participants think of themselves as mathematicians were evoked by their experiences? (2) To what extent did their courses or experiences in real analysis advance their development as mathematicians? Using CRT as a theoretical base, my conceptual framework also incorporates factors that emerge from research literature associated with graduate school experiences of students from HDG (Borum & Walker, 2012; Johnson-Bailey et al., 2009; McAfee & Ferguson, 2006; McGee & Martin, 2011).

For both Anna and Sasha, interview analysis reveals the classroom environment in their real analysis courses negatively affected their identity as a "strong mathematician" even after completing their doctorate. Sasha had the unique experience of having taken real analysis at the undergraduate level in Latin America as well as in the US. She completed her undergraduate and graduate studies in the US and reported that she did well in the courses. She "loved analysis" and incorporates some of the teaching strategies used by her professors in her current teaching. In contrast, Anna describes undergraduate real analysis as not particularly challenging and that she earned "about a B." However, she explained that she failed her graduate course in real analysis because of the amount of information she had to "memorize." Although their performance levels in the courses were distinct, other messages received from their professors and classmates contributed to a similar cost to their identities as mathematicians. Both experienced isolation because of their race or gender throughout their academic career, but Anna experienced it in her analysis class directly. This contributed to Anna's choice to avoid more analysis classes as she "wanted absolutely nothing to do with it," and this continues in her role as a faculty member. The stories of Anna and Sasha compel mathematicians to re-examine the role of real analysis in the curriculum and to integrate anti-deficit strategies that foster a supportive learning environment.

The MAJORWISE Survey Study: Why Students Leave and Stay in the Mathematics Major

Amanda Lake Heath
Middle Tennessee State University

Sarah K. Bleiler-Baxter
Middle Tennessee State University

Jordan E. Kirby
Francis Marion University

Jennifer Webster
Harpeth Hall School

Keywords: list 3-5 keywords here, Times New Roman 12-point, no italics

An overwhelming 52% of declared mathematics majors nationwide change their major in the course of their college career (Leu, 2017). To better understand retention and attrition in the mathematics major, our research team launched the **Ma**thematics **J**ourneys **o**f **R**etention: **W**hy **I**ndividuals **S**hift **E**ducational Paths (MAJORWISE) project. In this poster, we will address the question: Why do students choose to stay in and leave the mathematics major?

Background

Although several studies have investigated patterns of retention and attrition using quantitative measures (e.g., Rask, 2010; Rasmussen & Ellis, 2013), qualitative studies provide a deeper look into the reasons students provide for leaving mathematics. International qualitative studies have indicated students become disaffected with mathematics at the undergraduate level because they dislike lecture-based instruction and feel their courses place a strong emphasis on memorization (Hall et al., 2022; Rodd & Bartholomew, 2006; Ward-Penny et al., 2011).

Methods

During October 2023, we carried out a nationwide survey in the United States with free-response items of students who have been enrolled in a mathematics major during the years 2013-2023. In addition to demographic information, this survey solicited information such as reasons for enrolling in a mathematics major and timing of and reasons for deciding to either leave or stay in the mathematics major. We recruited participants through professional networks, social media, and snowball recruitment (requesting participants share the survey with others).

We analyzed free-response survey items using a predetermined coding scheme framed by Self-Determination Theory (Ryan & Deci, 2000), with codes for *autonomy*, *relatedness*, and *competency*. We then conducted an inductive analysis of responses in each category to describe specific experiences relevant to choosing to leave or stay in the mathematics major.

Presentation of Findings and Implications

The MAJORWISE online survey received 147 applicable responses. In our poster, we will report detailed findings from our analysis. For example, out of 40 responses to the question, “Why did you consider leaving the mathematics major?,” 22 (55%) were related to autonomy (or a lack thereof), 7 (17.5%) indicated a lack of relatedness, 15 (37.5%) concerned competence, and 13 (32.5%) cited sources of extrinsic motivation (e.g., job opportunities). These findings, along with our in-depth inductive analysis, provide insight into how relevant stakeholders can best promote the motivation and retention of mathematics majors.

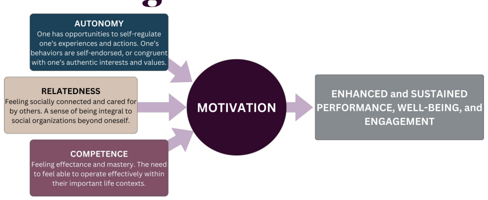
Framing & Methods



The Survey

- Demographic Information: Race/Ethnicity, Gender, Institution Type
- Basic Major Information: Years enrolled as a mathematics major, mathematics courses taken at the undergraduate level, time of major declaration, title of degree program, status with major (completed, still completing, considered switching, switched), current occupation
- Open-Response Questions for Applicable Participants

Recruitment & Participants

- Recruited participants through professional networks (e.g., RUME, EDGE, Jerry Becker ListServ), social media (e.g., Twitter/X, Facebook), and snowball recruitment.
- The survey received 147 applicable responses out of 176 total responses across 23 states.

Mathematics and Science Education Doctor of Philosophy Program

Online vs Face-to-Face Instruction: Affordances and Interactions

Valentina Postelnicu
Governors State University

Keywords: online instruction, affordances, interactions

The study reported focuses on the affordances of online instruction (Day & Lloyd, 2007), compared with face-to-face instruction. Participants were 51 undergraduate students, STEM majors, enrolled in two Discrete Mathematics sections, taught by the author, at a four-year university in the United States. In spring 2020, the COVID-19 pandemic changed the course instruction from face-to-face to online. The change affected the students' and the instructor's interactions with each other and with the mathematical content (Cohen, Raudenbush, Ball, 2003, p. 122). The following research questions are addressed:

1. How does the instructor use the online affordances to meet the students' learning needs?
2. How do the students use online affordances?
3. How does the online instruction of the course compare with the face-to-face instruction of the course with respect to meeting the students' learning needs, as perceived by instructor and students?
4. How does the online instruction of the course compare with the face-to-face instruction of the course with respect to students' success, as measured by their performance on the final exam?

The following data were collected: Student Questionnaire (SQ), Instructor Questionnaire (IQ), Blackboard Discussion Forum (BB Discussion Forum), and students' answers on the final exam.

SQ included questions related to how students interacted with the mathematical content, the instructor, and their colleagues during the face-to-face and online course instruction, as well as questions about satisfaction with specific instructional elements and preferences for future interactions.

IQ was a self-administered instrument. For both the face-to-face and the online instruction of the course, the questionnaire asked the instructor to rate her satisfaction with the convenience of the interaction with the mathematical content and the students, the quality of the interaction and the time spent, as well as to propose changes to better serve the students' learning needs.

Students posted their homework in Blackboard/Discussion Forum and were required to read their colleagues' postings and comment on one or two of their colleagues' answers. Data collected for this study came from two homework assignments with four tasks related to mathematical induction.

Students' answers on the final exam on two tasks referring to mathematical induction were scored and compared with previous scores from the final exams administered during the previous three semesters, when the course was delivered face-to-face. The scoring rubric for induction tasks was based on the mathematical and pedagogical considerations stated by Ernest (1984).

Data were analyzed using statistics, and social network analysis (Chai, Le, Lee & Lo, 2019; Ye & Pennisi, 2022).

The findings will be discussed and will inform recommendations for practitioners and directions for new research. Among those findings will be those referring to the importance of the BB Discussion Forum as a learning resource for students during the online delivery of the course, and the patterns of interaction between students.

Using Comparative Judgment to Assess the Quality of Explanations in Mathematics

Juan Pablo Mejía Ramos
Rutgers University

Tanya Evans
University of Auckland

Colin Jakob Rittberg
Vrije Universiteit Brussel

Matthew Inglis
Loughborough University

Keywords: Comparative Judgment, Explanation, Proof.

We describe evidence of the usefulness of the Comparative Judgment (CJ) approach to assess the quality of explanations in mathematics. In philosophy, some study how certain types of mathematics offer *explanations* of other mathematical phenomena. In the field of education, offering explanations is a central part of teaching mathematics, and understanding those explanations is a vital activity for learners. So, what makes a good explanation in mathematics?

In the philosophy of mathematics, explanation quality has been traditionally studied by investigating the properties of what are deemed to be exemplars of mathematical explanations (e.g., Steiner, 1978), often mathematical proofs. In education, the approach has been to use *general* frameworks (i.e., non-math specific) describing the features that high-quality instructional explanations may have (e.g., Wittwer & Renkl, 2008).

We propose a different approach: using the CJ method to explore the notion of explanation quality *as it exists among mathematicians and undergraduate students*. CJ approaches to understanding human judgment exploit the finding that people are better at comparing two objects against each other than at evaluating one object against specific criteria (Thurstone, 1927). Modern uses of comparative judgment in assessment rely upon the Bradley-Terry model (Bradley & Terry, 1952), which assumes that each stimulus has a numerical parameter which captures its quality on the dimension of interest. By presenting judges with repeated pairs of stimuli and asking them to assess which they would rate higher on the given dimension, empirical estimates of these parameters can be obtained.

Recent empirical studies (Mejía Ramos et al., 2021; Evans et al., 2022) have used the CJ approach to study the extent to which mathematicians and students can reliably judge the quality of explanations in mathematics. In the first study, 38 mathematicians made a total of 760 comparisons between two proofs of the same proposition. For each judgment, two proofs were randomly selected and positioned side-by-side for the participant to think about and select which argument best explained why the proposition holds (without focusing on how the proof might be received by a particular audience), an instruction aimed at investigating the more philosophical sense of explanation described above. Using a similar procedure, in the second study we asked 32 undergraduate students who had taken a Linear Algebra course and 16 mathematicians to judge explanations meant for a hypothetical mathematics undergraduate student who did not understand the concept of an abstract vector space, an instruction aimed at investigating the more pedagogical sense of explanation described above. Using split-half inter-reliability coefficients, we report very high levels of reliability in participants' judgments of explanation quality for both mathematicians and students. Furthermore, in the second study we found a very high correlation between the parameter estimates for mathematicians and those for students. Overall, these studies provide evidence of high level of agreement among participants regarding what makes a good explanation in mathematics. This method opens fascinating avenues for future research on the notion of explanation in mathematics.

A ‘Warm Demander’ in College Mathematics Drives STEM Student Persistence

Megan Selbach-Allen
Stanford University

Keywords: Community College, STEM, Student Persistence

Within the context of science, technology, engineering, and mathematics (STEM) many studies have shown the reality of the “leaky pipeline” with students dropping out of STEM majors along the way to completing a degree or dropping out of school (Flynn, 2016). Addressing the issues creating the leaky pipeline and students not persisting in STEM degrees is crucial to improving broader issues of diversity in STEM especially for students starting their academic journeys in community colleges.

Theoretical Framework

This work uses the framework of the ‘warm demander’ (Kleinfeld, 1975) from culturally relevant pedagogy to examine the teaching style and pedagogical choices of the instructor. A ‘warm demander’ is an instructor that holds high standards for their students since they know reaching these standards is important for their academic success, but they also create a caring and supportive environment in the classroom.

Research Questions

This work is focused on the case of an effective community college math instructor and considers what instructional moves appear to be driving increased student success. The research question is: What pedagogical choices of an experienced community college math instructor appear to be leading to increased student persistence in STEM trajectories?

Methods and Data

The instructor at the center of this study is an experienced community college math faculty member who has success in increasing student success rates. Success was defined through increased pass rates and persistence of students in follow on courses even if passing courses required multiple attempts. The success of students was defined both from institutional data and through interviews of students and alumni about their experiences and trajectories. Classroom videos were analyzed to understand the pedagogy of the instructor.

Findings and Discussion

The analysis shows that this instructor exhibits many characteristics of a ‘warm demander.’ He brings deliberate language of care into the classroom, not only in communicating his care to students but encouraging them to care about one another. The instructor also creates a warm environment through humor and encouragement. At the same time, he maintains high standards for students, pushing them to come to class on time, engage with the materials and pass demanding quizzes and tests. Powerfully, this combination seems to help students see their own potential even when they struggle. This aspect of instruction should be studied further to see how it may be enacted by other successful instructors and how professional development could be created to teach more instructors how to include warmth and standards in their math classrooms.

Keywords: Instructor Feedback, Actionable Feedback, Feedback Literacy, Student Success

Carless & Boud (2018) capture the definition of feedback best as "a process through which learners make sense of information… use it to enhance their work or learning strategies." This definition goes beyond feedback solely being the role of teachers and highlights the student component in making sense of the feedback (Carless & Boud, 2018). A more specific type of feedback that will be used in this study involves "actionable feedback" which allows the student more agency to revise their work independently (Hattie & Timperley, 2007).

Research Questions

1. What are the feedback types commonly used by instructors within a student homework sample?
2. Do the feedback types that instructors provide match those that the students prefer/find useful?

Methods, Results, and Benefits

Boise State University instructors were asked to complete an online questionnaire and to grade and leave written feedback on student work samples of the same task. No rubric was provided. A thematic analysis was conducted on their feedback practices and word choice to then classify into groups. The classification of feedback was based on a combination of Wahyuni (2023) and Lyster & Ranta (1997) written feedback clarification. Students' perceptions about feedback were gathered through a questionnaire to gain insight on how they use feedback, how highly they value it, and which feedback type they find most useful.

Results are currently pending, but preliminary results suggest that most instructors use a wide-variety of different feedback types. Most tend to be non-actionable feedback, while there is almost always at least one piece of feedback that provides the student with the agency to help revise their response. Instructors commonly followed a close pattern of feedback across their students.

This study is focused on BSU's Math Department, and as a result, we may be able to identify certain trends within the ways courses are currently taught and provide more awareness to better inform our department's grading practices across our entry level math courses. This information could be especially beneficial to present as training material for new GTAs.

An Analysis of Instructor Feedback

Olga Hawranick*, Dr. Margaret Kinzel, Dr. Sasha Wang, Dr. Joe Champion, and Dr. David Miller

Department of Mathematics, West Virginia University and Boise State University, Boise, ID 83725

BOISE STATE UNIVERSITY

Introduction

- Instructors across every discipline, especially those in entry-level courses, act as one of the key players in a beginning college student's journey into their course of study and play a pivotal role in students' personal and academic development.
- Their actions and choices in the classroom can highly influence a student's path in college, even including their use of feedback.

Defining Feedback

- Feedback is "a process through which learners make sense of information from various sources and use it to enhance their work or learning strategies" [2]. This goes beyond it solely being the role of teachers and highlights the student component in making sense of the information. We consider feedback to include teachers' comments, questions, and markings (such as check marks, X's, and addition of math content).
- Actionable Feedback allows the student the opportunity to identify an error and strategize about how to correct it themselves [3][4]. This type of feedback promotes student agency and independence.

Research Questions

1) What are the feedback types commonly used by instructors within a student homework sample?
2) Do the feedback types that instructors provide match those that the students prefer/find useful?

Methods

8 Boise State instructors (below Calculus level) completed 2 phases:

- online questionnaire about their grading practices
- a task involving grading and leaving feedback on 7 student work samples

22 Boise State students completed an anonymous questionnaire asking their preferences of feedback.

Classification

This study used a 9-category classification, extended from Lyster & Ranta (1997) and Wahyuni (2023) [5][6].

Feedback Type		Actionable?	Justification	Example
Indication		Non-Actionable	No words are included; it can be unclear to students how to proceed.	Praise		Non-Actionable	Adds no mathematical comments; only offers positive words.	Recast	1	Non-Actionable	A correction is only provided with no reason as to why there was an error.		2	Non-Actionable	All of the work is provided in the feedback, with no reason as to why there was an error.	Clarification Request		In Between	Comment suggests that the student's work is "ill-informed"; a revision is encouraged.	Summative	1	Non-Actionable	A comment about a specific performance acts similarly to Praise, as it is only acknowledging the work that was done.		2	Actionable	This feedback offers a comment about a certain action to be more aware of in the future.	Metalinguistic Feedback		Actionable	Feedback is offered about specific word choice used; correction may encourage students to use that terminology in the future.	Explicit Correction		Actionable	Feedback includes the error detection as well as the reason why it was incorrect.	Elicitation		Actionable	Feedback is in the form of a question or general comment with instructions on how to complete a given task.	Reference		Actionable	This directs a student to a certain reference, such as the instructor or a page in the textbook.	
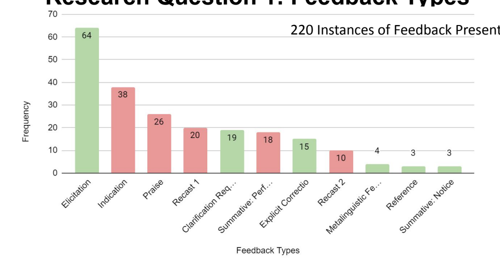
Table 1.1 Nine feedback types are categorized as being actionable or non-actionable.

Results

Research Question 1: Feedback Types



Research Question 2: A Match Between Instructor and Student?

COUNTA of Student		Student Experiences		
Feedback Type	Student Preference	Doesn't Receive	Receives	Grand Total
Actionable	Least	4	3	7
	Top	1	19	20
Actionable Total		5	22	27
Non-Actionable	Least	16	1	17
	Top	0	3	3
Non-Actionable Total		16	4	20
Grand Total		21	26	47

Conclusions

The results indicated that instructor feedback was overall actionable, which students preferred. This study found harmony among these two populations, inconsistent with other findings where teachers believe actionable feedback is less desired by students[1].

Acknowledgements

A huge thank you to Dr. Kinzell, my committee, the participants, and the Boise State Math Department for their support on my thesis research!

Opportunities for Reasoning-and-proving with Trigonometric Identities in Precalculus Textbooks

Matthew Hardee
Indiana University

Keywords: precalculus, trigonometry, proof, reasoning, justification

Outside of geometry, United States high school students have few opportunities to engage with proof (Thompson et al., 2012; Otten et al., 2014). It is therefore likely that for most precalculus students, proving trigonometric identities represents a significant departure from familiar modes of reasoning. As both a thorough understanding of the relationships between trigonometric functions and the ability to reason deductively are critical in undergraduate mathematics, learning trigonometric identities may be an opportune time for students to develop skills at all levels of Stylianides' (2009) taxonomy of reasoning-and-proving (RP) activities.

This poster will summarize a study that examined five precalculus textbooks for the opportunities they afford students to engage in RP activity in the context of trigonometric identities. One textbook was selected from each decade from the 1970s to the 2010s, and each represents a distinct instructional approach (Stylianides, 2008). The research questions were:

1. Across the five textbooks, what opportunities do students have to derive or prove essential trigonometric identities?
2. Across the five textbooks, what types of RP activity, and in what amounts, are expected of students in the context of learning to apply and verify trigonometric identities?

Twenty trigonometric identities were identified as *essential* (defined as necessary in future problems and/or in proofs of other identities). Each textbook's presentation of each identity was assigned one of six author-created codes, capturing the extent to which the text solicited student involvement in deriving it. A modified version of Otten et al.'s (2014) framework for coding RP opportunities in geometry textbooks was used to code justification-based problems in lessons about trigonometric identities. Percentages of items marked with each code were tabulated and trends identified. The poster will report on those trends, of which two were most salient:

1. In nearly all instances of an opportunity to derive an essential identity, the text provided enough guiding detail that a student would not bear the cognitive load of creating a proof.
2. The two 21st century textbooks afforded noticeably more frequent opportunities to make graphical arguments than the three 20th century textbooks.

The second finding is particularly significant in light of Stylianides' (2008) comments on the potential curricular effects of the 2000 NCTM Standards' unified view of reasoning and proof. Because of the small sample of textbooks under analysis, a natural next step would be to repeat the analysis with the precalculus and trigonometry textbooks that have been most popular over time. Significance tests of the differences in proportions of codes could show with greater clarity how responsive trigonometry curricula have been to long-term trends in instructional approaches.

Using Online Resources to Study Mathematics: Students' Perspectives on Effectiveness and Ethics

Ander Erickson
University of Washington Tacoma

Tramon Jones
University of Washington Seattle

Keywords: Information Literacy, Ethics, Technology

Students in undergraduate mathematics classes are using online resources to support their learning with increasing frequency (Erickson, 2019, 2020). The use of such online resources has not proven to be straightforward for students. Undergraduate students have well-documented difficulties locating, evaluating, and making use of information sources regardless of the topic area in question (Scott & O'Sullivan, 2005; Walraven, Brand-Gruwel, & Boshiuzen, 2008). These difficulties may vary depending on a student's familiarity or comfort with the field (Brand-Gruwel, Wopereis, & Vermetten, 2005). Thus, it is important to develop subject-specific models of student information-seeking. This is particularly important for the field of mathematics due to the role that lower-division math classes have often played as a gatekeeper for entry into STEM majors (Martin, Gholson, & Leonard, 2010).

This poster will present findings from a nationwide mixed method research project that has collected surveys from over 300 students across the country and follow-up semi-structured interviews with over 60 students intended to assess how students currently make use of online resources to support their learning in lower-division mathematics classes. These findings specifically address the following questions:

1. From the students' perspective, what does it mean to efficiently use online resources to study mathematics?
2. From the students' perspective, what does it mean to ethically use online resources to study mathematics?

These findings also include a mid-range theory of students' use of online resources based on a grounded theory (Strauss & Corbin, 1994) analysis of the interview transcripts. The poster will present this theoretical model in which we identify triggers for the use of online resources, along with the most common types of resources used and the accompanying goals. For example, students commonly make use of online video lectures if they are having trouble understanding what their instructor is saying in class or look up solutions in an answer engine when they feel that they need to double-check their homework.

We present evidence that students are generally conscientious in their use of such resources, struggling both with how to maximize their efficiency while also expressing concern that their practices are ethical. These two concerns are sometimes balanced against one another as is evidenced by a recurring student suggestion for their peers: start by learning on your own and only make use of online resources when you struggle.

Finally, our poster will present several representative cases in order to better capture the way in which students balance these concerns in different types of mathematics classes. These narratives have the potential to be used in classroom settings in order to help students become more effective and ethical users of online resources.
