Preface

As part of its on-going activities to foster research in undergraduate mathematics education and the dissemination of such research, the Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME) held its twenty-sixth annual Conference on Research in Undergraduate Mathematics Education in Omaha, Nebraska from February 22 - February 24, 2024.

The 26th RUME Conference enabled presenters and attendees the option to participate fully online such that travel was not a requirement, approximately 31% of participants were online.

The program included plenary addresses by Dr. Yvonne Lai, Dr. Michelle Friend, and Dr. Estrella Johnson and the presentation of 154 contributed, preliminary, and theoretical research reports and 97 posters. The conference was organized around the following themes: results of current research, contemporary theoretical perspectives and research paradigms, and innovative methodologies and analytic approaches as they pertain to the study of undergraduate mathematics education.

The proceedings include several types of papers that represent current work in undergraduate mathematics education, each underwent a rigorous review by three or more reviewers:

- Contributed Research Reports describe completed research studies
- Preliminary Research Reports describe ongoing research in early stages of analysis
- Theoretical Research Reports describe new theoretical perspectives for research
- Posters may fall into any of Contributed, Preliminary, or Theoretical and were presented in poster format. Authors contributed the poster itself, a summary of the work, or both.

The conference was hosted by the University of Nebraska – Omaha's Department of Mathematical and Statistical Sciences. Many members of the RUME community volunteered for the Program Committee where they reviewed many submissions such that every submission was reviewed by at least one member of the Program Committee. The Program Committee aided us in putting together this program and their hard work is greatly appreciated. The Local Organizing Committee were responsible for the smooth running of the presentations and on-site activities, which would not have been possible without the help of many volunteers, and we thank them for their tireless efforts to host a conference that runs smoothly.

Thank you to all of the researchers who submitted such strong proposals and ultimately made the conference a fun and joyous event.

Sam Cook, RUME Organizational Director and Conference Chair
Nikki Infante, RUME Conference Local Organizing Chair

Program Committee

Chairperson

Samuel Cook	Boston University

Committee Members

Aditya Adiredja	University of Arizona
Naneh Apkarian	Arizona State University

Learning in Pieces: Horizontal Décalage in Students' Thinking on Homework Tasks

Allison Dorko
Oklahoma State University

This report (a) documents the phenomenon that student learning from online homework may occur across a series of mathematical tasks and (b) provides a theoretical explanation for the phenomenon by characterizing some of the cognitive mechanisms that underpin it. Specifically, findings indicate one way students learn from online homework is by comparing similar tasks. The results add to knowledge about what and how students learn from homework. They also have implications both for practice and research in terms of how we define and measure learning. In particular, the results support the need to consider and design for learning across multiple mathematical tasks.

Keywords: assimilation, accommodation, online homework, equation solving

Rationale and Overview

Although many university students spend more time doing mathematics homework than they do in class (Ellis et al., 2015; Krause & Putnam, 2016; Lew & Zazkis, 2019), there is a paucity of research about student learning from homework. Research about what students learn from homework and the mechanisms by which they learn it can inform the creation of more effective homework assignments, which, given the amount of time students spend doing homework, could greatly improve student learning. This report, which focuses on student learning while doing online homework, makes several contributions. First, it documents what Piaget called horizontal décalage, or the phenomenon that there is often a temporal delay in learning. Specifically, the paper shows how some students' learning from online homework occurred across a series of mathematical tasks. Second, the paper characterizes some of the cognitive mechanisms that supported students' learning over the series of tasks.

Theoretical Perspective and Theoretical Literature

von Glasersfeld (1995) summarized Piaget's definition of learning as follows: learning "takes place when a scheme, instead of producing the expected result, leads to perturbation, and perturbation, in turn, to an accommodation that maintains or re-establishes equilibrium" (p. 68). A *scheme* is a construct describing how people organize knowledge. It consists of "(1) recognition of a certain situation; (2) a specific activity associated with that specific situation; and (3) the expectation that the activity produces a certain previously experienced result" (von Glasersfeld, 1995, p.65). The framework was chosen for the study in part because of its clear definition of learning, which afforded identifying when learning happened and what supported that learning.

People employ, construct, and modify schemes via assimilation, perturbation, equilibration, and accommodation. Consider a person engaging with a math task. *Assimilation* occurs if the person "treats new material *as an instance of something known*… [the] cognizing organism fits an experience into a conceptual structure it already has" (emphasis original; von Glasersfeld, 1995, p. 62). If the person is unable to fit the experience into an existing conceptual structure, they may be *perturbed,* meaning they recognize assimilation has failed. von Glasersfeld (1995) gives disappointment or surprise as examples of indicators that a person is perturbed. *Accommodation* is the modification of a scheme to remove perturbation. *Equilibration* describes the "construction process and [a] mechanism of change" by which a person accommodates a scheme and resolves perturbation. One way accommodation could occur is through the person reviewing the situation and identifying characteristics missed in the assimilation attempt; the identified characteristics "may effect a change in the recognition pattern and this in the conditions that will trigger the activity in the future" (von Glasersfeld, 1995, p. 65). A second way accommodation could occur is if the person creates a new recognition pattern (and hence a new scheme).

An accommodation is a semipermanent state; Piaget notes "it can take a certain time for a particular way of operating to spread to other contexts (*horizontal décalage*)" (von Glasersfeld, 1995, p. 71-72). Montangero and Maurice-Naville (1997) note that horizontal décalage "illustrates the limits of the generalization of a mental structure" (p. 89). That is, horizontal décalage can be thought of as the temporal delay in an individual's capacity to apply a scheme to a structurally-isomorphic task (i.e., engage in observer-oriented transfer). The idea that accommodation (learning) takes place over time and across contexts instead of as a single "lightbulb" moment, is the focus of this paper. The theory that learning occurs over time and across contexts is neither new nor unique to Piaget. di Sessa (1993) proposed the knowledge in pieces (KiP) framework, and Wagner (2006) characterized transfer as occurring in 'pieces.' KiP, developed in the context of physics learning, has been employed in empirical mathematics education work (e.g. Izsák, 2005).

Empirical Literature

The findings about student learning from homework indicate students' affinity for learning from examples (Dorko, 2021, 2020; Dorko, Cook, & DeHoyos, 2023; Aichele et al., 2011; Bissel, 2012; Erickson, 2020; Kanwal, 2020; Krause & Putnam, 2016; Lithner, 2003; Weinberg et al., 2012). Students appear to like examples in part because they provide an opportunity to reason via viewing a similar problem. However, the extant literature also indicates the learning from these problems tends to be procedural in nature, with students missing conceptual insights the professor intended.

When learning from online homework, multiple researchers have found students employ immediate feedback to inform their work (Dorko, 2020; Kontorovich & Locke, 2022). That is, students tend to submit an answer to a part of a problem, see if it is correct, and then proceed to the next part of the problem.

Methods

The data discussed are representative excerpts from video recorded sessions of five precalculus students doing online homework. I collected data at a large, public US university during fall 2022 and spring 2023. All five students had the same instructor. The entire data set consists of 27 online homework assignments between the six students, collected over a two-month period in each term. During the sessions, students were instructed to think aloud. Students received immediate feedback on their answers from the homework platform and had unlimited attempts for non-multiple choice problems.

During data collection, the researcher had observed that students might answer a problem correctly, only to struggle with a subsequent problem about the same mathematical idea. This was intriguing because it raised the question why the student did not employ the previously-successful scheme in the new context. Hence the first step in analysis was isolating all series of problems that dealt with the same mathematical idea and taking from that set the data in which a student struggled with some (but not all) of the problems. There were two goals in analyzing the data. The first was to evaluate the extent to which horizontal décalage described the students' struggles over a series of problems. Having determined that it did, the researcher then sought to characterize the mechanism of equilibration.

The criteria for evaluating if a student's work across the series of problems was an example of horizontal décalage was the student modifying a scheme over a series of problems, with evidence for those modifications coming from students' utterances and the answers they submitted. This follows from Piaget's characterization of accommodation as a semipermanent state and the definition of horizontal décalage (above). Evidence that students were perturbed came from their expressing confusion, disappointment, or surprise (von Glasersfeld, 1995). If students approached and solve a problem without difficulty (either explicitly expressed difficulty, or the researcher noticing activity like their writing/erasing in scratchwork), the students were considered to be in an unperturbed state and assimilating the problem to an extant scheme.

To characterize the mechanisms of equilibration, the researcher performed an analysis grounded in the data and informed by the theory. In terms of the theory, she sought evidence that the student had (upon an assimilation failing) explored the context to seek characteristics the assimilation had disregarded. This followed from von Glasersfeld's (1995) description of one way accommodation can occur. However, this explanation did not seem to fit the data under consideration. The researcher did notice that Dylan, the first student whose data she analyzed, made progress on a task in the middle of the series by re-examining his work on previous problems that he identified as similar. In accordance with grounded methods of analysis, the researcher evaluated data from other students to see if *comparison* appeared to be a cognitive mechanism that supported equilibration for other students (it did). This work is ongoing, and subsequent analysis will seek to identify other mechanisms of equilibration. The results shown below provide examples of (a) horizontal décalage as explaining students' difficulty on a series of tasks that employed the same mathematical idea and (b) comparison as a cognitive mechanism supporting equilibration. The illustrative excerpts correspond to the students' work on the following tasks[1], which are given in the order they appeared in the students' assignment. The course coordinator chose the problems because they all focused on the "solve for" idea but had variations in the formulas and task wording that might lead students to see them as different. For example, the GDP and gas mileage part A problems did not involve any constants, while the other tasks did. The gas mileage part B task differed from the other tasks because students had to set a variable as constant. The wordings also differed from "solve for E" to include "solve for t and express t as a function of V" to "to obtain a formula". That is, in some wording, students were told the answer was a function or a formula, while in others, they were not. Hence the tasks had enough variation that students might have to engage in cognitive work to see them as similar.

Gross domestic product (GDP) task. The gross domestic product, P, is calculated as the sum of personal consumption expenditures, C, gross private domestic investment, I, government gross investment G, and net exports E of goods and services. All are measured in billions of dollars. The formula is P = C + I + G + E. Solve the equation for E.

Boat task. The resale value, V, in thousands of dollars, of a boat is a function of the number of years *t* since the start of 2011, and the formula is V = 12.5 – 1.5t. Solve for t in the formula to obtain a formula expressing t as a function of V.

---

[1] The tasks are from Crauder et al. (2018). The presentation here paraphrases wording and omits parts of the tasks irrelevant to the report.

Gas mileage task: The distance, d, in mi., that you can travel without stopping depends on the number of gallons g of gas in your tank and the gas mileage, m, in mi/gal. The relationship is d = gm. (A) Solve the equation for m. (B) An engineer wants to ensure the car she is designing can go 415 miles on a full tank of gas. She does not yet know what gas mileage the car will get. Solve the equation d = gm for g using 415 for the distance.

Ant task: A scientist observed that the speed S (cm/sec) at which ants run was a function of T, the temperature (°C). He discovered the formula S = 0.2T – 2.7. Solve for T to obtain a formula expressing the temperature as a function of the speed.

Illustrative Excerpts

Dylan

Dylan's work on a series of three problems provides an example of horizontal décalage. The course content included solving an equation for a particular variable and having the answer be a formula instead of a number. That "solve for *x*" could result in an *x* = … expression in which the right side of the equation contained variables was a new idea for Dylan. By 'new idea', I mean he had been exposed to this meaning of "solve for" in lecture but was grappling with it on his own for the first time during the homework session. Dylan solved the GDP and boat tasks on the first try. On Gas Mileage part A, he solved d = gm for m correctly on his first try. In part B, however, Dylan was perturbed by the fact that a "solve for…" answers was a formula. Dylan's facility with the boat task and part A of the gas mileage task, but perturbation on part B of the gas mileage task, indicated to the researcher that Dylan was in the process of accommodating his "solve for…" scheme. Specifically, the perturbation on part B of the gas mileage task appeared to be an example of horizontal décalage because Dylan had just answered two similar tasks unperturbed. Dylan's thinking about part B of the gas mileage task is below. It provides evidence of how he equilibrated by *comparing* the problem at hand to the previous problems to remove his perturbation.

Dylan: I'm thinking, thinking I don't have enough information but, because I'm missing, missing m.

Interviewer: What do you mean [by] you don't have enough information?

Dylan: I mean well right now I'm thinking I only have one, only have one variable and I need two.

Int.: What makes you think you need two?

Dylan: That's kind of how it works, right? You're given, like you're given a variable, you're given like an equation and then you put in all the numbers.

Int.: So you think the answer, you think it needs to be g equals some number.

Dylan: Yeah. Because it's solving for the equation. But I guess I solved for the equation up here [moves mouse to part A]. So I guess not… if it [Webassign] took this [m=d/g as correct in part A] and it's asking part B the same that it's asking [in] this [part] I mean it's asking it in the same way. [Submits g=415/m, correct]

I take Dylan's comments about not having enough information and needing two variables so he could "put in all the numbers" as evidence of perturbation. I focus on how, following those comments, Dylan reviewed his earlier, correct m=d/g. He noted that his present task was worded the same way as that task; that is, he compared the wording of the tasks and employed the answer from the previously-solved task to support his solution in the unsolved task. I use the word *comparison* to characterize the mechanism of change as Dylan equilibrated[2]. Dylan solved the subsequent Ant Task without perturbation, which we take as evidence that accommodation to his "solve for…" scheme had occurred:

Int.: You have a formula that's got another variable and it's not just like all numbers. You feel okay about that?

Dylan: Yeah, yeah I do this time. Because I remember from up [above] that it worked.

Amy

Amy's work on a series of 4 tasks provides an example of horizontal décalage. Amy struggled with GDP task. She opened the e-book, located the answer to the problem, and said she understood why the answer was correct. Amy copied the book answer, submitted it, and the platform marked it correct. On the boat task, Amy noted the problem was "another 'solve for'." She wrote t = V(t); note this is an equation in which t = … and the right side of the equation contains only variables[3]. After submitting this answer and seeing it was wrong, Amy located the problem's answer in the e-book and commented she had never seen an answer like that before. She said the solution "looked right", though she did not understand why.

Amy: I don't quite get what that's asking for [opens the e-book].

Int.: What are you hoping to find there?

Amy: Something that explains this specific problem. [finds exact problem with answer key, looks at answer] this [answer] is not what I would have thought of… like I would think that you'd solve this equation for what E is, not in terms of variables. In my mind whenever you say solve that means like get an answer for E.

Int.: Get an answer like a number?

Amy: Yes…. [looks over answer in e-book] I understand why that's the answer.

Amy: [Boat task] It's another "solve for"… like "solve for t in the formula, expressing t as a function of V." My mind goes to like this type of answer [types t = V(t)] but I don't know if that's correct because given the past problem it probably isn't. [opens e-book] That's what we've always used for like functions of, whenever you're expressing t as a function of V it's like anything is a function of something else it's always been like, A, like B is a function of A it's like A(B). [submits answer, incorrect] I don't quite understand why this is wrong. [looks at answer in book] I've never seen something like this before. And I don't know how I would get this answer.

Int.: Does anything in that [book answer] make sense?

Amy: I mean yeah because I mean given the whole picture like this [highlights formula answer] does make sense and it is correct… Like looking at it, it looks right. Like if someone showed me this and explained how to get to it I would understand more how it was right.

---

[2] A difference in Gas Mileage Parts A and B is that A had three variables while B directed students to use d = 415. We do not have enough evidence to know if this difference caused Dylan's perturbation. Similarly, von Glasersfeld (1995) hypothesized a scheme could be modified to include new recognition criteria or the learner could create a new scheme. It is impossible to know which is the case here (in part because of the difficulty defining the boundaries of a scheme). These concerns are beyond the scope of this report; our goal is to (a) identify comparison as the mechanism of change and (b) show an example of horizontal décalage.

[3] As the interview excerpts indicate, Amy switched the independent and dependent variables here and in her generic A(B); this is immaterial to the point that what she wrote was an equation in which the right-hand side was an expression with variables, not a number.

We take Amy's "that's what we've always used for like functions of, whenever you're expressing t as a function of V it's like… like B is a function of A it's like A(B)" as evidence that she assimilated the boat task to a scheme for "function of" instead of a "solve for" scheme, though she clearly knew (because she had stated) it was a "solve for" problem. We consider this an example of horizontal décalage because she had indicated that she understood why the answer to the previous GDP problem was correct, identified the boat problem as similar to the GDP problem because they were both "solve for" tasks, but did not use her "solve for" scheme. That is, the boat problem context was somehow different enough for there to be a time delay (decalage) in terms of Amy's scheme use. On the next task, Amy correctly solved the problem and stated that while she thought "solves" meant to get a number, she was seeing in the problems that these answers were not numbers. Amy described the answers in these tasks as "rearrang[ing]" the equations. We take those statements as evidence that her "solve for" scheme was being modified from her engagement in the tasks. Like Dylan, the mechanism in equilibration was comparing. Amy compared the gas mileage task to the previous problems:

> *Amy*: [Gas mileage tasks] [types m = d/g] Given like these previous problems I'm starting to pick up that what I think would be the answer, like my original first thought, is not the answer.
> *Int.*: You said this is like, so so far these haven't been what you thought it would be.
> *Amy*: Yes.
> *Int.*: So you still want that m to be some number, like that's your initial instinct?
> *Amy*: Yes.
> *Int.*: But, you said based on the past couple problems, you feel like that's not the way to go on these.
> *Amy*: Yes. I guess like looking at like "solve", like I said "solves" to me means get a number… but because of the previous problems and like the previous explanations via the textbooks, the answers the textbooks have given, and also this thing down here, it's very obvious that like you're not getting a number. This [highlights GDP problem] is technically the same format that this [highlights b in current problem] is asking this in [the "solve for…"], solve the given equation for a variable, I put a number in here, it was not correct, and then it gave me basically this original formula, rearranged, and then the same down here, this original formula, rearranged… that's how I'm getting this, it's just this original formula that's given to you, essentially rearranged… Like solving the given equation for a variable means, I guess in like the simplest form of like terms, like rearranging the original formula to put t on, like by itself, and then all the other ones would be rearranged to equal t.

In the ant task, Amy answered the question correctly on the first answer. When asked how she got the answer, Amy said, "rearranging this [given] formula." We took this as more evidence that she had accommodated her "solve for" scheme.

Discussion, Significance, and Implications for Instruction and Research

A limitation of this work is that it only analyzed data from five students completing somewhat procedural problems. However, these preliminary results support extant classroom practices (a legitimate way research can inform practice). For example, Dylan and Amy learned when “solving for” a variable, the answer can be a formula. This is an example of student learning via online homework, which supports other evidence of online homework as efficacious (e.g. Dorko, 2021, 2020; Ellis et al., 2015). Another implication is that instructors should consider providing students with explicit opportunities to compare problems to identify underlying mathematical structure, if they are not already doing so. This was the mental activity that supported Dylan and Amy’s success on the task series in question. Specifically, it seems important to provide students with multiple tasks that explore the same mathematical idea, followed by an explicit reflection task engaging students in identifying the underlying similarity.

The results here extend prior work about student learning from similar examples in homework (Dorko, 2021). While that work identified one way of learning as students following steps of similar problems, this study found another way students learn from homework is by identifying a series of tasks as similar, then comparing across them to identify an underlying mathematical structure or meaning. That students here learned a new meaning for “solve for…” is also a novel finding because it gives empirical evidence of conceptual learning from homework, somewhat contrasting other findings that students’ learning from online homework is primarily procedural in nature and that students often miss conceptual insights the professor intended they learn (Dorko, 2019; Dorko, Cook, & DeHoyos, 2023). A limitation of the paper is that the tasks were somewhat procedural practice problems. Future research could focus on homework problems that are intended to extend what students might have seen in class.

Various features within the online homework platform supported students’ learning. For example, Amy opened the e-book and made use of the solutions it provided to homework problems. While printed textbooks tend to have solutions to some exercises in the back of the book, the e-book in this course had direct links from some problems to their solutions. The homework platform’s immediate feedback supported Dylan’s reasoning because he knew something had “worked” in a previous problem that the platform marked as correct, and this allowed him to compare subsequent tasks to correct solutions. This finding provides more support for findings that students employ immediate feedback from online homework platforms to guide their work (Dorko, 2020; Kontorovich & Locke, 2022).

The results have implications for how we define and measure learning in classroom and research settings. The evidence shows that learning occurs over time, implying a need for classroom practices that support this. This could include helping students form growth mindsets so they come to see struggling as a necessary and acceptable part of the learning process. Another way to acknowledge learning as happening over time could be extant practices such as mastery-based grading (e.g., allowing a final exam grade to replace a lower preliminary exam score). In terms of research, the horizontal décalage supports designs that examine student thinking about a mathematical idea in multiple contexts because a student might struggle with the idea in one context but not another. This is likely of particular importance in a study that employs a single task-based interview with multiple students, because one question about a given mathematical idea could yield an incomplete picture about the student’s understanding of the idea.

Metaphors in Discrete Math: Not All Sameness is the Same

Rachel Rupnow
Northern Illinois University

Cassandra Mohr
Northern Illinois University

While sameness is a theme that appears throughout mathematics courses, limited work has examined how multiple types of sameness are understood within the same course. In this paper, we examine survey responses from 49 discrete mathematics students who characterized how they would explain equivalence relations, numerical congruence, and graph isomorphism to a child. Results include language conveying notions of sameness in response to all three prompts but variations in how the sameness was framed for the different concepts. Implications include the need for more work characterizing nuanced differences in students' understandings of similar concepts within specific courses.

Keywords: discrete mathematics, isomorphism, congruence, equivalence relation, sameness

A variety of concepts conveying a notion of sameness have stipulated definitions throughout mathematics and serve purposes that suit their contexts (Rupnow et al., 2022). For instance, isomorphism in abstract algebra and homeomorphism in topology serve similar purposes in conveying structural sameness (in the form of maintaining how elements interact under the defined operations in isomorphism and maintaining continuity in topology). Nevertheless, their definitions differ in order to provide rigor with respect to the relevant objects and to attend to properties that are important to their contexts. However, while some research has examined students' understandings of types of sameness across different courses (e.g., Rupnow et al, 2023), limited work has examined how students attend to multiple types of sameness within the same course context. Thus, we seek to address two research questions:

1. How are discrete mathematics students' characterizations of equivalence relations, congruence, and isomorphism similar?
2. How are discrete mathematics students' characterizations of equivalence relations, congruence, and isomorphism different?

Background Literature

Historically, limited work in mathematics education has attended to sameness as a conceptual area of study; however, notions of sameness have received more attention recently. Students' notions of sameness may impact their understanding of mathematical concepts in ways researchers do not expect, such as claiming multiplication and division are the same binary operation because the same numerical value can be obtained from related operations (Melhuish & Czocher, 2020) or not claiming that having the same graphs indicates having the same functions (Mirin, 2018; Mirin & Zazkis, 2020). However, mathematicians also treat sameness as an understandable concept, including characterizing relative levels of sameness conveyed by concepts (Rupnow & Sassman, 2022). Mathematicians have also highlighted multiple concepts conveying sameness across mathematics, including graph isomorphism, numerical equivalence, and equivalence relations (Rupnow et al., 2022). Much like sameness, equivalence has received more attention of late, including mathematicians' evolving notions of equivalence (Asghari, 2019), characterizations of students' productive interpretations of equivalence (Cook et al., 2021; Cook et al., 2022), and conceptualizations of substitution equivalence (e.g., Wladis et al., 2022).

Moreover, many types of sameness, including equality and congruence, play central roles in the mathematics curriculum. Extensive research on students' understanding of equality has highlighted the value of a relational understanding of equality, in which students understand both sides of the equal sign to have the same value, as this often assists students in understanding algebraic manipulations (e.g., Alibali et al., 2007; Jones et al., 2012; Knuth et al., 2006). Some research has connected students' understanding of sameness to geometric congruence (e.g., Rahim & Olson, 1998; Zazkis & Leron, 1991) or group isomorphism (e.g., Rupnow et al., 2022). Nevertheless, no extant research appears to exist on students' conceptions of equivalence relations, numerical congruence, or graph isomorphism in the context of discrete mathematics.

Theoretical Perspective

Conceptual metaphors is a theoretical perspective intended to provide insight into how individuals' thinking is structured, using their language choices to guide that interpretation (e.g., Lakoff & Johnson, 1980; Lakoff & Núñez, 1997). Cross-domain conceptual mappings connect the cognitive structure of a target concept (e.g., congruence, isomorphism) to the more developed thoughts in source domains (e.g., same properties, classification mechanism). For instance, "An equivalence relation is a classification mechanism" is a conceptual metaphor that gives information about a target domain (equivalence relation) by relating it to a source domain that is already understood in some way (a classification mechanism). We acknowledge that this theoretical perspective imposes the researchers' views on our participants' statements, but believe this lens permits insight into ways of reasoning about our target concepts.

Prior work using conceptual metaphors include examinations of mathematicians' views of isomorphism and homomorphism in abstract algebra (Rupnow, 2021; Rupnow & Randazzo, 2022; Rupnow & Sassman, 2022). Other work has examined undergraduate students' understandings of bases and linear transformations in linear algebra (Zandieh et al., 2017; Adiredja & Zandieh, 2020) and of isomorphism and homomorphism in abstract algebra (Melhuish et al., 2020; Rupnow, 2017). Here we aim to extend the use of conceptual metaphors to other concepts conveying a type of sameness (Rupnow et al., 2022) in discrete mathematics. In particular, we build upon the metaphors identified in Rupnow (2021) and the metaphor clusters identified in Rupnow and Randazzo (2022).

Methods

Data was collected from surveys sent to the Fall 2022 and Spring 2023 sections of the first author's discrete mathematics course. 21 students completed the survey in Fall 2022, and 28 students completed the survey in Spring 2023. We did not observe major differences between the sections and thus combine our reporting into one dataset of 49 students' responses. Students in this course were mostly computer science majors and included freshmen through seniors. Course topics included sets, equivalence relations, functions, modular arithmetic, combinatorics, graph theory, and coding theory. The course textbook was Dossey et al. (2005). Because the instructor's research interests include understandings of sameness in mathematics, equivalence relations, congruence, and isomorphism were all highlighted as types of sameness when those concepts were discussed in class. The surveys were given the last week of classes in each semester, after students had taken in-term exams assessing equivalence relations, numerical congruence, and graph isomorphism. Initial questions on the survey asked about what it means to be the same in math and in discrete math specifically. However, the analysis here focuses on responses to three questions from the middle of the survey:

1. How would you describe the concept of an equivalence relation to a ten-year-old?

2. How would you describe the concept of numerical congruence to a ten-year-old?
3. How would you describe the concept of isomorphic/isomorphism to a ten-year-old?

Data was analyzed by two researchers who coded independently, then discussed and came to consensus for each response. While students were prompted to provide explanations about concepts that could be understood by a child, which itself encourages providing comparative explanations, we (the researchers) sought to classify the underlying meanings conveyed by these explanations according to our interpretations of the participants' responses. Thus, we used the metaphors for isomorphism (in abstract algebra) highlighted in Rupnow (2021) as an initial codebook but added new metaphors when necessary for our data set. This process aligns with codebook thematic analysis (Braun et al., 2019), in which existing codes are used as a basis for coding but new codes are permitted to be added to adequately capture the nuances in data.

Results

We organize the results of our coding into three distinct subsections separated by topic. The first subsection characterizes metaphors utilized to describe the concept of equivalence relation, the second examines metaphors used to describe congruence, and the third depicts metaphors describing isomorphism. In Table 1, we provide an initial overview of the frequencies of each metaphor divided by concept. Metaphors are organized by cluster, with some belonging to sameness-based clusters such as sameness (*generic sameness*, *same properties*, *same but looks different*, *classification mechanism*, *same remainder/leftovers*), sameness/mapping (*renaming/relabeling*, *matching*), and sameness/formal definition (*structure-preservation*) clusters. Other metaphors belong to the mapping cluster (*generic mapping/relation*, *morphing/transformation*, *invertible*), the formal definition cluster (*literal formal definition*, *computation*), or made *no attempt*/*unclear*. Within each cluster, metaphors are arranged by frequency. It should be noted that while 49 responses were examined, the sum of any single column may be greater than 49 due to some students having more than one code per response.

Table 1. Frequencies of metaphors by concept out of 49 total responses.

Metaphor Cluster	Metaphor Code	Equivalence Relation	Congruence	Isomorphism
Sameness	Generic sameness	15	6	9
	Same properties	2	2	19
	Same but looks different	3	3	19
	Same remainder/leftovers	0	20	0
	Classification mechanism	6	0	0
Sameness/ mapping	Matching	0	0	4
	Renaming/relabeling	0	0	1
Sameness/formal definition	Structure-preservation	0	0	2
Mapping	Generic mapping/relation	4	0	1
	Invertible	1	0	4
	Morphing/transformation	0	0	2
Formal definition	Literal formal definition	20	0	0
	Computation	0	8	0
No attempt/ unclear	Unclear/no attempt	6	13	5

Equivalence Relation

The first metaphors we will examine relate to describing the concept of an equivalence relation. For reference, the definition of equivalence relation given in the course textbook was: "A relation on S that is reflexive, symmetric, and transitive is called an equivalence relation" (Dossey et al., 2005, p. 50) and that "A relation R on a set S may have any of the following special properties:

(a) If for each $x \in S$, $x\ R\ x$ is true, then R is called reflexive.
(b) If $y\ R\ x$ is true whenever $x\ R\ y$ is true, then R is called symmetric.
(c) If $x\ R\ z$ is true whenever $x\ R\ y$ and $y\ R\ z$ are both true, then R is called transitive." (Dossey et al., 2005, p. 49)

Overall, the most common metaphor was *literal formal definition*, followed by *generic sameness* and *classification mechanism*. Many responses invoked a mathematically precise definition when asked to describe equivalence relation to a child. The majority of these responses specifically discussed the necessity of being reflexive, symmetric, and transitive. Some achieved this through mathematically rigorous descriptions, such as the following student who used ordered pair notation: "An equivalence relation is a set of ordered pairs that is reflexive (for each x in the ordered pair, there should be (x,x)), symmetric(if (x,y) is in the set, then (y,x) has to be), and transitive(if (x,y) and (y,z) are in the set, then (x,z) must be as well)." Other students described these concepts in a less formal way, utilizing everyday objects and concepts:

> Equivalence relation is a concept that finds the relation between two sets and is reflexive, transitive, symmetric… Imagine reflexive like standing Infront of a mirror, the picture on mirror is the same as a reflection. Symmetric is like taking a paper and drawing a circle and folding it in the middle, now it is a half circle, but when you open it, the symmetric of the half circle is shown making a full circle. Transitive is like saying, Peter and Tom are friends … Tom and Jerry are friends …which will mean Peter and Jerry can be friends.

This response emphasizes the underlying formal structure of an equivalence relation but utilizes visual descriptions, physical action, and common scenarios to convey the key properties involved instead of relying on formal vocabulary and notation.

Other responses characterized equivalence relations using *generic sameness* language. Most of these responses made statements about finding similarity across objects or groups of items: "An equivalence relation is a way of comparing things to see if they are the same in a certain way" or "an equivalence relation is where you can measure the 'sameness' between 2 sets." These metaphors emphasize commonality across elements or sets, while simultaneously conveying the possible variety in what it can mean to be the same.

Another metaphor that many respondents utilized to describe equivalence relations is that of *classification mechanism*. This particular metaphor is unique to equivalence relation, as it describes how elements can be sorted or binned to form distinct groups within an equivalence relation. Many of the responses described grouping everyday objects by some defining characteristic such as color or shape:

> An equivalence relation is a way to group things together based on certain rules. For example, imagine you have a bunch of toys that you want to group based on their color. If you have a blue toy, a red toy, and a green toy, you can group the blue toy with other blue toys, the red toy with other red toys, and the green toy with other green toys. This is an example of an equivalence relation.

Several responses also depicted equivalence relation using *generic relation*. This metaphor was unique to equivalence relation and conveys a relation between elements or groups, such as "A relationship between two or more things that follows some rules." Others provided an *unclear/no attempt* response, of which many simply stated that they were unsure of how to the explain the concept: "It took me a two whole lectures and a Youtube video to piece all of this together myself; tha[t] ten-year-old will leave that conversation more confused than they started."

Congruence

The second group of metaphors relate to congruence. The definition for congruence given in the textbook was: "Let m be an integer greater than 1. If x and y are integers, we say that x is congruent to y modulo m if $x - y$ is divisible by m. If x is congruent to y modulo m, we write $x \equiv y\ (mod\ m)$; otherwise, we write $x \not\equiv y\ (mod\ m)$. We call this relation on the set of integers congruence modulo m" (Dossey et al., 2005, p. 100). Congruence was most frequently described using *same remainder/leftovers*, followed by *computation* and *generic sameness*. Over 25% of respondents provided an unclear response or made no attempt to depict congruence; this was by far the concept with the most responses not attempting to answer the question.

Same remainder/leftovers was the most common metaphor. Many instances of this metaphor were contextless and directly defined congruence, such as "If one number and another number can both be divided by another third number, and they have the same left overs, they are congruent." Other responses introduced context, such as using candy, specific numbers, or cake as in the following: "let's say you have 2 cakes and divide each cake by the same number each cake, if the number of slices left in each cake is the same, then they are congruent." One respondent focused on the sameness of quotients rather than remainders, stating "If you divide both numbers by a single number, and get the same answer." This response was included in the *same remainder/leftovers* category because we felt they intended to describe what was the same numerically, albeit inaccurately.

Just as *same remainder/leftovers* was a metaphor unique to congruence, so too was *computation*. Respondents who conveyed congruence via *computation* often described the action of adding or subtracting a fixed number so as to maintain congruence. In some instances, this was done explicitly: "you take a number and then are able to either add or subtract by another number as many times as you want." Other cases were more implicit, as below:

> Let's say I have a bucket of apples which can only hold 12 apples; when I fill that bucket up, I have to go empty it somewhere (modulo 12). No matter how many apples I put in that "somewhere," I can't put more than 12 apples in my bucket, and I will never keep 12 apples in the bucket (the number is between 0 and 11). So, if I grab 38 apples, there will be 2 apples left in the bucket at the end.

In addition to metaphors unique to congruence, some responses also used *generic sameness* as a metaphor for congruence. Most of these responses discussed congruence in terms of some connection or flavor of sameness across numerical values: "Numerical congruence are the pairs of numbers that are the same as each other in the context of some dimension of numbers."

Isomorphism

The final concept we discuss is isomorphism. The textbook's definition for isomorphism was: "A graph G_1 is isomorphic to a graph G_2 when there is a one-to-one correspondence f between the vertices of G_1 and G_2 such that the vertices U and W are adjacent in G_1 if and only if the vertices $f(U)$ and $f(W)$ are adjacent in G_2. The function f is called an isomorphism of G_1 with G_2 (Dossey et al., 2005, p. 159). Both *same properties* and *same but looks different* were commonly used as a metaphor for isomorphism, as was *generic sameness*. It is notable that metaphors for isomorphism were more focused on appearance than our other two concepts. Isomorphism also had the greatest variety in metaphor codes.

Many of the metaphors discussed shared properties across groups of objects. As isomorphism in Discrete Math is centered on graphs, a large number of these metaphors described graphs with the same properties: "two graphs will need the same number of points to be there, it will also need the same points to be put connected, finally it will need the same number of lines." Other responses emphasized common properties across other 2D or 3D shapes: "imagine you have a shape made out of blue blocks, and another shape made out of red blocks. They look different, but they have the same number of blocks and the same angles between the blocks." This response seems to emphasize notions of geometrical congruence that need not be present in isomorphic graphs (angle measures) as well as notions that apply to graph isomorphism (same number of vertices).

Another commonly used metaphor for isomorphism was *generic sameness.* Focusing first on contexts regarding graphs, the majority of metaphors in this category emphasized the underlying sameness of two graphs: "isomorphic is being of identical or similar form, shape, or structure." One response pulled from a Chemistry perspective, discussing isomorphism as occurring "When two or more crystals have similar chemical compositions exist in the same crystalline form."

Still another metaphor characterizing isomorphism was same *but looks different*. These types of instances might be viewed as a variation on *generic sameness*, but placed emphasis on the idea that while isomorphic objects have the same underlying structure or properties, they may appear different from a visual standpoint. The context of these metaphors varied; as with *same properties*, many discussed graphs: "for two graphs to be isomorphic they are pretty much the same but with a different shape." Others emphasized the underlying action behind these surface differences through a variety of mediums, including play dough and stick figures:

> Let's say you have a stickman, the vertices are the stickman joints such as the knees, elbows, and shoulders, you can pose the stickman to have his arms up, be sitting down, or running, but he will always be isomorphic to the stickman that is just standing in place, because the arms and legs and head are all still connected to the same points.

While not as frequently utilized, there are several additional metaphors that were unique to isomorphism. The physical action of *morphing* or *transforming* from one shape to another was described as a way to demonstrate isomorphism, such as "if you have some play doh, even if you morph the play doh, you still have the same clump of play doh." Others used *matching* language, emphasizing that elements in one object can be directly matched to elements of another:

> For example, imagine you have two puzzles. One puzzle is a picture of a dog and the other puzzle is a picture of a cat. Even though the pictures are different, the puzzles might have the same number of pieces and the same shape for each piece. If you were to switch the pieces between the two puzzles, you could still put them together in the same way. This means the puzzles are isomorphic[.]

Still others described the *structure-preservation* of isomorphism: "an isomorphism is a structure-preserving mapping between two structures of the same type that can be reversed by an inverse mapping." Interestingly, both instances of this particular metaphor also included the metaphor *invertible*. There was also one mention of *renaming/relabeling* elements so as to demonstrate the concept of isomorphism, placing emphasis on the arbitrariness and interchangeability of labels in a graph: "If we have two graphs, and they look kinda similar, and we take the names of the points away, and can put them back to make the graphs looks the same, they are isomorphic."

Discussion

This study examined discrete mathematics students' explanations of equivalence relations, congruence, and isomorphism. By using the conceptual metaphor lens, we observed that many explanations focused on sameness, including metaphors from the sameness, sameness/mapping, and sameness/formal definition clusters. Some explanations also highlighted metaphors from the mapping and formal definition clusters or made *no attempt*/*unclear*. We recognize that students using sameness-infused language is not surprising, given the context. The students were asked about notions of sameness earlier in the survey, and their instructor highlighted each concept as a type of sameness both in class and in the class notes. What we do find interesting is that students highlighted different metaphors for the three concepts. Sameness was salient but conveyed through different common metaphors (or non-attempts) for each concept: *literal formal definition* and *generic sameness* for equivalence relations, *same remainder/leftovers* and *unclear/no attempt* for congruence, and *same properties* and *same but looks different* for isomorphism.

Then again, perhaps this variation in metaphors should not be surprising, since the instructional emphasis varied in each unit. In the first unit, where equivalence relations were introduced, a key purpose was to familiarize students with the use of mathematical definitions, so extensive time was spent on understanding and verifying whether the reflexive, symmetric, and transitive properties held for each relation. It is possible that this instructional choice obscured the notion of an equivalence relation conveying sameness or serving a classification purpose for some students. For congruence, many students did note the sameness of the remainders, but this also was the concept for which the most students struggled to give a clear description. Perhaps the computation-heavy applications in subsequent lessons (i.e., in the RSA Method) obscured the meaning of congruence itself. Finally, isomorphism had the most variety in metaphors. Notions of sameness came through clearly in students' language for isomorphism, but what was the same varied across lists of properties, a core sameness despite the difference in appearance, and being able to match aspects of different graphs. It is possible that the instructor's more extensive experience in graph theory led to clearer instructional experiences. However, more research is needed on the differential impact of the instructional context versus the concepts themselves.

Additionally, the underlying objects relevant for each concept vary widely in abstractness from almost anything (equivalence relations) to numbers (congruence) to graphs (isomorphism). While previous research has attended to the objects to which sameness-based concepts are applied (Rupnow et al., 2022; Rupnow & Sassman, 2022), this work raises new questions about the direction of the impact of objects and concepts. In particular, do the underlying objects (e.g., graphs) influence our conceptions of the concepts (e.g., isomorphism), the concepts influence our conceptions of the objects, or do the concepts and objects mutually impact each other? For students who later see isomorphism in other contexts (e.g., linear algebra), how might first seeing graph isomorphism impact how they interpret isomorphism of vector spaces?

Finally, the students were prompted to explain in a manner understandable to a 10-year-old. Admittedly, this is an unusual prompt, especially to students who do not intend to teach, but our goal was not to assess the age appropriateness of the explanations. Rather, we believe this prompt permitted a different window into students' understandings than just asking them to describe each concept, as it encouraged a distillation of key idea(s) each student took away. Moreover, it encouraged students to be creative, as displayed in the wide variety of contexts in which students chose to position their explanations (e.g., blocks, candies, Play Doh). Future work can further examine ways to build on the creative examples students highlighted while supporting students to integrate their intuitive understandings with those of the formal definition.

Affordances of Semantic and Syntactic Proof Approaches for Isomorphism and Homomorphism

Rachel Rupnow
Northern Illinois University

Brooke Randazzo
Augustana College

Group isomorphism and homomorphism are core concepts in abstract algebra, but limited work has directly examined student conceptions of homomorphism or how students approach finding particular mappings. Based on interviews with two students, we contrast one student who used predominantly syntactic proof approaches for homomorphism with one who used semantic approaches, noting that both experienced success in finding homomorphisms in most cases.

Keywords: isomorphism, homomorphism, semantic, syntactic

Introduction

Students' understandings of multiple areas of abstract algebra content have received attention, including binary operation (e.g., Melhuish & Fagan, 2018; Melhuish, Ellis, & Hicks, 2020), inverses (e.g., Serbin, 2023; Wasserman, 2017), and functions (e.g., Melhuish, Lew, et al., 2020; Uscanga & Cook, 2022). We build on the attention to functions, in particular the focus on student understanding of isomorphism (e.g., Weber & Alcock, 2004; Melhuish, 2018) and homomorphism (e.g., Melhuish, Lew, et al., 2020). Specifically, we examine students' reasoning when creating isomorphisms and homomorphisms from a proof production perspective. We believe this work holds two contributions to the literature. First, this paper extends our currently limited knowledge of how students understand homomorphism and solve problems related to homomorphism. Second, this paper provides insight into the relationship between students' success while problem solving and their proof approaches.

Literature Review

Isomorphism was one of the first abstract algebra topics studied in the undergraduate mathematics education community (e.g., Dubinsky et al., 1994; Leron et al., 1995). This early work characterized properties students attended to when assessing whether groups may be isomorphic, such as checking cardinality (Dubinsky et al., 1994), determining alignment between the orders of elements, and determining whether groups were abelian (Leron et al., 1995).

Other work, whose primary aim was examinations of proof approaches, contrasted undergraduates' and doctoral students' (Weber, 2001; Weber & Alcock, 2004) or undergraduates' and algebraists' (Weber & Alcock, 2004) approaches to determining whether groups were isomorphic. Weber (2001) also examined approaches to proofs focused on homomorphism. Of note, doctoral students and algebraists relied more on semantic reasoning, wherein their knowledge of properties of groups and holistic understanding of theorems were key aspects of their reasoning and seemed to be important aspects in graduate students' success. In contrast, undergraduates tended to reason syntactically, wherein they largely focused on symbol pushing with the formal definition, and experienced more struggles in proving more difficult statements. Moreover, semantic reasoning was linked to Skemp's (1976) relational understanding construct, which emphasizes understanding both how and why notions work as well as what to do to solve a problem, whereas syntactic reasoning was linked to instrumental understanding, which only requires understanding what to do (i.e., procedural knowledge). More recently, in Melhuish's (2018) replication study, undergraduates at times successfully used properties to reason about whether groups were isomorphic but seemed to check these properties procedurally, suggesting the need for further research on connections between semantic reasoning, relational understanding, syntactic reasoning, and instrumental understanding.

However, explicit discussion of students' understandings of homomorphism has been more limited (e.g., Weber, 2001). Moreover, research on approaches to homomorphism have focused on students' and instructors' language (e.g., Melhuish, Lew, et al., 2020; Rupnow, 2021; Rupnow & Randazzo, 2022), rather than centering their approaches to proof, suggesting a need for a concentrated look at proof strategies with homomorphism.

Methods and Theoretical Perspective

This paper is grounded in a wider study examining instruction in introductory (junior level) abstract algebra at a land-grant university in the Mid-Atlantic United States. Here we focus on two participants, Bryce and Blake, who were in a section taught with a mixture of lecture and activity days. The students' names are gender-neutral pseudonyms, and they/them pronouns are used throughout. Participants each engaged in a semi-structured interview (Fylan, 2005) lasting roughly one hour. The interview occurred after instruction and an exam on group isomorphism and homomorphism had been completed. Interviews were audio and video recorded and any written work was collected. The interview questions analyzed here focused on finding mappings between specific groups: $\mathbb{Z}_3$ and $\mathbb{Z}_6$, $\mathbb{Z}$ and $2\mathbb{Z}$, and two groups given in Cayley tables (one representing $\mathbb{Z}_2 \times \mathbb{Z}_2$ and the other $\mathbb{Z}_4$). If students were able to determine one mapping, they were often asked to determine if another isomorphism or homomorphism could be formed.

The interviews and videos were transcribed and coded in alignment with the definitions of semantic and syntactic proof production given in Weber and Alcock (2004). Semantic proof production is characterized by the use of "instantiation(s) of the mathematical object(s) to which the statement applies to suggest and guide the formal inferences" that are drawn whereas syntactic proof production is "written solely by manipulating correctly stated definitions and other relevant facts in a logically permissible way" or could be viewed as symbol-pushing (Weber & Alcock, 2004, p. 210). For instance, an isomorphism proof in which a student uses properties and theorems, especially by drawing on their knowledge of the groups involved, would be a semantic proof, whereas a proof in which a student directly uses the formal definition (i.e., for group isomorphism, show bijectivity and the homomorphism property) would be a syntactic proof. From this analysis, we address the following research question: What patterns exist between proof production approaches and success in creating isomorphisms and homomorphisms?

Results

We present vignettes of two students who were generally successful at the tasks, but one approached homomorphism tasks syntactically (Bryce) and the other semantically (Blake).

Bryce

$\mathbb{Z}_3$ and $\mathbb{Z}_6$. Bryce quickly said these groups were not isomorphic because they are different sizes: "Okay, so can't be an isomorphism because this has order three and this is order six, so elements in $\mathbb{Z}_3$ would have to map to more than one element in $\mathbb{Z}_6$, so it's not one-to-one." While Bryce attempted to explain this property, we note their explanation seems to conflate function and one-to-one definitions and does not focus on the groups' structures.

Regarding the homomorphism task, Bryce realized that nontrivial homomorphisms should exist because three divides six. They were initially unsuccessful in finding homomorphisms when trying to map individual elements. However, they found success when they created formulas to describe maps rather than mapping elements, beginning with the map $f([x]_3) = [2x]_6$ from $\mathbb{Z}_3$ to $\mathbb{Z}_6$. They started checking the homomorphism property element-by-element, but then realized that they could do this process generally (see Figure 1). Later, they also generalized their map to include "any multiple of 2… it could be like 2, 4, 6, any of those."

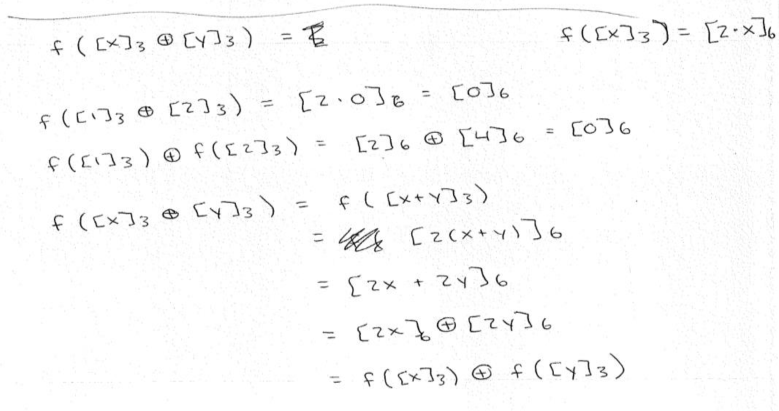

Figure 1. Bryce's Homomorphism from $\mathbb{Z}_3$ to $\mathbb{Z}_6$.

Going from $\mathbb{Z}_6$ to $\mathbb{Z}_3$, Bryce was successful in finding all homomorphisms. In particular, they mentioned the identity map, the map $f([x]_6) = [2x]_3$ ("2 times x… or any multiple of that") and the trivial homomorphism, which they stumbled upon by considering odd multiples.

B: I don't know if an odd number would work too. So if you were just multiplying by 3 instead… I guess if you multiply by 3 here, that would always work cuz that would always go to 0 mod 3, and any multiple of 3 would reduce down to 0 mod 3. So any multiple of 3 would work…

I: So you're mapping everything to 0.

B: Mmhmm…that would be a group homomorphism. Because if you had 1 mod 6 and 4 mod 6, they were both being mapped to 0. Then 0 mod 3 plus 0 mod 3 is still 0.

Note Bryce was very successful in the syntactic approach of applying the definition to construct homomorphisms but did not appear to be thinking about the groups structurally. Interestingly, they did not explicitly acknowledge that the "multiple of 3" map they constructed is the trivial homomorphism and continued to check the homomorphism property for this map.

$\mathbb{Z}$ and $2\mathbb{Z}$. Bryce noticed that both of these groups are infinite but did not use that to say they were isomorphic. Instead, they set up a specific map and appeared to mentally verify that particular pairs of elements would satisfy the homomorphism property while creating their map.

> So they both have an infinite order to them, and I want to say that [2ℤ] has half the order that the other one does, but when you have infinite orders in your groups that doesn't really matter, so I feel like it could be an isomorphism. I'm not sure how I would set it up, but…[rereading] you'd always have 0 mapped to 0, and then 1 would have to map to 2, cuz that's the next one, and 2 would have to go to 4, so if you just had $f(x)$ where x is in $\mathbb{Z}$, x is an integer, if you map that to $2x$, then it's always going to map to something in $2\mathbb{Z}$. And then 3 would go to 6, so I think that would work for an isomorphism.

Going the other direction, Bryce used $f(x) = x/2$, noticing that this was the inverse of the map previously found. They again noted that "they're infinite, they have the 'same order' [air quotes and sarcastic voice] sort of" and used this to say, "that would make it…one-to-one". Here, they grudgingly accepted the standard mathematical claim that $\mathbb{Z}$ and $2\mathbb{Z}$ have the same cardinality and used this to say the map must be one-to-one, while being uncomfortable with this notion of infinity. This is consistent with their tendency to focus on syntactic verification of the existence of these maps, rather than claiming structural sameness between the groups based on theorems.

For the homomorphism task, going from $\mathbb{Z}$ to $2\mathbb{Z}$, Bryce identified maps involving linear functions with even coefficients, noting that these will not be isomorphisms since they are not one-to-one. When asked to consider whether there would be other homomorphisms, Bryce said:

> I don't think so, because… if you did like instead of $2x$ this was $4x$, then that leaves out 2 and -2, -6, anything that's not divisible by 4, but it has to be one-to-one. So I guess there's no other isomorphisms, but there could be a homomorphism. If you had any other even integer here, then it would be a homomorphism, but it would fail to be one-to-one.

Going from $2\mathbb{Z}$ to $\mathbb{Z}$, aside from the previously discovered isomorphism, they did not find any homomorphisms because "you can't do any other even integer down here [in the denominator] because if you had like 4, then you'd run into problems where you're not mapping to an integer." They seemed to be focused on only using maps that were similar to their isomorphism.

Cayley Tables. For the Cayley table task, Bryce made a comment about the tables needing to "match up" and initially said the groups could not be isomorphic because one group has all self-inverses, and the other does not; but they were reluctant to use the term "inverse" and focused on whether the results of particular computations align with the homomorphism definition.

> So to show an isomorphism, usually the Cayley tables at least match up in a way…I mean they look similar. So everything in this one [the first group] is symmetrical around this diagonal. Everything over here is symmetrical around this diagonal. I don't think it would be an isomorphism because over here every element operated on itself gives back the same thing, so that would be your, I don't want to say inverse… And [in the second group] every element operated on itself doesn't always give you the same element, so I don't think they're isomorphic.

Later, they became unsure of this conclusion and proceeded to count the orders of the elements to check. During this process, they noted that one group was cyclic and the other was not.

> You have an order 4 over here and order 2 over here. So they can't match up. Or you don't have any order 4 over here, so that's why they're not an isomorphism. You could also say this one is cyclic, cuz c would generate the whole group, and this one's not cyclic.

For the homomorphism aspect, they knew that "ultimately it has to respect the group operation" and wrote $f(x * y) = f(x) + f(y)$, but otherwise were unsure how to proceed. In this case, Bryce's syntactic approach focused on definitions and maps was not productive, as they were unsure how to visualize setting up homomorphisms using the Cayley tables.

Blake

$\mathbb{Z}_3$ ***and*** $\mathbb{Z}_6$. Blake immediately said that these groups were not isomorphic without giving an explanation. We note this was the fourth of the original set of tasks the students were given, and Blake had previously used the justification of different sizes to explain a lack of isomorphism (for $\mathbb{Z}_5$ to $5\mathbb{Z}$, and $\mathbb{Z}_5$ to $\mathbb{Z}_6$), so we assume they were using the same reasoning here.

Unlike Bryce, Blake found homomorphisms here by considering subgroups: "There is a homomorphism because $\mathbb{Z}$ mod 6 has a three-element subgroup because three divides six so we can just set each element of $\mathbb{Z}$ mod 3 to those elements" [referencing the 0 to 0, 1 to 2, and 2 to 4 mapping written on their paper]. When asked why this would be a homomorphism, Blake struggled to explain, saying "I guess I would have to do it out fully in order to fully convince myself… I would just try to check the $f(ab) = f(a) * f(b)$". However, they never checked this, suggesting that they valued the use of theorems asserting existence more than specific mappings. They also noted the trivial homomorphism would be a homomorphism and believed they had found all homomorphisms "because of the divisors of six and three and matching up the subgroups and stuff." Later in the interview, they were prompted to consider the 0 to 0, 1 to 4, 2 to 2 mapping and reexamine their original map. When asked whether this new map was a homomorphism, Blake again responded with an answer highlighting the structure of the groups.

B: Because 0, 2, and 4 form a subgroup within ℤ mod 6. [Long pause] Because this is isomorphic to ℤ mod 3, so yeah. This looks like it would work. If you add these two, you get the identity back… It looks like I had something along that train of thought before…

I: So is it surprising or not surprising that both of those seem to form homomorphisms?

B: [Blake thinking] I guess it's not surprising because 0, 2, and 4 both form a three-element subgroup of ℤ mod 6 and because three is prime, each of those elements is going to be generators of the whole group, so they're kinda gonna behave similarly. So it's not surprising that you might be able to just switch them around like in this case.

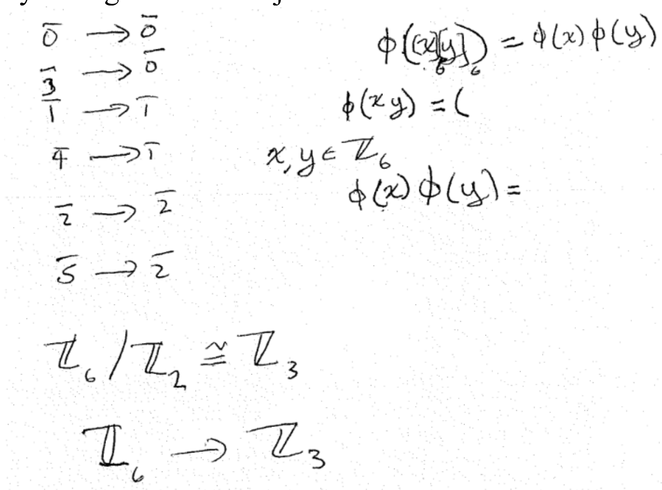

Figure 2. Blake's Homomorphism from $\mathbb{Z}_6$ to $\mathbb{Z}_3$.

Going from $\mathbb{Z}_6$ to $\mathbb{Z}_3$, Blake again used a semantic approach. They found a map, but when pressed to show it was a homomorphism, they were hesitant and struggled to do this syntactically (see Figure 2). Instead, they invoked the Fundamental Homomorphism Theorem (FHT).

B: There's the trivial homomorphism, there should be another homomorphism as well. Which is…taking the two elements which are order three and mapping it to 1 bar…[writing and thinking] Yeah. I think there is one where you can find two elements in ℤ mod 6 and send them each to one element in ℤ mod 3, but I haven't fully figured out which ones those are, but I think the multiple of 3 will go to 0 bar, and it can work out.

I: Ok. If you can complete that mapping, I would appreciate it.

B: Ok. [writing and thinking] Alright. [turns paper] I just sent all of the elements that are congruent mod 3 to what they're congruent to.

I: Ok. And how do you know that's a homomorphism?

B: Because I know, because of the way modular addition is defined. It should work out pretty nicely in the proof.

I: Just for the sake of doing that once, what would that proof look like?

B: … For some reason, I'm having trouble with this way. But if you go back to the Fundamental Homomorphism Theorem… the kernel of this transformation is isomorphic to ℤ mod 2, and ℤ mod 6 mod ℤ mod 2 is isomorphic to ℤ mod 3 by that theorem. Which means that the function ℤ mod 6 to ℤ mod 3, which has this [air-circling 0 and 3] as its kernel, gives a homomorphism.

The FHT as stated in Blake's textbook is: "Let $f: G \to H$ be a homomorphism of G onto H. If K is the kernel of f, then $H \cong G/K$" (Pinter, 2010, p.151). This theorem is generally used to show the existence of isomorphisms and cannot be used to show a particular map is a homomorphism. Nevertheless, Blake seems to have used the requirements of the theorem to convince themselves that the map they had created would be a homomorphism and provide a kernel as described.

ℤ and 2ℤ. Blake said that these groups are isomorphic because they are both infinite and cyclic, remembering that these properties are sufficient to guarantee isomorphic groups: "I've seen the proof that any two cyclic groups of an infinite size are isomorphic, and then I can just find a generator in each one, and then feel reasonably confident in saying they're isomorphic." This is likely the reasoning they used to set up the map where "every integer k will get sent to $2k$" or "you could do negative $2k$". When pressed, they successfully used the formal definition to check that their map satisfied the homomorphism property (see Figure 3).

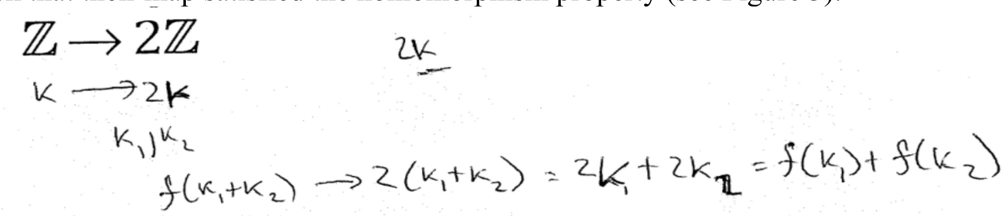

Figure 3. Blake's Isomorphism from ℤ to 2ℤ.

Regarding homomorphisms from ℤ to 2ℤ, they mentioned "you could probably send them to multiples of 4, or multiples of any other even [number]." Going the other way, they suggested the relation is invertible: "Isomorphism is symmetric so it is indeed isomorphic, I think. You can just take the inverse of that function." They also realized the homomorphisms in this direction will be similar: "So you can construct a function like $2x$ again. You just get multiples of 4 which is again infinite and cyclic, but that should be a homomorphism." Again, they used semantic approaches in setting up homomorphisms, as they mention the image will be infinite and cyclic.

Cayley Tables. Blake, like Bryce, claimed that these groups were not isomorphic because the orders of elements did not align. However, they were different in pointing out the isomorphism class of these groups, stating that one is $\mathbb{Z}_4$ and the other is likely the Klein four-group. From here, they began to look at subgroups in order to find homomorphisms and were generally successful going from $\mathbb{Z}_4$ to the Klein four-group. Blake again attempted to use the FHT for justification, but they were not confident in their answer.

B: So, one of these has to be ℤ mod 4 I think.

I: Why is that?

B: …I think that there are only two groups of order 4. I'm not completely certain about that but I think I'm gonna go with that… [writing and thinking] You might be able to map ℤ mod 4 onto a two element subgroup of this other one which might be the Klein, or something. I don't really remember. But you could probably choose just a two element subgroup. a seems to be the identity here and each element squared returns a, so yeah. You could just choose like a, b or a, c or a, d and map them [gesture] onto one another.

I: Ok. So how do you know that would work?

B: [Blake writing and thinking]…I'm not sure it's going to work. Because I was going to say something about the Fundamental Homomorphism Theorem but then I remembered that this function then has to be onto. And if we're doing anything like that, we're gonna not hit every element in this group, so I'm not completely confident that'll work.

As we can see, Blake used the structure of the groups, focusing on order of elements and subgroups, to determine a homomorphism, despite their lack of confidence in the mapping.

Discussion

We focused on two students' approaches to three tasks. For the isomorphism tasks, both students correctly applied their knowledge of the properties of the groups to identify whether or not the groups were isomorphic. For $\mathbb{Z}_3$ and $\mathbb{Z}_6$, this amounted to noticing the groups had different sizes, though Bryce expanded to say that this means you cannot create a one-to-one map. For $\mathbb{Z}$ and $2\mathbb{Z}$, both students knew these groups are infinite and were able to set up at least one specific isomorphism in each direction. However, Blake used the fact that both groups are also cyclic to confirm that they should be isomorphic. For the Cayley table task, both students referenced the orders of the elements to justify a lack of isomorphism. However, the proof approaches on the homomorphism tasks were more different. In particular, both semantic and syntactic proof approaches were successfully employed to draw conclusions, and both were linked to struggles at times. Bryce used syntactic approaches to the homomorphism tasks and was both successful and comfortable working with generalized algebraic notation in the definition. In contrast, Blake mostly used semantic approaches to the homomorphism tasks, wherein they focused on the properties and structures of the relevant groups.

While syntactic reasoning generally aligned with instrumental understanding, like Melhuish (2018), we note that semantic approaches did not always seem to suggest a relational understanding. In particular, both students used semantic approaches to finding isomorphisms, but Bryce appeared to be checking memorized properties, more in alignment with instrumental understanding, while Blake seemed perpetually attuned to structure, suggesting a relational understanding. For the homomorphism tasks, Bryce mostly used syntactic approaches in a manner demonstrating instrumental understanding. In contrast, Blake behaved more like the graduate students of Weber (2001) in their semantic approaches, displaying a relational understanding, wherein they intently considered the structures of groups.

We note that the task of finding homomorphisms between groups presented in a Cayley table was particularly difficult. This was also the only task featuring a non-cyclic group. Moreover, while their course had engaged with isomorphism tasks where the groups were presented in Cayley tables, they had not done such a homomorphism task. Rather, this required the students to really understand what homomorphisms do structurally and use properties of the groups since they could not write an algebraic formula for the maps. Thus, instrumental understanding was less likely to be sufficient for this task, and this manifested in only Blake making headway on the homomorphism part of the task. Future research could examine how students' reasoning as portrayed through language relates to their proof approaches and success on tasks, thus binding together Weber and Alcock (2004), Melhuish (2018), and this work with that of Melhuish, Lew, et al., (2020), Rupnow (2021), and Rupnow and Randazzo (2022).

A Teaching Experiment for U-Substitution Based on Quantitative Reasoning

Leilani C. Fonbuena
Brigham Young University

Steven R. Jones
Brigham Young University

Prior work has created approaches to calculus based on crucial quantitative reasoning. For integration, however, the major topic of u-substitution has generally not been fully detailed in these paradigms. This paper presents a study where students were taught u-substitution from a quantitative perspective based on a three-part quantitative structure: differential quantity, integrand quantity, bounds quantity. The students reasoned about the quantitative conversions in flexible ways, and used various quantitative relationship types in their reasoning. However, reasoning about the differential quantity was difficult, and a new type of "collapse" metaphor was identified. By the end, the students had all developed a good quantitative basis for u-sub.

Keywords: calculus, integrals, u-substitution, quantitative reasoning, teaching experiment

Research has strongly established quantities-based meanings for calculus concepts as essential for robust student understanding and for productive usage outside of math classes (Byerley, 2019; Jones & Ely, 2023; Oehrtman & Simmons, 2023; Thompson, 1994). For integrals, this means moving away from the purely "area under a curve" meaning in favor of a "sum of small bits" meaning (Ely, 2017; Jones, 2015; Sealey, 2006). Several studies have examined teaching integrals and students' reasoning and modeling with integrals through this meaning (Bajracharya et al., 2023; Blomhøj & Kjeldsen, 2007; Chhetri & Oehrtman, 2015; Dray & Manogue, 2023; Sealey, 2014; Stevens & Jones, 2023; Von Korff & Rebello, 2012). However, the major "u-substitution" method has largely been absent from explicit research examination in these paradigms, despite its importance as the first in a long line of substitution techniques, and as a means in the sciences and engineering for converting between quantitative expressions (e.g., see Koretsky, 2012). Treating u-substitution quantitatively can allow students both to effectively *use* it and to understand the mechanisms for *why* it works. Very recent theoretical work has examined u-substitution through a quantitative paradigm (Jones & Fonbuena, 2024), and here we contribute by extending this theoretical work to an empirical examination of students learning u-substitution in this way. Our research questions were: (1) In teaching u-substitution through this paradigm, what quantitative reasoning did students use? (2) What understandings did they construct for the individual parts of u-substitution and for the overall u-substitution process?

Brief Review of Closely Related Literature

Research work has put forward a quantitative structure for definite integrals called *adding up pieces* (AUP) (Jones, 2013; Jones & Ely, 2023). AUP is comprised of three parts: *partition*, *target quantity*, and *sum* (see also Dray & Manogue, 2023; Sealey, 2014; Von Korff & Rebello, 2012). To explain these, consider the example of a solar panel generating energy (in kJ), where power is defined as the rate of energy generation (kJ/hr) over time (hr): $E = P \cdot t$. If power is constant, Oehrtman and Simmons (2023) call this a *basic model*. If power varies over time, this basic product cannot be used to find the total energy. Rather, time must be *partitioned* into essentially infinitesimally small pieces, denoted by the differential *dt* (Ely, 2020). In other words, *dt* is a very tiny Δt (Ely & Ellis, 2018). While differentials can be rigorously formalized by limits or hyperreals (see Jones & Ely, 2023), the more loosely-defined "essentially infinitesimal" is quite common across the sciences and is the crucial idea for quantitative reasoning, even if no specific threshold is defined for passing from "Δ" to "*d*" (Amos & Heckler, 2015; Hu & Rebello, 2013; Pina & Loverude, 2019; Thompson & Dreyfus, 2016; Von Korff & Rebello, 2014).

With infinitesimal partition pieces, power can be considered essentially constant over each *dt* piece, so the basic model can be applied to find the tiny bit of energy produced within each *dt*: $dE = P \cdot dt$. Here, energy is called the *target quantity*, and the application of the basic model to an infinitesimal piece is called the *local model* (Oehrtman & Simmons, 2023). While integrals in AUP can utilize any quantitative relationship (Simmons & Oehrtman, 2017), in this paper we primarily focus only on quantitative relationships defined through a product: $Q3 = Q1 \cdot Q2$.

With a conceptualization of tiny bits of the target quantity in each infinitesimal partition piece, *sum* refers to the literal summation of these target quantity bits to obtain the total target quantity amount. AUP follows Leibniz's convention (Katz, 2009) in using the integral symbol, ∫, as a literal "sum" symbol. For example, $\int_{t1}^{t2} P(t)dt$ is the sum of infinitesimal bits of energy (each produced by $P \cdot dt$) across the *dt* pieces between $t = t_1$ and $t = t_2$, yielding the total energy.

Finally, to introduce some terminology, because time is an input for the varying power, $P(t)$, as well as for the target quantity, $E(P, t)$, we call it the main *input quantity* (Jones & Fonbuena, 2024). Because power becomes the integrand in the integral, we call it the *integrand quantity*.

Theoretical Perspective: Quantitative Reasoning Applied to U-Substitution

Thompson (Smith & Thompson, 2007; Thompson, 1990) defined quantitative reasoning as "the analysis of a situation into a quantitative structure" (1990, p. 12). Quantitative structures are based on quantitative relationships, defined as "the conception of three quantities, [any] two of which determine the third" (1990, p. 12) (Figure 1a, below). In particular, a product-based definite integral captures a quantitative relationship between an *input quantity*, an *integrand quantity*, and a *target quantity* (Figure 1b). Our previous work applied quantitative reasoning to u-substitution (Jones & Fonbuena, 2024), which we recap here through the solar panel example.

Suppose the sun rises at 6am ($t = 0$) and reaches its zenith at 12pm ($t = 6$). A horizontal solar panel would have less power in the early morning, but power would increase to a maximum at noon. We use $P(t) = 250 \sin\left(\frac{\pi}{12}t\right)$ kJ/hr as a reasonable model for this situation. Based on the explanations in the previous section, this means that for each *dt* interval, the local model would be $dE = 250 \sin\left(\frac{\pi}{12}t\right) \cdot dt$, and the total energy would be given by $E = \int_0^6 250 \sin\left(\frac{\pi}{12}t\right) dt$.

To now move to u-substitution, note that while energy can be tracked over time, the power is mostly due to the sun's *angle* with the panel, so it might make sense to switch from time as the input to the sun's *angle*. This is exactly the quantitative question we claim u-substitution is built on: What if we want to track the target quantity in terms of a new input quantity (e.g., θ), rather than the original input (e.g., t)? To start the conversion, note there is a relationship from $t \to \theta \to P$, or $P(\theta(t))$, which is called *nested multivariation (MV)* (Jones, 2022). In the "quantity triangle" (Figure 1c), this nested MV is located along the edge of the triangle between the original input and integrand quantity. Time and angle are related by $\theta = \frac{\pi}{12}t$, meaning we can

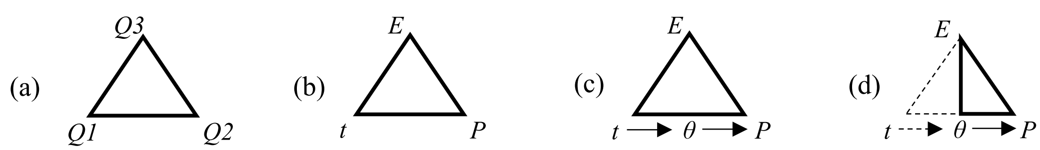

Figure 1. A basic quantitative relationship (a); and u-substitution as the transformation of the original integral relationship (b), through the nested MV between t, θ, and P (c), to a new integral relationship (d)

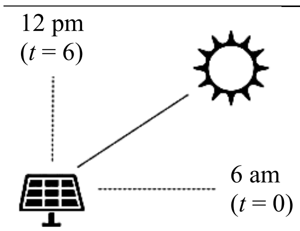
convert $P(\theta(t)) = 250\sin(\theta(t))$ to simply $P(\theta) = 250\sin(\theta)$. This relation also means that a change in angle is always $\pi/12$ as big as the change in time, so $d\theta = \frac{\pi}{12}dt$, or $dt = \frac{12}{\pi}d\theta$. The local model can now be fully described in terms of θ: $dE = 250\sin(\theta) \cdot \frac{12}{\pi}d\theta$. Finally, the sum over *dt* pieces from $0 \le t \le 6$ hr is equivalent to a sum over *dθ* pieces from $0 \le \theta \le \frac{\pi}{2}$ rad. Taken together, $E = \int_{t=0}^{t=6} 250\sin\left(\frac{\pi}{12}t\right)dt$ transforms to $E = \int_{\theta=0}^{\theta=\pi/2} 250\sin(\theta)\frac{12}{\pi}d\theta$. Our previous theoretical work defined u-substitution quantitatively as *transforming the original relationship by shifting the vertex from t to θ, to form a new relationship* (Figure 1d).

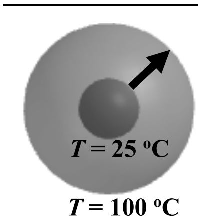
How is this transformation enacted? Our previous work also detailed a three-part process to do so: *differential, integrand,* and *bounds* (Jones & Fonbuena, 2024). These parts match the *partition, target quantity,* and *sum* structure of AUP. *Differential* means converting infinitesimal pieces of the original input to infinitesimal pieces of the new input (e.g., $dt \to [conversion]d\theta$). *Integrand* means using the nested MV structure to redefine the integrand quantity in terms of the new input (e.g., $P(t) \to P(\theta)$), allowing the target quantity to be determined by the new input (e.g., $E(P,t) \to E(P,\theta)$). *Bounds* means re-describing the sum over the original input pieces to a sum over the new input pieces (e.g., a sum over $0 \le t \le 6$ hrs to a sum over $0 \le \theta \le \pi/2$).

Methods

For this study, we designed an experimental lesson consisting of two u-substitution tasks using real-world contexts (Figure 2). The first author was the researcher-instructor for the lesson. In Task 1, the goal was for students to construct an integral and then enact the u-substitution conversions outlined in our theoretical perspective section. In Task 2, the goal was similarly for students to identify the three-part transformation of (a) *bounds*: converting between the sum over $25 \le T \le 100$ and the sum over $10 \le r \le 15$, (b) *integrand*: converting between $4\pi(\sqrt{T}+5)^2$ and $4\pi r^2$, and (c) *differential*: using the relation $dr = \frac{1}{2\sqrt{T}}dT$ to convert between *dr* and *dT*.



Task 1: A solar panel generates energy in joules, J. Power is the rate at which energy is produced (joules per hour, J/hr). Note that power depends on the location of the sun and is maximized when the sun is directly overhead (12 pm). We'll use $P(t) = 250\sin\left(\frac{\pi}{12}t\right)$ as a reasonable model, because it is zero at 6 am (*t* = 0), increases from $0 \le t \le 6$ hours, and is maximized at 12 pm (*t* = 6).
(a) Construct an integral (in time) for the total energy generated over these 6 hours.
(b) The sun's angle is what really matters for power. What if we tracked the total energy produced with respect to angle instead? How does that change the integral?



Task 2: The gas inside a spherical balloon is heated from the inside from *T* = 25 ºC to *T* = 100 ºC. As the gas expands, the sphere grows [a dynamic visual is provided]. Suppose the radius (in cm) is given by $r(T) = \sqrt{T} + 5$. Note that at a given moment, for a tiny change in temperature, the tiny bit of increased volume is essentially the product of the current surface area and the corresponding tiny change in the radius.
(a) Consider the following two integrals, and explain how they each find the total change in volume: $\int_{T=25}^{T=100} 4\pi(\sqrt{T}+5)^2 \frac{1}{2\sqrt{T}}dT$ and $\int_{r=10}^{r=15} 4\pi r^2\, dr$.
(b) Explain how these two integrals are equivalent to each other.

Figure 2. Abbreviated versions of the two interview lesson tasks

To ensure participating students had the needed background, we recruited from a first-semester calculus class (*not* taught by the authors) that incorporated quantitative meanings for calculus concepts. We recruited when the unit on integration had started, so they would have basic knowledge about definite integrals through an AUP perspective. We recruited six students and paired them into three groups of two students each: Luke and Liam, Matt and Mark, and Ruby and Rafael. We analyzed the data as follows. First, for quantitative reasoning, we coded excerpts according to whether they referred to (a) the quantities, (b) the units, (c) relationships between quantities, and (d) operations done on quantities. We also coded for contraindications of quantitative reasoning, such symbol manipulations without attention to quantities. Second, to connect their reasoning to u-substitution, we coded excerpts according to the three parts in our breakdown: (a) *differentials*, (b) *integrand*, and (c) *bounds*. We looked for connections between their quantitative reasoning and each of the parts. Finally, the researcher-instructor asked the students at times to recap what they understood about u-substitution and what it meant. We summarized these general understandings for each student about u-substitution.

Results

Research Question #1: Students' Use of Quantity and Quantitative Relationships

We first describe how our students used quantities and quantitative relationships. One important aspect was what Redish (2005) called loading meaning onto symbols, which means the students directly interpreted the symbols and expressions as referents to the quantities in a productive way. To illustrate, consider these excerpts from Matt and Ruby:

> *Matt*: This [points to sin(π/12 t)], is showing how much joules you're getting per hour. And this [points to dt] is showing small time, in hours.

> *Ruby*: That equation [i.e., expression, points to $\frac{1}{2\sqrt{T}}\,dT$] is essentially equal to bits of radius.

Next, recall that Thompson's (1990) definition of quantitative relationships is of three quantities, where any two determine the third. Our students certainly used this type of relationship across the interviews for time-power-energy, angle-power-energy, temperature-area-volume, and radius-area-volume. However, our students also exhibited different types of relationships outside of this classic definition. The first type was "two-quantity relationships."

> *Rafael* (Task 2, after converting to radius): Well, it's just a much more direct relationship between radius and volume. The relationship between temperature and volume isn't as direct.

> *Liam* (Task 1, in converting the differential): We also want the relationship between dt and $d\theta$.

In fact, these two-quantity covariational relationships (Carlson et al., 2002) were a key part of the students' work. While each context held four quantities (e.g., time, angle, power, energy), decomposing into two-quantity relationships helped them track the conversions (cf. Jones, 2022).

Also, some three-quantity relationships the students imagined did not have Thompson's triangle format (Figure 1). Rather, some relationships followed the nested MV structure instead.

> *Liam*: At that time… The angle of the sun at a certain time, and like the amount of energy produced.

> *Mark*: Our tiny change in temperature… how this temperature affects the radius at that specific temperature and all that stuff we're adding up… we're adding up different volumes.

Liam described a relationship of *time* → *angle* → *energy*. Mark described a relationship of *temperature* → *radius* → *volume*. Importantly, though, note that the students' descriptions go from *original input* → *new input* → ***target*** *quantity*, skipping the integrand quantity. This result conflicts with the study's intended *input* → *new input* → ***integrand*** *quantity*, suggesting the lesson did not properly scaffold this particular nested MV relationship entailed in u-substitution.

Research Question #2: Students' Quantitative Conversions

We now explain the results pertinent to each of the three parts in the u-substitution structure: *differential, integrand,* and *bounds*. First, the *integrand* and *bounds* were mostly unproblematic for the students. The students readily converted the summation bounds from one quantity to the other and demonstrated understanding the quantitative equivalence. For example Matt explained,

> *Matt*: Your degree Celsius is going to start at 25 degrees and going to 100 degrees… It's kind of the same thing as radius… We're both [i.e., temperature and radius] changing at the same time. It's just you calling this one in terms of temperature instead of radius, even though they both happen at the same time… It's the same thing as showing when your radius is changing from 10 to 15.

The students also readily converted the integrand quantity from a dependence on the original input to the new input. These conversions, though, tended to be based on symbolic appearance at first, and were only later justified through quantities. Yet, we view this symbolic work as fine, so long as the quantitative relationships were understood, as demonstrated in these excerpts:

> *Mark*: Basically, because this *is* [emphasis in original] the angle right here [points to $\frac{\pi}{12}t$]. Like, that's the sine of theta [$\sin(\theta)$], it's our power output and this [again points to $\frac{\pi}{12}t$] would be what θ would be equal to.

> *Luke*: [We have] the relationship between *r* and *T* [i.e., the function $r(T) = \sqrt{T} + 5$], so we know that, like, for whatever *T* we put in there [i.e., into "$4\pi\left(\sqrt{T}+5\right)^2$"], it's gonna come up to the right *r* to get the same result as this one [points to the integral with "$4\pi r^2$"].

While *differential* and *integrand* were fairly unproblematic, one of the more important results was that the differential quantitative conversion was particularly cognitively demanding. The students spent significant time there and needed to carefully reason about the relationships. The first big difficulty was assuming that the differentials, such as *dt* and *dθ*, could be directly substituted. In fact, all three groups initially did so in Task 1 (Figure 3). It seemed based on the idea that all "infinitesimals" must be equivalent, since they are all so small. This idea is similar to Oehrtman's (2009) "collapse" metaphor, though it is different in that instead of collapsing to "nothing", these infinitesimals seem to all collapse to a single "infinitesimal sameness."

(a)  (b)  (c) 
Figure 3. Evidence from each group of initially equating dt and dθ

To help, the interviewer pointed out this implicit assumption and asked if the differentials were actually equal. The students reasoned about the quantities in order to realize they were not.

> *Luke*: I think they'd be proportional, but I don't know if they'd be exactly the same… One hour is equal to *π*/12, but in my mind they don't mean the same thing [*dt* and *dθ*]. Because *π*/12 is a ratio.

The interviewer followed up by asking if 1/100th of an hour was equal to 1/100th of a radian. This helped the students see and resolve the issue. This excerpt shows how one group began to do so:

> *Rafael*: *dt* is infinitesimal, getter smaller over a period of 6 hours. Where that's, where *dθ* is getting infinitely smaller over the range of *π*/2 [i.e., 0 to *π*/2].

Based on this reasoning, Rafael set up a proportion: $\frac{dt}{6} = \frac{d\theta}{\pi/2}$. He rearranged this relation to produce $d\theta = \pi/12\ \ dt$. We note that once this issue was resolved in Task 1, it did not reappear in Task 2. The students referred back to Task 1, now explaining that the differentials might be different sizes, and that some comparative relation between them needed to be identified.

A separate issue with differentials was interpreting "*d*" to just mean "derivative." This is sensible because the derivative was the other major concept they had experienced that used the differential notation "*d*", as in *dy/dx*. When interpreting *d* in this way, the students operated computationally and lost sight of the quantities. For example, in Task 2, Ruby interpreted "*dr*" as the derivative of the function $r(T) = \sqrt{T} + 5$, leading her to assert that $dr = \frac{1}{2\sqrt{T}}$. She then created the differential-less integral: $\int_{25}^{100} 4\pi\left(\sqrt{T} + 5\right)^2 \left(\frac{\sqrt{T}}{2T}\right)$. When asked about it, Rafael realized there was essentially no "local model" in the integral because of the absence of a *dT*.

Rafael: This isn't, this is just for one temperature. It's not 'as we're getting smaller.'

This realization helped the students see the need to think of *dr* and *dT* as representing *quantities*.

Of course, using derivatives was not always a problem and was sometimes necessary and useful. The students needed to derive $r(T) = \sqrt{T} + 5$ to find the relationship $dr = 1/(2\sqrt{T})\, dT$. Even so, they still tended to lose sight of the quantities within that computation and had to reconceptualize the quantitative relationship in the differential equation after the fact.

Our last result to highlight here is that the students successfully enacted the three parts of u-substitution (*differential, integrand, bounds*) in different orders, suggesting that these do not need to be enacted in a specific order. Table 1 shows the orders the groups used for each task.

Table 1. The three-part u-substitution conversion enacted in different orders by the groups across the tasks

	Task 1: Solar panel	Task 2: Sphere volume
Group 1	*bounds → integrand → differential*	*integrand → bounds → differential*
Group 2	*integrand → differential → bounds*	*integrand → differential → bounds*
Group 3	*integrand → bounds → differential*	*integrand → differential → bounds*

Research Question #2: General Understanding of U-Substitution

By the end of the interview lesson, all of the students had developed an understanding of the three-part structure of u-substitution: *differential, integrand, bounds*. They expressed the need for the two integrals to be equivalent in all aspects, as seen in Mark's representative explanation.

Mark: If we're going to go from one relationship to the other, like radius to temperature, or from, you know, time to degrees or I guess radians, we had to change our function, bounds, and our differential. We had to make sure that they were still equivalent statements.

The students also understood the need to find a relationship between the original input and the new input. As stated before, though, the nested MV relationship from these to the integrand quantity was somewhat blurred and pointed to a needed revision in the lessons.

We thus claim that this lesson was generally successful in helping the students (a) to reason about the quantitative nature of converting from one input quantity to another, and (b) to develop a personal understanding of the *differential-integrand-bounds* structure for u-substitution. However, we describe here one other unanticipated issue that cropped up during the lesson that points to a needed revision. While the students were reasoning quantitatively and understanding the u-substitution process, a couple of students (Ruby in particular) occasionally expressed confusion about what the point of doing these conversions would be.

Ruby: Well, I feel like, I mean, there must be a reason that we're doing it [converting from time to angle], but it seems like a lot of work, um, for not really anything.

After the completed process, though, Ruby had some recognition why it might be useful.

> *Ruby*: I think that this [seeing the two completed integrals] solves my problem, that this [the integral in time] is harder than this [the integral in angle]… Over here [the integral in angle] we have, we have the numbers plugged in in a way that will solve that for us [i.e., an easier antiderivative].

While Ruby began to the see the computational benefits of u-substitution, the lesson still did not help the students see possible scientific motivation for converting between quantities. For example, in Task 2, radius information might be easier to come by than temperature information.

Discussion

The major contribution of this study is to help induct u-substitution within a quantitative reasoning paradigm for calculus. This study extended prior theoretical work (Jones & Fonbuena, 2024) to an empirical analysis of students learning u-substitution in this way, which provided several insights into a quantitative u-substitution. First, the students used several distinct quantitative relationships, including classic three-quantity relationships (Smith & Thompson, 2007; Thompson, 1990), two-quantity covariational relationships (Carlson et al., 2002), and nested MV relationships (Jones, 2022). However, interestingly, the identified nested relationship was not the intended *original input → new input → integrand quantity*. This result suggests the need to scaffold this particular MV relationship to make it more salient in the lesson.

In the three-part structure of u-substitution (*differential, integrand, bounds*), the quantitative treatment of the differential was the most cognitively demanding. Crucially, we observed a new type of "collapse" distinct from Oehrtman's (2009). Rather than collapsing to "nothing," the differentials seemed to collapse, in the students' minds, to a single infinitesimal "sameness." It took careful work to consider the relationship between changes in the original input versus the new input to identify that even at very small scales there is a conversion factor between an infinitesimal bit in one quantity versus an infinitesimal bit of another. This strengthens the case that gaining the ability to reason about increasingly small increments of a quantity in calculus is important for quantitative reasoning (Ellis et al., 2020; Ely & Ellis, 2018).

Another implication from our study for teaching u-substitution is the need to ensure a motivating "why" for doing it (Harel, 2013). A couple students were unsure of the benefit of converting from time to angle, or from temperature to radius. One motivation, of course is the computationally practical "easier antiderivative" used in typical pure-math approaches. But we believe it is important to also weave in the scientific reasons for converting between quantities at times (e.g., see Koretsky, 2012). For example, it is possible that certain data is more available, or easier to obtain, which would definitely be the case for radius versus temperature in Task 2.

Overall, we believe this study to be a proof-of-concept of teaching u-substitution through a quantitative paradigm and teaching it in a way that illuminates the quantitative structures inherent in it. We believe that doing so can help students construct the *differential-integrand-bounds* structure that would allow flexibility in using u-substitution. However, beyond simply enacting the substitutions, our students also came to understand the mechanisms for why the substitutions work, and could reason about the conversions in context. Further, we believe that understanding u-substitution in this way can provide a strong basis for understanding future substitution techniques, such as trigonometric substitution or multivariable change of variables. For example, trigonometric substitution uses a different nested MV relationship where the new input ($\sin(\theta)$) *precedes* the original input (x), as in $\sin(\theta) \to x \to f(x)$. Thus, we claim that understanding these relationships can help students in future math learning and science usage.

Physics Students' Challenges Coordinating Multiplication with the Definite Integral Concept

Olha Sus
Tufts University

Andrew Izsák
Tufts University

Integration plays a significant role in applied problems, including those set in a wide range of physical phenomena. Past research has shown that students often experience difficulties applying calculus knowledge to physics, engineering, and other subjects. More specifically, recent research has identified students' difficulties constructing the "product layer," $f(x) \cdot dx$*, as a core part of the definite integral. In this study, we extend research on students' understandings of the definite integral by focusing on how they reason about multiplication with quantities, physical units, and the construction of the "product layer."*

Keywords: Calculus, Integration, Product layer, Knowledge-in-Pieces

Introduction and Literature Review

Research on the teaching and learning of calculus has focused primarily on limits and differentiation (e.g., Larsen et al., 2017; Rasmussen et al., 2014), but there is an emerging body of literature on integration. Among other things, research on integration has observed that the "product layer," $f(x) \cdot dx$, can pose particular challenges for students. This same literature has not examined closely how students coordinate reasoning about multiplication with quantities and reasoning about integrals. This gap limits our ability to help students develop more robust understandings of the "product layer" and of the definite integral.

We emphasize three themes in the literature on definite integrals. First, students often interpret the definite integral as "area under the curve," as a "derivative/antiderivative" relationship, or as "adding up pieces/multiplicatively-based summation" (e.g., Jones, 2015a, 2015b; Ely & Jones, 2023; Jones & Ely, 2023). These researchers have argued that first two interpretations provide limited help to students when making sense of the definite integral in problem situations and that the third interpretation is more helpful when applying the integral to problems in physics, engineering, and other fields.

Second, students often have difficulties interpreting the "product layer," $f(x) \cdot dx$, as expressing multiplication (e.g., Ely, 2017; Jones, 2013; Sealey, 2014). Sealey (2014) presented the most direct framework for characterizing student understanding of Riemann sums and definite integrals. This framework consists of five layers: orienting, product, summation, limit, function. She reported that conceptualizing the "product layer" was the most complex part of constructing definite integrals to model problem situations. She concluded that students had trouble not with calculations but with "understanding what is being multiplied together and what quantity is produced from that multiplication" (p. 240).

Third, students often have difficulties with modeling quantities such as distance and work with rectangular areas (e.g., Thompson et al., 2013; Nguyen & Rebello, 2011; Christensen & Thompson, 2010). Thompson and Silverman (2008) pointed out that for students to perceive the area under a curve as representing a quantity other than area (e.g., velocity, force), it is important for students to consider the quantity being accumulated as a sum of infinitesimal elements formed multiplicatively. As a result, they proposed a model which emphasizes two "layers" of integration: the multiplicative layer when the bits are formed and the summation layer when the bits are accumulated.

In the present study, we examined how students construct the "product layer," which can be used to relate quantities and to build new quantities in the given problem situation. In addition, we focused on knowledge resources students used in the process of forming the "product layer." We asked the following two research questions:

1. *How do students use/construct the "product layer" to relate quantities and form new quantities in problem situations?*
2. *What knowledge resources do students apply when using/constructing the "product layer" to relate quantities and form new quantities in problem situations?*

Theoretical Framework

In this section we present the theoretical framework which best spans the results obtained in the study. It combines mathematical structure (as perceived by experts) with cognitive components evidenced by students.

Vergnaud (1983, 1988) analyzed mathematical structures for multiplication with quantities and distinguished two subtypes of multiplication situations. Each component in a product is associated with a *measure space* and the relation between the components is either an *isomorphism-of-measure-spaces* situation *(I-O-M)* or a *product-of-measure-spaces* situation *(P-O-M)*. The former means that the product structure consists of a simple direct proportion between two measure spaces M_1 and M_2 (1983, p. 129). An example is the product structure which has the form $\frac{meters}{second} \cdot seconds$. The latter means the product structure consists of the Cartesian composition of two measure spaces, M_1 and M_2, into a third, M_3 (1983, p. 134). An example is the product structure which has the form $area\ (cm^2) \cdot height\ (cm)$. These subcategorization of problem situations helps us delineate definite integral problems which possess two different product structures.

For the cognitive component, we draw from the knowledge-in-pieces epistemological perspective. The perspective was first developed in science education research on conceptual change (e.g., diSessa, 1993, 2006). It has since been applied to various topics in mathematics, including whole-number multiplication (Izsák, 2005), functions (e.g., Izsák, 2004; Moschkovich, 1998), and integrals (Jones, 2013). From this perspective reasoning is supported by diverse, fine-grained knowledge resources and more novice knowledge evolves into more expert knowledge through processes such as the construction of knowledge resources that are sensitive to context for activation, refinement of contexts in which resources are applied, and reorganization that can involve forming new connections among some recourses and loosing connections among others. In the present study, we were particularly interested in knowledge resources students evidenced when reasoning about multiplication in the context of definite integrals and across both *I-O-M* and *P-O-M* situations.

Methods

We conducted three one-to-one, semi-structured, think-aloud interviews to assess how five students enrolled in the first-semester calculus-based physics course at the selective university reasoned about the integral concept in different problem situations, with particular attention to whether and how they constructed the product layer. Each interview lasted approximately 1 hour.

The *first* interview examined physics students' reasoning about multiplication in I-O-M and P-O-M problem situations. This interview consisted of three situations. None of the tasks mentioned integrals, but for each situation one could first multiply and then add to construct a total. We paid close attention to how students assigned units of measurement to the quantities and how they used the later to identify unknown quantities in each problem situation. The *second* interview examined physics students' reasoning when connecting definite integrals to I-O-M and P-O-M problem situations. In addition, we examined how students identified multiplicative structures and related them to graphical representations. The *third* interview intended to examine how students reasoned about the definite integral concept in I-O-M and P-O-M situations, but we were only able to pursue the I-O-M situations in the allotted time. Again, we paid close attention to how students reasoned about multiplicative structures and graphical representations as a part of the definite integral concept.

We recorded the interviews using two cameras, one to capture the student (body movements, hand gestures, etc.) and the interviewer and one to capture the student's written work. We collected all written work at the end of each interview. We used a computer to synchronize the two video recordings into a single file and transcribed the interviews verbatim.

We watched videos for all five students side-by-side with the transcripts, checking the transcripts for accuracy. All students had trouble at one point or another coordinating multiplication with the "product layer" and definite integrals. After multiple viewings of the interview data, it became clear that Iliana's data was particularly useful for our research questions because she first struggled to reason about multiplication in the context of the integration tasks, but then constructed the product layer appropriately. Her case is all the more noteworthy because she self-reported strong performance in calculus (Calculus, A+; AP Calculus AB, 5; AP Calculus BC, 5). We generated summaries of the Iliana's reasoning that attended to her spoken language, hand gestures, and drawings as she worked on each task.

Results

Iliana's Work

Due to space limits, we focus on Interview 3. During Interview 1, Iliana relied on recalled formulas for transforming units when determining what to multiply — for instance, she recalled that $ft/sec \cdot \sec = ft$ and that $cm^2 \cdot cm = cm^3$. The main additional result from Interview 2 was that, in the context of a problem that provided equally-spaced, cross-sectional areas of a liver and asked for an approximate volume, Iliana multiplied cross-sectional areas by lengths to construct small pieces of volume which she then added, appropriately. At the same time, when using integral notation to express her reasoning, she included both Δx to denote small lengths and dx (Figure 2). When asked to interpret dx, she explained:

Iliana: I think maybe that just like everything's like in respect to x, I don't know, honestly, like that's always like added at the end and it's like I, we've definitely like gone over exactly why.

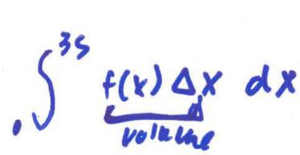

Figure 2. Iliana's definite integral representation (Interview 2)

Thus, in the Liver task Iliana perceived products in terms consistent with normatively correct Riemann sums and integrals but, for her, the dx notation did not indicate a factor to multiply. Interview 3 would reveal additional challenges experienced by Iliana.

Data. Task 1 from Interview 3 asked Iliana to approximate the total force from water pressure on a tank wall. The task included a picture of the 3ft-by-4ft wall and stated that the pressure on the wall varied with the depth, x, according to $P(x) = 15x$. A normatively correct integral would be $\int_0^3 4 \bullet 15x dx$. The physics course had yet to cover the relationship between pressure and force, and we anticipated that the context would be novel for Iliana. Indeed, she said she had to think about how pressure relates to force. She then integrated $15x$ "on the bounds from zero to x, x being whatever the depth is" to calculate the "sum of all the surface areas." Finally, she explained that she thought the pressure pointed down to the bottom of the tank (Figure 3). For this reason, she did not "feel the 4 feet of the width has anything to do with that."

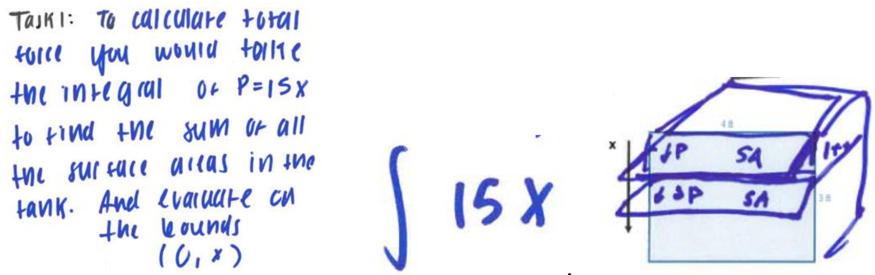

Figure 3. Iliana's work on calculating the total force (Task 1)

When the interviewer asked about force acting in another direction, Iliana continued to view pressure vertically. At the same time, she was not confident and reported that she did not know if force and pressure were related through a derivative/antiderivative, where the width of the wall would come in, and how to interpret the phrase "pressure across a surface area." Finally, Iliana sketched an appropriate graph for $P(x) = 15x$ but did not discuss area under the curve.

Analysis. Iliana's work on Task 1 provided access to how she approached integration in a novel situation, not in one where she recalled certain multiplicative relationships or formulae. An interconnected set of ideas (i.e., uncertainty about the pressure and force relationship, downward pressure) impeded her construction of products used in normatively correct Riemann sums and definite integrals. First, although the problem statement asked explicitly about pressure on the wall, Iliana consistently focused on downward pressure. This orientation side-stepped the need to consider small pieces of wall area, $4dx$, as one factor in a product. Second, similar to her work in Task 2 summarized above, Iliana did not view multiplication by dx as transforming units. Rather, she integrated the pressure function, $P(x) = 15x$, to get a total pressure. Third, similar to her work on the Liver task discussed above, she did not treat dx as a conceptually essential piece of the definite integral. In fact, she omitted the notation. Thus, how she oriented pressure in the situation directed her attention away from multiplying small areas of the wall ($4dx$) with pressures ($15x$), and it was unclear whether she noticed the absence of unit transformation through multiplication. If transformation of units through multiplication were central to her understanding of definite integrals, integrating a pressure function to get total pressure might have indicated to her that something was off.

Data. Task 2 asked Iliana to consider an automobile accelerating at $a(t)$ (m/sec^2) for 9 seconds and to find the velocity after 9 seconds. First, Iliana recalled an appropriate velocity formula, $v = v_0 + at$. She substituted 0 for v_0 and 9 for both a and t, arriving at 81 *m/s*. She then wrote $v = 9a$ (Figure 4). When asked how she knew to multiply, Iliana responded:

Iliana: a is the acceleration, which is just equal to, over here, like the amount that the, the amount that the, the like velocity is changing like per second, which in terms of units is meters per second second. Because meters per second is the unit for velocity, and then you add an extra second in the denominator because it's the change of velocity per second. So then when you multiply by time, which is just seconds, it cancels out and you have this, the unit for velocity again.

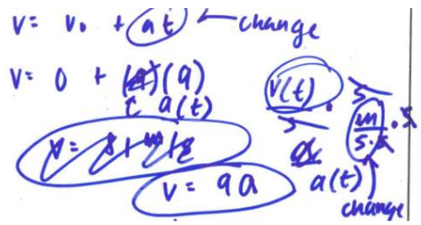

Figure 4. Iliana's work on calculating the velocity value for 9 seconds (Task 2)

Finally, Iliana mentioned the derivative/antiderivative relation between the acceleration and velocity quantities: "velocity is the antiderivative of acceleration", that is, "given like acceleration, let's say, $8x$, you can think that integral of acceleration evaluated on the time period zero to t, where t is the number of seconds that the system did."

Analysis. Iliana's work, including her discussion of anti-derivatives, suggested prior experience with problems relating velocities and acceleration. She introduced multiplication through a recalled formula and formal cancellation of units. From her discussion, it appeared that she recalled appropriate units for acceleration and for velocity and then reasoned about how to get from one to the other by cancelling units of time. Given that at one point she substituted 9 for both a and t, it is likely that she presumed a to be constant. This could explain why she did not use multiplication to construct small changes in velocities which could then be added, in contrast to the way she did use multiplication to construct small pieces of liver volume.

Data. Task 3 asked Iliana to explain the meaning of the definite integral and its interpretation in Task 1 and 2. Iliana stated that "it's harder than I thought to quantify what [the integral] exactly means." She then explained that the integral means "the sum of like a function per like change" and that "d just means like the change." (Figure 5). She added that "from a to b" means the summation of "those like areas of $f(x)$ per each change, like d of x." She concluded by saying "you are thinking of each small area and then adding them up." An exchange later she added, "Like change for each x, like per x, that's the change."

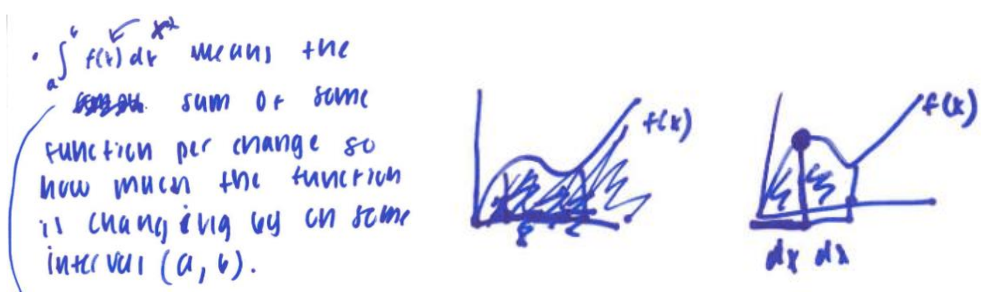

Figure 5. Iliana's definition of the definite integral and graphical representation of $f(x) \cdot dx$ (Task 3)

The interviewer then asked Iliana to explain her understanding of areas. Iliana graphed a function, shaded the area below it, and said "the summation kind of means like, you want to find what's under here, right?" When interviewer then asked Iliana where she saw dx and the product $f(x)dx$, Iliana drew horizontal brackets to indicate instances of dx and a large point on her graph to indicate $f(x)dx$ (Figure 5).

Analysis. Iliana demonstrated several ideas relevant to explaining definite integrals. These included summation of pieces, attending to changes in x, and areas. At the same time, there was no evidence that products were central for her. Similar to her work on the Water Pressure task, she talked about summing the function $f(x)$, not $f(x) \bullet dx$, and her discussion of change for each x and change per x suggested that she thought more in terms of a correspondence between values of $f(x)$ and instances of dx than a product of the two. Her plots of dx and $f(x)dx$ provided further evidence that she did not connect this notation to products and small areas.

Data. Next, Iliana interpreted the definite integral in the context of the acceleration task. First, she wrote appropriate integral notation and stated: "It's actually really the same thing, a of t per change in time. And then you're summing for, to evaluate the change of velocity per the amount of time done basically." Then she produced a graph corresponding to her explanation and drew the large point to indicate where she saw the expression $a(t)dt$ (Figure 6, middle).

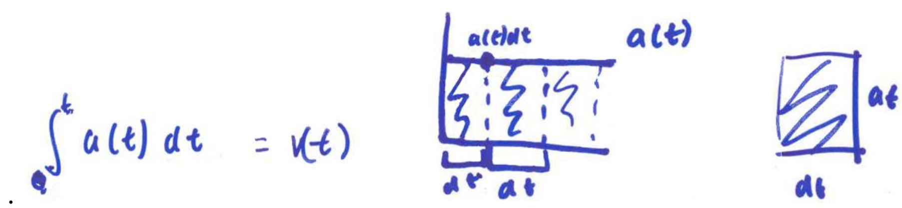

Figure 6. Iliana's meaning of the definite integral (Task 3)

Right after this answer, Iliana expressed some confusion about the dt term in her expression:

Iliana: Now, I'm confused what dt exactly is like representing. Because like sometimes it just feels like it's just there and doesn't really represent something. But like, obviously I know it does…. it's just like something that's kind of there, I don't know.

When the interviewer asked "What are you indicating when you add the squiggly lines?", Iliana responded the "area under the line" which was the "change in velocity for that time period."

Then the interviewer asked the following question, which made multiplication explicit:

Interviewer: Does this area that you indicated here (points to the squiggly lines, Figure 6, middle), and that expression $a(t)$ multiplied by dt has any relation or no for you?

After thinking for few seconds, Iliana changed her reasoning:

Iliana: Well, that is the area. Okay. Maybe this is making a little more sense now actually. Dt multiplied by a(t) gives you this area because it's just a box and you know that like to find an area of a rectangle is just like the base times height or whatever, you know. So, when you multiply those together, that gives you an area and the summation is just saying the sum of each of those areas for one, some time period. So, this isn't a point (points to $a(t)dt$). This is all of this, (points to shaded region) the a of t d of t is the squiggly lines.

Iliana shifted her reasoning and produced a new rectangular area picture (Figure 6, right), where she indicated $a(t)$ to be the height of the rectangle and dt its width. She reported that connecting $a(t)dt$ to an area was new to her. Finally, Iliana stated that integration will give her the velocity quantity and pointed to the sum of areas under the curve as the total velocity value on that time interval determined by the bounds in the integral notation. There was not time to return to the Water Pressure problem.

Analysis. Initially, Iliana interpreted the integral of $a(t)dt$ in ways similar to her interpretation of $f(x)dx$. She thought of a summation of pieces that corresponded to instances of dt but that did not think of those pieces as products for which dt was a factor. Just as she interpreted $f(x)dx$ as point, so again did she interpret $a(t)dt$ as a point. In both cases, associating dx and dt with intervals on the horizontal axis was insufficient to cue multiplication for Iliana. Once the interviewer introduced interpreting $a(t)dt$ as a product, Iliana generated a normatively correct interpretation that coordinated multiplication with the definite integral for the first time during the interviews.

Remaining Four Students. The remaining four students also demonstrated a range of resources for reasoning about multiplication—including formal unit cancelation manipulations—and evidenced a range of challenges reasoning about multiplication in the context of definite integrals. For the Water Pressure task, a second student integrated $15x$, one student considered integrating P/A, one student considered the product $15x \cdot 4x$, and one student avoided integrals altogether and reasoned instead about average pressure. We also observed further instances in which students did not associate dx notation with small horizontal lengths.

Discussion and Conclusion

The present study extends prior reports (e.g., Sealy, 2014) that students have trouble with the "product layer" when constructing definite integrals. In particular, we considered the possibility that students' difficulties might reflect where and how they use knowledge resources related to multiplication, as well as how they understand integral notation. Data on Iliana provided particularly good access to knowledge resources used by one high-achieving student. We found that Iliana had a range of resources for modeling problem situations with multiplication—including recalled formulas and strategies for transforming units—as well as a range of understandings about integrals—including thinking of areas under curves and derivative/anti-derivate relationships. We are not claiming that this is an exhaustive list of Iliana's resources related to multiplication and integration, only that they were ones central to her progress by the end of Interview 3. Iliana's work on the Liver problem demonstrated a case where she drew on prior knowledge about multiplication to form small pieces of volume that she then added. Thus, in some contexts she reasoned in ways consistent with Riemann sums but was not able to connect this reasoning to normatively correct integral notation. A main issue was her uncertainty about the meaning of the dx notation. Iliana's work on the Water Pressure problem demonstrated a case where the way she perceived novel quantities (i.e., downward pressure) directed her attention away from products. Her challenge was compounded by the fact that she did not perceive a product in the integrand that transformed units, in this case units of pressure. Finally, at the end of Interview 3, and in response to some direct suggestions by the interviewer, Iliana perceived dt for the first time as a factor in a product and combined thinking about products, transformation of acceleration into bits of velocity, and integral notation appropriately. Such complex coordination provides new evidence for why forming the "product layer" can be challenging for students. Our results are based on a small sample, but they do suggest that research on integration should pay more explicit attention to the knowledge resources students have for modeling situations with multiplication and how those combine with understandings of the definite integral.

What is the Correct Amount of Change? A Case Study on Kala's Covariational Reasoning

Irma E. Stevens	Jess Tolchinsky	Megan Robillard
University of Rhode Island	University of Rhode Island	Coventry High School

Students' understanding of the mathematics of change has been a crucial topic in the teaching and learning of precalculus. Various studies have indicated that covariational reasoning – reasoning about two quantities changing together—is critical for constructing productive meanings for rate of change. The Bottle Problem is one way teachers have supported students' covariational reasoning. We report on a case study of one student – Kala – an Applied Precalculus student. Through analysis of her work on the Precalculus Content Assessment (PCA), course assignments, and a cognitive interview, we report on her reasoning with amounts of change—a level of covariational reasoning. As a result, we highlight the importance of using appropriate amounts of change to analyze situations covariationally. This study contributes to literature on students' development of productive amounts of change reasoning.

Keywords: Covariational Reasoning, Precalculus, Cognition, Bottle Problem

Supporting students in constructing productive meanings for rates of change has been an aim for researchers for decades (Thomspon & Carlson, 2017). From middle school on, various materials aim to support students in reasoning with rates (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Ellis et al., 2015; Johnson, 2015; Tasova, 2021; Yu, 2022). The Bottle Problem (e.g., Carlson et al, 2002) is one well known example. Nevertheless, students still enter their post-secondary courses struggling with ideas of rates of change (Carlson, Oehrtman, & Engelke, 2010). The Precalculus Content Assessment (PCA) is one assessment that not only helps identify students' precalculus content knowledge, but also attends specifically to students' covariational reasoning—reasoning about two quantities changing in tandem (Carlson et al., 2002) (heretofore CR). Our research topic was to explore students' ways of reasoning when they attempt to reason about changing quantities quantitatively but struggle to construct or interpret representations. This interest led us to explore Kala's reasoning via her and her classmates' results on the PCA and the Bottle Problem. Our results provide insights into the importance of selecting appropriate *amounts of change*—one of the levels of covariational reasoning. We conclude by discussing the implications of her reasoning to the research on CR.

Background and Theoretical Framework

Covariational Reasoning and the Bottle Problem

Carlson et al. (2002) illustrated their framework for covariational reasoning with the Bottle Problem, a problem used and adapted in several settings with various populations. In Carlson et al.'s (2002) version of the Bottle Problem, students receive an image of a cross-section of a spherical bottle with a cap and asked to imagine the bottle filling with water and to "sketch a graph of the height as a function of the amount of water in the bottle." Their resulting framework consisted of five mental actions: *coordination of change*, *directional change*, *amounts of change*, *average rate of change*, and *instantaneous rate of change*. For example, students who coordinated the quantities might say that the height is changing as the amount of water is changing. Students with *directional reasoning* might say that the height is increasing as the amount of water is increasing. Students with *amounts of change reasoning* might say that for equal changes in the amount of water added, the water is increasing by increasing amounts. From these descriptions, we can recognize increasing precision about how the quantities change.

In this study, we were interested in exploring more in depth about how students develop CR. Johnson, Castillo-Garsow, Moore and colleagues (e.g., Castillo-Garsow, Moore, & Johnson, 2013; Johnson, 2015; Moore et al, 2019) have already done work in this area, reporting how students visualize quantities changing (such as the speed of the change or considering discrete vs. continuous change) and how their meanings for graphs can impact their reasoning. Another relevant result is from Stevens (2023), in which students compared the steepness of lines on a graph (i.e., the slope) to determine increasing rates of change.

Precalculus Content Assessment (PCA)

The goal of the Precalculus Content Assessment (PCA) is to provide a means to evaluate how effective a curriculum and its instruction are in setting students up to be successful in calculus (e.g., effectiveness of College Algebra (Carlson, 2010)) and link between AP Calculus and PCA (Meylani, 2011). In Carlson's (2010) study of 902 precalculus students, the average score on the PCA was 41% with a reliability coefficient of 0.73. The average score on the PCA for the covariation reasoning abilities was 50% with a reliability coefficient of 0.46. Though these reports pull out students' covariational reasoning problems (which we also do in this study), it is important to note that a factor analysis on the PCA indicated the use of a single total score on the PCA may be the "most psychometrically defensible method of scoring the instrument" (Jones, 2021, p. 78).

Intellectual Need

Because this study is attempting to explore in depth a student's CR, Harel's (2008) *intellectual need* became a key idea in the analysis of the data in identifying reasons a student might engage in covariational reasoning. Harel (2008) defined *intellectual need* as the need to reach an equilibrium (i.e., no state of perturbation) by learning a new piece of knowledge. For instance, when choosing to graph a straight line or a curve, a student may recognize a need to attend to the rate at which quantities are changing in the situation to reach a state of equilibrium.

Methods

Subjects and Setting

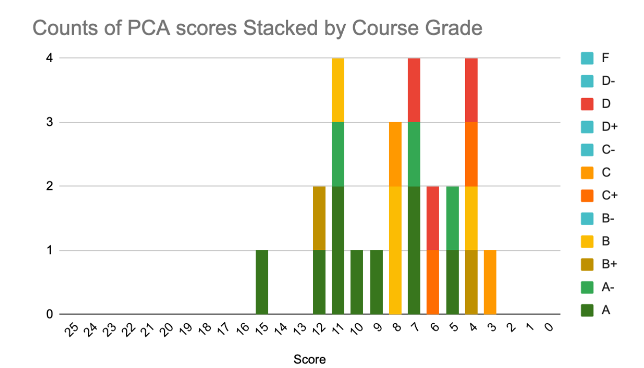
This study was conducted with an Applied Precalculus class of 39 students at a medium-sized university in the northeastern US. The coordinated course had students with various majors (but not Mathematics or Engineering). The students were assigned four different assignments throughout the semester, one of which included an extended version of the Bottle Problem from Moore's *Advancing Reasoning* NSF project (see results for details) and a prompt to submit a video explaining their reasoning. 25 of the students completed the optional PCA in class at the end of the semester. One student, Kala, volunteered to be part of a semi-structured clinical interview (Clement, 2000) after the semester ended in which she, once again and with no advance knowledge, went through a subset of the problems from the four classroom assignments.

Analysis

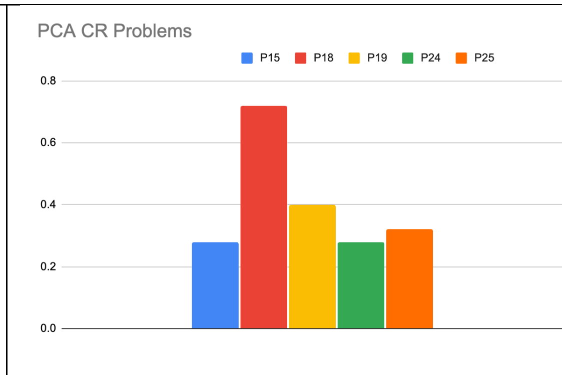
We recorded PCA responses and scanned student work, we downloaded the classroom assignments from the course's LMS where students had uploaded pdfs and video files, and we video-recorded and transcribed the interview (camera and screen recording of iPad). We analyzed the PCA results by question (correctness, summary data, distribution of responses), and then focused on the problems Carlson, Oehrtman, & Engelke (2010) identified as relevant to CR (heretofore PCA CR problems). We used Carlson et al.'s (2002) CR framework to analyze the student work on those problems, and we then compared student's work with Kala's work. We then analyzed Kala's student work and video associated with the Bottle Problem assignment, coding her *amounts of change reasoning*, which we analyzed further using Kala's interview on the Bottle Problem.

Results

Kala's Overall PCA Results Compared with Classmates



(a)



(b)

	Total PCA by problem	PCA CR by problem	Total PCA by student	PCA CR by student

Figure 1: (a) Total PCA scores with course grade (b) % correct for PCA CR problems (c) Summary statistics by problem/student for the total PCA and for PCA CR problems and (d) non-CR categories for PCA CR problems.

The PCA results from the 25 students' scores are summarized in Figure 1a. Kala was one of four students who scored 4 points (out of 25) and received a B+ in the course. Figure 1b shows the results of the student responses on the PCA CR problems. Kala was one of the 7 students (i.e., 28% of the class) who got Problem 15 (P15) correct on the PCA, but all her other PCA CR problem responses were incorrect. Problem 15 was the most like the Bottle Problem, because it involved choosing a geometric 3D shape that could represent a given height vs. volume graph (other PCA CR classifications in Figure 1d). Figure 1c provides PCA summary statistics. In the first two columns, we see 76% of students answered the most correctly answered PCA problem correctly, while it was 72% for the max PCA CR problem. Also, students performed better on average on the PCA CR problems than the total PCA assessment (31.2% vs 42.8%). Kala scored a 16% on the PCA and a 20% on the PCA CR problems alone, both below average scores.

Kala's PCA CR Problems Results Compared with Classmates

Kala only got one of the five PCA CR problems correct (P15). In this section, I (i) state how she answered the problems (ii) compare her responses to her peers' responses, and (iii) report on whether (and how) the content was covered in the Applied Precalculus course she took.

On P15, students chose a shape that represented a given volume-height graph. Most students chose shapes that had the opposite rate of change as what was represented in a given volume-height graph. Kala (no written work) was part of the 28% of students who answered correctly. In class, students did a very similar task (i.e., the Bottle Problem).

On P18, students needed to determine the *direction of change* and an extreme function value from given formula. P18 was the second most correctly answered PCA problem. Most students substituted values to solve this problem. Kala (no written work) got P18 incorrect. For P19, 40% of students correctly described the behavior of a function when given a graph. Only one student (not Kala) incorrectly identified the *directional change*, but the most common response included the opposite rate of change. Kala and one other student identified a constant rate. In class, students determined *directional change*.

For P24 and P25, students described the end behavior of a function given a graph and a rational function definition, respectively. 28% and 32% of students correctly identified end behavior, respectively. Kala did not correctly identify any end behavior statements for either problem. End behavior was not explicitly taught in the course.

From Kala's work on these problems, we identify the following characteristics. Kala did not demonstrate a way to reason about the *direction of change* when given a function definition (P18), but she could when given a graph (P19). Kala did not demonstrate a way to reason about the end behavior of a function when given a graph or a function definition (P24/P25). Kala inconsistently reasoned about rates of change when given a graph (P15/P19). To gain more insight into Kala's reasoning, we turn to her work on Assignment 3 and her cognitive interview.

Assignment 3 (The Bottle Problem) Results

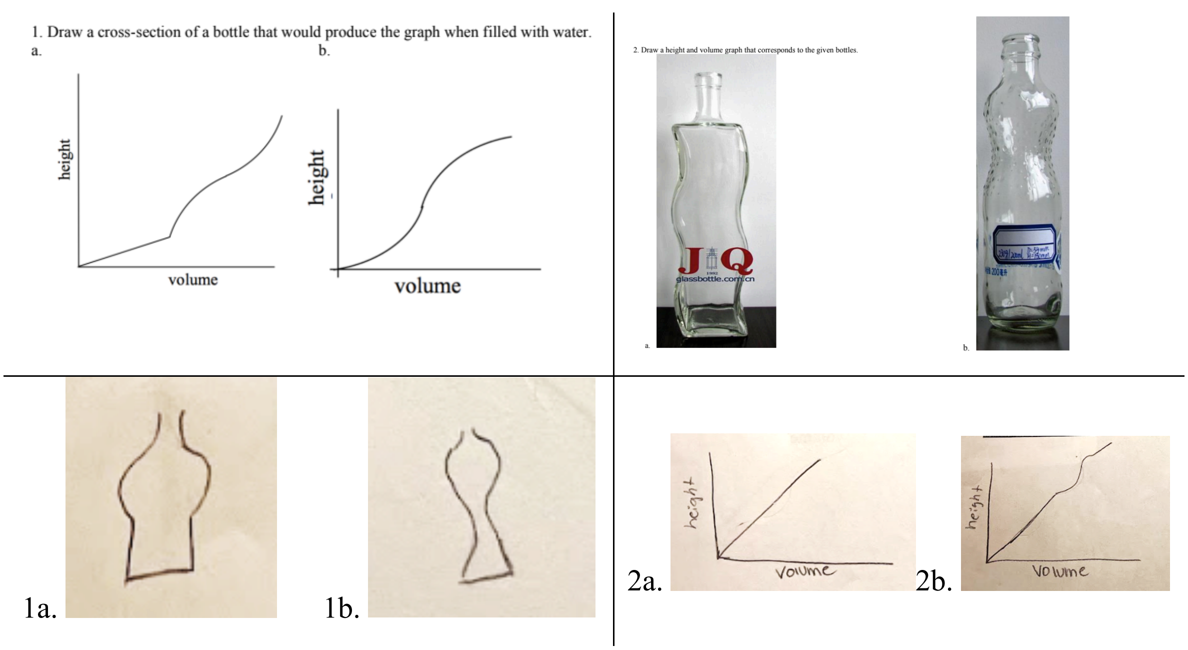

Figure 2: (top) Assignment 3: Part 1 and (bottom) Kala's solutions.

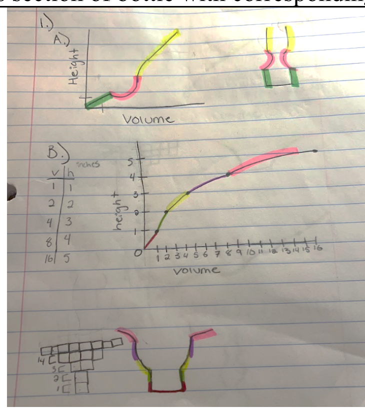
1a. Height-Volume graph with corresponding cross section of bottle.
1b. Height-Volume graph; the water doubles in volume for each additional inch of height.
1c. Height-Volume graph; for each inch in height the bottle increases, the volume of the bottle increases by two more inches cubed in volume that the previous increase.
2. Cross section of bottle with corresponding Height-Volume graph.



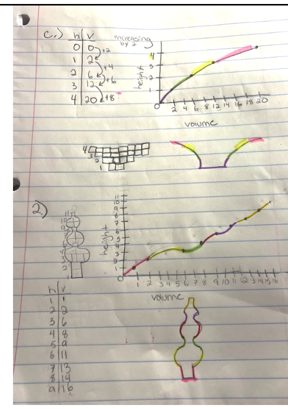


Figure 3: Kala's Assignment 3: Part 2 solutions with summary of problem statements in top row.

During the semester, students worked on a modified version of the Bottle Problem. Part 1 (Figure 2) is above with Kala's solutions. For 1a, her cross section of the bottle is a normative solution. For 1b, there is extra curvature in her bottle not represented in the given graph. For 2a and 2b, her graphs are potentially missing curvature in her graph to represent the inward curvature underneath the cap of the bottle. We return to 2b, as does Kala, in her interview.

In analyzing Kala's submitted work (Figure 3) and video from Part 2, we note three aspects. First, in Part 2: Problem 1a, Kala highlights a single upward curvature in her graph with a corresponding pink cross section of her bottle in which the height has *both* an increasing and decreasing rate of height with respect to volume. In describing the pink section in her graph, she stated it is "dip[ping] down" and "the volume is decreasing, while the height is still increasing." When relating that to the pink section in her bottle, she stated "because the volume is decreasing, so the bottle gets skinnier at that part". Similar work is in Part 2: Problem 2 (e.g., green section). Thus, we infer Kala associated a thinner portion of a bottle with a "dip" in her graph.

Second, Kala uses unit squares to represent equal unit cubes of volume. For example, in Part 2: Problem 1c, in which the volume of the bottle increases by two units for each additional inch in height, Kala created a table of volume values and then drew a corresponding unit cube sketch using her table values. She described her construction of this "cube diagram" as follows: "So we start with two, we do for our one inch of height, we have two blocks of volume. And then two inches, we have a total of six." The two and six correspond to the volume values in her table for a height of one and two inches, respectively. Similar work is in Part 2: Problem 2.

Third, after plotting points and creating sketches using unit squares using tables she constructed, she inconsistently connects the points and creates final bottles. For instance, Part 2: Problem 1b does not have a smooth curve in her graph, whereas Part 2: 1c does. Similarly, Part 2: Problem 1b does not have a smooth curve in her final bottle, whereas Part 2: 1c does. Her interview provides more details on how she chose to connect points on her graph.

Kala's Interview on the Bottle Problem

Figure 4 is Kala's final work on the Bottle Problem (left) and her additional work done throughout the interview on the Bottle Problem (right). Note that the bottle is the same one from

Part 1: Problem 2b (Figure 1) and that the resulting graphs are very similar. However, new for the interview was her use of a "cube diagram", a table of values, and plotted points (methods she used during Part II (Figure 3)). In this section, we focus explicitly on Kala's CR given (i) we have insights into her methods for constructing graphs from the Bottle Problem assignment and (ii) the interview enabled more in-depth questioning given its semi-structured nature.

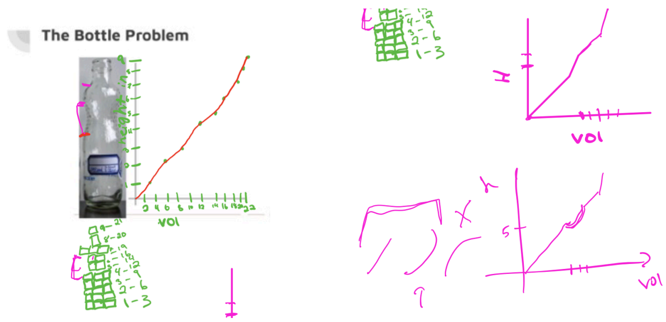

Figure 4: Kala's final work on the Bottle Problem during her cognitive interview.

First, we note Kala's quantification of volume and height using a diagram of the cross section of the bottle. Her use of her "cube" method to quantify volume enables her to draw a diagram in which she can measure volume via counting the cubes. She also defines "layers" of cubes, each layer corresponding to one inch of height. In the green "cube diagram" in Figure 3, Kala uses this diagram to measure the volume in the bottle for each additional inch of height (e.g., "1-3" indicates at 1 inch of height, the volume is 3 unit cubes, and then 2-6, 3-9, 4-12, 5-14, and so on).

Second, we note that Kala attempts to describe how her two quantities, height and volume, are changing together in her graph. For instance, she describes the initial straight segment emanating from the origin (in all her graphs, but her final graph, specifically) the following way: "what this is kind of showing that it's increasing at the same time, as the height is increasing, the volume is increasing at the same time". This corresponds to the second level of CR.

Third, we note that Kala recognizes that the "dips" in the cross section of the bottle impact how much volume can fit within a single layer. For instance, when describing what happens after the straight section of the bottle, she states "the height of the water is gonna increase, and the volume-there's less room for water." She uses that observation to justify why her *graph* should not continue to be straight at these "dips". She states, "the height is staying the same but the volume is gonna decrease, because there's less room so we kind of dip-kind of like dip a little bit and then come back up." Here, although she states the *volume* is going to decrease, she is referencing her layers in her bottle, noting that the layers are going from three unit cubes down to two unit cubes. She also clarifies later that it was the one inch increment that "is staying the same" for the height and that "the height is still increasing as we go up, since we're moving up the bottle since we are filling it up." Thus, though not explicitly using *amounts of change* language, we see Kala attending to and comparing changes in height and changes in volume.

Lastly, we note the perturbation Kala experienced when trying justify straight segments versus curved segments. To discuss this perturbation, we focus on when Kala is referencing the bottle from four to six inches, which corresponded to the pink region labeled on the given cross section of the bottle (i.e., the "dip"). In her cube diagram, this region corresponded to two layers of two unit cubes each. In her graph, this corresponded to the curve immediately after the straight portion of her graph (see bolded region and the three curves she considered in Figure 4 (right)).

When considering using straight lines in her graph, her reasoning is as follows:

Kala: So we're at five inches, which is where that fifth layer shrinks to two, and then I have fourteen cubic whatever is of volume, and then the volume, the height is still increasing, so we jump to six, but it's only fourteen units of volume.

From this quote, we see that Kala identified that there is less volume gained per inch of height in the layers (that each have two cubes) than the first four layers (that each have three cubes). She concluded that the line segment corresponding to that "dip" in the bottle has a steeper slope than the line segment corresponding to the first section. This use of "increasing rate" implying "steeper" straight line segment is what Stevens (in press) described.

When considering curved lines, she hesitated to associate it only with the curve of the bottle, referencing her bottle from Assignment 3: Part 1 2a (Figure 2), where the curvy bottle still resulted in a graph with a straight line. She stated she felt like the bottle was "trying to trick me and make me want it [the graph] to be curvy" because "the bottle is curvy". In the end, she chose her final graph to have a curved segment in that region vs. a straight segment, though admitting, "So I honestly don't know which is the move-but let's go curvy".

In summary, Kala wanted to justify a "curvy" graph, but given her reasoning with the bottle's cross section, she could not. In the discussion, we discuss why Kala's reasoning with the diagram was both quantitative and limited, and its implications for students' *amounts of change* CR.

Discussion and Implications

Across Kala's work, we noted ways of reasoning about *directional change* but a struggle to reason about rates of change relative to her peers. From her PCA results and assignment, there was not much evidence about how she determined rates of change, only that she seemed to connect the idea to "dips" in the bottle in the Bottle Problem. However, in her interview, where she used her quantitatively appropriate "cube diagram" method, we find Kala's *amounts of change* reasoning had one major limitation: she chose height intervals that spanned across two different rates of change (i.e., decreasing rate then increasing rate). This decision resulted in *equal* changes in volume for a successive change in height in her cube diagram given the symmetry of the dip in the bottle. Because this constant change matched the constant changes in volume she identified for successive changes in height for the straight segment of the bottle, and because that constant change in volume is how she justified a straight line segment in her graph, she concluded that the "dip" should do the same (but steeper to accommodate less volume added). However, this conclusion perturbed Kala, who still drew a curve on her graph.

To justify appropriate curvature, Kala would have needed to identify smaller amounts of change in height, successive changes in height that started at the beginning of the inward curvature of the bottle and symmetric with the outer curve of the bottle (e.g., Figure 5). Understanding the necessity of this careful construction of *amounts of change* is crucial for making appropriate quantitative conclusions about the CR of the quantities. From Kala's work, we see the importance of supporting this intellectual need for the careful construction of *amounts of change*. This need goes beyond a need to compare amounts of change in one quantity for equal successive changes in another quantity, because as Kala illustrated, she had that goal.

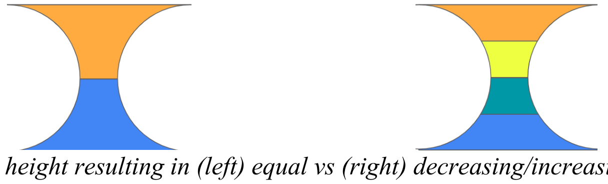

Figure 5: Equal changes in height resulting in (left) equal vs (right) decreasing/increasing changes in volume.

Whiteness-at-work in Mathematics Department Initiatives to Ameliorate Racialized Gatekeeping in Calculus

R. Taylor McNeill
Vanderbilt University

Melissa Gresalfi
Vanderbilt University

Luis A. Leyva
Vanderbilt University

Racialized gatekeeping in calculus courses is a national, systemic concern. However, research on equitable calculus instruction has focused on classroom-level changes, providing limited guidance for department-level reforms necessary to implement change in large calculus programs. To extend such work, we present a case study of a mathematics department at a large university engaged in improving its calculus program to better serve Black and Latin students. Informed by critical whiteness studies, we explore how whiteness was maintained amidst this equity-oriented initiative. Findings exhibit disciplinary-specific forms of whiteness that stymied departmental reform. Implications are provided for equity-oriented, department-level change.*

Keywords: whiteness, mathematics faculty, calculus, testing

Study Purpose & Background

Across the nation, undergraduate calculus serves as a source of racialized attrition from STEM majors (Chen, 2013). In response, mathematics education research has increasingly explored racialized aspects of undergraduate mathematics to offer guidance for advancing equity through instruction (Larnell, 2016; Leyva et al., 2021). However, disciplinary and departmental factors can hinder the implementation of such antiracist instructional recommendations (Ching & Roberts, 2022). The prevalence of faculty's colorblind beliefs that mathematics is a neutral space (McNeill et al., 2022) can impede sociopolitical noticing in the classroom (Louie et al., 2021), making it difficult for instructors to enact equitable instruction. Furthermore, racially-conscious instructors can find their agency to implement instructional changes limited by the coordination of calculus courses across multiple sections. Prior research has explored department-level change efforts in coordinated calculus courses, but such interventions have largely focused on implementing generally supportive practices (e.g., incorporating active learning pedagogies; Williams et al., 2022). Such practices leave the racialization of undergraduate mathematics uninterrogated, including the role of calculus as a gatekeeper to STEM majors, and therefore fall short in improving course experiences among racially minoritized students (Leyva et al., 2022).

Higher education research shows that departmental changes are mediated by faculty's racial beliefs as well as historically white institutional structures and policies. During equity-oriented systemic change efforts, these manifestations of whiteness can contribute to internal contradictions that can cause interventions to fall short of their antiracist aims (Dowd & Bensimon, 2015). Critical analysis of race in such research has been reserved for student experiences, leaving little guidance about how to counteract whiteness in faculty politics. Such analyses are necessary in undergraduate mathematics where disciplinary values, which reflect the values of white, male elites who historically codified academic mathematics (McNeill & Jefferson, in press), also mediate departmental change. Systemic solutions to address racialized gatekeeping in calculus must anticipate and counter ideological forces of whiteness in both the discipline and educational structures to actualize equity-oriented aims. This requires understanding the functions of whiteness in disciplinary values and institutional structures.

This paper presents a case study of a mathematics department at Wesselman University (pseudonym), an institution engaged in reforming its calculus program to better serve Black and Latin* students. Informed by critical whiteness studies, we assume that whiteness is omnipresent and explore its workings in this change initiative through the following research questions: (1) How is whiteness functioning in the mathematics department's initiatives to ameliorate racial inequities in calculus courses?; and (2) What role does mathematics, as a discipline, play in the reproduction and disruption of whiteness within calculus courses and the department?

Theoretical Perspectives on Whiteness

Whiteness is a set of ideologies that reinforce white supremacy, antiblackness, and systemic racism (Bonilla-Silva, 2006). For example, of particular relevance to the present analysis is the ideology of "quantity over quality" (Jones & Okun, 2001), which describes placing a high value on outputs, especially those counted or quantified. This ideology is prevalent in mathematics as a quantitative field, privileging abstract and generalizable approaches to produce expedient solutions over problem-solving approaches that attend to social context and purpose. Consequently, mathematical procedures are leveraged in situations like warfare with limited ethical consideration (Ernest, 2018) and, furthermore, dehumanize mathematics students by prioritizing the productivity of their labor over the learning experience (Ladson-Billings, 1997). Characteristics of whiteness such as these structure norms in undergraduate mathematics classes that reinforce racialized access to participation and recognition (Leyva et al., 2021).

We engage two theories of whiteness to guide our analysis. First, the theory of white institutional space (Moore, 2008) characterizes how organizations and institutions, such as law schools (the context in which the theory was developed), enact whiteness to maintain racial inequity. Moore characterized white institutional spaces as having four features:

> (1) Racist exclusion of people of color from elite law schools and positions of power in legal institutions, which results in the accumulation of white economic and political power, (2) The development of a white frame that organizes the logic of these institutions and normalizes white racial superiority, (3) The historical construction of a curricular model based on the thinking of white elites, and (4) The assertion of law as a neutral and impartial body of doctrine unconnected to power relations. (p. 27)

A white frame can be understood as a set of perspectives, shaped by ideologies of whiteness, that are used to make sense of everyday situations and shape individuals' inclinations to action.

Historically, whiteness has flexibly adapted to maintain dominance in a dynamic U.S. racial context (e.g. Bonilla-Silva, 2006). Whiteness-at-work (Yoon, 2012), the second guiding perspective for our analysis, characterizes these adaptations. Whiteness-at-work describes how individuals ascribe to ideologies that embody contradictions and paradoxes, thus creating the appearance of having progressive racial values while reinforcing racial oppression. For example, a white teacher expressing a desire to 'call out' colleagues on their racially- oppressive beliefs while simultaneously avoiding workplace conflict demonstrates whiteness-at-work (Yoon, 2012).

Together, whiteness-at-work and white institutional space complemented each other to guide our analysis of whiteness in the Wesselman mathematics department. Namely, we examined how whiteness-at-work among faculty gives rise to contradictions that impede equity-oriented reform and thus maintain workings of the mathematics department as a white institutional space. An illustrative example of whiteness-at-work maintaining a white institutional space in a mathematics department is a predominantly white faculty ensuring a short list of job candidates is racially diverse and then eliminating a Black candidate because her job talk used mathematics to interrogate racialized policing (McNeill & Jefferson, in press).

Methods

Research Context and Participants

Wesselman University is a large, elite, predominantly white, research-intensive university in the southern U.S. During the 2022-2023 academic year, the mathematics department had approximately 30 tenure-track faculty, 20 postdoctoral faculty, 10 senior lecturers, and 25 doctoral students. The demographics of the entire teaching staff were approximately 70% white and 85% male. During the same year, the domestic undergraduate population was roughly 40% white, 20% Asian American, 10% Black, 10% Latin*, 5% multiracial, and 5% unknown race.

In 2020, the department and university identified a need to improve the calculus program, particularly to ameliorate racial disparities in calculus grades and attrition from STEM majors. Before changes were initiated, weekly course meetings consisted of three lectures taught by the instructor (a graduate student, postdoc, or lecturer) in groups of 40 students, and a discussion taught by a graduate teaching assistant in groups of 20 students. All class meetings, including discussions, were led in a lecture-based format. Assessment structures included four midterm exams and a final exam. Exams took place in large lecture halls that held multiple sections of the course. Hats, backpacks, and other items were not allowed. Instructors were directed to "actively proctor" exams. Questions were not permitted. Students experienced exams as high-stress environments and frequently reported that they did not have enough time for the exam.

The research team (the three authors) began a collaboration with the Wesselman mathematics department in Spring 2021. Our partnership was structured in three phases: (1) Documenting Black and Latin* students' experiences in calculus; (2) Exploring instructor and stakeholder sensemaking about racial equity in calculus courses and related interventions, and (3) Facilitating professional development with calculus staff. The present analysis is based on data from the second phase, during which several interventions were being piloted. These included some implementation of active learning, the introduction of undergraduate course assistants who led small study groups outside of class, and replacing the fourth midterm with a "redemption test" that could replace a midterm grade. Indicators suggested that these interventions improved, but did not eliminate, racial disparities in grades. The mathematics department continued to function as a white institutional space despite these interventions. Corresponding to Moore's characteristics of white institutional spaces, this is demonstrated by: (1) A mathematics faculty that is approximately 70% white; (2) Shared departmental values that reflect whiteness, such as wanting to treat all students the same; (3) A curriculum supported by textbooks written almost entirely by white men; and (4) A shared perception of mathematics as socially-neutral.

Prior to the beginning of the Fall 2022 semester, instructors teaching calculus I courses were invited to participate in the study at an in-person meeting of calculus staff, and again through email. Faculty who were stakeholders in calculus reform efforts, such as the department chair, the coordinator for calculus courses, the director of undergraduate studies, and members of the "rethinking calculus" committee, were also invited to participate through email. All who expressed interest participated. In this report, we describe participants in aggregate to preserve anonymity given the unique departmental context. The 22 participants consisted of 11 calculus instructors (five lecturers and six doctoral students) and 13 stakeholders (seven tenure-track faculty members, five lecturers, and a postdoctoral scholar), with two participants serving in both instructor and stakeholder roles. Participants were majority white and men.

Data Collection & Researcher Positionality

Data consists of interviews with instructors and stakeholders as well as class observations and departmental artifacts. All interviews were semi-structured, audio recorded, and transcribed verbatim. Interview questions solicited instructor and stakeholder perspectives on: (1) the role of race in students' experiences and instructors' decisionmaking; (2) traditions in and changes to the calculus program; and (3) participants' role and agency in the mathematics department.

Interviews averaged one hour in length, with stakeholders participating in one interview and instructors participating in four. While the topics discussed with instructors and stakeholders were similar, interviews with instructors were more oriented towards instructional sensemaking. For example, the third interview asked instructors to read excerpts from interviews with Black and Latin* students from the first phase of the study, and consider to what extent students in their course(s) might have similar experiences. One abbreviated excerpt is presented below.

> When I'm under [test] time pressure stress, I just start making stupid mistakes. But then when I do take my time, I don't finish my problems on time… When I just saw that [exam] grade, I was like, "Oh…that's really going to hurt my GPA."... That was what compelled me to drop the class... It was just a matter of weighing what was going to push me farther in life… I don't want to be another Black kid just growing up to be nothing. I feel like breaking those social norms or those social views of being Black, that just pushes me to be successful… And so me not doing well in calculus wasn't really an option, per se.

Interviews with stakeholders had a more expansive focus beyond the classroom and into the departmental context. For example, stakeholder participants explored connections between interview topics and their involvement with the calculus program (e.g., as a member of the "rethinking calculus" committee).

Secondary data sources included classroom observations and departmental artifacts. Each instructor was observed four times. Observations were documented with field notes and audio recordings. Departmental artifacts included course syllabi, instructional policy documents, and reports produced by department members that proposed or evaluated interventions.

Two authors collaborated with the mathematics department to build rapport with participants and enhance our understanding of the research context. The second author, a white woman, participated on a search committee. The first author, a white transgender person, taught a calculus course and served as an instructor participant in the present study. The first author conducted all data collection for which they were not a participant, allowing them to provide instructional feedback and raise topics from informal collegial conversation during interviews. The third author, a Latino man, provided an outside lens for analysis informed by his research expertise on equity issues in undergraduate mathematics education. Collectively, we were reflective about how our respective experiences of privilege and oppression shaped our perceptions of whiteness in mathematics. The team resisted deficit interpretations of participants' reflections while maintaining critical awareness that participants served as representatives of a discipline and institution that are historically entrenched in racism.

Data Analysis

Theoretical perspectives of whiteness-at-work and white institutional space guided data analysis that followed an open, axial, and selective coding scheme (Strauss & Corbin, 1998). We used three sets of open codes. One set of open codes captured white racial frames (Moore, 2008), such as paternalism and individualism (Jones & Okun, 2001), used in participants' sensemaking about race, change initiatives, and their role in the calculus reform. This set of open codes contributed to answering our first research question about how whiteness influenced reform initiatives. Another set of open codes flagged organizational tensions. These included collegial conflicts or lack of support, organizational barriers that impede change, and mixed messaging from faculty leadership. The focus on organizational tensions highlights contradictions and paradoxes that exemplify whiteness-at-work (Yoon, 2012), also addressing our first research question. An additional set of open codes flagged instances where the mathematics discipline shaped participant sensemaking about racial equity and related change initiatives in calculus. This included using mathematical language, applying quantitative or formal logic, and appealing to mathematics epistemological values (e.g., abstraction, generalizability; McNeill & Jefferson, in press). This set of open codes supported our exploration of the second research question about how white frames and organizational actions are shaped by the mathematics discipline.

We used two sets of axial codes. One set flagged connections between white racial frames and organizational tensions to address our first research question about whiteness-at-work. Another flagged connections between white racial frames and mathematics, addressing our second research question about mathematical influences on departmental reform in calculus. Selective codes extracted contradictions that exemplify departmental whiteness-at-work.

Findings

For brevity, this report presents one form of whiteness, "quantity over quality," through two contradictions that exemplify whiteness-at-work in calculus reform. We use testing as a focal context to illustrate the maintenance of whiteness amidst equity-oriented reform.

The department privileged quantitative evaluations of student performance through testing over qualitative aspects of learning despite little inquiry into the validity of quantitative evaluation measures. Such valorizing of quantitative evaluations was based on the departmental beliefs that quantities provided a neutral measure of merit. Since evaluation structures were constructed to ensure some failure, this departmental practice functioned as a meritocratic mechanism for denying resources (e.g., access to more advanced courses) among those deemed unfit and therefore reproduced racialized gatekeeping in calculus.

Contradiction 1: Trying to Reduce DFW Rates While Maintaining Historical GPAs

Whiteness-at-work was evident in the department's effort to maintain the historical GPAs while expressing a desire to improve student success in calculus. As one stakeholder articulated,

> If we define success as getting… a C or higher… pretty reliably, 80% of students succeed in calculus. Then there's the 20% who aren't succeeding and we want to figure out why, so that we can propose solutions to help those students succeed. We don't expect everybody to succeed… but 20% seems like a high number.

Improving the proportion of students who receive a C or higher in the course would require that students receive higher grades on tests, given that test scores constituted 85% of a student's grade. Thus, maintaining historical GPAs conflicted with commitments to improving success rates.

Test design was a central context that contributed to whiteness-at-work, wherein whiteness in the form of "quantity over quality" framed the department's underemphasis on qualitative aspects of learning. The appropriateness of a test was determined primarily by the range of scores it produced, with less oversight given, for example, to the alignment of test questions with course learning goals. As one stakeholder shared,

> There were no TA meetings, there was no emphasis or monitoring, mentoring of first-time instructors. There were no discussions about where everybody was in the course… It was this idea that the principle of academic freedom meant that you could teach whatever you wanted, however you wanted, as long as the average of a test exam was X. And nobody really monitored... What was the validity of X? How do we get X? How do we design a test?

A focus on exam averages rather than content supported reductionist views of tests as either easy or hard. To produce tests that were the desired difficulty, instructors described constructing test questions from textbook problems beyond those assigned for homework. One instructor shared that "some problems… are super similar to the problem set, which will be more easier ones," and "If you go to every section… to the 60s and 70s, although those ones aren't [assigned], I do look at some of those to try to see about slightly harder ones to turn into a more harder exam problem." The same instructor described receiving feedback from students that "people wanted to see… more exam-type problems in class," suggesting that students perceived that class did not prepare them for the exams. Such test-design strategies reflected the sentiment that a stakeholder perceived as common on student evaluations: "assessments are harder or different than what is being taught in the class or what is being practiced on out-of-class assignments."

Adherence to historical averages was a central priority, despite the department's professed commitment to advancing equity and the qualitative misalignments between presented, practiced, and tested content. Following the first midterm, one instructor was advised to produce lower test scores on subsequent exams. In a later discussion with a stakeholder about implementing this advice, the impact on STEM persistence among Black students, who had received lower test averages as a group, was framed as a lesser concern than reproducing historical averages.

Instructor: In terms of test writing for the next time… I'm imagining what the score distribution might have been if I had just made a harder test, and I'm imagining that [racial] gap between 83 and 70 moving to 75 and 62, or something like that… given that [Calculus I] is a prerequisite and a required class for so many students' majors, it feels like shifting the test average for Black students in my class down to a 62 potentially could have some real ramifications on their careers.

Stakeholder: Given the fact that the Black students are getting lower averages than the white kids, then if you make your exam… harder… to lower your average, then you're going to put these kids in dangerous territory. On the other hand, I think that you probably don't want to be in a position where we are just starting tweaking with how we teach calculus in your course. I don't think it would be a problem if your course has an average 85 or whatever, but from the point of view of how things are currently set up in the math department that would spark a lot of probably unpleasant conversations. Right? You don't want to be there. It's not up to you to be tackling this problem right now.

Whiteness in the form of "quantity over quality" was visible in the department's adherence to historical GPAs. This prevented addressing testing structures that were an established source of STEM attrition among Black and Latin* students, thus reflecting whiteness-at-work in the contradictions between faculty's commitments to equity and the reproduction of DFW rates that the department wished to address.

Contradiction 2: Teaching and Learning Priorities Disincentivized by Evaluation Practices

Instructors and stakeholders expressed beliefs that students motivated by test scores would engage in rote learning. This was misaligned with desires for students to engage in collaborative mathematical sensemaking. The department's evaluation practices strongly emphasized scores. At the same time, reducing the percentage of students' grades that were determined by tests or redesigning tests to better incentivize desired forms of learning were not widely-considered interventions. Instead, instructors and stakeholders described a need for students to hone test-taking skills, in some cases advocating for more class time devoted to test-taking strategies. Whiteness in the form of "quantity over quality" can be seen in the department's loyalty to traditional quantitative assessment strategies, even when such assessments were at odds with qualitative aspects of their teaching goals as well as Black and Latin* students' wellbeing.

When responding to the interview prompt about testing, GPAs, and racialized pressure (see "Methods" section), an instructor claimed that prioritizing test scores hindered student learning.

> *Instructor*: This always makes me cringe. It [the interview prompt] was just like "This is really going to hurt my GPA."
>
> *Interviewer*: What's cringey about that to you?
>
> *Instructor*: Oh, I guess it's the fixation on grades, just this shows that this is in many students' eyes, and maybe rationally... "It's my job here to be the good grade getter."
>
> *Interviewer*: You feel like it gets in the way of learning?
>
> *Instructor:* I think so.

Simultaneously, preparation for tests often included instructional messages like the following:

> You have to put your economics hat on when you take tests and do a cost-benefit analysis… Time is currency that you have, the good that you are going to get back is points. Don't invest too much of your currency into a not-valuable commodity.

In emphasizing test-taking strategies in these ways, the department explicitly directed students to focus on aspects of the course that were viewed as unproductive for learning.

The misalignment between learning goals and the emphasis on testing limited the efficacy of an intervention designed to better support Black and Latin* students. Structured study groups led by undergraduate course assistants were implemented to foster peer support and a sense of belonging, particularly for racially minoritized students. A report on the efficacy of the piloted course assistant program found it to be successful in achieving these goals. However, attendance waned because students did not perceive that attending study groups helped them with exams. Commenting on this pattern, the report stated, "We believe that it would be a dereliction of our duty as instructors to teach our students that the only calculus problems that are worth thinking about and doing are the ones that could appear on an exam." In response, the report suggested calculus staff should "step up our messaging to the students about the purpose of the [study group] tasks" rather than consider how assessment structures could better incentivize the socially-supportive study group learning. In this way, this intervention embodied a paradox: aiming to ameliorate racial disparities in grades by encouraging Black and Latin* students to engage in mathematical work that students perceived to not significantly influence their grade.

Discussion & Implications

Our analysis highlighted two contradictions depicting whiteness-at-work. Whiteness functioned through a focus on quantitative measurables (i.e., grades), and a de-emphasis of qualitative aspects of calculus teaching and learning. While interventions introduced did improve calculus courses and reduce racial disparities in grades, such improvements were incremental and preserved functions of the mathematics department as a white institutional space. Such incremental changes reflect how institutions of mathematics education appear to be progressive, and at the same time, reflect forms of self-correction that reproduce racism (Martin, 2019).

Critical analysis of local data is important to produce change within mathematics departments (Bressoud & Rasmussen, 2015; Felix et al., 2015). Although student evaluations, test scores, and overall GPAs can serve as such local data, faculty must approach these data with equity-mindedness (Dowd & Bensimon, 2015) to mitigate possibilities for white racial frames, such as values around quantitative evaluation, to drive reform efforts and, thus, stymie their equity-oriented goals. Institutions invested in department-level equity reform should consider ways to integrate support and accountability for faculty within mathematics departments to ensure that implemented interventions are aligned with broader equity goals.

How Students Reconcile Incongruous Mathematics Self-Efficacy

Bridgette Russell
Lake Superior State University

Christine M. Phelps-Gregory
Central Michigan University

Incongruous mathematics self-efficacy (IMSE) is when a student's self-efficacy does not match their performance. We present a subset of results from a larger qualitative study examining IMSE in collegiate intermediate algebra. We used qualitative interviews and surveys to longitudinally follow students for their entire semester in intermediate algebra and present the cases of three students with IMSE (over confidence). We show that participants' over confidence seemed to stem from them doubting their performance would be predictive of their future success; participants did eventually lower their self-efficacy in response to repeated low performance. Results have implications for college mathematics instructors and for the study of self-efficacy.

Keywords: Beliefs, College algebra, Incongruous mathematics self-efficacy, Mathematics self-efficacy

In this paper, we present a subset of the results from a larger study that sought to examine and describe instances of incongruous mathematics self-efficacy (when students' mathematics confidence does not match their mathematics performance). For this paper, we present the cases of three students who had incongruous mathematics self-efficacy in their college intermediate algebra class, and we describe how, throughout the course of the semester, the students reconciled their self-efficacy to their actual performance. Previous research on incongruous mathematics self-efficacy is limited and no previous research has examined how students reconcile their self-efficacy with their performance. This work has important implications for self-efficacy theory at the undergraduate level as well as for college instructors who teach introductory classes and want to help their students better calibrate their work and effort to be successful in their college mathematics classes.

Conceptual Framework and Literature Review

Mathematics self-efficacy (MSE) is defined as a person's beliefs about their ability to learn or perform mathematics (Bandura, 1986). MSE is individualized to the student. That is, a student might make the statement "I am good at math" and this could mean that they are good at algebraic computations or Calculus, depending on the level of mathematics they have taken. A person's self-efficacy is an individual judgement that only they can make; it is a belief about themselves constructed from their perceptions and experiences. These beliefs are subjective. In spite of this, MSE is a reliable predictor of performance and perseverance, suggesting that a large percent of the time students' MSE judgements are probably aligned with their abilities (Hackett, 1985; Hackett & Betz, 1982; Hackett & Betz, 1989; Hutchison et al., 2006; MacPhee et al., 2013; Marra et al., 2009; Multon et al., 1991). However, previous research has found that sometimes self-efficacy beliefs and external measures of ability do not match (Chen, 2006; Dassa & Nichols, 2019; Pajares & Miller, 1994; Schraw, 1995; Sheldrake, 2016; Stolp & Zabrucky, 2009). This has been called the "feeling-of- knowing accuracy" (Schraw, 1995, p. 401), a student's calibration (Pajares & Miller, 1994), or incongruous mathematics self-efficacy (IMSE) (Russell & Phelps-Gregory, 2022), the term we will use in this paper.

Students who have IMSE can either be “under confident” (their self-efficacy is lower than their external performance would suggest) or “over confident” (their self-efficacy is higher than their external performance would suggest). Confidence and self-efficacy are not the same (confidence is a broader domain general feeling and self-efficacy is a person’s specific subject-based beliefs in their performance) (Morony et al., 2013). However, for ease of communication, we will use these terms instead of under-efficacious and over-efficacious. IMSE can have multiple drawbacks on students’ learning. For example, over confidence might lead to students not studying or asking for help (Bandura, 1986).

Previous research on IMSE is lacking but does suggest that it exists. Several studies of incongruous self-efficacy (not in mathematics) have been conducted with prospective teachers. These studies have found that many prospective teachers demonstrate over confidence in their teaching efficacy, rating their teaching ability as higher than outside observers rate it (Dassa & Nichols, 2019; Wyatt, 2014). In terms of mathematics, previous research has shown evidence IMSE exists (Champion, 2010; Chen, 2006; Labuhn et al., 2010; Lopez & Lent, 1992; Russell & Phelps-Gregory, 2022; Sheldrake, 2016; Tellhed et al., 2017). However, this research is often limited in sample size and, in many cases, did not set out to identify IMSE. For example, Chen (2006) examined seventh graders’ MSE assessments and their teachers’ assessments of their abilities in mathematics problem solving. Chen found that students’ judgements were less aligned with their performance than their teachers’ judgements, suggesting at least some of the students had IMSE (but describing IMSE no further).

Why might IMSE develop and how might students hold these beliefs in spite of their performance? Previous research has confirmed Bandura’s (1986) theory that MSE develops based on four sources: (1) mastery experiences (performance on assessments and in mathematics courses), (2) vicarious experiences (judgements based on comparison with peers or colleagues), (3) social persuasions (verbal encouragement or discouragement from parents or teachers), and (4) affective or physiological state (a physical response, like crying during a mathematics test) (see, e.g., Hackett and Betz, 1982; Lopez and Lent, 1992; Zeldin et al., 2008). It is likely that these four sources also influence the development of IMSE though little research has examined this. One study, Sheldrake (2016), found that students with congruous self-efficacy appeared to have mostly based their self-efficacy on past performance. In contrast, Sheldrake found that under confident students appeared to have based their MSE on perceived peer comparison, perceived teacher encouragement, and interests in mathematics. The over confident students appeared to base their beliefs on their high perceived belief in the utility of mathematics. This work suggests that students may use different sources to form their MSE and which source they use may determine if they develop IMSE or not. However, further work is needed to examine this relationship. In addition, no work has examined how students continue to hold these beliefs in spite of their performance (or adjust their beliefs in response to continued performance measures that run contrary with their beliefs). In this paper, we sought to examine this. Our research question was:

How do undergraduate intermediate algebra students who have IMSE (over confidence) reconcile their self-efficacy beliefs with their performance during the semester?

Methods

To identify students with IMSE, we conducted a larger study. Participants in the larger study were undergraduate students enrolled in one of many intermediate algebra courses at a Midwestern public university. Students in this course who consented were given a survey to identify their MSE and then students with high and low MSE were invited to participate in two interviews and to complete two additional surveys, administered at various points throughout the semester. Fifteen participants were invited to interviews in the larger study, 11 identified as women and 4 identified as male, non-binary, or transgender. To protect the identities of the participants, we have given them all pseudonyms (using female or non-binary pseudonyms), and we will use non-binary pronouns (they/them) for all participants.

Interview 1 included questions designed to better understand students' self-efficacy generally and their self-efficacy for intermediate algebra in particular. In it, we asked the students questions such as "How would you describe yourself as a math student?" and "On your [first] survey you responded by saying [paraphrase], can you tell me why you feel that way?" Survey 2 was an online survey administered immediately after the first exam, before students received their grades for the exam. In it, participants were asked about how they thought they had performed on the first exam and how they expected to perform in the course overall. Interview 2 occurred after students had received their exam grades and before the next exam; we again asked participants about their MSE beliefs as related to their experience with the first exam and about their MSE for the course overall. There was overlap in what the interviews covered because they were designed to examine changes in participants' MSE throughout the semester. Finally, survey 3 was administered electronically at the end of the semester once the students had received their final grades. This survey included questions about the participants' final grades as well as how they felt about their MSE after the course was over and how it compared to their experiences during the semester. The final survey also asked students questions about how their second and third exams went, including questions for students to describe how they felt leading up to, during, and after each exam compared to the grade they received. Having these final pieces of data enabled us to compare students' MSE beliefs longitudinally throughout the course and to compare how those beliefs relate to their final grade.

The interviews were transcribed and coded for analysis. The codes were based on a pilot study with additional codes developed inductively based on the data (Lichtman, 2012). To ensure trustworthiness, we used peer debriefing, member checks, and a coding reliability check with a third (non-author) researcher (Campbell et al., 2013; Lincoln and Guba, 1985). Once coding was complete, we developed emergent themes based on the coding. We defined cases of IMSE as when a participant's predicted grade was at least one full letter grade (10 percentage points) apart from their actual grade. That is, a student who predicted they would receive a B- but received a C- or lower would be identified as having IMSE. For this paper, we focus specifically on three participants who demonstrated IMSE for the course. The three participants were over confident, expecting to perform better in the course than they actually performed. We will describe how, over the course of the semester, these three participants reconciled their MSE with their ongoing lower than expected performance with the larger goal of better understanding IMSE and how MSE develops and changes as a result of repeated performance measures.

Results

Michelle, Lisa, and Adrian were all over confident in their ability to succeed in intermediate algebra. Michelle predicted (at the start of the semester) they would receive an A in the course but their final grade was a B. Lisa predicted they would receive an A- but received a C. And Adrian predicted they would receive a low B but failed the course with an F. We will examine each case individually with the goal of examining how each participant reconciled their MSE with their performance in the course. Across all three cases, we will see that participants did lower their MSE during the semester, though not always in line with their actual performance. And participants did use their algebra performance to judge their MSE; however, they often had reasons to doubt their performance would be predictive of their future success which may explain why they maintained their over confidence.

Michelle

When describing why they felt confident about their math work, Michelle said it was because they felt the material was mostly review. They said, "[I feel] pretty confident, especially in the class I am in now because the stuff we're doing, I have already done." When asked about understanding the material Michelle said, "Just from my academic background, I feel that I'll be able to get through the course fairly easy because I've done math similar to this before." In spite of this, by the end of the course, Michelle's performance was lower than they initially predicted.

We can see their grade predictions throughout the course in Table 1. They initially predicted they would receive an A, changed to an A or B after exam 1, to a B or A (with the B first) in interview 2, and ended the semester with a B. In interviews, Michelle remained confident even after exam 1 because they attributed their low score on exam 1 to them forgetting their calculator. That is, they said, "I didn't get as good as the grade I would have gotten I believe with a calculator." They also said, "I thought I would have done way better and like looking at the exam doing it… it's just little tedious mistakes, which I believe from not having a calculator kind of screwed me over." However, as the course went on, Michelle continued to perform lower than they expected. After the first exam, when asked what they would do differently, Michelle said "I would bring a calculator, and maybe go slower… maybe some of the mistakes I could have prevented but I honestly think most of them were from the calculator." After the third exam they stated, "I was nervous about this exam and ended up making dumb mistakes. So, I was disappointed with this score (71%) because it was low, because of little mistakes and not actually because I don't know the concepts."

Table 1. Over Confident Grade Predictions Over the Semester.

Participant	First Prediction (before exam 1)	Survey 2 Prediction (before grade for exam 1)	Interview 2 Prediction (after exam 1 grade)	Final Grade
Lisa	A-	A	B or C	C
Michelle	A	A or B	B or A	B
Adrian	Low B	High C, Low B	C	F

In general, Michelle initially seemed to be over confident because they believed the material was review. However, they then seemed to maintain their overconfidence because they blamed their lower performance on what they termed "little mistakes" and forgetting a calculator. This type of reasoning, blaming something external like a calculator, is often called an external attribution (Kelley & Michela, 1980). In the end, Michelle did reconcile their performance with their MSE by slowly lowering their MSE (suggesting a B was possible by Interview 2) but they never entirely gave up their prediction of receiving an A. That is, Michelle seems to be a case of remaining slightly over confident throughout the semester, with some reconciliation happening around Interview 2.

Lisa

Like Michelle, Lisa also believed the math in the intermediate algebra course was review. Lisa said "I've noticed, especially in [intermediate algebra], I feel like it's the same stuff I learned in Algebra 2 [High School]. So, I feel like I'm reviewing a lot of the time." And "It kind of just feels like I've been reviewing, I mean I know it's only like four weeks in… So, I don't really know what to expect in the future, but as of right now, I feel like it's all review." Based on this initial belief, Lisa predicted they would receive an A- in the course. Table 1 shows their grade predictions throughout the course of the semester. We see that after exam 1 (before they received their score) their MSE had increased, and they believed they would receive an A. However, by Interview 2, they had lowered their MSE closer to their actual final grade. In Interview 1, they said they felt "pretty confident" in the course but, when asked how they felt in the second interview, they said "not very confident." Despite this, Lisa continued to be somewhat surprised by their exam scores throughout the semester; for example, regarding the third exam Lisa said, "I thought I'd do better on this exam."

Lisa's initial over confidence seemed to stem from their belief that the course was review and this over confidence seemed initially reinforced by the exam. In addition, like Michelle, Lisa also demonstrated an external attribution for her lower performance, and this seemed to help maintain her over confidence. In particular, Lisa partially blamed the instructor for their lower-than-expected scores. Lisa said, "[My professor] doesn't teach in a way that I have normally been taught to do math and this unit is something that I've never done before like rational expressions and equations. So, I've been struggling." Lisa also stated of their instructor "I don't really think my teacher has covered enough of [the material] for me to understand." As the semester went on, Lisa also felt the material became more difficult, which may be why they lowered their MSE. These lower-than-expected scores were motivating to them, causing them to study harder which helped them sustain higher MSE (believing the extra studying would raise their performance). Regarding the final exam they stated, "I definitely studied a lot more leading up to the final after I received my previous test grades." Despite this, Lisa received a C in the course and, in the final survey, expressed not understanding the material as well as they thought.

In the end, Lisa did not reconcile their performance with their MSE until Interview 2, where they predicted a C was possible and described themselves as not very confident. Lisa seems to be a case of being over confident in the beginning but, as the difficulty of the material increased and they continued to perform poorly, reconciling their MSE and performance by lowering their MSE. In addition, we also see that external attributions for poor performance helped Lisa maintain their over confidence.

Adrian

Adrian demonstrates a different reason for over confidence than Michelle and Lisa. Adrian had actually taken the course before, referencing that this was their third or fourth time through this same material. From the beginning, they expressed a lot of doubt in their abilities to succeed in math courses in general; they specifically said that they were not confident, yet were hopeful, that they would pass intermediate algebra at the college level. Adrian initially predicted they would receive a low B in the course.

As shown in Table 1, between Interview 1 and Interview 2, Adrian's MSE did fall but did not align with their final course performance. In fact, Adrian's MSE never fully aligned with their performance. There seemed to be several reasons for this. First, Adrian responded to lower-than-expected performance by working more and getting help. They said, "I attempted to study more, by working out more problems and getting help from others in the class." Overall, Adrian seemed to believe working out more problems and working with classmates would result in better performance though, sadly, it did not. Adrian also believed that their homework and quiz scores could make up for poor exam performance, leading them to believe they could still perform well in the course. They said, "I know that I absolutely will not ace any exams, but I can probably still pass [the course] with the quizzes and homework." Unfortunately, this is not true with the grade calculations of the course.

Finally, one other reason for Adrian's high MSE seemed to be that, during the course, they were diagnosed with ADHD for the first time. In the second interview, Adrian seemed more hopeful that the course would go well because they finally felt like they could learn to navigate having ADHD and then do better in the class. Adrian said, "Currently I'm trying to find a medication that works for my ADHD and getting accommodations... So that may help once I find the right medication [and] actually get the accommodations." Adrian seemed to attribute their past low performance externally, to ADHD, and seemed to believe that fixing this ADHD would help them succeed. However, in the end, Adrian was not able to pass the course.

Across the Cases

Looking across the three cases, two themes emerge. First, all three students did lower their MSE during the semester. That is, their continued lower than expected performance did lead to lower confidence in their ability to be successful in intermediate algebra. However, this reconciliation was slow (happening around interview 2 and not always ever fully aligning with their final grade). Second, the reason this reconciliation was slow varied by participant but included students externally attributing their poor performance (it was the teacher, the lack of a calculator, or ADHD) as well as believing that changes (studying more or getting ADHD treatment) would raise their future performance. Overall, we see that all participants doubted that their initial exam scores were predictive of future performance (allowing them to maintain over confidence). Their MSE only started to lower once they had repeated lower performance.

Discussion

Previous research has shown IMSE can exist though this research often lacked detail, was not at the collegiate level, or was not in mathematics (Chen, 2006; Dassa & Nichols, 2019; Wyatt, 2014). Our work shows that IMSE does exist in collegiate mathematics and describes qualitatively what that IMSE can look like. In addition, no previous research had examined how IMSE was reconciled with performance. Our study shows that over confident students do slowly reconcile their IMSE with their performance by lowering their MSE. However, this can be slow because students externally attribute their low scores and have reasons to doubt their performance scores will be predictive (because they are changing their behavior).

Recall that Sheldrake (2016) found that students with IMSE may base their MSE on sources other than mastery experiences (performance). Sheldrake found, in particular, that over confident students based their MSE beliefs on the perceived utility of mathematics. Unlike in Sheldrake's study, our participants never mentioned the utility of mathematics as a reason for their MSE; however, given they were taking a mathematics course required for graduation, they were presumably aware of the utility for their degree. Also in contrast with Sheldrake, we did not find that participants were basing their MSE on sources other than performance; that is, they were not basing their MSE on social comparison, vicarious experience, or affective/ physiological state. Instead, we found that participants with IMSE were using performance as a source of MSE but had reasons to doubt their performance measures were predictive of the future because they externally attributed their low performance and changed their behavior. However, these external attributions and behavior changes did not lead to them being more successful.

Limitations and Future Work

The first limitation of this study is the small sample size. Having only fifteen participants, all from the same university, limits our ability to extrapolate results. The choice of a small sample size allowed us to collect detailed qualitative data at five points in time throughout the semester. However, while we were able to identify three cases of over confidence, we were unable to identify cases of under confidence. It is unclear if this is because this is rare or if participants with under confidence simply did not participate in the study. This could be a topic for future research where larger sample sizes might help better identify such participants.

An additional limitation is the self-reporting nature of the surveys. Self-reporting is necessary to capture the MSE beliefs of students at a point in time and is common in previous research on MSE (Dassa & Nichols, 2019; Hackett, 1985; Pajares & Miller, 1995). However, one issue that can arise is students' desire to give the "correct" answer, how they think they "should" feel. To account for this, in the interviews, we asked students to describe and elaborate on their MSE beliefs multiple times and then used member checking to ensure trustworthiness. However, it is always possible that students did not share the full truth with us as researchers.

Implications for Practice

The findings in this study indicate that instructors should be aware of students who are under or over confident and potentially take measures to help students calibrate their MSE beliefs with their performances. This is not to say that we need to go around lowering or raising students' MSE beliefs, but rather that we should try to help students become aware of their own abilities in realistic ways. Perhaps we can design instructional material that includes components of introspection alongside the content. Such introspection could increase the likelihood that students will adjust their MSE beliefs accordingly.

Another aspect of this study that is informative for instructors is that MSE beliefs can change over the course of the semester. What this means for instructors is the need to "keep a pulse" on their students and their MSE beliefs. This is especially true with repeated performances that are not what the student initially expected. Instructors could help students by encouraging them to have a personal meeting with the instructor after the first or each exam. This session would not have to be very long, but it would be a time to address the student's performance on the exam, any questions they missed, and the long-term effects of the exam and their current homework or quiz performances on their grade. This counseling session could help students to have a better understanding of the situation they are in and calibrate their MSE and performance better.

Overall, our results show that IMSE exists, is a result of specific reasons from the students' course (e.g., initially seeming easy), and is based on factors similar to MSE but with students perhaps interpreting these factors differently than instructors. Learning about IMSE serves as an opportunity for instructors to better understand their students and help their students better understand themselves and what leads to their success. If we can continue the pursuit of helping students achieve their goals and learn about themselves, we can increase student success in mathematics.

Knowledge Resources for Multiplication and Challenges Reasoning About the Product Layer

Andrew Izsák
Tufts University

Olha Sus
Tufts University

Research on students' construction and interpretation of integrals has grown significantly over the past decade. Some work has identified classes of interpretation for definite integral notation that include areas under curves, antiderivatives, and adding up pieces. The present study contributes to recent research on challenges students experience with the "product layer," $f(x) \cdot dx$, *when reasoning about adding up pieces. In particular, we present a case study in which 1 college student in a first-semester, calculus-based physics course drew on multiple knowledge resources associated with multiplication as she tried to construct a definite integral in a situation that for her was novel. Our results suggest that students' understandings of multiplication with quantities is understudied in the literature on integration and an important direction for further research.*

Keywords: Calculus, Integration, Product layer, Knowledge-in-Pieces

Introduction

An earlier generation of research on the teaching and learning of calculus focused primarily on limits and differentiation (e.g., Larsen et al., 2017; Rasmussen et al., 2014). Although research on integration goes back several decades (e.g., Orton, 1983), research on the topic has accelerated considerably in the last decade (e.g., Jones & Ely, 2023). We concur with Oehrtman and Simmons' (2023) recent observation that research to date has focused on "students' meanings associated to components and relationships within the standard definition of a limit of Riemann sums" (p. 36). Less research exists on students' moment-to-moment reasoning when constructing integrals to model problem situations. Furthermore, in our reading, existing literature has hinted at challenges students can experience coordinating multiplicative relationships between quantities with understandings of integration. This same literature, however, has stopped short of examining such challenges closely.

In the present study, we analyze in detail the reasoning of Larisa, one college student drawn from a larger study in which we examined how first-semester, calculus-based physics students coordinated reasoning about multiplication with quantities with reasoning about definite integrals. The analysis provides an existence proof that such coordination can be complex and, thus, suggests that inattention to students' reasoning about multiplication with quantities is understudied in the literature on integration and an important direction for further research. We asked the following research questions:

1. *What knowledge resources did Larisa evidence when reasoning about multiplication with quantities?*
2. *How did Larisa coordinate her multiplication resources with understandings of definite integrals to solve what was for her a novel problem?*

The first question asks about resources related to multiplication broadly and independently of integration. The second question avoids situations where Larisa might simply recall previously learned relationships—for instance, that velocity is the integral of acceleration.

Literature Review

Although definite integrals are defined as limits of Riemann sums, researchers have debated the role of these sums in students' reasoning. Jones (2013, 2015a) drew on Sherin's (2001) symbolic forms to classify how nine college students interpretated definite integral notation. He reported three primary forms. For the *perimeter and area* form students interpreted the integrand, the limits of integration, and the x-axis as boundaries of an enclosed region *not* partitioned further or approximated. For the *function matching* form, students interpreted the differential, *dx*, as indicating that the function to be integrated, *f*(*x*), is the derivative of some other function that is yet to be determined. For the *adding up pieces* form, students interpreted the $f(x)dx$ notation as indicating small amounts of a target quantity that are then added. Finally, if one interprets $f(x)dx$ as a product, then one can think of a multiplicatively-based summation (e.g., Jones 2015a). Thus, this last form is well-aligned with the definition of a Riemann sum. (Thompson & Silverman, 2008, developed an alternative approach to integration based on *accumulation from rate*.)

We highlight four themes related to the *adding up pieces* form. First, even after instruction, Riemann sums often remain peripheral to students' understanding of definite integrals (e.g., Jones, 2015a, 2015b; Jones et al., 2017; Rasslan & Tall, 2002). Second, students can be confused by using rectangular areas to model other quantities, such as distances (Thompson et al., 2013). Third, within the traditional $\int_a^b f(x)dx$ notation students can have trouble interpreting $f(x)dx$ as expressing multiplication (e.g., Ely, 2017; Jones, 2013; Sealey, 2014). Sealey provided the most direct result: She decomposed reasoning about definite integrals into five layers—orientation, product, summation, limit, and function—and reported that college calculus students had the most difficulty reasoning about $f(x)dx$ in the product layer. She concluded that students had trouble not with calculations but with "**understanding what is being multiplied together and what quantity is produced from that multiplication**" (p. 240). Fourth, there is debate over the range of situations to which the multiplicatively-based summation and Riemann sum interpretations can apply. Meredith and Marrongelle (2008) claimed that (a) multiplicatively-based summation only makes sense when the quantity being integrated can be conceived of as a rate and (b) thinking about the electric field at a point, q_1, due to a bar charge is better thought of as summation of small effects. We question whether this really is a counter-example: The small effects in this linear situation can be thought of as the accumulation of the rate of field strength per unit of charge, $\frac{k}{r^2}$, multiplied by the charge in small segment of the bar, Δq, a distance *r* from q_1.Thus, conceiving of the quantity being integrated as a rate applies more broadly than previously acknowledged.

The present study builds most directly on Oehrtman and Simmons' (2023) recent discussion of *Emergent Quantitative Models* for definite integrals, which consists in turn of three primary models. A *basic* model is based on constant values for quantities. A *local* model is an adaptation of a basic model to a small portion of an object or event in which quantities may be approximated as constant. A *global model* is derived from the accumulation of local models. These researchers presented examples to demonstrate that student reasoning can involve varied interactions among basic, local, and global models. Examples include making different choices for (a) which factor in a product to treat as infinitesimal and (b) partitioning. At the same time, they stopped short of considering students' ecology of knowledge resources for multiplication.

Theoretical Framework

Our theoretical frame combines mathematical structure (as perceived by experts) with cognitive components evidenced by students. Vergnaud (1983, 1988) analyzed mathematical structures for multiplication with quantities and distinguished two subtypes of multiplication situations. In an *isomorphism-of-measure-spaces* situation (I-O-M) the multiplicative structure consists of a simple direct proportion between two measure spaces M_1 and M_2 (1983, p. 129). An example is a measure space for time in seconds, a measure space for distances in meters, and the relationship $\frac{meters}{second} \cdot seconds$. In a *product-of-measure-spaces* situation (P-O-M) the multiplicative structure consists of the Cartesian composition of two measure spaces, M_1 and M_2, into a third, M_3 (1983, p. 134). An example is a measure space for area in cm^2, a measure space for height in cm, and the relationship $area\ (cm^2) \cdot height\ (cm)$. The distinction between I-O-M and P-O-M situations highlights two different ways one might interpret $A \bullet B$ as a basic model.

For the cognitive component, we draw from the knowledge-in-pieces epistemological perspective. The perspective was first developed in science education research on conceptual change (e.g., diSessa, 1993, 2006) and has been applied to various topics in mathematics, including multiplication (Izsák, 2005; Izsák et al., 2021), functions (e.g., Moschkovich, 1998), and integrals (Jones, 2013). From this perspective, reasoning is supported by diverse, fine-grained knowledge resources and novice knowledge evolves into expert knowledge through processes such as the construction of new knowledge resources that are sensitive to context for activation, refinement of contexts in which resources are applied, and reorganization that can involve forming new connections among some resources and loosing connections among others. In the present study, we examined knowledge resources Larisa cued and evidenced when reasoning about multiplication with quantities in the context of definite integrals.

Methods

We conducted one-to-one, semi-structured interviews (e.g., Bernard, 1994; Ginsburg, 1997) to assess how physics students reason about multiplication with quantities and the integral concept in both I-O-M and P-O-M situations. In Spring 2023, we recruited five students enrolled in first-semester, calculus-based physics at a selective university. Each participant completed three, 1-hour interviews spaced a few weeks apart.

The first interview asked students to reason about three situations—two I-O-M situations about estimating distance from varying velocity and one P-O-M situation about estimating volume from varying cross-sectional areas. The tasks were ones for which one could first multiply and then add to construct a total, but there was no mention of integration. We paid close attention to how students assigned units of measurement to quantities when multiplying. The second interview asked students to reason about two P-O-M problem situations (one estimating volume from cross-sectional areas and one about person-hours) and then to interpret the $\int_a^b f(x)dx$ notation in the context of each. We paid close attention to how students reasoned about units and graphical representations when interpreting integrals. The third interview asked students to reason about two I-O-M situations (one about water pressure on wall and one about acceleration from rest) and then to interpret the $\int_a^b f(x)dx$ notation in the context of each. Again, we paid close attention to how students reasoned about units and graphical representations when interpreting integrals.

We recorded the interviews using two cameras, one to capture the student (body movements, hand gestures, etc.) and the interviewer and one to capture close ups of the student's written work. We collected all written work for later analysis at the end of each interview. We used a computer to synchronize and combine the two video recordings file into a single file. In addition, we transcribed the interviews verbatim.

We watched videos for all five students side-by-side with the transcripts. After multiple viewings of the interview data, we narrowed our attention to Larisa and studied her as a particularly good case for our research questions. She provided evidence for several resources related to multiplication with quantities but, at the same time, coordinating those resources with her understandings of definite integrals was not straight forward, particularly when working on the Water Pressure task in Interview 3. We then traced Larisa's spoken language, hand gestures, and drawings in more detail to make sense of her reasoning.

Results

Larisa was majoring in engineering and self-reported good grades (B range) in her prior precalculus and calculus courses and on the calculus AB exam. We summarize a few key points from Interview 1 and Interview 2 before discussing in detail her performance in Interview 3.

In Interview 1, Larisa used the trapezoid method on a velocity graph to estimate distance traveled and focused on computations—for instance, when asked where she saw distance in her work, she canceled units in $\frac{feet}{\cancel{second}} \cdot \cancel{seconds}$. She appeared to understand such cancelation as a formal method for determining units for the product, but she did not connect her symbol manipulation to her graph. She also gave a fluent explanation for how to estimate the volume of liver when given cross-sectional areas in cm^2 and spaced 2 *cm* apart. In particular, she recalled multiplication from the formula "length times width times height gives you volume." In Interview 2, Larisa considered a similar liver problem when given cross-sectional areas in cm^2 and spaced 1/3 *inches* apart. This time, she discussed the integral as giving the area under a curve; but, her explanation for the role of multiplication was imprecise. At one point she commented "if you multiply the *x* axis by the *y* axis….you get the whole area under [the graph]." At another point, she commented "I just kind of know you have to write the *dx*. I kind of, like I haven't done integrals in a while, so I kind of forget why it's exactly that way, but it's like this means integral. So this means area under the curve." Finally, she mentioned "the integral is the opposing, I guess the inverse of the derivative." Thus, in Interview 1 and Interview 2, Larisa articulated two meanings for integrals (areas under curves and anti-derivatives) and recalled how multiplication related quantities in familiar situations; but, she did not provide evidence for interpreting $f(x)dx$ as a product.

For Interview 3, we adapted the Water Pressure task (Figure 1) from prior studies (e.g., Oehrtman & Simmons, 2023; Sealy, 2014). In so doing, we deliberately omitted direct references to multiplication and integration because we wanted to see how students would reason about these spontaneously in what for them was a novel task. We also omitted units for pressure and for force, because we did not want students to rely on formal cancelation of units. Using Oehrtman and Simmons' (2023) terms, the basic model would be *pressure* • *area* = *force*, or $P \bullet A = F$, and the corresponding local model would be $15x \bullet 4\Delta x$. Larisa did not produce a complete correct solution, but the multiplication knowledge resources she cued could play a central role in one or another of at least three different correct solutions. The first solution follows Oehrtman and Simmons' local model and computes $\int_0^3 15x \bullet 4dx = 270$. The second solution considers the average pressure on the wall. Because the pressure varies linearly with respect to depth, the total force on the wall is the pressure at the average depth multiplied by the area of the wall. In this case, 22.5 • 12 = 270. The third solution considers the force per 1-foot width of wall multiplied by the width of the wall in feet. In this case, $\int_0^3 15x\,dx$ • 4 = 67.5 • 4 = 270.

> Pressure, P, applied across a surface area, A, creates a total force, F. Consider a vertical side wall of a tank with a width of 4 feet and a maximum depth of 3 feet (see picture below). Assume that the tank is full of water. The pressure on the tank wall increases with the depth of the water according to the following law: $P = 15x$, where x is the depth of the water (the deeper the water, the greater the pressure). Given this information, describe a method for approximating the total force from the water pressure on the wall.

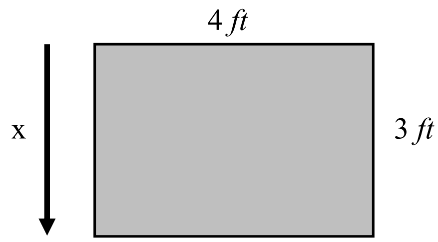

Figure 1. The Water Pressure task

Data

Upon reading the task aloud, Larisa reported that she did not recall working similar tasks in her prior experience. She graphed pressure as a function of depth, shaded the area under her graph, and stated that "taking like the integral of this bottom piece here would probably get you the total force kind of applied throughout" (Figure 2). She then computed the area of the triangle, $\frac{3 \bullet 45}{2} = 45 + \frac{45}{2} = 67.5$, and stated she was not sure what units to attach to force. Finally, she computed the area of the wall and multiplied 67.5 • 12, stating that 67.5 was the "average pressure." She concluded with the following explanation for how she saw multiplication in the situation:

> *Larisa*: Some pressure applied across a surface area creates a total force. That sounds like a very English way of saying like *P* times *A* equals *F*. Um, I think I would definitely like think you need to take the average in order to at least have it be an easier problem, because I don't know how you would do it if you were just kind of going like piece-by-piece as the pressure is increasing. That seems difficult and weird.

Analysis

Larisa relied on the text to cue multiplication in a novel situation and articulated an appropriate basic model, *P* • *A* = *F*. She also introduced both holistic and local approaches to the task. She initiated the holistic approach by cuing the notion of an average value, which she incorrectly associated with the integral or area under her graph of the pressure function. She then multiplied what she took to be the average pressure, 67.5, and multiplied by the area of the wall. This reasoning overlapped with the second solution discussed above when she multiplied by 12 and with the third solution discussed above when integrating the pressure function from 0 to 3.

When reasoning that integrating a pressure function would give an average pressure, Larisa did not seem aware that the units for the region under her graph would be different than those for pressure. This complemented the data from Interview 2 that multiplication with quantities was not well-coordinated with reasoning about integrals. At the same time, Larisa's discussion of “going like piece-by-piece” suggested that she gave initial consideration to a solution based on adding up pieces but predicted that this approach would be “difficult and weird.”

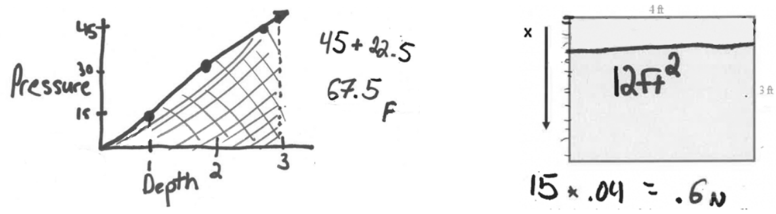

Figure 2. Larisa’s work on Water Pressure task (converted to grayscale)

Data

Larisa continued to compare her approach based on averages to an approach based on adding up pieces. On the one hand, she recalled how the meaning of the integral was explained in her past calculus classes: “That’s like how they explain integrals in class. They’ll explain it as like a ton of really small sections, and then you just add them all up.” At the same time, she remained skeptical: “I think if you were to do the force on like one of those really, really, really small sections, it would just be really small, because the surface area would be basically nothing. So you kind of need it to be a larger scale thing.” At the interviewer’s request, Larisa drew a horizontal line on the wall to indicate what she meant by a “small section” and wrote an appropriate multiplicative expression (i.e., the local model) for the force: $15 * .04 = .6\ N$ (Figure 2). She explained:

> *Larisa*: Like at 1 foot, and it’s 0.01 part of a section. So it would be 15, which is the pressure at that depth, and then times .01 times 4, so like .04, and then that would equal .6 Newtons. And that’s like just a really small amount. And like you can go smaller than that, and you like, it like just infinitely gets smaller to the point where like it doesn’t matter, nobody’s going to ask you that question. Because like you’re asking about just like the pressure on like a crack in the glass, and that’s not, that’s not helpful.”

Analysis

Larisa clearly recalled from past instruction the adding up pieces interpretation of the definite integral, and she gave a clear explanation for a normatively correct local model where she assumed a constant pressure over a thin, rectangular area. At the same time, even though she knew such reasoning would be encouraged in class, she rejected it in favor of “a larger scale thing.” Thus, Larisa’s appropriate local model was in tension with her sense of what could contribute to a consequential effect. Part of the issue may have been lack of experience accumulating many small contributions into a larger effect.

Data

An exchange later, the interviewer recalled Larisa’s comment about an English way of indicating multiplication and asked for more detail. Larisa responded:

> *Larisa*: Multiplication makes sense because I don’t, because addition doesn’t because, and I don’t know the units, but like in order to get a new unit, it would need to be multiplication or division. Because addition would just be like, you can’t add pressure and surface area. It’s not like terms. You would need to multiply them to create a new term, which would be force.

She reiterated that “total” cued multiplication and explained that division would be for a “specific point.” A few exchanges later, she restated that the area under her graph for the pressure function gave an average pressure and provided another example analogous to her 67.5 • 12 calculation—she considered 1 foot of water depth and multiplied the triangular area under the pressure graph by the area of a 1 *ft*-by-4 *ft* section of wall, 7.5 • 4.

Finally, after working for a while on another task, Larisa returned to the Water Pressure task, wrote "$\int of\ P$", computed $\frac{15x^2}{2}$, and explained that she was trying to see if this would also solve the problem. She evaluated her expression at $x = 3$ and got 67.5 once more.

Analysis

Similar to her work in Interview 1, Larisa demonstrated connections between multiplication and transformation of units when she said, "You would need to multiply them to create a new term, which would be force." We think it likely she was thinking about "new terms" when she performed her 67.5 • 12 and 7.5 • 4 calculations, even if she was unsure which units to use for pressure and for force. At the same time, she did not reference transformation of units when thinking about area under her graph of the pressure function. She characterized this area as the average pressure early on in her work and restated this interpretation after discussing multiplication to create a "new term." Somehow notions of area under a curve did not cue for Larisa a similar transformation of units.

Conclusion

To answer our first research question, Larisa demonstrated a variety of knowledge resources associated with multiplication, including some specific results (e.g., recalled *speed* • *time* = *distance* and *area* • *height* = *volume* relationships) and some general associations with finding totals, transforming units, and taking averages. She used these resources to distinguish multiplication situations from those calling for addition, subtraction, or division. Because each of these multiplication resources could support one or another of the three solutions we mapped for the Water Pressure task, none was inherently correct or incorrect. What mattered was how she employed subsets of the these resources when reasoning. To answer our second research question, Larisa mentioned antiderivatives in passing when working on the Water Pressure task, and discussed antiderivatives to a greater extent when working on further tasks about relationships among distance, velocity, and acceleration. More often, she attended to areas under curves, but did so in different ways. In Interview 1, she clearly broke up areas into trapezoidal pieces and added, but in Interview 3 she did not partition the area under her graph for the pressure function. Instead, motivated by what she perceived to be an efficient solution, she computed integrals as areas of triangles. From our perspective, when interpreting these areas as averages, Larisa combined using the total area of the wall from the second solution we mapped with the force per 1-foot width from the third solution we mapped. Again, using averages was not inherently correct or incorrect. Most striking was her use of multiplication to construct the normatively correct local model which she then rejected as less useful than a holistic approach. Larisa' use of relevant resources in combinations that do quite work and competition between a normatively correct local model with others of her resources underscore the complexity of coordinating reasoning about multiplication with reasoning about integration.

Moving Between Abstraction Levels by Linking Recursion and Induction

L. Marizza A. Bailey

Dov Zazkis
Arizona State University

Alison Mirin
University of Arizona

The relationship between mathematical induction (MI) and recursion compels us to ask how we could leverage recursive functions to bolster students' understanding of MI. We describe task-based interviews that utilized concurrent interactions with MI tasks and recursive functions that mirrored those induction tasks via a character-based user-interface. To gain insights into how students' conceptions of MI and recursion co-evolved as they interacted with these tasks, it was necessary to accommodate these multiple concurrent contexts by extending Hazzan's (1999) Reducing Abstraction framework. Our extended framework, called the Navigating Abstraction framework, documents ascending, descending, and transferring abstraction levels across contexts. Viewing the data through this lens allowed us to illustrate the way in which these three mechanisms together play a crucial role in students joint development of their understandings of both recursion and induction.

Keywords: Mathematical Induction, Recursion, Proof, Reducing Abstraction

In this paper, we study how students cope with the abstraction required to understand both mathematical induction (MI) and recursion by leveraging the link between them. Accordingly, we designed and implemented an instructional sequence of parallel recursion-MI tasks. In order to determine the abstraction level at which students understood recursion and MI, it was necessary to extend the Reducing Abstraction framework (Hazzan, 1999, 2003). Our extended framework, called the *Navigating Abstraction* framework, provided a lens for examining how students' understanding of recursion and induction co-evolved as they ascended and descended levels of abstraction as well as transferred levels of abstraction across contexts. We use the term *recursive program* to describe a computer program whose primary purpose is educational, but whose primary mechanism is recursion. Our study addresses the two research questions:

1. How does interaction with a recursive program (which mirrors an MI task) affect students' conception of MI?
2. How does concurrent interaction with both a recursive program and MI task affect student's understanding of the relationship between them?

Literature and Framework

Mathematical Induction involves a logical statement which is applied as a technique for proving statements involving countably infinite sets. In fact, taken separately, the abstract nature of proofs (Davis et al., 2009; Healy & Hoyles, 2000; Knuth et al., 2009), complex logical statements (Durand-Guerrier, 2003; Roh, 2010; Stylianides et al., 2004), and infinity (Davis et al., 2009; Wijeratne & Zazkis, 2015; Dubinsky et al., 2005) have all been shown to entail conceptual hurdles, resulting in a substantial body of literature on MI highlighting obstacles to its conceptualization (Baker, 1996; Brown, 2008; Dubinsky, 1989; Harel & Sowder, 1998). Research on students' understanding of MI (Brown, 2008; Davis et al., 2009; Harel, 2002) suggests that the inductive step may pose an obstacle to understanding MI. Furthermore, findings from these studies indicate that understanding the inductive step of MI requires a transition from perceiving MI as a process relating finitely many cases to interpreting MI as an infinite iterative process (Brown, 2008). Additionally, the statement of MI is a complex conditional statement regarding the truth value of a predicate function defined on the positive integers, and studies have found that conditional statements are often misinterpreted (Hoyles & Küchemann, 2002; Stylianides et al., 2004).

Given that the Reducing Abstraction framework (Hazzan, 1999, 2003) has been effectively used in both computer science education research (Hazzan & Hadar, 2005; Rich & Yadav, 2020; Sakhnini & Hazzan, 2008) and in mathematics education research (Hazzan, 1999; Hazzan & Zazkis, 2003; Raychaudhuri, 2014), we felt it was well suited for our Computer Science/Mathematics context.

Hazzan's (1999, 2003) framework is built on a variety of interpretations of abstraction that collectively form the basis of the framework. Each interpretation can be applied to examine students' understanding of concepts in pure mathematics, applied mathematics, computation, and data structures. We summarize the characterizations of each of her interpretations of abstraction below:

1. *Abstraction level as the quality of the relationship (QR) between the object of thought and the thinking person* (Hazzan, 1999) refers to the interpretation that abstraction is not an inherent property of a concept, but rather the relationship between the person thinking about the concept and the concept itself. For example, when students are confronted with a problem and are "fumbling in the dark without any mental object to hang onto" (Hazzan, 2003, p. 107), they may subconsciously reduce the level of abstraction by turning to a familiar concept, experience, or object.
2. *Abstraction level as reflection of the process-object duality (POD)* (Hazzan, 1999) is built on earlier work on the process object distinction (Dubinsky, 1991; Sfard, 1991*)*. This construct refers to the interpretation that conceiving a mathematical concept as a process is at a lower level of abstraction than examining it as a mathematical object. When a concept is understood as an object, one can examine the relationships between two concepts. However, if it is perceived as a process, the concept is expressed using canonical procedures (Hazzan, 2003).
3. *Abstraction level as the degree of complexity (DC) of the mathematical concept (Hazzan, 1999)* refers to the interpretation that the more complex an idea is, the more abstract it is. One may reduce the level of abstraction of an object by reducing its complexity. For example, a student may replace a set with an element of the set.

To demonstrate the utility of Hazzan's framework, we view the following results from existing MI literature through the interpretations the framework provides. (1) We could interpret Harel and Sowder's (1998) findings that students viewed MI as generalizing a conclusion by computing a few cases as reducing the abstraction level as the quality of the relationship (QR) because they were choosing to rely on more familiar computations of concrete examples rather than the unfamiliar concept of MI. (2) We can interpret Brown's (2008) observation that students had ignored some aspects of an MI task and "reduced the task to an algebraic" (p.13) process as reducing abstraction as a reflection of process-object duality (POD). Finally, (3) interpreting the results of Baker (1996) through the lens of reducing abstraction, we can conclude that by omitting the base case, students removed a conjunction from the hypothesis of MI. This rendered the complex statement comprising MI, which is of the form " if [P and (Q implies R)] then S" to a simpler statement "If [Q implies R], then S", thereby reducing the abstraction level of MI as the degree of complexity (DC). The above three examples demonstrate established results from MI literature can be viewed through the lens that the reducing abstraction framework provides.

During our analyses of students working on parallel MI-recursion tasks, it became clear that (a) students sometimes engage with recursion and MI at different levels of abstraction and (b) as students used parallel contexts, their movement between levels of abstraction was not limited to reducing levels of abstraction. These observations catalyzed our expansion of the framework. We call this expanded framework the *Navigating Abstraction* framework. The expanded framework utilizes constructs not included in Hazzans (1999) framework. More specifically, we say that one *ascends levels of abstraction* when they move from a lower to a higher level of abstraction and *descends levels of abstraction* when they move from a higher to a lower level of abstraction. Additionally, we identify instances when a student navigates through different aspects of the task but remains on the same level of abstraction. When such a phenomenon occurs, we say that the student has *transferred abstraction levels* from one aspect to another. Therefore, our framework provides a lens through which we can make sense of the interplay between a student's movement between levels of abstraction and between the MI and recursion aspects of our tasks. This allows us to document how interacting with the tasks in this study facilitates the development of students' understandings of MI and recursion and the connection between them.

The framework for analyzing the level of abstraction as QR with respect to each aspect of a task is shown in Figure 1. There are analogous figures for navigating abstraction via the other interpretations in the framework, but they are too large to fit within the margins of this paper.

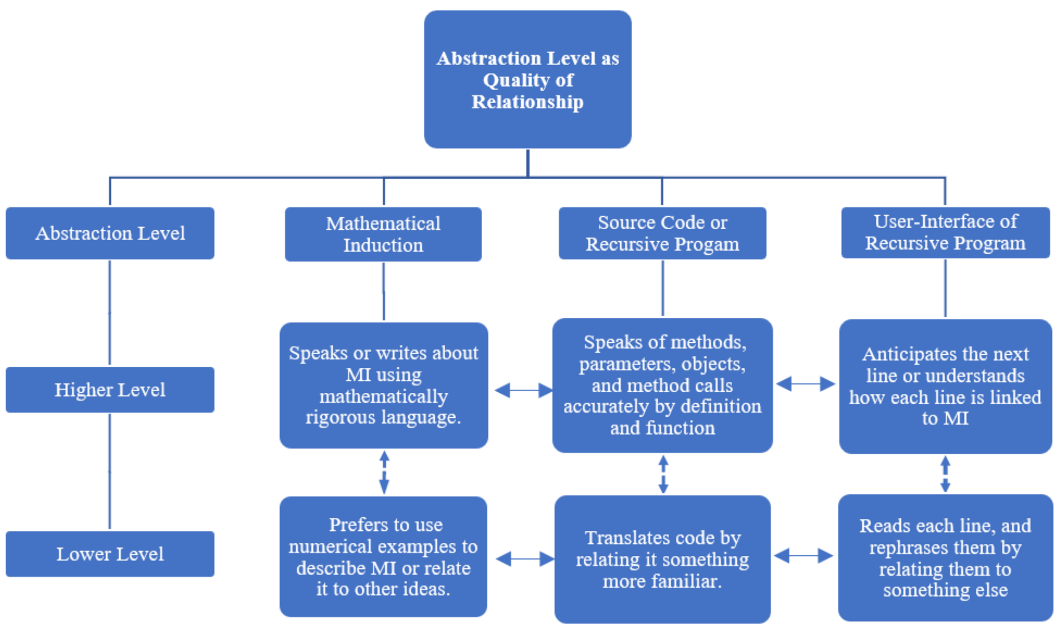

Figure 1. Framework for analyzing abstraction levels as QR with respect to the three aspects of each task.

Methods

Mario, Harry, and Sarah were senior math majors at a public university who took part in a 90-minute, semi-structured, task-based interview study, based on the exploratory teaching experiment methodology (Steffe & Thompson, 2000). The first author of this manuscript functioned as the teacher/researcher and performed the interviews.

The interviews consisted of tasks where MI was presented along with a user-interface and the source code for the corresponding recursive program, to which students could attend at their own pace. Students were prompted to think aloud while they worked, especially if the direction of their gaze changed from screen to paper, or vice-versa. While we found that the *Navigating Abstraction* framework was productive for accounting for our entire data set, due to space constraints, we limit ourselves to discussing Mario's work on Task 1 (The sum of the first n integers is $\frac{n(n+1)}{2}$) and Task 4 (Every positive integer can be written as a sum of powers of 2).

Results

To identify movement between abstraction levels, we focused on the utterances and inscriptions that indicated the participants were directing attention to mathematical induction (MI), the source code (RS), or the output of the recursive program (RP). We focus on two episodes that illustrate how Mario both transferred and navigated between abstraction levels. These examples simultaneously illustrate our *Navigating Abstraction* framework and provide insights into how a student might leverage the connections between MI and recursion to strengthen their understanding of both.

Mario Ascends Abstraction Levels

When Mario worked on Task 1 before accessing its corresponding recursive program, he only spoke about the computation required to validate the equation on which induction was to be performed. Mario's work, which can be seen in Figure 2, does not include explanations or justifications. Later in this manuscript, we will see that Mario understood MI the full logical complexity of its statement, but there was no indication that he was evaluating the validity or truth of any statement; therefore, he did not understand that MI involved a predicate. As seen in Figure 2, Mario considered the entire hypothesis of MI from his written work, but never states the conclusion of MI to finish the proof. We interpret this interaction as working at a lower level of abstraction as POD while working at a higher level of abstraction as DC.

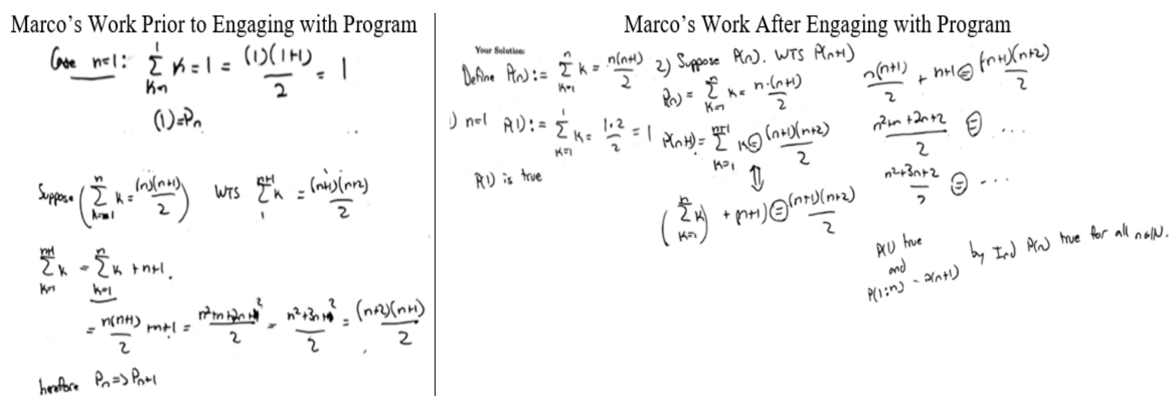

Figure 2. Marco's work on Task 1 before (left) and after (right) working with the recursive program.

The excerpt below highlights how he first makes sense of the MI task:

Mario: What I want to show is that the sum from 1 to n + 1 is n times $n(n+1)/2$. If I can show that this (the sum from 1 to n is $n(n+1)/2$) implies this (the sum from 1 to n +1 is $(n+1)(n+2)/2$). I have the sum that looks like the thing that I'm assuming I know what it is, and if I manipulate it, I should get the thing that I want.

While engaging with the RP aspect of Task 1, Mario first interpreted $P(n)$ not as a predicate, but as the partial sum from 1 to n, and then corrected himself: "Oh. It (the program) defines the statement ($P(n)$) to mean that those two things (left and right side of the equation) are equal. That's not the same thing." Mario expressed a shift in his thinking from $P(n)$ as an algebraic expression in n, to an algebraic statement in n which is either true or false. In other words, Mario was starting to conceptualize $P(n)$ as a predicate which indicates that he ascended levels of abstraction as POD with respect to the RP aspect of Task 1.

Mario chose to re-attempt the MI aspect of Task 1 and defined $P(n)$ as a function of n at the onset of the task, shown in Figure 2. After verifying the base case, he wrote "$P(1)$ is true", indicating that he now thought of $P(n)$ as a Boolean-valued function. Mario had transferred his perception of $P(n)$ as a predicate from the RP aspect of the task to the MI aspect of the task.

Furthermore, as seen at the bottom right of Figure 2, Mario finished the proof by writing the entire statement of MI, which was not included in the program's output or source code. Now that Mario is considering the entire conditional statement when working with the MI aspect of Task 1, we can deduce that he has ascended levels of abstraction as DC.

Mario navigates between abstraction levels

When attending to Task 4, Mario asked a question that he had not asked during any of the other tasks.

Mario: What's my $P(n)$ statement? My first thought is maybe I don't want to use induction on n, but maybe I do. I guess I'll try induction on n and see if that's the right thing. So what's my $P(n)$ statement? n is equal to a sum (pause) is equal to the sum over i equals something to something else.

Although Mario had not hesitated to define the predicate during the other tasks, his work in Figure 3 exhibits his indecision. In the previous tasks, MI was applied to a single-variable equation, but the equation generated by the statement in Task 4 had three unknowns. Mario's question demonstrates an unfamiliarity with the type of MI statement in Task 4. His discomfort with this new type of problem may explain his decision to work out some examples, as shown in Figure 3. Computing examples requires substituting variables with numerical values, consequently decreasing the number of variables. Thus, we could interpret Mario's decision to compute examples as working at a lower level of abstraction as QR with respect to the MI aspect of Task 4.

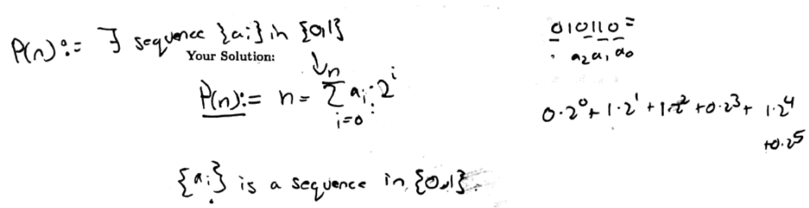

Figure 3. Mario's work prior to interacting with the recursive program.

To see more examples, Mario decided to use the recursive program for Task 4. By delegating the calculation of examples to the RP aspect of Task 4, Mario transferred the level of abstraction as QR from the MI aspect to the RP aspect of Task 4.

Mario: Okay, so we start, I guess an interesting case might be 15 because that's when we overflow the ones into a bunch of zeros.

Mario fluidly transitioned between the MI task and the recursive program's user-interface and source code. After each interaction with the program, Mario progressed further with the MI task. The excerpt below exemplifies the connections Mario was making between the MI aspect of Task 4 and the recursive function, Power2, located in the source code.

Mario: PowerTwo returns the string, which is yeah, the, the sum of powers of two that equal the number that you give it. So, how does it know to stop when n is greater or equal to

0?.. Oh, I have an idea. So, it recursively divides your, the integer by two. Okay and so I can do that too.

Interviewer: So, what gave you that idea?

Mario: Yeah, the PowerTwo. As long as we have a positive integer. Okay, it recursively divides by two and looks at it whether it's zero or one. So, I guess that is how you get the binary decomposition of a number. You keep dividing by two and you see if the thing you get is even or odd. So yeah, and this method uses that recursive loop to construct the sequence.

After connecting Power2 to a proof strategy, Mario resumed writing his proof. Note that Mario interpreted the code in Power2 in terms of its function as a program, indicating that he was working at a higher level of abstraction as QR with respect to RS aspect of Task 4.

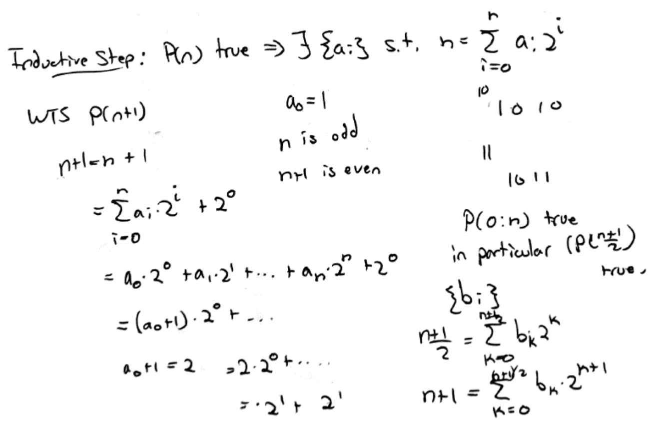

Figure 4. Mario's Proof of the Inductive Step of Task 4.

In his proof, shown in Figure 4, Mario divides $n+1$ by 2, then uses strong induction to represent $(n+1)/2$ as a sum of powers of 2. The sophistication of using two cases along with strong induction indicates an increase of rigor in his proof, suggesting that Mario transferred the higher level of abstraction as QR from the RS aspect to the MI aspect of Task 4. Hence, Mario ascended levels of abstraction as QR with respect to the MI aspect of Task 4.

During the final segment of the interview, the interviewer asked Mario how he conceived of mathematical induction. His response indicates that completing the tasks allowed him to make connections between recursion and induction that shifted his perception of MI.

Mario: Something I noticed. Instead of starting with *n* and going to *n* +1, you are decomposing *n* +1 into *n*…which reminds me a lot of recursion. Then induction is still *P*(*n*) implies *P*(*n*+1), but the way to do it is decompose *P*(*n*+1) into *P*(*n*) and that reminds me a lot of recursion.

To Mario, making the link between induction and recursion provided him with an additional strategy when approaching MI tasks. Specifically, he explains "if you know how to do an easy problem and you know how to decompose a hard problem into an easy problem, then you know how to do the hard problem."

Summary

During Task 1, Mario ascended abstraction as POD from the MI aspect of the task to the RP aspect of the task and then transferred the higher abstraction level from the RP aspect of Task 1 to the MI aspect of Task 1. Additionally, as shown in Figure 5, after interacting with the program, Mario ascended abstraction levels as DC with respect to the MI aspect of the task.

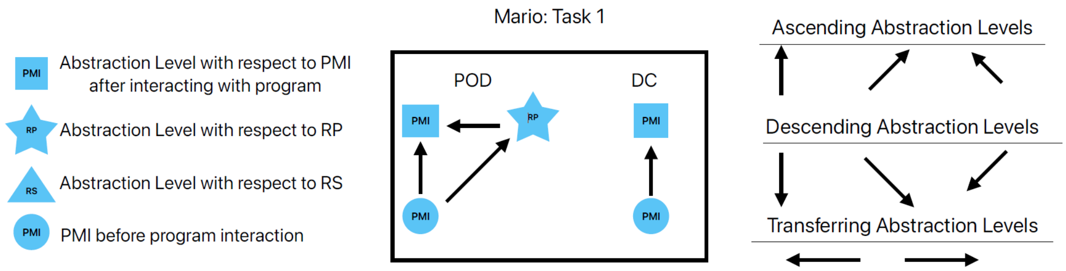

Figure 5. The Navigating Abstraction Framework applied to Mario's work on Task 1

During Task 4, Mario found it necessary to reduce the abstraction level as QR before ascending abstraction levels with respect to the MI aspect of the task. As shown in Figure 6, Mario transferred the lower level of abstraction as QR with respect to MI by interacting with the user-interface of the program and leveraged the source code to ascend levels of abstraction.

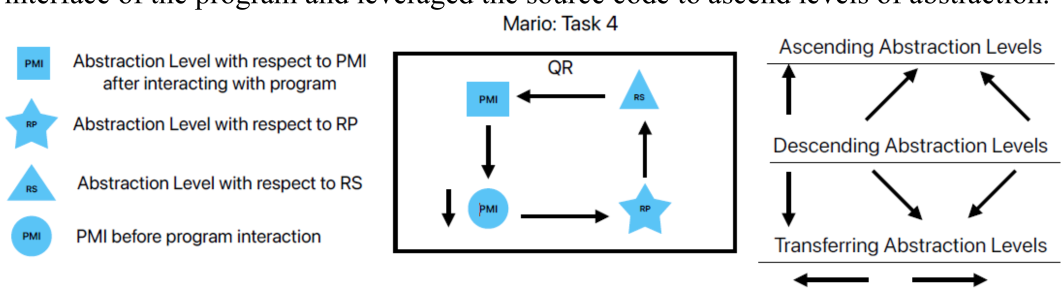

Figure 5. The Navigating Abstraction Framework applied to Mario's work on Task 4..

Discussion

Modifying the reducing abstraction framework to highlight the link between a proof by mathematical induction and a recursive program allowed us to recognize instances in which students transferred an abstraction level from their mathematical proof-work to their interaction with the recursive programs. Whereas Hazzan's (1999) Reducing Abstraction framework was a useful lens in determining when students reduced the abstraction level to cope with a concept, it did not provide the tools to account for how students moved *between* levels of abstraction or contexts. By extending the Reducing Abstraction framework to our *Navigating Abstraction* framework, we were able to recognize and examine how students navigated between abstraction levels and transferred abstraction levels to better understand both recursion and MI.

This framework provided a lens to interpret how students leveraged the back-and-forth navigation between induction/recursion and lower/higher levels of abstraction to ascend levels of abstraction, thereby allowing us to gain insights into how students understanding of induction and recursion co-evolved. This, in turn, helps demonstrate both the educational potential of using recursive programs to reinforce students' understanding of induction as well as the potential for using induction to enforce their understanding of recursion. Hence, the *Navigating Abstraction* framework is itself a research contribution in that it characterizes the movement between abstraction levels while simultaneously providing a bridge between mathematical and computational levels of abstraction.

The practice of generalization is a fundamental aspect of mathematics that requires further investigation, particularly in advanced contexts. This paper has sought to address the research gap by presenting a preliminary framework that captures how and on what basis undergraduate students develop and evaluate mathematical generalization. I illustrate each aspect of the framework using examples from two focal students' generalization of the concept of a group in Abstract Algebra, uncovering important mechanisms and thinking behind their emergent generalizing ideas. The framework has potential to be used more broadly in other mathematical contexts and to inform instructional designs aimed at promoting students' generalization skills. Key takeaways and potential directions for future research are discussed.

Keywords: Student Thinking/Cognition, Abstract Algebra, Generalization

Generalization is a fundamental practice of the mathematics community (e.g., Aigner, 2003; National Council of Teachers of Mathematics, 2014). While a significant amount of research has investigated younger students' generalizing activities (Carraher, Martinez & Schliemann, 2008; Radford, 2006), much remains to be understood about how undergraduate students generalize formal, axiomatic mathematics concepts (Reed, 2018). In addition, despite the fact that frameworks exist for distinguishing different types of generalization (e.g., Radford, 2003) and for characterizing generalization processes (Ellis et al., 2017), many aspects on *how* and *on what basis* students develop and evaluate the logical validity of mathematical generalization are still incomplete. This paper seeks to contribute to the generalization literature by providing a preliminary framework on the epistemic grounds upon which students develop and evaluate mathematical generalization in advanced settings. For the purpose of this paper, I define *epistemic grounds* to be the foundation or basis upon which knowledge and beliefs are justified or supported. Some examples of epistemic grounds include evidence from empirical data, logical arguments, personal experience, and testimony from reliable sources.

Given that Abstract Algebra is a natural extension of arithmetic and generalization naturally manifests itself in its content (Fraleigh, 2003), I intentionally situate my work in this area. Widely acknowledged as challenging (Melhuish, 2015), Abstract Algebra demands a significant leap to formalism and axiomatization that many mathematics majors find intimidating (Huang, 2022). It is my hope that by investigating students' generalization of a fundamental Group-theory concept, this work can contribute to a more solid understanding of generalization and the ways in which students reason about axiomatic constructs in Abstract Algebra and beyond.

Theoretical Background

Studies have drawn attention to how generalization is vital in fundamental areas such as algebraic reasoning (Amit & Neria, 2008; Stacey, 1989), problem solving (Sriraman 2003), and functional thinking (Ellis 2011; Rivera & Becker 2007). Radford's (2003) categorization of factual, contextual, and symbolic generalization reflects the broader trend among researchers to classify forms of generalization. According to Radford (2003), factual generalization is abstracted from "actions undertaken on objects at the concrete level" (p. 47); contextual generalization occurs when students manage to objectify an "operational scheme that acts on abstract — although contextually situated — objects" (p. 54); and symbolic generalization capitalizes on symbols in the generalizing activity. At the undergraduate level, Harel and Tall (1991) categorized three types of generalization: expansive generalization involves expanding the scope of an existing schema without reconstructing it; reconstructive generalization entails reconstructing relevant schema to adapt to the expansion; disjunctive generalization occurs when students create a new, “disjoint” schema to cope with new problems (Harel & Tall, 1991, p. 39).

In contrast with the common approach of evaluating students’ generalization with respect to certain predetermined benchmarks (e.g., see above), Ellis (2007) proposed to understand generalization from an actor-oriented perspective. This perspective foregrounds actions that students take in the generalization process and views these actions from the perspective of the students (Reed, 2018). According to Ellis (2007), there are three major categories of generalizing actions: relating, searching, and extending. Relating involves recognizing and creating mathematical relationships between objects or situations; searching is an active investigation of whether certain mathematical properties persist across different cases; and extending entails expanding a “pattern or relationship into a more general structure” (Ellis, 2007, p. 241). While Ellis’ (2007) taxonomy originated from observations of middle-school students’ generalizing activities, it has been applied to the undergraduate level (e.g., Reed & Lockwood, 2018) and it lays the foundation for the Relating, Forming, Extending (R-F-E) framework (Ellis et al., 2017).

The R-F-E framework draws from both cognitive and sociocultural research to create a more fine-grained model of students’ generalizing activities (Reed, 2018). This framework distinguishes inter-contextual generalization from intra-contextual generalization, submitting that the former involves establishing similarities across situations and the latter entails forming and extending similarities within one task (Ellis et al., 2017, p. 680). As the primary form of inter-contextual generalization, *relating* centers on developing meaningful mathematical relations and it can be further divided into three subcategories: relating situations, relating ideas or strategies, and recursive embedding (Ellis et al., 2017). As a major form of intra-contextual generalization, *forming* is about perceiving regularities across one’s own activity and it consists of four subcategories: associating objects, searching for similarities, isolating constancy, and identifying a regularity. *Extending* is another form of intra-contextual generalization, which involves applying established patterns and regularities (e.g., those from relating or forming) to novel contexts. According to Ellis et al. (2017), extending includes continuing an existing pattern beyond familiar contexts, operating on an identified relationship, transforming a generalization, and removing particular details so as to express an identified regularity more generally.

While the above perspectives and frameworks offer insights into characterizing generalization, they fall short in addressing the underlying mechanisms that drive students’ generalization process and a majority of the existing frameworks are too broad to meaningfully inform instruction. Indeed, Radford’s (2003) and Harel and Tall’s (1991) works are valuable in distinguishing different forms of generalization, but their broad categorizations obscure students’ actions and fail to shed light on the essential skills or practices required of developing robust mathematical generalization. Ellis’ (2007) taxonomy foregrounds students’ generalizing actions and the later R-F-E framework (Ellis et. al., 2017) provides fine-grained analysis; yet they do not capture the details or nuances in students’ reasoning nor do they provide insights into why or on what basis students spontaneously think or behave in a certain way in the generalization process.

A Preliminary Framework on the Epistemic Grounds of Mathematical Generalization

Through extensive micro-level analysis of undergraduate students’ generalization of the concept of a Group in Abstract Algebra, I developed a preliminary framework that aimed to capture how and on what basis students developed and evaluated their emergent generalizing ideas. The framework was created in the context of design-based research (Bakker, 2018), where I iteratively conducted four design-enactment-reflection-refinement cycles (Lewis et al., 2020) with volunteer participants recruited among undergraduates at UC Berkeley. I integrated Ellis' (2007) actor-oriented perspective with my observer-researcher lens in the data analysis process: I carefully analyzed video-recordings of the students' generalization, envisioned myself in the students' positions, and made informed hypotheses about how and why the students used certain strategies to develop or justify their emergent ideas. The resulting hypotheses became the initial draft of the framework shown in Figure 1, which was later revised according to results from a bottom-up approach in analyzing the video-recordings as well as students' written works. The fact that I have similar undergraduate mathematics experience as those of my research participants (as I earned a B.S. in Mathematics from a similar institution) and a relative expertise in the content (as demonstrated by my recent A in a graduate-level Abstract Algebra course) positions my data analysis and the creation of the framework as accounting for both students' and experts' perspectives. More information about the design and methods can be found in Huang (2022). For the sake of consistency and due to space constraints, I will illustrate the proposed framework using examples from two focal undergraduate participants only. Eden and Jane (pseudonym) participated in this study as a pair for two hours in 2022, and I had been a teaching assistant for their Calculus course for 13 weeks prior to their participation.

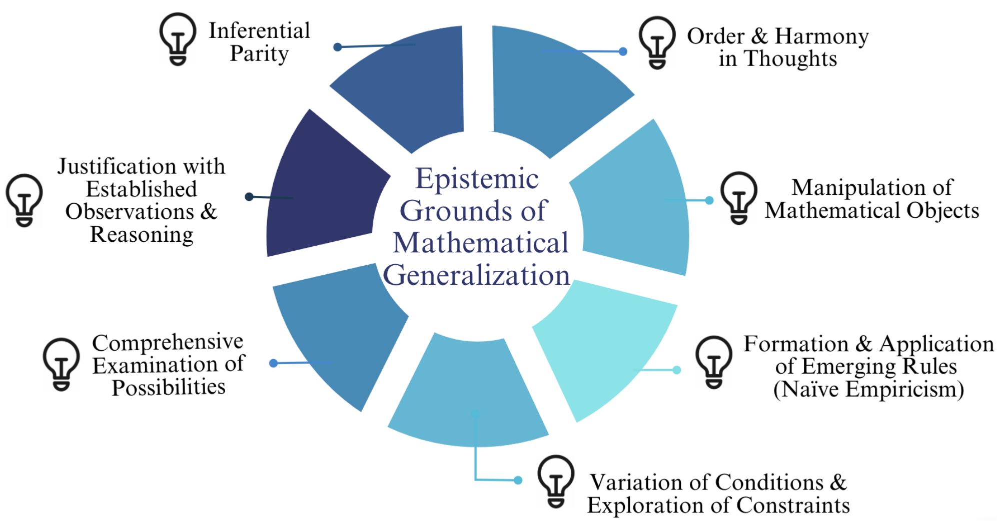

Figure 1. A preliminary framework on the epistemic grounds of developing mathematical generalization

Order and Harmony in Thoughts. This fundamental ground for developing generalization is closely related to the notion of equilibrium in Gestalt psychology (Koffka, 2013) and the common attribution of understanding to structured, harmonious mental organization (e.g., Sierpinska, 1994). According to Piaget (1976), the equilibrium of cognitive structures can be achieved through mental operations of assimilation and accommodation, which will then lead to order and harmony in people's minds. In a similar vein, Sierpinska (1994) proposes that understanding entails "finding a unifying principle, a relation that 'founds' what we want to understand" (p. 33), and that order and harmony as well as the feeling that "it fits" constitute the "most obvious criterion" of understanding (p. 32). In the process of zooming in and out of different algebraic systems and formulating similarities across different cases, Eden and Jane bounced ideas off of each other and made multiple utterances that conveyed similar meanings as

"Oh, it makes sense". I believe these utterances signify moments when they felt a sense of order, harmony, and coherence in their thoughts, and thus accepted their emergent mathematical ideas.

Manipulation of Mathematical Objects. This epistemic ground of generalization centers on an important epistemological practice of generating and validating mathematical knowledge by means of *doing* mathematics. The (manual and mental) manipulation of mathematical objects can involve a variety of techniques and tools, including physically manipulating artifacts, performing algebraic operations, constructing geometric figures, visualizing abstract properties, applying analytic techniques, and many more. Overall, the manipulation of mathematical objects is a crucial epistemic ground for developing generalization, as it allows students to generate and justify new insights, techniques, and results, providing a solid foundation for students to explore mathematical structures and relationships. It is important to note that besides attending to students' "mental math", I intentionally leveraged the embodied aspect of mathematical manipulation (which is often overlooked in undergraduate math classrooms). More specifically, I provided physical artifacts to invite rotation and reflection of geometric figures as a means to explore example Groups (e.g., Dihedral Groups), and scaffolded with semiotic tools such as tables to support students' reflexive abstraction (Vygotsky, 1978) of defining Group properties.

Formation & Application of Emerging Rules (Naïve Empiricism). This epistemic ground for developing generalization involves discerning an emerging mathematical rule from a limited number of empirical cases and utilizing it without rigorous justification. Historically, humans have made extensive use of this approach, due to various constraints such as limited access to data, insufficient analytical tools, and cost and time constraints (Gibson, & Papafragou, 2016). In the context of abstracting properties of multiplication in number systems (and later operations across example Groups), Eden and Jane concluded that "for three numbers in multiplication, order doesn't matter [or more precisely, it is associative]" after randomly picking some set of integers and checking that $(3 \times 4) \times 5 = 3 \times (4 \times 5)$ and $(7 \times 9) \times 100 = 7 \times (9 \times 100)$. As another example, Eden used $2 \heartsuit 6 = 5$ (marked blue in Fig. 2) to challenge Jane's result of $6 \heartsuit 2 = 4$ (marked red in Fig. 2) in the Symmetry Group of an equilateral triangle, based on their established observation that "order doesn't matter [or more precisely, operation is commutative]" for previous example Groups. But making $6 \heartsuit 2 = 6 \heartsuit 2 = 5$ raised another problem, as Jane quickly noticed that there was already a 5 in the same row of the operation table (marked green in Fig. 2). Jane's refutation was supported by their agreed-upon observation that each element appears exactly once in each row and each column of an operation table. Note that

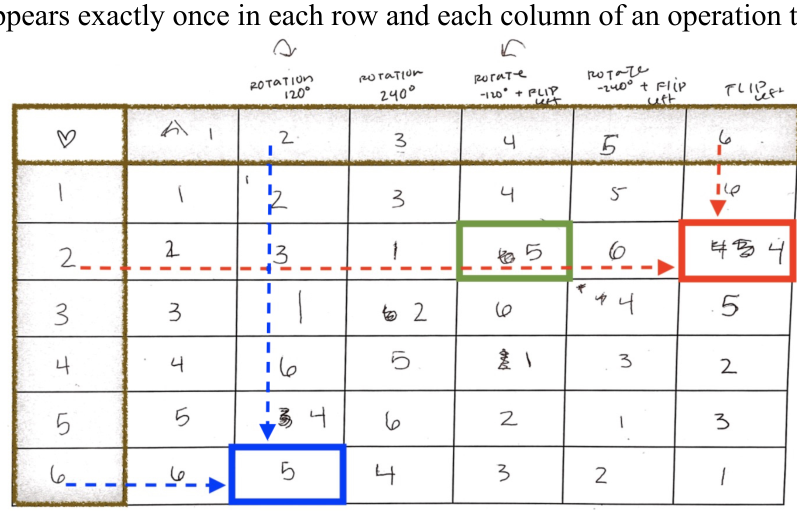

Figure 2. Formation and application of emerging rules: the case of 6♡2

the three emerging rules (i.e., multiplication is associative, commutativity is a defining similarity, operation table satisfies the "Sudoku property") played a crucial role in Eden and Jane's generalization of a Group, although they made no attempts to justify or refine these rules. Since students tend to search for similarities across their mathematical activities and generalize inductively from concrete cases, this epistemic ground is closely related to the idea of forming in the R-F-E framework (Ellis et al., 2017), Radford's (2003) notion of factual generalization, as well as Pólya's (1945) heuristics of "consider special cases" and "look for patterns". Despite its common usage, however, relying on naïve empiricism can lead to over-generalization or underestimation of the underlying mathematical structures, resulting in incorrect conclusions (Bollen et al., 2015). Thus, more sophisticated approaches (e.g., see below) are recommended to extend empirical findings to more generalizable and robust mathematical principles.

Variation of Conditions & Exploration of Constraints. This epistemic ground foregrounds an essential aspect of developing mathematical generalization, that of exploring conditions under which a generalization holds true and identifying any constraints that may apply. This is similar to Pólya's (1945) "variation of problems" heuristic in that both involve changing conditions; yet Pólya's (1945) heuristic focuses on generating new problems to help solve the original problem, while this epistemic ground aims to support the creation of more precise, powerful generalization by specifying its scope and constraints. During Eden and Jane's investigation of "order" (a student-generated vocabulary that bootstrapped their later differentiation between commutativity and associativity), I as their researcher-tutor probed: "We agree that 'order doesn't matter' for two elements in the first few examples, but what about three elements? Will adding parentheses in any way we want affect the result of operations?" In a swift response, Eden bounced back with an unanticipated question: "Does it have to be a set of three elements?" In retrospect, I realize that Eden's question was intended to vary the condition and facilitate an exploration of relevant constraints within their domain of investigation. After knowing that they could certainly investigate more than three elements at the same time (which broadened the scope of my original question), Eden and Jane went on to test operations with three and then four elements, creating a richer foundation for them to unpack underlying principles (e.g., associativity for three elements implies associativity for more elements) and generalize defining properties for Groups. Note that by varying conditions and exploring constraints, students not only generalize actions taken for specific numbers but also abstract the actions themselves. This suggests that they move beyond the realm of concrete examples and consider a broader set of possibilities; in the words of Radford (2003), students are engaged in contextual (and possibly symbolic) generalization.

Comprehensive Examination of Possibilities. In developing generalization, this epistemic ground concerns rigorously examining different situations as a means to assess the validity and soundness of an emerging generalizing idea, which is in mutual reinforcement with the previous epistemic ground. For example, when Eden and Jane tried to test whether "order matters" (or more precisely, whether associativity holds) for more than three numbers in multiplication, they attempted to exhaust all possible ways of adding parentheses in their randomly chosen expression $4 \times 2 \times 3 \times 5$. As a summary, they examined $(4 \times 2) \times 3 \times 5$, $4 \times (2 \times 3) \times 5$, and $4 \times 2 \times (3 \times 5)$, which all turned out to be 120. It is important to note that the first attempt $(4 \times 2) \times 3 \times 5$ was equivalent to $(4 \times 2 \times 3) \times 5$ and that those *were* all the possibilities they could thought of at the moment, despite the fact that advanced thinkers may find another possibility of $4 \times (2 \times 3 \times 5)$ left untested. Through comprehensive analysis of all possible cases, students can identify patterns and connections that may not be immediately apparent, contributing to their more robust understanding of the underlying principles. Since both *comprehensive examination of possibilities* and *variation of conditions & exploration of constraints* demand active investigation of whether certain emerging mathematical properties persist across different situations, the two epistemic grounds are inseparably linked to the idea of searching in Ellis' (2007) taxonomy. Moreover, as students often use logic to systematically exhaust all possibilities, it naturally leads to the next epistemic ground.

Justification with Established Observations & Reasoning. This epistemic ground highlights the importance of justification and proofs in developing mathematical generalization (or more generally in *any* mathematical activity). With the help of existing observations and logical reasoning, mathematics students learn to justify conjectures by showing that it is a logical consequence of certain principles and assumptions. As a standard practice in mathematics, justification involves higher-order thinking skills such as deductive reasoning, analyzing, and critical thinking, providing a rigorous and reliable way to establish the truth of mathematical statements. An example of this could be found in Eden and Jane's scrutiny of "order" in the modulo 5 system under addition. Knowing that "order doesn't matter" when they add integers, Jane argued that "order doesn't matter" in the modulo 5 system either because "You can mod 5 with like any number, and if you are gonna be adding something to it, order does not matter." Jane managed to extend her understanding of the set of integers to the new context of the modulo 5 system, and it is clear that her use of logic was mathematically correct. Note that Eden and Jane had not successfully distinguished commutativity and associativity at this point; the reasoning was valid regardless of the specific "order" they referred to. This example illustrates how justification is closely intertwined with the notion of extending in the R-F-E framework (Ellis et al., 2017), as it operates to establish a universal structure that transcends specific cases, personal viewpoints, and historical eras. Moreover, this epistemic ground bears resemblances to Pólya's (1945) heuristics of "using direct reasoning" as well as Radford's (2003) contextual and symbolic generalization in that all four prioritize logical reasoning in mathematical pursuits.

Inferential Parity. This epistemic ground is taken from Abrahamson (2014) to allow for a more detailed elaboration on how students reconcile their intuitive generalization with formal mathematics concepts. According to Abrahamson, inferential parity refers to the idea that students perceive a formal structure as "bearing the same information about the target property of the source phenomenon as their informal judgment" (2014, p. 13). Through the lens of inferential parity, researchers can capture moments when students recognize a connection between their informal knowledge and the established mathematical ideas, shedding light on how students utilize their intuitive generalization to navigate through formal mathematics. An illustrative example could be found when Eden and Jane compared their generalized concept with the formal definition of a Group. "A Group is an ordered pair where G is a set and ★ is a binary operation on G," read Eden, "that's kind of what we have here, right?" Jane nodded, pointing to the first row of their similarity table (marked blue in Fig. 3). Moments later, they skimmed through the defining properties of identity and inverse in the formal definition, prompting Eden to exclaimed: "Ohhh! That's cool! We are doing that!" They stared at their self-generated terminologies of "prime" (see Fig. 3, which bears the same meaning as identity or "e") and "undoing #s" (see Fig. 3, which bears the same meaning as inverse or " a^{-1} "), turned to each other, and then laughed. In the meantime, Jane copied "e" and " a^{-1} " from the formal definition to the left of their corresponding terminologies (marked red in Fig. 3). A later reflective interview revealed that the experience of struggling through unfamiliar mathematics (with support) and eventually uncovering how their intuitive generalization connected to (or more precisely, encapsulated) the formal, textbook definition was a valuable learning experience, leading to Eden and Jane's renewed sense of agency and ownership in their mathematical learning.

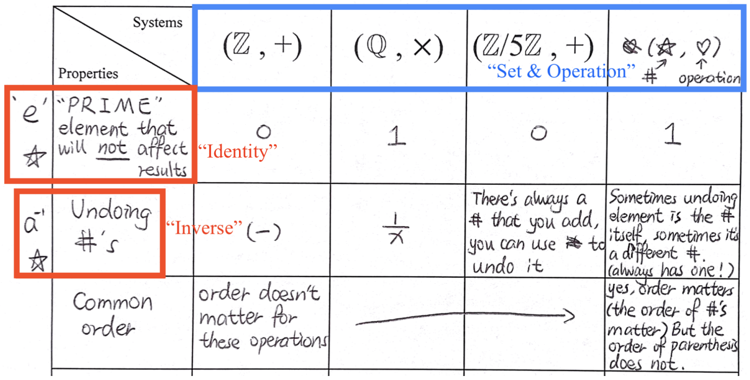

Figure 3: Inferential parity: connections between the formal and the informal

Concluding Remarks

While a fair amount of research has investigated younger students' generalizing activities, existing frameworks and perspectives often fall short in more advanced contexts and they fail to address the specific grounds upon which students develop mathematical generalization. This paper has sought to address the research gap by presenting a preliminary framework that captures *how* and *on what basis* students develop and evaluate their emergent generalizing ideas at the undergraduate level. The seven epistemic grounds highlighted by the framework are: Order & Harmony in Thoughts, Manipulation of Mathematical Objects, Formation & Application of Emerging Rules (Naïve Empiricism), Variation of Conditions & Exploration of Constraints, Comprehensive Examination of Possibilities, Justification with Established Observations & Reasoning, and Inferential Parity. I provided illustrations of each epistemic ground with examples from two undergraduate students' generalization of the concept of a Group in Abstract Algebra. It is important to note that this paper not only uncovers important mechanisms and thinking behind students' emergent generalizing ideas in Abstract Algebra, but also develops theoretical constructs that characterize students' generalization of axiomatic mathematics concepts and that hold potential to be applied more broadly to other mathematical contexts.

In addition to the framework presented in this paper, there are several key takeaways and potential directions for future research. First, while the proposed framework is grounded in literature and my observations in students' generalization of an Abstract Algebra concept, it is preliminary in nature and it requires refinement and empirical validation from other advanced content areas (e.g., Real Analysis). It is hoped that this paper can inspire further investigation into mathematical generalizations that are of a formal, axiomatic nature. Second, I do not claim that the identified epistemic grounds are mutually exclusive; further research is needed to better understand the interrelations among them for different students and different contexts. Third, the framework identifies important generalization-related mechanisms that could potentially inform or even guide instructional designs; future research could explore the framework's effectiveness in facilitating students' critical reflection upon and the development of their generalization-related skills and practices. Finally, it is worth emphasizing that mathematical generalization is a complex and multifaceted practice that demands students to engage in knowledge integration, problem solving, and critical thinking. By enhancing our understanding of the epistemic grounds that underpin this practice, we can better support students in developing the essential skills and knowledge needed for success in (both formal and informal) mathematics and beyond.

Faculty Perceptions of Making Connections: A Story of Obligations and Constraints

Rachel Rupnow
Northern Illinois University

Alexandra Hill
Northern Illinois University

Mathematics is central to STEM coursework, yet limited research has examined how instructors in math and other STEM courses facilitate connections between courses for their students. Based on four focus group meetings with ten faculty members, we characterize factors that assist or hinder making connections between courses and examine their relationship to professional obligations. Results include the largely negative impact of institutional obligations on faculty's willingness and ability to make connections. Implications include the need for institutions to give opportunities to make personal connections across departments and incentivize the development of connections.

Keywords: interdisciplinary connections, professional obligations, instructor decision-making

Introduction and Background Literature

Faculty in science, technology, engineering, and mathematics (STEM) disciplines recognize that math is relevant to their students and their teaching, as evidenced by requirements for students to take specific math classes for their major and the related role of math as gatekeeper to STEM (e.g., Bressoud et al., 2015). Nevertheless, while examinations of better ways to connect math and science or engineering have occurred at administrative or departmental levels (e.g., Robayo et al., 2022; Vroom et al., 2022), limited work has directly attended to individual faculty members' experiences. We thus seek to address the following research question: What factors assist or hinder connections that faculty can make between courses/content areas?

Meaningfully connecting content between disciplines is challenging, as jargon forms barriers to non-members of those communities of practice (Wenger, 1999). Separations exist between STEM faculty members and, by extension, their courses. Thus, research has begun examining how content like definite integrals and bases are communicated and used in different disciplines and how differences impact students' understanding (e.g., Jones, 2015; Serbin & Wawro, 2022).

Furthermore, STEM educators have placed increasing emphasis on math skills or concepts undergirding scientific content and ways instruction can better relate these content areas. Foci include interpretations of graphs in math and science (e.g., Christensen & Thompson, 2012; Rodriguez et al., 2018; 2019) and connections between content in particular courses, such as calculus and biology or chemistry (e.g., Jones, 2019a; 2019b; Williams et al., 2021), calculus or differential equations and physics (e.g., Jones, 2015; Roundy et al., 2015; Schermerhorn & Thompson, 2019a; 2019b; Smith et al., 2013), and linear algebra and physics (e.g., Schermerhorn et al., 2022; Serbin et al., 2020; Wawro et al., 2020). Some work also seeks to connect higher level math to science, including relating discrete math or abstract algebra to chemistry (e.g., Bergman & French, 2019; Bergman, 2020) and biology (Robeva et al., 2010). Considering the many interfaces of math and science, it is understandable that STEM majors may struggle to draw on appropriate math coursework in their science and engineering courses and that math faculty may be unaware of how their content is used in other courses. This paper builds on these cross-disciplinary efforts by examining how the use of focus groups centered on connections between courses' content could be used to illuminate current connections made between courses and gain insight into faculty's perspectives on what could support making connections in future.

Theoretical Perspective

To conceptualize factors that impact making connections between content areas, we draw on professional obligations as characterized by Herbst and Chazan (2011). This perspective is grounded in the theory of practical rationality, wherein mathematics teachers' instructional actions are taken to be sensible based on the norms and obligations that motivate them and theorizes what norms and obligations are impactful to teachers' decision making in different contexts. Whereas norms characterize the typical roles a teacher would play in instruction, professional obligations are characterized as "justifications (or refutations) that participants might give to actions that depart from a situational (or contractual) norm" (p.450). They also characterized four categories of professional obligations: disciplinary, individual, interpersonal, and institutional. Disciplinary obligations relate to providing a valid representation of mathematics as an area of knowledge and a practice. Individual obligations include the need to attend to students' identities and needs. Interpersonal obligations relate to shaping interactions and classroom discourse. Institutional obligations relate to attending to the broader aspects of schooling as an institution, including policies, exams, and curriculum.

While these obligations were originally characterized in the context of K-12 mathematics teaching, here we modify these obligations slightly to attend to teaching in a university setting and do not limit ourselves to the perspective of math teachers. We believe this is appropriate for examining obligations attended to when making connections between one's own course and other courses, because knowing the perspective of both math and non-math teachers is important for symmetric connections to be built. This changed emphasis leads us to slightly reframe the interpersonal obligations as interpersonal and personal obligations to emphasize any interpersonal contexts, including those outside the classroom with colleagues and self-reflection on one's obligations to one's own work-life balance and mental health needs.

Methods

Data was collected from four focus group meetings of ten faculty at one regional university in Spring 2023. Two meetings were held in February and two in April. Each participant was intended to participate in one February and one April meeting, but two participants were unable to attend in April. Gender-neutral pseudonyms, departments, and which meetings were attended are in Table 1. Faculty were solicited from those who completed a survey on their background and perceptions of connections between their courses and mathematics. In the focus groups, each question was asked to the group and each participant was given an opportunity to respond. After everyone had responded, everyone was given an additional opportunity to respond to what others had said. Questions focused on perceived connections between their course and other courses, supports used and desired for making connections, the connections between their courses and math, and supports they suggested or desired for helping students struggling with math content or skills. The focus groups were audio and video recorded and transcribed prior to analysis.

Table 1. Participants' backgrounds and meetings attended.

Pseudonym	Department	February Meeting	April Meeting
Addison	Earth, Atmosphere, and Environment	B	B
Bergen	Curriculum and Instruction	A	A
Carey	Physics	A	A
Darien	Mathematics	B	A
Elliot	Earth, Atmosphere, and Environment	B	A
Freddie	Mathematics	A	A

Gayle	Mathematics	B	none
Harper	Computer Science	B	B
Indigo	Leadership, Educational Psychology, and Foundations	A	B
Jun	Mechanical Engineering	B	none

Data was analyzed by two researchers who coded independently, then discussed and came to consensus on each section of the transcript. We did not enter analysis with a codebook, but used the notion of obligations to guide what we attended to. Both researchers open coded the two February meetings in alignment with descriptive coding (Saldaña, 2016), came to consensus on a codebook, recoded transcripts in alignment with the new codes, and came to consensus on coding. We then, after minor adjustment, coded the two April meetings, added new codes as needed, and came to consensus. Finally, we classified the codes into obligation categories, using three of the obligations of Herbst and Chazan (2011) directly and a modified version of the fourth. This process aligns with codebook thematic analysis (Braun et al., 2019), as we had some sense of the categories but not the particular codes we would use when entering analysis, and had the flexibility to add codes and categories to capture new ideas as analysis progressed.

Results

We present results according to alignment with each of the obligations: Disciplinary, Individual, Interpersonal and Personal, and Institutional. Codes are italicized.

Disciplinary Obligations

Disciplinary obligations in this study manifested as participants' desire to teach the content of their discipline, though this could hinder or assist making connections to other courses. The instructors agreed on the *importance of connections* across content. For example, Bergen stated, "I think it really behooves us as professors, as instructors to make those connections, because if we don't, then we're really not making it relevant to our students…. all the different topics, the fields connect." The instructors also discussed the importance of *showing students connections*, as students can struggle with finding the connections on their own. For instance, Freddie noted:

> …they don't see the connections. They've seen that trig; they've seen the quadratics. But outside of maybe a question at the end of a section, at the end of a unit....in math class…they're focused more on the math rather than the physics. And then when they get to you, it's like "Oh, wait. I know the math. I just got to figure out that physics equation that my math teacher gave me. Where does that come from?"

In addition, Addison recalled student feedback about examples that stated, "I wish those types of examples were in calculus. It didn't make sense why I was learning this".

Instructors also noted hindrances in terms of student knowledge. One issue was that *students had not seen content* required for their course. As Freddie noted, "The problem with the students who are taking that class, they've never seen parametric equations. They've never seen the idea that time controls this, the horizontal and vertical. No clue about it." Another perceived issue was that *students do not retain knowledge* from previous courses. Carey noted: "You can tell there's a light that's like 'Oh, yeah. I've seen that. I remember trig functions at some point.' But how much they remember about trig functions and inverse trig function[s] and that sort of thing is another question." Relatedly, participants perceived *students as not having conceptual mastery of the skills* required from previous courses. In an algebra-based physics course that Carey teaches, they noticed, "So in principle, it's stuff that they should have been exposed to, at least in high school, but it's really nothing new…. I think one of the challenges I'm having is that they don't have the mastery, so they're – in a company of mathematicians, I hate to say that math is a distraction. But it's kind of a distraction from the physics." Instructors also stated actions they take to help combat these issues, such as *helping students review*. Harper shared:

> And so it's never the case, where you walked into a class and everybody knows every single thing from every single prerequisite. And sometimes you have to take a little detour. But you can't spend a lot of time there, simply because that's not the course.…If they're really largely, all of them, wholesale not getting it… then there's no point in going on with the lecture. You have to take a detour in real time and try to give them a week's worth of whatever math in about 15 minutes, hopefully, as a refresher.

Individual Obligations

We classified as individual obligations anything that pertains to the student's mathematical identity and their needs going into their classes. Many aspects related to affective considerations, such as *students being anxious about math*. Bergen said of their students, "They are still terrified of math, oftentimes more so after taking the math classes." Relatedly, Elliot claimed that *helping students reduce anxiety* should be a goal of math courses: "So on the philosophical side, I think that one of the goals of the math classes should be to help students get over their fear of math, because many of them come in with that fear and they are disinclined to pursue occupations, majors, whatever, that have any kind of quantitative aspect to them." Others, like Darien, taught particular tools to reduce anxiety: "We go over developing growing mindset, trying to get them to know that math is for everyone and there is not people that are good or bad at mathematics." Darien also relayed a time that focused on community building and *motivated their students*:

> I had an intervention…So instead of going into content that day, we just sat.…And I just told them, 'What do you want from me?' ... Because I am not going to be your teacher this whole time, during these four years.…And they were like, 'Oh yeah. If we tell you to change something, it's not going to affect us directly.…We have to learn how to move to other courses. We have to improve our skills. We have to study more.' So they were… brainstorming of what they could do to just be better at math. And I've been having good outputs off that: attendance was better, and they were more motivated…after that.

Other aspects related to knowledge of students. Addison noted *student backgrounds are sometimes unknown* based on students transferring and lack of knowledge of courses in other disciplines: "I learned from googling precalc, so I thought it was all algebra, but I was wrong. There's some precalc in there too. Yeah but it is hard when we have transfers and not everyone has to take the full calculus sequence because we don't require everyone to take it." Others, like Indigo, built on their *knowledge of students' backgrounds*: "because most of my teachers in training are not statisticians and not trained in that, I take that as my job to inform them."

Finally, some topics related affect and content, such as the *need for students to be motivated to do the work*. Elliot said, "And I feel like they get a lot of, they're told that this is a mathematical relationship between variables, but they don't grasp, like, 'What are the variables that I might actually work with, and why do I care about all this?'" Darien seemed to suggest that student motivation is misdirected at procedural rather than conceptual understanding: "We are trying to help them understand concepts, but they don't want to because they think that that's not important…it's like, 'Tell me what I need for those skills that I need so I can pass my next calc courses.'" Elliot suggested *building community* with alumni to impact motivation:

> Whatever discipline you're in, having students exposed to people who actually use math in a career… I do think there are more than a few who don't think it's important for

where they see themselves going.…the more they can see people that they can model and see 'I could be like that. That person is like and was like me.' Because when employers come in, a lot of time, they're alumni. They will literally say, 'I was in that chair. I sat in that chair in this class, and I felt exactly the same way you do…this is where I am now.'

Interpersonal and Personal Obligations

We characterized interpersonal and personal obligations as shaping classroom discourse and interactions outside the classroom as well as one's own views. When instructors are *not familiar with other course content*, that can impact assumptions. For example, Addison states:

My hydrogeology class is a math class and that's how I start my class, by saying it is. And I'm a little embarrassed to say, yeah, I've never really spoken to math teachers about what I teach in it. And to the point when I did your survey, I google[d] to find out what classes some of those concepts were taught in because I couldn't remember.

Additionally, Addison noted the impact of their *personal experiences with course material* and a career outside academia on their teaching: "I had to take through Calc 3 when I was an undergrad and forgot it, a lot of it going on. And I didn't really need it in the sense of knowing those foundations. I worked after my bachelor's degree and most students are just going to go out and work. They don't need to know all that specifics." Based on Addison's experience of not using advanced math in their career, they saw limited value in their students having that knowledge. Instructors' *limited time* affects how much they can put into a course. Darien shared their experience with a new course: "I don't feel I'm doing a great job, especially because I'm always running out of time…So I come up with examples that are similar to a textbook…, just to explain the concept and continue with the next class." Freddie noted a lack of familiarity with colleagues: "I guess I'm still the newbie here. I don't know much of anybody." Not knowing colleagues meant they *did not know who to talk to* about connecting content.

However, instructors did not exclusively note challenges. Freddie was *familiar with* math and science K-12 *content* and stated, "I do the proportions that they're going to mostly see in the book, but I also make sure I fold in some of the gas laws…Charles's law or Boyle's laws." In some cases, like Freddie's, instructors may already know other course information. For those that do not, Elliot recommended ways to *gain information about other courses*: "I've thought for years that mathematicians should maybe come into our classes and say, 'All right, here's the nuts and bolts of this,' or the people who do the applied math should provide examples for the people who are teaching the math and say, 'This is how we do this.'" Others noted positive ways their *personal experiences of courses* impacted instruction, such as Carey:

For introductory physics, one of the things I try to do…is to try and use math terminology that I think they would be familiar with from a math class…so the slope of your position-versus-time graph is the velocity. So we look at our position-versus-time graph and we start, 'Oh, if I want to calculate the average velocity, how do I do that?' Then I look at this and it's like, 'Oh, we measure how much this way. Oh, this is like a rise. And now we measure how much this way. And this is like a run. And, oh, if we take the rise over the run, right, oh, that's the slope, right?' And with some of the trig stuff…I specifically use term opposite and adjacent and hypotenuse and similar sort of terms that hopefully they'll be familiar with from math and might start to engage their memory a little bit.

Instructors also noted *time saving strategies* they can use. One of the most common strategies was looking online for resources. Carey had knowledge of a research field that would be likely to have resources: "Physics for the Life Sciences basically is this whole thing, and there's people out there who've had curricula and how they set things up." Additionally, Bergen shared advice on how to *build relationships with colleagues* to encourage collaboration:

> It's interesting that the advice I was given when I first got here 13 years ago. Department chair at the time, he said, 'I want you to join [committee].'…And that was one of the best decisions or… the best voluntelling…Because then I got to…meet people from all over campus...and that's the best way to make you feel like you belong some place.

Institutional Obligations

We characterized institutional obligations as attention to institutional policies impacting promotion and curriculum; most of these obligations hindered making connections across courses. Many instructors noted that *finding others who want to collaborate was difficult* and in many *ways the university did not seem to value the need for connections*. Addison emphasized the need for working with others to be incentivized: "I have to not get dinged for taking the time to reach out to people because, yeah, unfortunately, research is really the key." Similarly, Elliot stated, "Until I see or feel that there's a lot of incentives to do that, and that would also require…changing the whole structure, not of departments but how the university sees these classes." *Others* also need to *value collaboration for connections to be built*, as Carey experienced: "Several of us in the physics department tried to have this conversation with the biology folks.…they sent over their advisor, and basically, he said, 'Oh, they just need to take the MCAT,' which wasn't very helpful for us.…at least based on what he said, physics has no relevance to biology other than doing well on the MCAT." University policies also seemed to encourage competition rather than cooperation. This was especially impactful in *course design* and *credit hour requirements*. For example, Darien and Addison discussed whether a new or different calculus course should be a prerequisite for Addison's course:

> *Addison:* If I didn't let students who either were co-taking calculus or had failed and they're going to retake it, take my class, I wouldn't have a lot of students.…So I have to show the applied and I'm not sure I would be good at teaching those foundational things beyond… "Don't you remember this? It's okay if you don't. We're going to keep going."
>
> *Darien:* Do you think that an applied calculus class will help with that as a prerequisite? Because we don't have an applied class right now. We just have a business and social science class.
>
> *Addison:* In principle, yes. Do I want to make them take another class? No.

In addition to limiting prerequisites from other disciplines to save space for major courses, starting *new courses* could be extremely *competitive*. Harper shared:

> The single most impactful thing that the university could do in order to help the issue you raised is to change the manner in which new courses are being developed or proposed. It's not designed as such but what it actually is is a land rush. It's the first one to market gets to claim the course…That's not thoughtful, it's competitive.

Finally, when creating requirements for courses, instructors build on their own personal experience, but *courses change over time*. For example, consider the following conversation:

> *Harper*: Okay. Do they do proofs in Calc? Calc 1 and Calc 2?
>
> *Interviewer*: No.
>
> *Harper*: Things have changed since I took Calc 1 and Calc 2.
>
> *Gayle*: Depends on who teaches Calc a little bit.
>
> *Harper*: Which is to say that a lot of time has passed since I took Calc 1 and Calc 2, but things have definitely changed.

On the somewhat positive side, Gayle noted they had *collaborated* with Carey *on a co-requisite course*, but also acknowledged some challenges: "For freshman engineering students…

usually like the Calc schedule gets all wonky because we'll end up doing either Rolls [Theorem]… in week 2 or something just so that they have it and like they can then use that for kinematics … so they apply it and do physics labs and things like that." Gayle noted that this arrangement between physics and calculus could lead to an unusual calculus schedule, where applications that typically follow differentiation techniques instead are addressed early in the semester, though this was done to benefit students' understanding in their physics course.

Discussion

This study examined disciplinary, individual, interpersonal and personal, and institutional obligations as perceived by faculty, especially as they support or hinder making connections between courses. Participants highlighted disciplinary obligations as motivation for them to make connections but noted obstacles like a perceived lack of student knowledge or mastery, preventing students from fully understanding the connection or preventing faculty from attempting to make connections. Individual obligations manifested through faculty's attention to students' content backgrounds and affective needs. The supports and hindrances in this case mirrored each other, as faculty highlighted anxiety as a common issue but also shared ways to address this; similarly, they highlighted both a lack of knowledge about students' backgrounds and ways this knowledge could be leveraged if known. Interpersonal and personal obligations emphasized the instructors' knowledge and relationships and their impact on making connections between courses. In these obligations also, supports and hindrances mirrored each other, with some participants extolling the power of connecting with colleagues while others wondered how to make those personal connections; similarly, faculty's prior experiences with courses could either incentivize or prevent making connections. Finally, institutional obligations highlighted the need to attend to existing policies. In most cases, these obligations served as hindrances to making connections, as making connections is not valued for tenure and promotion and policies fostered competition between departments over course design and maximizing credit hours.

We believe applying the lens of professional obligations (Herbst & Chazan, 2011) to our data provides three useful insights. First, our participants were likely a best-case scenario for making connections between math and other areas; they were willing to take time to attend focus groups and saw value in making connections. However, even they highlighted hindrances to connections across all four types of professional obligations, especially institutional obligations. Second, multiple instances arose where faculty did not see the purpose of having certain prerequisites, whether because they viewed the information as irrelevant for their students, likely to drive students away from their own courses, or unlikely to be remembered when needed in subsequent courses. Considering calculus's current role as the gateway to STEM (Bressoud et al., 2015) and other studies with faculty questioning the importance of math courses for learning STEM content (e.g., Rupnow et al., 2023), such perceptions from other disciplines are important to consider to ensure math courses are performing their expected role in the curriculum and valued by other disciplines. Finally, our participants had almost exclusively negative things to say about the impact of the institution on the making of connections. Some policies may be difficult to change (e.g., activities valued for tenure, budgetary formulas) whereas others would require less effort (e.g., providing collaboration spaces for likeminded faculty). We encourage future work on the impact of these policies and how they could be changed to support connections across courses.

“Close but not Exact”: An Alternative to Introducing Derivatives

Franklin Yu
Arizona State University

In this paper, I report on the findings of two students engaged in a teaching experiment on instantaneous rate of change (derivatives). While derivatives are a quantification of how two quantities covary, many students tend to have static images of the derivative (Zandieh, 2000). This teaching experiment was designed to support the students in building a meaning for instantaneous rate of change based in quantitative and covariational reasoning. The results of this study provide empirical evidence of the benefit of alternative teaching methods to the current standard curriculum.

Keywords: Derivative, Quantitative Reasoning, Teaching Experiment

Research on Calculus education has been extensive and covers many topics. In particular, there is a large body of research on the learning and teaching of derivatives and instantaneous rate of change (e.g., Orton, 1983; Ferrini-Mundy & Graham, 1991; Zandieh, 2000; Yu, 2020). One typical method of introducing the derivative concept involves sliding secant lines towards one of the endpoints to get continuously better approximations of a tangent line, the slope of which represents a quantity we call *instantaneous rate of change*. However, researchers have indicated that students often struggle with connecting this sliding secant line imagery with rate of change (Ferrini-Mundy & Graham, 1991; Zandieh, 2000; Ubuz, 2007). This idea of quantities changing continuously and covarationally is central to the idea of derivative, yet the research is clear that students often do not associate quantities as covarying when they think about derivatives (Zandieh, 2000; Byerley et al., 2012; Yu, 2020). Due to these issues, this manuscript reports on the results of a teaching experiment designed to support students in developing a productive understanding of instantaneous rate of change.

Theoretical Background

If we examine the limit definition of derivative, $f'(x) = \lim_{\Delta x \to 0} \frac{f(x+\Delta x)-f(x)}{(x+\Delta x)-x}$, the derivative involves an average rate of change between the input values x and $x + \Delta x$ ($\frac{f(x+\Delta x)-f(x)}{(x+\Delta x)-x}$) where the variation in the value of x gets smaller and smaller ($\lim_{\Delta x \to 0}$). In the standard presentation, where a sliding secant line converges to a tangent line, students need not attend to what the average rate of change describes about a given context. This is evident in the literature (Zandieh, 2000; Byerley et al., 2012) when students interpret the value of a derivative (e.g., $f'(3) = 7$), as being only associated with the slope of a tangent line and not necessarily attending to how quantities may be covarying. Therefore, it stands to reason that students should simultaneously attend to x and $f(x)$ covarying and how choosing smaller and smaller input intervals can net us what we call an instantaneous rate of change.

Relevant Literature

Ely and Ellis (2018) proposed that leveraging what they call *scaling-continuous covariational reasoning* could support Calculus students in developing productive ways of thinking. Building off this, Ely and Samuels (2019) provide empirical evidence of alternative ways of teaching the idea of derivative with their "Zoom in Infinitely" method. These studies indicate that supporting students in reasoning about how two quantities' values covary together can help them better understand the derivative concept. This study provides another example of teaching one aspect of the derivative (the limiting portion) using an alternative method that deliberately focuses on supporting students in reasoning quantitatively. Compared to the works of Ely and Samuels, the students are not zooming in on an existing graph of a function. Instead, the students create a piecewise linear function and continually choose smaller and smaller intervals to model an object's movement. This study's research question is: What understanding of the derivative concept do individual students develop during an instructional sequence designed to support students' quantitative and covariational reasoning?

Methodology

This study was part of a larger study conducted by engaging students in individual teaching experiments (Steffe & Thompson, 2000). The students selected were enrolled in a Calculus 1 for Engineers course before learning about secant lines and instantaneous rate of change. The teaching experiment involved six sessions (1 pre-interview and 5 teaching sessions) that focused on characterizing and advancing students' ways of thinking about rate of change. This document reports on two students in the fourth teaching session, where the teacher worked with the students to develop a basis for a productive understanding of instantaneous rate of change. In this session, the way of thinking that the instructor wanted students to develop was the idea that "One can obtain better approximations of the (instantaneous) rate of change at a given value of the input variable by determining average rates ($\frac{f(x+\Delta x)-f(x)}{(x+\Delta x)-x}$) of change on smaller and smaller intervals ($\lim_{\Delta x \to 0}$) that include that value of the input variable."

Background

Before the fourth teaching session, the third session involved having the students program (writing a piecewise linear position function) to model the movement of a runner by choosing smaller and smaller intervals (Yu, 2023). That session was primarily focused on developing a productive meaning for average rate of change as an imagined constant rate of change that would provide the same net changes in the output quantity over the same input interval. Additionally, it also seeded the fundamental idea of this paper by providing an animation of their programmed function that showed their model's movements as getting more accurate to the actual runner (Figure 1).

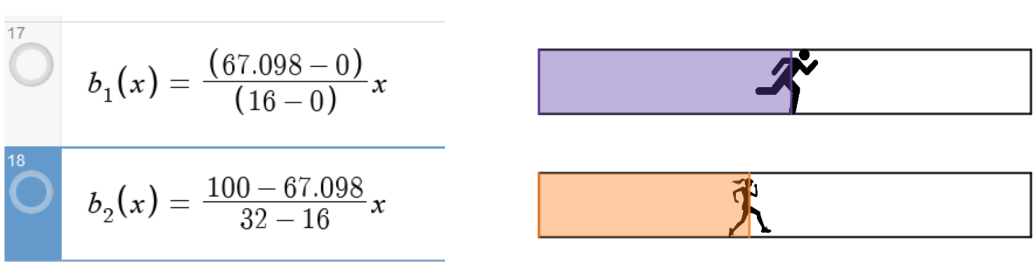

Figure 1: Example of Programming the Bottom Runner using the Average Speed of the Top Runner

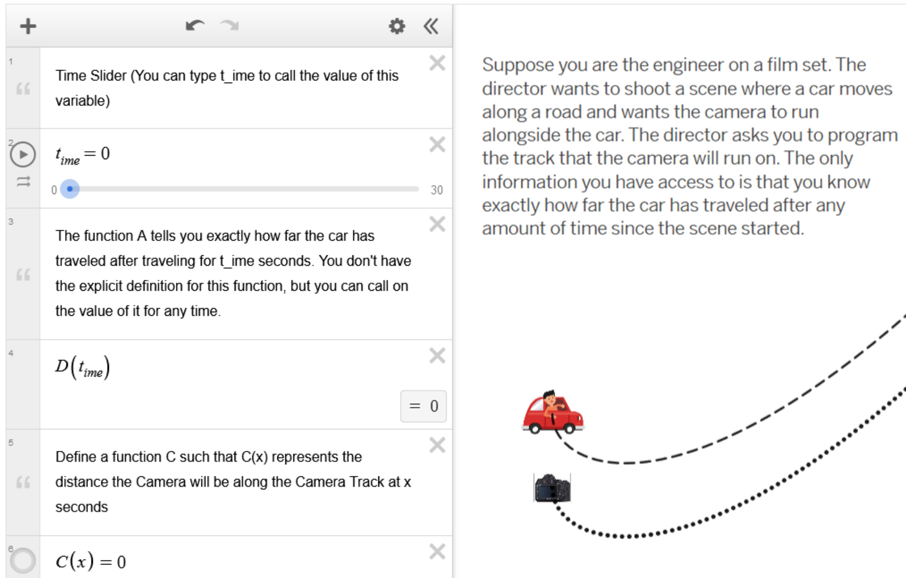

Figure 2: The Camera Task

In the fourth session, students worked through a Desmos Applet and were tasked with modeling the motion of a camera to match a car's motion (Figure 2). While this task is similar to the third teaching session, one important note is that the Desmos Applet provided no indication to construct a piecewise linear function using average rates of change. Instead, students were prompted to discuss their thinking and how they would attempt to mirror the car's movement. Later in the session were questions on how they might determine the speed at a particular time value and approximate future values of a function using that speed.

Teaching Session 4 – Scott

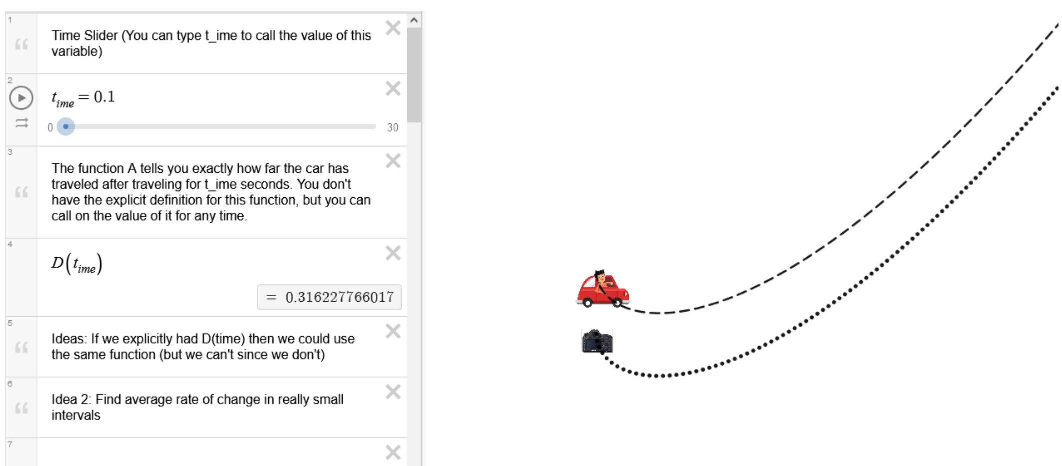

Figure 3: The Camera Problem and Scott's initial ideas

The camera problem prompted students to program a camera's movement on a track to mirror the movement of a car on a parallel track. Scott initially stated that he wanted to determine the equation of the line that would create the same path the camera was on. In other words, Scott wanted a function where the physical shape of that function's graph matched the shape of the track he saw on the Desmos applet. However, he realized that having the function whose graph matched the physical shape of the track path would not model how the camera's distance traveled would vary as time varied. Scott then suggested using the given distance function of the car, D, but soon recognized he could not do this since he did not have the function definition for D (Figure 3). Scott then decided that we could "find the average rate of change in really small intervals where it would be pretty close but not exact." As Scott started to define a function, C, where he used the car's average speed and multiplied it by an amount of time, he verbalized that he wanted to use the same method as the Runner Task (Figure 1) by using average rates of change. Scott's choice to utilize average rates of change is essential to note since the questions accompanying the Desmos applet did not have any prompts to define piecewise linear functions or use average rates of change to model the camera's motion. Scott broke up the 30-second interval into one-second intervals (Figure 4). As he defined his piecewise linear function, he checked his work by playing the animation to ensure that the camera moved according to his expectations.

$t_{IntNumber}$	m	d_{car}

Figure 4: Scott programming the camera's distance traveled over time using the car's average speed in each one-second interval

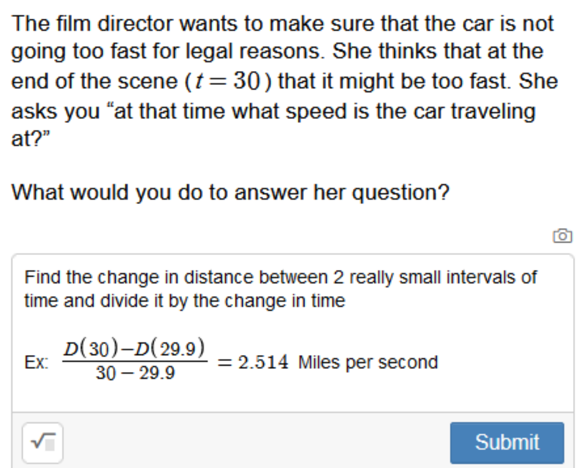

Figure 5: Scott's response to finding the speed of the car at a given input value

After programming the function to model the camera's distance traveled along the track with respect to time elapsed, Scott was asked a series of questions on determining the car's speed at a particular value of time (Figure 5). Scott stated that he would "find the change in distance between 2 really small intervals of time and divide it by the change in time." He later generalized this statement: "I would just take 2 values very close to that time, and I would calculate the rate of change between them." There are several aspects of Scott's worth response worth highlighting:

1. The sizes of the time intervals he chose to determine the speed at $t = 30$ (Figure 5) were different from the size he used to program the camera's motion (Figure 4). For

programming the camera's distance traveled, he used the car's average speed in 1-second intervals, and for the speed at $t = 30$, he used the car's average speed in a 0.1-second interval. This suggests that Scott's choice in the "2 values very close to that time" was arbitrary and that no specific interval size was needed.

2. Scott verbalized that using average rates of change over a small time interval "would be pretty close but not exact" to modeling the car's motion as time passed. As he answered each of the prompts about determining the car's speed at a particular time, he never verbalized a need to justify that they were close approximations. It is likely that because the animation displayed the motion of the camera and the car was essentially the same; he might have believed that his approximations were good enough and that the difference between the actual and the approximated distance functions was insignificant.

Teaching Session 4 – Hans

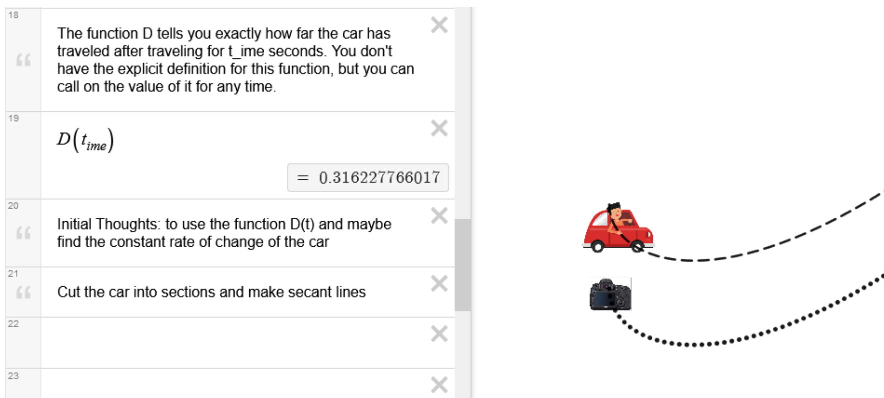

Figure 6: The Camera Problem and Hans' Initial Ideas

Like Scott, Hans' initial approach to the camera problem was to determine the equation of the line whose graph matched the path of the road. He then suggested finding "the constant rate of change of the car." However, after playing the animation, Hans recognized that the car was moving at varying speeds, so he proposed that we "cut the car into sections and make secant lines" (Figure 6). Hans verbalized that this was similar to the third teaching session, and he wanted to build a piecewise linear function using the car's average speed over small time intervals to model the camera's motion.

Hans employed 3-second intervals (Figure 7) and did not play the animation until he finished defining the piecewise function. After playing the animation, he noticed that the camera and the car's movements did not align adequately in the first few seconds. He then suggested, "we could do better if I made it like 1 second [the interval size] instead." Rather than having Hans rewrite his piecewise function, the interviewer asked hypothetical questions such as "suppose we wanted to do 1-second intervals, what would we need to change?". Hans replied that he would have to change everything since "you wouldn't be able to use like 3 seconds…like how these are done. I would have to re-do them to resize these rates of change." After this round of questioning, Hans demonstrated that he could obtain better approximations of the car's distance traveled with respect to time elapsed by using average rates of change over a smaller time interval.

	$t_{IntNumber}$	m	d_{car}
	1	$\frac{(D(3)-D(0))}{3-0}$	0
	2	$\frac{D(6)-D(3)}{6-3}$	$D(3)$
	3	$\frac{D(9)-D(6)}{9-6}$	$D(6)$
	4	$\frac{D(12)-D(9)}{12-9}$	$D(9)$
	5	$\frac{D(15)-D(12)}{15-12}$	$D(12)$
	6	$\frac{D(18)-D(15)}{18-15}$	$D(15)$
	7	$\frac{D(21)-D(18)}{21-18}$	$D(18)$
	8	$\frac{D(24)-D(21)}{24-21}$	$D(21)$
	9	$\frac{D(27)-D(24)}{27-24}$	$D(24)$
	10	$\frac{D(30)-D(27)}{30-27}$	$D(27)$

Figure 7: Hans' programming the camera's distance traveled over time using the car's average speed in each three-second interval

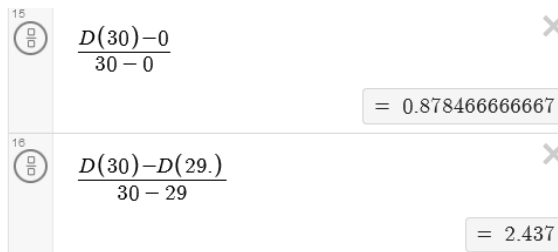

Figure 8: Hans moving from $\frac{D(30)}{30}$ *to* $\frac{D(30)-D(29)}{30-29}$

The interviewer then asked Hans how he might determine the speed at $t = 30$. Hans initially stated "$\frac{D(30)}{30}$ since it is the rate of change for 30… err… it's just a rate, not a rate of change." He later clarified that $\frac{D(30)}{30}$ "is a rate [and not a rate of change] because it remains a constant value of 0.878 like it would be the constant rate at 30." The interviewer then wrote $\frac{D(30)}{30}$ as $\frac{D(30)-0}{30-0}$ and asked what $\frac{D(30)-0}{30-0}$ would represent in this context. Hans identified that $\frac{D(30)-0}{30-0}$ would be the car's average speed between 0 and 30 seconds, and then quickly realized that $\frac{D(30)}{30}$ would not be the car's speed at 30 seconds. Afterward, he suggested we could determine the average speed between 29 and 30 seconds since "it's in the region that we want it in like 30, so it's close enough to the speed" (Figure 8). On the other tasks that prompted Hans to determine the speed at a given time value, Hans' responses indicated that he would determine the average rate of change over a small interval near the requested time (Figure 9).

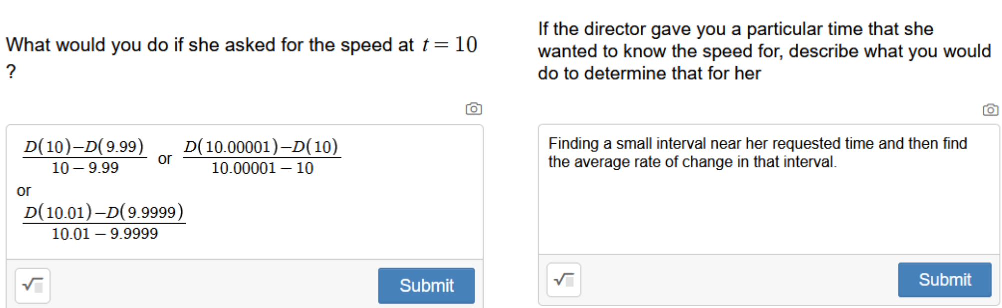

Figure 9: Hans' explanation of how to find a speed at a given input value

Several aspects of Hans' responses are important to discuss.

1. Hans thought about $\frac{D(30)}{30}$ as a "rate not a rate of change." His expression, $\frac{D(30)}{30}$, suggested that a fraction with a singular distance divided by a singular time would determine a

"rate," and something of the form $\frac{y_2-y_1}{x_2-x_1}$ would determine a "rate of change" since the numerator and denominator represented a change in one quantity's value. It was likely through reconceiving $\frac{D(30)}{30}$ as being equivalent to $\frac{D(30)-D(0)}{30-0}$ (which he identified as the car's average speed between 0 and 30 seconds) that supported Hans in conceiving $\frac{D(30)}{30}$ as the car's average speed over 30 seconds.

2. Another possibility for his response of $\frac{D(30)}{30}$ as the car's speed at 30 seconds is that he considered that a rate was "distance over time," and so he used the distance at 30 seconds, $D(30)$ and divided it by the time value of 30 seconds. In either case, what supported Hans in shifting his conception of $\frac{D(30)}{30}$ was the prompting to explain what each portion of his expression represented. Additionally, writing an equivalent expression in the form that he was familiar with (e.g., recognizing that $\frac{D(30)-D(0)}{30-0}$ would represent an average speed) aided him in reflecting on the quantities he attempted to represent.

Like Scott, Hans also demonstrated an understanding of the arbitrariness of choosing how small an interval had to be when determining the speed at a given input value. When determining how he might determine the speed at $t = 10$, Hans initially wrote $\frac{D(10)-D(9.99)}{10-9.99}$ but also noted that he could choose other sized intervals like the subsequent ones he wrote in Figure 9.

Discussion

The findings of this study present a possible alternative to how Calculus instructors can introduce the idea of instantaneous rate of change compared to the traditional sliding secant line methods used by popular textbooks (e.g., Stewart). In this study, both students benefitted from connecting their mathematical expressions with an applet to model their mathematics. Additionally, the applet provided a medium for the students to visualize how choosing small enough input intervals could be useful in approximating an instantaneous rate of change. Compared to the standard receding-secant line method, where the secant lines converge to one single point (in other words, a demonstration of approximating the instantaneous rate of change at only one particular value), the students in this study were engaged with developing an entire rate of change function as they constructed their piecewise linear functions. As a result, both students in this study demonstrated that they likely internalized this process of approximating an instantaneous rate of change since they described the process as involving an average rate of change over a small enough input interval.

While motion-based contexts should not be the only examples Calculus students should interact with, they can provide a tangible situation that students can associate their mathematical understandings with (Berry & Nyman, 2003). This study builds off the existing literature (Ely & Samuels, 2019) of alternative ways to introduce the idea of derivatives to support students in quantitative reasoning.

Limitations and Future Directions

While the results of this study show promising results for alternative teaching methods, the results can only be known to be true for the students in the study. Future studies can continue to investigate how we can support students in reasoning covariationally in Calculus and how to implement these alternative methods in the classroom.

Bridging the Mathematical and Social Dimensions of Undergraduate Calculus: Students' Perspectives on a Program of Weekly Guided Collaborative Problems Solving

Nadav Ehrenfeld
Weizmann Institute of Science

Alice Mark
Vanderbilt University

This study explores undergraduate Calculus students' perspectives on the Course Assistants (CA) program at a southern US university, where upper-class undergraduates guide weekly Math Lab sessions of collaborative problem-solving. Using sociocultural theories and qualitative methods the research investigates what aspects of Math Lab students and CAs found useful or not. Students' interviews and CAs' weekly reflections indicate that, on the one hand, students by and large appreciate the experiences of collaborating over the weekly problems with their peers and the CAs, the social networking it provided, and the mathematical confidence it helped build. In our own words, students appreciated how the academic and social dimensions of math learning came together. However, many students and CAs are skeptical about the connections between the weekly tasks and success in the course exams. Relatedly, students often complained about Math Lab being another structured hour in an already time-consuming course and about varying student engagement.

Keywords: undergraduate calculus; collaborative problem solving; course assistants

Research and professional reports of undergraduate mathematics education often state the promises and challenges of shifting learning towards more active approaches (where *active learning* is conceived broadly and inclusively). For example, research reports in the proceedings of the 2022 Research of Undergraduate Mathematics Education conference (RUME 2022) addressed a variety of issues around active learning including instructors' workshops (Archie et al., 2022), instructors' dispositions (Ireland et al., 2022), online active learning (Kerrigan et al., 2022), linguistic diversity (Rios, 2022), and more. Such RUME research reports often cite as a starting point The Common Vision (Saxe & Braddy, 2015) and empirical evidence about the impact of active learning in undergraduate STEM courses (Freeman et al., 2014; Laursen, 2019; Laursen et al., 2014; Theobald et al., 2020). Side by side with these encouraging outcomes, we also know that K-16 efforts to implement collaborative math learning approaches (the specific type of active learning which is the focus here) are complex to incorporate and facilitate, sometimes fall short, and might even amplify exclusionary dynamics (Ehrenfeld & Horn, 2020; Louie, 2017; Reinholz et al., 2022; Rios, 2022; Shah & Lewis, 2019). In this paper we explore such tensions in the context of a Course Assistants (CA) program, in which upper class undergraduate students facilitated weekly collaborative problem solving sessions (known as Math Lab) in Calculus courses at a private southern US university. First, we provide a general overview of the program. Then, we share our sociocultural theoretical perspective, an overview of the data and methods of analysis we used, and finally, the main themes that emerged from the data. The overall question we address in this report are *What aspects of Math Lab students and CAs found more or less useful, how, and why?*

Research Context: The CA Program

The overarching goal of the CA program was to support undergraduate Calculus students mathematically and socially during this transition to college. Students worked in small groups of 3-9 with a CA in weekly Math Lab sessions on calculus problems which were longer and more conceptual in nature than typical homework and exam questions. Those problems were written collaboratively by the course instructors, with direct relation to the weekly materials. Socially and mathematically, we hoped that students' experiences in the Math Lab would support them in developing collaborative study skills, conceptual understanding, and a sense of community and belonging in the course. After a pilot semester in Spring 2022, the Fall 2022 program started in one course with 20 course assistants (CAs) who facilitated 40 Math Lab groups which served ~250 students. The Spring 2023 program expanded to three courses with 20 CAs (17 returning and 3 new) who facilitated 40 Math Lab groups which served ~250 students. Math Lab was required only for students in the first Calculus course of their sequence. The rationale behind not requiring it in the following course was that by the time students are taking a second semester course, they have more practice in figuring out what kind of support they need and should have more agency to decide that for themselves.

Theoretical Framework: Sociocultural Theories of Mathematics Learning

Sociocultural theories of mathematics learning extend a cognitive focus on individual learners, instead focusing on the participation of learners in social practices within a particular context (Danish & Gresalfi, 2018; Sfard, 1998). They inform our work by providing core assumptions about students' mathematical competencies and identities as constructed through interactions within context rather than predetermined, acontextual, and act as individuals' static traits (Ehrenfeld & Heyd-Metzuyanim, 2019; Gresalfi et al., 2009; Gresalfi & Hand, 2019). These theoretical assumptions often imply a tendency towards qualitative methodologies that allow a deeper look at how participants engage within their learning environments, navigating and reconciling the mathematical and social aspects of learning.

Methodology

In this section we describe the data we collected along the year, including students' interviews and recordings of the CA training across two semesters (see Table 1 for a summary). We then describe how we reviewed and interpreted the data, with students' interviews being the primary data for this report.

Data Collection

In Fall 2022, the study was approved by the IRB around week 7 of the semester. At this point we started to video record the last 7 weekly CA training sessions. In Spring 2023, we video recorded 13 of the 14 weekly CA training meetings in the Department of Mathematics. Finally, we interviewed nine students about their Math Lab experiences. The students were not chosen by us individually but rather answered our general call for interviews. Some of the students participated in the program in Fall 2022 and decided to register or not in Spring 2023 as well. Some of the students repeated their course with Math Lab at their second round and spoke about their experience in the same course with and without Math Lab. One student simply took both the course and the Math Lab for the first time in Spring 2023

Table 1. Summary of data collected for this study.

Data for this study		
<u>Semester</u>	<u>Data</u>	<u>Including…</u>
Fall 2022	7 (of 14) weekly CA meetings	Video + groups audio
Spring 2023	13 (of 14) weekly CA meetings	Video + groups audio
Spring 2023		Zoom interviews

	End of semester interviews with 9 students	(primary data for this paper)

Data Analysis

For the purposes of this paper we primarily reviewed the end of Spring 2023 semester interviews with the nine students. As secondary data we also used recordings of the weekly CA meetings where students reflected on their Math Lab facilitation. We collected codes and then themes (e.g., Charmaz, 2006; Strauss & Corbin, 1990), allowing our reading of the data to suggest the themes, rather than searching for themes identified a priori. In practice, this meant assigning initial codes to episodes where students and CAs were talking about aspects of Math Lab as more or less useful for the students. Note that after reviewing all interviews and about half of the CA training data we reached a point of saturation where codes repeated, and we almost did not encounter new ones. At this point we had an initial set of 10 codes under Strengths describing participant-identified dimensions of utility of the MathLab, and a set of 10 codes under Weaknesses describing less useful participant-identified aspects of Math Lab. In the final phase we merged and reduced each category of codes into three themes that were common in the data, significant for the students, and provoked generative points for this discussion.

Themes Emerging From the Data

In this section we first describe and illustrate three strengths of the program from the students' and CAs' perspectives: the social support and network that Math Lab provided, the opportunities to develop mathematical competence and confidence through conversations about math problems, and the affordances of near-peer math support. These repeating themes sketch a collective image of what was found conducive to success in Calculus by the interviewed participants. All three themes illustrate how students found useful bringing together the social and academic dimension of mathematics learning. Some also contrast this interrelatedness with typical mathematics lectures and university life. Then, we describe and illustrate three problems, areas for revision, or less useful aspects of the program, from the students' and CAs' perspectives: The fact that it requires extra time in courses that are already dense and demanding, that students and CAs are not seeing the weekly Math Lab assignment as directly connected to the tests, and that for some, fully participating within the group was a challenge. Finally, we briefly discuss the implications of these themes, how they add to a collective image of needs, pressures, and valued support for success.

Strengths of the Program and Things Students and CAs Found More Useful

Social support and networks. Many students and CAs described their Math Lab groups as a friendly and fun environment, where positive relationships were established. For some, these relationships stayed within the scope of the Math Lab meetings. For example, Student 3 said that "our group like even though we didn't really talk outside of Math Lab we always had the really like friendly funny conversations during math lab we were always cracking jokes and everything." For others, those relationships extended onto the general course, or more broadly to social life on campus. For example, when asked what the highlight of Math Lab was for her, Student 4 said:

> [The highlight is] the people that you meet. Especially first semester just because like you know during that time everything is so stressful and especially if you don't know people in the class. And like maybe you are someone that struggles, [...] or like just like have

> questions sometimes. I think that like being in the Math Lab group is important because you have like just a few- handful people you know you can reach out to like if you need help. And I feel like that is better because sometimes being like in a class with 30 students is little intimidating when you like want to speak to other people and ask where they are at, but the Math Lab group kind of makes it a little bit more like a social- like add a social aspect which I think is important especially when you are a first semester freshman...

All in all, often students and CAs saw their Math Lab groups as a friendly and welcoming environment, where positive bonds were created (sometimes contrasting it with other courses without Math Lab). These relations were of different type and scope: with some being more local in nature, just within Math Lab (as Student 1 described), some extended to the course classroom (as Student 6 described), and for some (like Student 4) those relations continued to students' ongoing academic and social campus life. Importantly, we know from the data and the literature that improvements in sense of belonging and deeper social connections in turn translate to better learning outcomes. The next theme further illustrates how students experienced the convergence of the social and the mathematical.

Communicating about math and developing competence & confidence. When we asked students what their Math Lab looked like, they often described positive experiences of doing math together, communicating and reasoning collaboratively about the content. Sometimes they also connected this type of math to their sense of confidence and competence, or to the advantages of explaining math out loud or being exposed to the ways other students are thinking about the weekly problems. For example, Student 2, who described herself as someone who "hates math" and wished she wouldn't have to take any math courses, told us that the best thing about Math Lab was "I think the most beneficial thing for me in Math Lab was like knowing that I can do these sort of problems, this is a good confidence thing..." In another example, Student 6 shared:

> we would just go problem by problem and a lot of- we would be like "hmm: what did people like get for solutions on problem 1." And if there was like difference in opinions we would hmmm like go to the whiteboard and work out our work or show our work on paper or ipad and discuss and like discuss collaboratively about different methods for this solutions and what do we think we should put on the group doc we submitted.

Similarly, Student 8 shared how they were "talking it through" and her insight that "going through your line of reasoning could help you better understand how you look at math and how others look at math, and that can inform a more solid foundation…" as well as how sharing her thinking with the group and being validated by the CA was gave her a "confidence boost." Finally, Student 9 concluded his Math Lab experience with the insight that it is really good to have a dedicated time for groupwork because "sometimes you can learn more from your fellow students in a way that you can't from your instructor or the TA."

Near-peer support. While many students appreciated the opportunities to do math with their peers, the Math Lab experiences were different from a regular student learning group at least in one significant way: having their near-peer support. Near-peer support was discussed both in terms of the CAs, and sometimes also in terms of their upper-level Math Lab friends (e.g., freshmen and sophomores in the same groups). In addition, near-peer support was mostly discussed in terms of math support during Math Lab, but it also extended to other aspects of students' life like choosing courses and applying for summer jobs. Near-peers were also mentioned in contrast to TAs and to instructors, as being more approachable and as allowing to form closer mentoring relationships. The CAs reflections pointed out similar narratives. Capturing nicely the near-peer theme, Student 6 articulated the experience of being with a near-peer CA as being both “formal and informal,” She said: “My CA did a really good job about making it like formal but also informal at the same time. Kind of like just a different setting than the actual class which I think was helpful.” Describing the work with the same CA, student 8 explained the importance of the CA being someone who took this class recently:

> [The CA] was awesome she was really [unclear] and she understood the importance of the emotional support aspects, and like, someone who took the course and she is sophomore so she is like close to our age actually one of the kids in our lab group is older than her, and it felt like a peer relationship and she was very open if you guys need anything at all i'm always here for advice.

Others often mentioned their CAs for their math support (Student 1), their ability to get to know students and how they feel (Student 4), and their support with academic issues beyond math content (Student 3). Student 3, who is a student of color who had in the Fall semester a CA of color, described how the two are still in touch one semester after the course ended. She particularly appreciated how beyond the math assignments, the CA “loved to like… she was always talking about, like, doing internships and encouraging us to, like, apply ourselves outside the math lab and do different programs and stuff and so, um, yeah. She was awesome and we all realized that very early on.”

In sum, the near-peer support was a recurring motif in students’ and CAs’ descriptions of Math Lab, and this position seemed to offer some affordances that are different from the support typically provided by same-level peers, by TAs, and by instructors.

Weaknesses of the Program: Things Students and CAs Found Problematic, Less Useful, or Requiring Revision

Math Lab takes extra time in already time-demanding courses. With the Math Lab (and its weekly problems), the TA discussions, and the daily homework, Calculus students at the university have a relatively extended set of obligations. For example, the first thing that Student 1 told us about, was that she was surprised by the time demands of the calculus sequence. In the context of an already-demanding course, the Math Lab could seem like an added burden to students having an experience like that of Student 1. Similarly, Student 6 explained that “for some students it can be hard to justify like showing up somewhere for another extra hour a week especially when we are all kind of like busy.” For Student 3, who was generally happy with her Math Lab experience in the Fall, time constraints were the main reason she decided not to continue with Math Lab for the Spring when it was not required. Just as Student 1, she explained at the very start of the interview that “math is a lot of work here, it's a lot of homework and I feel like I have math every single day with the math lab and lecture and discussion....” Then, when we asked why she decided on not going to Math Lab on MATH 1201 she added:

> Math is basically like everyday here with the lectures and discussions so I thought like if I didn't have to sign up for Math Lab to begin with, so maybe it would help my schedule just a little bit. Because I just remember last semester like trying to balance Math Lab with like clubs and everything was a lot of work so I thought like it would be better to allocate that time to something else, some organization or something else on campus.

As we illustrate in the next section, others questioned the usefulness of Math Lab because they did not see the direct connections between the weekly problems and the exams.

Students and CAs are not seeing connectedness to exams. The concern that the weekly Math Lab problems are not useful for students because they are not similar in nature to the daily homework question nor to the exam (e.g., longer, more conceptual, open ended, use tech like Desmos), came up across students' interviews and CAs' discussions. For example, when we discussed metacognition in the CA training, we asked the CAs when and how they were noticing students' frustration with the weekly problems. One CAs answered as follows.

> I feel like where I see the peak of frustration so like- my group they work on their homework as well, so like they go through the problem set and the homework because it is due the same day. And so their frustration is often times the weekly [Math Lab problem] is different than the [non Math Lab] homework, like significantly different. So in their minds it's like how is this benefiting me because I have to worry about my homework right now which is like my grade that has like a higher grade [weight], I see more of the correlation from this to my exam vs. like some of the... [...] they wouldn't be writing something like that [on the exam]. I guess it's gonna be more you're given a function and then you write the derivative something like that. So they get frustrated because they are comparing both of them [non Math Lab homework and weekly Math Lab problem] because they are doing it at the same time. I don't know how to explain like why the dynamic should be different because you don't do the same thing. That's not gonna benefit you.

These conversations were typical in the CA training where CAs described their students' perspective about the tasks, their own perspectives, and their concerns with regards to responding to students complaints. And while in some interviews with students we did hear some appreciation to the conceptual nature of the weekly assignments, students mostly expressed dismay with not seeing connectedness to exams. For example, when asked to elaborate on different aspects of Math Lab, Student 1 said:

> I feel like the actual Math Lab tasks were very- they felt very like disconnected at times from what we were actually learning. Because none of the stuff we did in Math Lab was never on any test like I feel like it always required some outside knowledge [...]

In sum, many MATH 1200, 1201 students and their CAs identified and struggled with the incoherence between the Math Lab and other course activities, including those who appreciated the opportunity to do math with peers and the CA and generally enjoyed their Math Lab. It is worthwhile to note that MATH 1300 students generally responded better to the open and conceptual nature of the problems, and more easily saw the connections between the Math Lab assignments and the course.

Limited student engagement within the Math Lab group. While we aspired to provide students with productive and inclusive mathematical work in small groups, this was not always exactly what played out in practice. Students and CAs often described less effective ways of working together (and not together) and encountered different forms of disengagement. Interpretations of disengagement ranged from deficit-oriented (e.g., a student described some students as "piggybacking" the group submission) to acknowledging that it is challenging to learn how to do math together, and it might require time and support for students to "put themselves out there."

We start by illustrating how students themselves pointed out certain group dynamics as troubling. Some students described them as a constant concern across the semester, and others as growth pains at the beginning of the semester. For example, when Student 2 was asked what makes a good Math Lab, she mentioned having regular attendance and that it should be clear that "if you are in a group you participate in doing the work." She then elaborated, expressing frustration that some students were "piggybacking" on the submission, showing up but not really participating. Student 8 shared a similar feeling. However in her case group dynamics shifted after the first 2-3 weeks:

> I was worried in the beginning like not everyone putting in effort but as we went on I think everyone started to see how valuable the assignments were and how like talking it through and going through your line of reasoning could help you [...] The first like two or three meetings it was kind of mostly 2 other girls and me sort of carrying stuff and everyone else were kind of silent. I don't know exactly why it changed but it did. And then everyone started contributing very equally and I felt more comfortable coming in with questions rather than answers.

The narrative of group growth across the semester towards more effective and inclusive participation repeated in interviews with the CAs at the end of Fall semester and in their end of year feedback. These accounts were typical in the CA training, and we encouraged CAs not to share just "success stories" but also everyday problems. Our hope was that they will develop sensitivity to notice non-productive and exclusionary patterns of student engagement, and will improve their capacity to respond to them.

Conclusions and Implications

Students and CAs found several aspects in this program useful, including the development of social support networks, enhanced mathematical competence and confidence through collaborative problem-solving, and the value of near-peer support from CAs. These strengths illustrate that students found important the convergence of the social and academic dimensions of mathematics learning, which they often noted as missing in their undergraduate math journey. With regards to areas of revision, students felt that Math Lab added to the time demands of an already challenging course, and they struggled to see direct connections between Math Lab assignments and course exams. These themes could be interpreted either from the CA program perspective or from a general Calculus program perspective. From the CA program perspective, one attempt we made in the Spring to bridge for students the Math Lab weekly tasks with other course activities for students was to include some related homework/exam-like exercises with each conceptual lab problem that are rooted in the same mathematical concepts but are not for submission. From a general program perspective, if conceptual understanding is a goal of Calculus programs overall, building coherence across component of the course might also imply broader changes in the course. In that sense, the themes we presented are not only addressing students' perspective on this specific CA program, but they also direct us to the general needs of undergraduate Calculus students. These findings highlight the value and complexities of implementing undergraduate Calculus collaborative math learning approaches that bridge the academic and social dimensions of mathematics learning.

This contributed report describes the development and validation of a new measure—the College Mathematics Beliefs and Belonging (CMBB) survey. The CMBB provides a contemporary measurement of undergraduate students' perceptions of their mathematical proficiency and reasoning, beliefs about mathematics, and sense of belonging in mathematics. Primarily first- and second-year undergraduate students in five courses at a large public university in the United States completed multiple surveys to provide the data used for survey development. Confirmatory factor analysis (N = 935) and a reliability analysis indicate that the CMBB is a survey with fifteen factors that adequately measure various aspects of perceived mathematical proficiency and reasoning, beliefs, and sense of belonging. The CMBB survey is intended for use by both researchers and instructors to assess undergraduate students' perceptions across these three domains with the aim of improving students' experiences in college mathematics courses.

Keywords: proficiency, mathematical reasoning, beliefs, belonging, factor analysis

For decades, mathematicians, mathematics educators, and psychologists have explored individual differences and instructional factors that affect students' achievement and motivation in postsecondary mathematics. There is a long tradition of postsecondary mathematics instructors identifying habits, beliefs, and abilities that are viewed as critical for effective mathematical practice. This collection of habits, beliefs, and abilities is sometimes referred to collectively as "mathematical maturity" (Faulkner et al., 2019; Garrity, 2011; Lew, 2019; Steen, 1983). In a first step toward delineating specific key habits, abilities, and beliefs, mathematicians engaged in scholarly teaching have produced practitioner-focused reports documenting developmental goals for postsecondary mathematics students, often through the work of professional societies such as the Mathematical Association of America (MAA). The MAA Committee for the Undergraduate Program in Mathematics has long been active in this work, producing the series of Curriculum Guides to Majors in the Mathematical Sciences (MAA, 2015) and The Curriculum Foundations Project (Ganter & Barker, 2004), created by the Curriculum Renewal Across the First Two Years subcommittee. This work has been complemented by a growing body of research in undergraduate mathematics education involving a range of themes including student thinking, student-instructor interaction, and effective pedagogy, among others (e.g., Bressoud et al., 2015; Carlson & Rasmussen, 2008; Laursen & Rasmussen, 2019).

Psychologists have also pursued parallel lines of investigation. Psychological research has revealed that students' persistence in STEM courses is highly influenced by their beliefs about math, perceptions of their own learning, and their academic motivation more broadly (e.g., Hulleman & Harackiewicz, 2009; see Eccles & Wigfield, 2020, for a review). However, many existing measures of students' beliefs, motivation, and sense of belonging in mathematics based on psychological research have paid insufficient attention to how mathematicians and mathematics educators conceptualize student learning in the context of college mathematics.

The goal of the current investigation was to develop an instrument to measure college students' beliefs about mathematics, and beliefs about their own mathematics learning, that have been identified as effective for mathematics practice by scholarship, research, and theory from multiple communities of practice. The *College Mathematics Beliefs and Belonging* (CMBB) survey can be used by researchers and instructors to assess student attitudes and beliefs in undergraduate mathematics courses, including students' views about their own mathematical proficiency, their beliefs about the nature of mathematics, aspects of what motivates them in mathematics learning, and multiple facets of their sense of belonging in mathematics. By considering the contributions of multiple communities of practice, we believe that the CMBB survey is representative of a wide range of perspectives that reflect the increasing diversity of undergraduate students taking introductory mathematics courses at the postsecondary level.

Theoretical Frameworks

Mathematical Proficiency and Reasoning

First, we sought to capture student individual differences in theoretically meaningful aspects of their mathematical proficiency and reasoning. One influential framework is the 5-strand model from the National Research Council's (NRC) "Adding It Up: Helping Children Learn Mathematics" report (Kilpatrick et al., 2001). The 5-strand model is comprised of five theoretically unique, but related, aspects of students' knowledge: Conceptual Understanding, Procedural Fluency, Strategic Competence, Adaptive Reasoning, and Productive Disposition. The NRC Committee proposes that these five strands of mathematical proficiency and reasoning are separable yet interwoven constructs, with each supporting the others and productive disposition bringing together all strands. This view is also aligned by psychological research on conceptual and procedural understanding in mathematics (e.g., Rittle-Johnson & Siegler, 2021) and academic motivation (e.g., Eccles & Wigfield, 2020).

In addition to these five strands, we reintroduce Gray and Tall's (1994) conceptualization of proceptual thinking, a separate construct that focuses on the fundamental integration between understanding a procedural process and understanding conceptual mathematical relationships. Proceptual thinking reflects a key aspect of how mathematicians perceive mathematical symbols. Gray and Tall argue that mathematicians' perception of symbols includes understanding processes that a symbol represents, the mathematical object a process produces, and an understanding of the symbol flexible enough to include both the processes and object.

Beliefs About Mathematics

Postsecondary students enter college with a range of beliefs about the nature of mathematics (see Philipp, 2007). For example, some students think of mathematics as a collection of relatively independent rules and procedures (Schifter, 1990). Another common belief is that mathematics is fundamentally a form of logical thinking (Dossey, 1992). Finally, some students consider efficiency to be a key characteristic of doing mathematics (Boaler et al., 2015). Many of these beliefs held by students do not accurately reflect mathematicians' conceptions of mathematics (Gold et al., 2017; Hersh & John-Steiner, 2010). Thus, we aimed for our contemporary scale to reliably assess how undergraduate students conceptualize the nature of mathematics.

Students also possess motivational beliefs about mathematics (Kloosterman, 2002; Royster et al., 1999), including the usefulness of mathematics (utility value; Eccles & Wigfield, 2020), confidence in their own mathematical proficiency (self-efficacy; Bandura, 1997), and their own and others' abilities to learn and understand mathematics (growth mindset; Yeager et al., 2019). Importantly, motivational beliefs often uniquely predict academic outcomes, over and above mere content knowledge. For example, classroom-based experimental studies reveal that when students can see the utility of their college STEM classes, they are more likely to persist in STEM majors years later (Asher et al., 2023). Additionally, mathematical confidence is a driving factor in persistence in college mathematics, especially among women (Ellis et al., 2016). Finally, students who understand that mistakes are a part of learning are more likely to persist in advanced mathematics and earn higher grades in mathematics courses (Yeager et al., 2019).

Given these considerations, our view is that understanding the multidimensional nature of student beliefs of mathematics is pivotal to fostering student learning, understanding differences between groups of students (e.g., gender differences) within a course, and assessing the impact of different pedagogical approaches. Thus, we aimed to include a broad range of belief-oriented items—encompassing both beliefs about the nature of mathematics and motivational beliefs about mathematics—in our survey.

Centering Equity and Inclusion through Sense of Belonging

A growing body of work has adopted sociocultural frameworks that acknowledge the importance of the broader learning context—such as belonging—in shaping student learning and engagement (Allen et al., 2016). Sense of belonging is defined as "the feeling that a member fits in, belongs to, or is a member of the academic community in question" (Good et al., 2012, p. 700). Among college students, sense of belonging affects mathematics motivation differently for different students. For example, Good and colleagues (2012) found that when women experienced a decline in sense of belonging across the academic year, they were less likely to intend to enroll in additional courses in mathematics.

There is also substantial overlap between sense of belonging and research regarding inclusive and equitable teaching practices and the development of supportive learning communities. Leyva et al. (2022) analyzed Black and Latine students' perceptions of practices in calculus instruction intended to be supportive for all students, finding that these were generally perceived as necessary but insufficient to create equitable opportunities and content access. Following reflection and re-evaluation of data from the MAA's National Studies of College Calculus, Hagman (2019) articulated that diversity, inclusion, and equity practices constituted a critical factor for student success; this factor was not considered explicitly in the original findings of the MAA studies. Further, many mathematicians and mathematics educators have reported on their efforts to build inclusive and welcoming communities within mathematical contexts (Cunningham et al., 2021; Hardin & Shahriari, 2022; Karaali, 2022).

Initial Instrument Development

Our instrument development process unfolded in two distinct stages. First, we developed a set of preliminary survey items based on an extensive literature review, piloted the survey with a small sample of students, and conducted a preliminary analysis to assess the factor structure of these survey items. Second, based on results of our preliminary analysis, we revised the survey items and collected data to assess the validity and reliability of the measures.

Item Development and Pilot Data Analysis

The 5-strand model combined with proceptual reasoning combine to provide six strands of proficiency: Conceptual Understanding, Procedural Fluency, Strategic Competence, Adaptive Reasoning, Productive Disposition, and Proceptual Thinking. For each of these strands, the two lead authors wrote specific items guided by both the construct definitions and the specific content knowledge that students in undergraduate mathematics courses should master, with a focus on courses taken by first-year students. All items were designed as Likert-type items on a 1–6 scale (strongly disagree to strongly agree, with no neutral option). All items in the initial version of the survey are available on our Open Science Framework (OSF) page https://osf.io/683ek/?view_only=cadf80e3935d41caa88699d9f1f3e4a8.

We also sought to characterize students' feelings of belonging, membership, and acceptance in the mathematics community (Good et al., 2012). Items in this section were modeled after Good et al.'s (2012) scale of sense of belonging in mathematics, questions asked by Piatek-Jimenez (2008) in their interviews of women in mathematical careers, and themes described in Oppland-Cordell and Martin (2015). The remaining items were written by the two lead authors to capture students' feelings of belonging and community when working with peers in the classroom and students' own identification with mathematics.

In Summer 2022, we conducted an Exploratory Factor Analysis (EFA) on the initial survey data. The EFA showed that we should remove most reverse-coded items and clarify the item questions regarding beliefs about mathematics. The EFA for the first version of our survey did show that there were two factors clearly loading on proficiency/beliefs and belonging; thus, we determined it was appropriate to revise the survey and collect new data. The final survey items are available on our OSF page.

Reliability and Validity Study on Final Survey Items

To establish reliability and validity, we adopted the approach set forth in the Standards for Educational and Psychological Measurement in Education (AERA, APA, & NCME, 2014) in which the importance is placed on gathering multiple sources of validity evidence relevant to the interpretation of an instrument. The Standards recommend considering five types of validity evidence: test content, response processes, internal structure, relation to other variables, and consequences of testing. Validity evidence from item content was addressed by drawing on literature in the content domains of interest and by the composition of a multidisciplinary team of content experts. Our multidisciplinary team of mathematicians, cognitive developmental psychologists, mathematics educators, and an engineer required several discussions about test content as we aimed to have a shared understanding of how the items informed each scale and the overall purpose of the survey from our multiple perspectives.

Validity Evidence: Response Process and Test Content

Six undergraduate college students were recruited for 30- to 45-minute cognitive interviews in Fall 2022. A cognitive interview is an interview procedure meant to explore a participant's comprehension of an item or task (Leighton, 2017). When participants articulate their thoughts in response to an item survey (i.e., a "talk-aloud" concurrent verbal report; see Ericsson & Simon, 1993), researchers can determine if their interpretation of an item matches the construct it was designed to measure. The interviews indicated that college students interpreted most of the items as they were intentionally designed.

Reliability and Validity Evidence: Internal Structure

To provide validity evidence for internal structure, we conducted independent analyses on the data we collected at the beginning and at the end of the Fall 2022 semester. In one dataset, we conducted an exploratory factor analysis (EFA). The EFA was used to guide a confirmatory factor analysis (CFA) on a second dataset.

Revised survey administration. We administered the CMBB survey to students in five university mathematics courses (Contemporary Mathematics, College Algebra, Precalculus, Calculus I, Calculus III) that primarily serve first- and second-year undergraduates. The surveys were administered using an online survey software (Qualtrics); they were advertised and distributed by course instructors on our behalf.

Participants. After removing participants who did not pass an attention check item or had less than 30% survey response completion, our analytic sample included 1,135 students who completed the pre-survey and 935 students who completed the post-survey. Approximately half of the students in the pre-survey (49%) and the post-survey (53%) reported currently being in a mathematics-intensive major. More women than men completed the survey: 56–57% women, 34% men, 0.2–0.4% transgender, 1% nonbinary, and 5–6% other. In both the pre-survey and post-survey, the racial and ethnic distribution of the data was highly similar with 80–82% reporting as White, 8–10% Black/African American, 1% American Indian or Alaskan Native, 5% Asian, 0.5% Native Hawaiian and Other Pacific Islander, and 5% reporting as other. In both the pre-survey and post-survey, the first-generation student composition is representative of the university at which the data were collected, with 26–27% of the students reporting that their parents do not hold at least a 4-year college degree.

Exploratory factor analysis. First, we carried out a parallel analysis leading to an EFA on the pre-survey data. Computations were done in RStudio version 2022.07.1+554 using the base R package. The parallel analysis suggested an 18-factor model, where this large number of factors aligned with the design of the instrument, therefore orthogonal (varimax) rotation was used in the EFA to minimize correlations between factors. In the resulting EFA with 18 factors, two of the factors had no items load above .3, and one of the factors had only one item load at .31. Combining the EFA results with validity evidence considerations, we proceeded with a 15-factor model on 56 items. The loading matrix and item correlations for the EFA analysis are available on our OSF page.

Confirmatory factor analysis. Next, to confirm that our hypothesized 15-factor model fit the data, we conducted a CFA on the post-data using maximum likelihood estimation with the *lavaan* package version 0.6-12. The CFA model is represented in Figure 1. To interpret our goodness-of-fit indicators, CFI and RMSEA, we used equivalence testing to establish comparison and cutoff values (Marcoulides & Yuan, 2016). Using equivalence-testing based cutoffs, we find that an RMSEA of .047 is identified as a "Close" fit while a CFI of .92 is identified as a "Fair" fit (our T-size RMSEA and CFI values were .048 and .91, respectively). Thus, we conclude from our equivalence testing that our 15-factor model is a good fit for the data. Note that the subscales within each factor are also aligned with the constructs in our literature review.

Reliability and relationships among factor scores. To assess reliability, we examined Cronbach's alpha for items within each subscale (factor). Alpha scores ranged from .74–.95 with one scale having an alpha of .66. Thus, most subscales had high internal consistency. To provide additional validity evidence, we calculated correlations between the item subscales associated with each factor (see Figure 2).

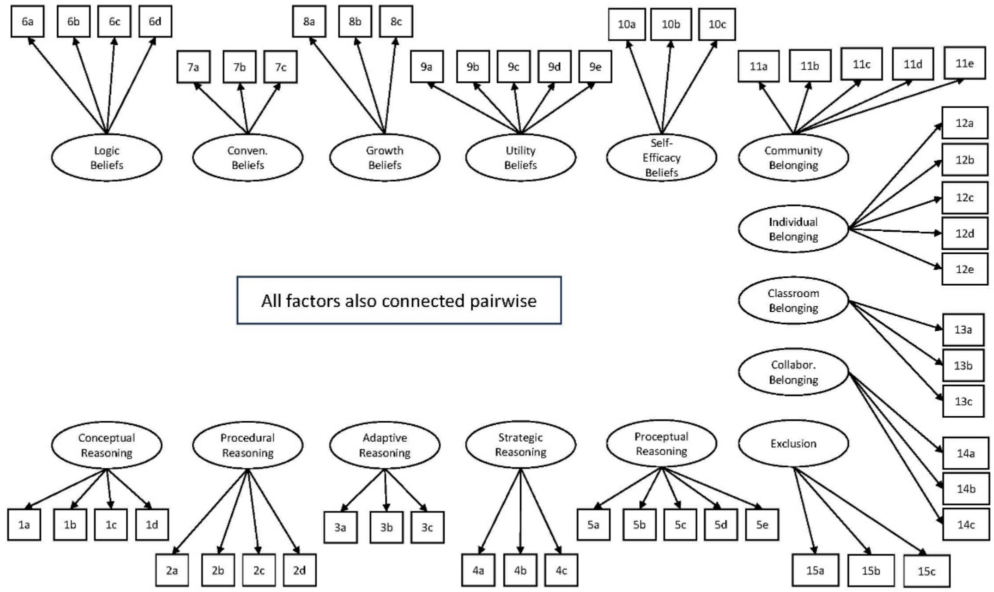

Figure 1. This graphic presents our CFA model, including the 15 factors and the items that load onto them.

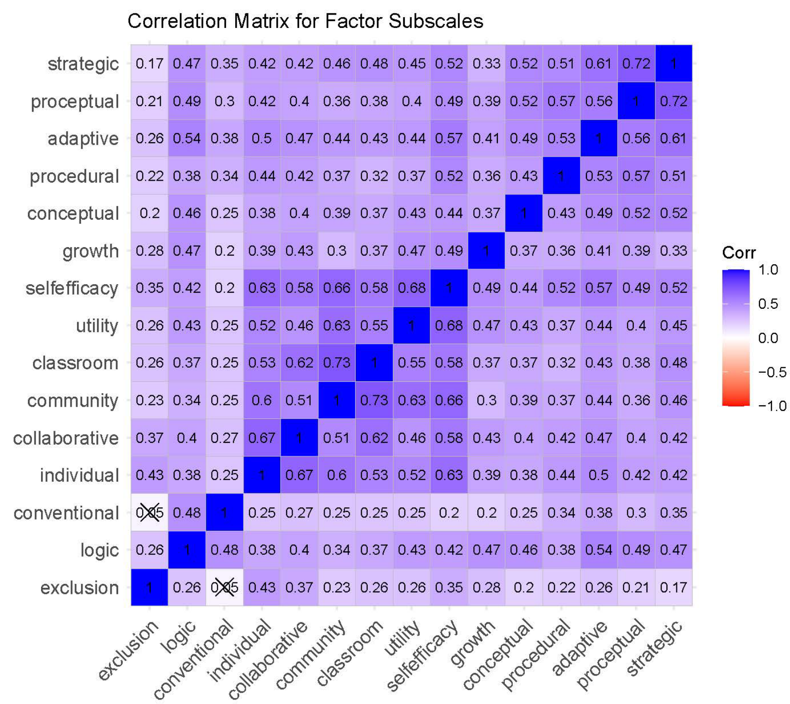

Figure 2. Correlation matrix for factor subscales. All correlations are significant at the alpha = .05 level except those indicated with an X.

Importantly, our analysis reveals strong correlations among items tapping components of belonging (Community, Individual, Classroom, Collaborative), suggesting that these subscales do, indeed, measure interrelated aspects of students' sense of belonging in mathematics. In contrast, belonging subscales are less strongly correlated with students' beliefs about the nature of mathematics and their self-perceived proficiency. Likewise, subscales that measure students' self-perceived proficiency (Conceptual, Procedural, Strategic, Adaptive, Proceptual) are strongly related to each other as well as the Self-Efficacy subscale and the Logic beliefs subscale. In sum, the general pattern of correlations across subscales reflects our expected theoretical structure.

Discussion and Conclusions

Researchers and educators interested in understanding how instructional factors in postsecondary mathematics education shape students' beliefs about mathematics and their own approaches to mathematics need a valid and reliable tool for measuring these beliefs. Our team successfully developed a contemporary instrument, the College Mathematics Beliefs and Belonging (CMBB) survey, to assess a variety of related theoretically meaningful constructs that capture various students' experiences in college mathematics courses. The survey assesses students' self-perceived proficiency in a way that is aligned with theory and prior research delineating the multiple facets of student reasoning that are crucial for engaging in college mathematics. The survey also measures a variety of beliefs, including students' beliefs about the nature of mathematics, the utility of the mathematics they are learning, their own abilities to learn mathematics, and the possibilities for growth in mathematical knowledge. In sum, the College Mathematics Beliefs and Belonging (CMBB) survey captures meaningful variability in students' beliefs and is a valid tool for gathering information about college students' beliefs and sense of belonging in mathematics. It is our hope that postsecondary mathematics instructors and education researchers can use this tool to examine and improve students' experiences in mathematics courses.

How do calculus instructors frame tasks for introducing derivatives symbolically? Identifying Calculus-specific instructional situations

Saba Gerami
University of Michigan

In this study, I describe how seven U.S. college calculus instructors framed instructional tasks for introducing derivatives symbolically to students. During one-on-one interviews, the instructors were presented with before and after student conceptions and were asked to propose tasks for introducing derivatives symbolically using the limit definition of derivative, both at a point and as a function. The instructors' task framings reveal the types of mathematical problems students are expected to work on with respect to the content at stake: symbolic definitions of derivatives. Although the instructors heavily relied on calculating situations to introduce derivatives symbolically, some also used graphing, exploring, installing, and proving situations, which shows the high variability of task framing in calculus even when student conceptions before and after working on the tasks are predetermined.

Keywords: Calculus teaching, instructional tasks, derivatives, instructional situations

Despite the continuing research on students' understandings of calculus concepts, there is less research on the teaching of calculus (Larsen et al., 2017). The scarce research in this area focuses on the student outcomes of instructional treatments (e.g., Borji et al., 2018; Hähkiöniemi, 2006) or tasks that instructors use in their assignments, textbooks, and exams (e.g., Tallman et al., 2016; White & Mesa, 2014). I focus on teaching of calculus by investigating instructional tasks, or activities that are used during instruction "to focus students' attention on a particular mathematical idea" (Stein et al., 1996, p. 460). As basic units of instruction and "objects of students' activity" in mathematics classrooms (Ni et al., 2018; Sullivan et al., 2009, p. 859), instructional tasks are often seen as the conceptual bridge between teaching and learning (Christiansen & Walther, 1986; Stein & Lane, 1996).

I contribute to this line of research by focusing on the ways college Calculus I instructors shape, or *frame*, students' mathematical work during instruction of one specific piece of content: derivatives. By focusing on these subject-specific *framings* in tasks, we learn about the learning opportunities that are offered to students during instruction (Herbst et al., 2018). Here, I address the following research question: How do college Calculus I instructors frame instructional tasks to introduce derivatives symbolically?

Theoretical Frameworks

Framing

The concept of framing originates from the work of social scientists and sociologists Gregory Bateson (1904-1980) and Erving Goffman (1922-1982). Bateson (1974/2003) referred to framings as definitions of reality, determined by the culture, that allow people to interpret and respond to objects and events during social interactions. For Goffman, framing is simply one's answer to the question "What is it that's going on here?"; the answer, implicitly or explicitly, informs the person about acceptable and unacceptable (re)actions and behaviors during a social event (1974/1986, p. 8). To unpack college calculus instructors' framing of instructional tasks for teaching derivatives, I divide Goffman's question of 'what is it that is going on here' into two questions: 1) What is it that is going on here with respect to the content presented in the task? and 2) What is it that is going on with respect to interaction with other actors? I refer to the answers to these questions as *Framing for Interaction with Content* and *Framing for Social Interaction*. Although students make sense of what they should and should not do during a lesson by answering both questions, I only focus on the former here due to space reasons.

To answer the question about framing of a task for interaction with the content, I rely on Herbst and colleagues' (2020) notion of instructional situations (or situations in short) within the notion of didactical contract that govern the teacher-student relationship in the teaching and learning of mathematics (Brousseau, 1984). Instructional situations, as subject-specific types of mathematical problems in a course of studies, communicate teacher's and students' appropriate and customary units of work regarding the knowledge at stake (Herbst et al., 2020, p. 5). Given an instructional situation (e.g., finding the equation of a line in an algebra task), students know what kind of problem they are presented with and what kind of mathematical work and interactions they should prototype (Herbst & Chazan, 2012). The eight generic types of problems they have identified so far in geometry and algebra include: *graphing*; *calculation*; *exploration/conjecturing*; *doing proofs*; *generating a new definition or installing a new concept*; *installing a new theorem, property, or formula*; *solving equations with known methods*; and *solving word problems* (see Herbst et al., 2010).

Conceptions of Derivatives

To ground instructors in the students' conceptions of derivatives, I used Zandieh's (2000) framework for the concepts of derivative (Table 1). Zandieh (2000) organized students' conceptions by representation (graphical, verbal, physical, symbolic) and process-object layers (ratio, limit, function). The process-object layers are hierarchical, as each layer is found by taking the process of that layer over the previous layer as an object. For example, the limit layer is found by the *process of* finding the limit of the ratio as an *object*. Here, I focus on instructors' tasks that were proposed to introduce derivatives symbolically at the limit layer and at the function layer.

Table 1. Zandieh's (2000) adapted framework for the concepts of derivative.

		Representations			
		Graphical	Verbal	Physical	Symbolic
Process-Object Layer	Ratio	Slope of the secant line	Average rate of change	Average velocity	Difference quotient
	Limit	Slope of the tangent line	Instantaneous rate of change	Instantaneous velocity	Limit of the difference quotient
	Function	Graph of the derivative function	Rate of change of a function	Velocity as a function of time	Derivative as a function

Methods

Using an in-take survey of 48 calculus instructors, I purposefully selected eight interviewees with different patterns of inquiry (see Gerami, 2023 for details): Adrian, Barry, Gopher, Justin, Matthew (He/Him pronouns), Monica (She/Her pronouns), Max (They/Them pronouns), and Alex (all pronouns). The participants were tenured and had more than four semesters of experience teaching Calculus I with inquiry. My focus on teaching experience and using inquiry was intentional; as my aim was to have instructors suggest diverse instructional tasks based on targeted students' conceptions of derivatives during the interviews, I assumed that experienced instructors who employ inquiry-based teaching methods for calculus are more likely to know of and consider student thinking when proposing tasks, and that they would propose a broader range of instructional tasks compared to those who teach calculus more traditionally (e.g., following conventional textbooks, lecturing). I conducted four semi-structured interviews (1-2 hour long each) with each instructor, as they proposed up to eight instructional tasks for introducing derivatives. I structured the interviews based on Zandieh's (2000) framework. During each interview, the instructors were asked to propose two tasks that targeted students' conception at the limit and the function layer within one representation. They could use their teaching materials to propose already used tasks or design new tasks for the future. Here, I report the findings based on the tasks proposed in response to Prompt 7 and 8:

> **Prompt 7:** Assume that you have already taught about the difference quotient ($\frac{f(x)-f(x_0)}{x-x_0}$ or $\frac{f(x+h)-f(x)}{h}$) and want students to learn about the derivative of a function at a point ($f'(x_0) = \lim_{x \to x_0} \frac{f(x)-f(x_0)}{x-x_0}$ or $f'(x_0) = \lim_{h \to 0} \frac{f(x_0+h)-f(x_0)}{h}$). Propose a task where students have to figure out the derivative of a function at a point.
>
> **Prompt 8:** Assume that you have already taught about the derivative of a function at a point ($f'(x_0) = \lim_{x \to x_0} \frac{f(x)-f(x_0)}{x-x_0}$ or $f'(x_0) = \lim_{h \to 0} \frac{f(x_0+h)-f(x_0)}{h}$) and want students to learn about the derivative function ($f'(x) = \lim_{h \to 0} \frac{f(x+h)-f(x)}{h}$). Propose a task where students have to represent the derivative function.

Because calculus-specific instructional situations have not been identified in the literature, I used inductive/deductive hybrid thematic analysis (Proudfoot, 2022) to identify them. The analysis entailed using pre-ordinate themes "through the application of an explicit theoretical framework developed through engagement with the literature" (the deductive element) to generate themes from the data (the inductive element; Proudfoot, 2022, p. 1). For the deductive portion, I used the generic types of problems: *graphing*; *calculation*; *exploration/conjecturing*; *doing proofs*; *generating a new definition or installing a new concept*; *installing a new theorem, property, or formula*; *solving equations with known methods*; and *solving word problems* (Herbst et al., 2010). For the inductive portion, I identified the emerging instructional situations by focusing on the mathematical work that instructors expected of their students would do within a generic type of problem. I also listened to the interviews and read the transcripts to find relevant information that instructors mentioned but did not include in the task description. After three rounds of coding, I identified 36 calculus-specific instructional situations across *all* eight tasks.

Findings

Figure 1 lists the 12 calculus-specific instructional situations that instructors used in their two tasks proposed for teaching derivatives symbolically at a point and as a function (Prompt 7 an 8).[1] All seven instructors who proposed tasks used one or two specific calculating situations to frame their tasks: *Calculating derivative at a point using a limit definition* (C6) and *Calculating derivative function $f'(x)$ using a limit definition* (C11). Four instructors utilized other types of situations to frame their tasks. Alex, Max, and Adrian used graphing situations at different layers

[1] Each instructional situation is identified by a letter representing the generic situation type (C for Calculating, E for Exploring/Conjecturing, G for Graphing, I for Installing, and P for Proving), and a number to differentiate it from other situations in the same category. Although Figure 1 only includes the situations that appeared in the tasks for introducing derivatives symbolically, I kept the original numbering system to keep my findings across research reports consistent.

(secant line [ratio, G1], tangent line [limit, G2], derivative function by plotting [function, G3]). Alex, Max, and Monica used the tasks to install ideas and formulas (e.g., power rule, I7). Finally, Max was the only instructor who used exploring and proving situations (E11 and P1).

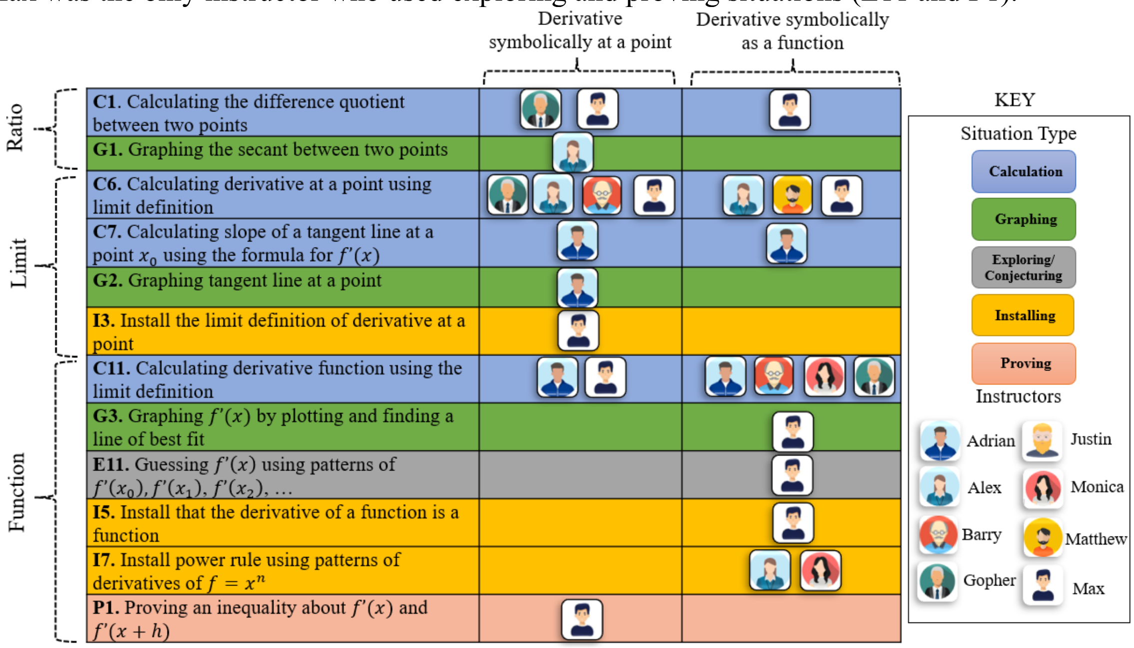

Figure 1. Identified instructional situations for introducing derivatives symbolically at a point and as a function and instructors who used them. Situations are organized by layer and generic type.

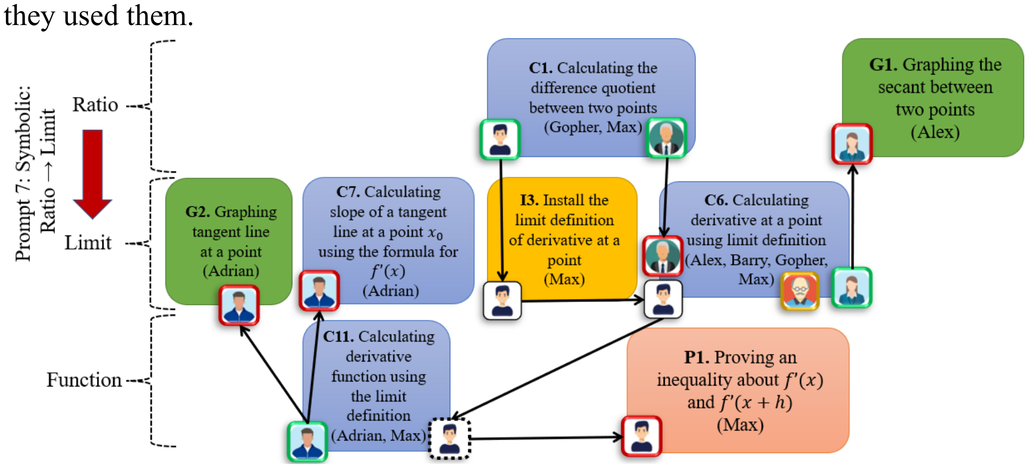
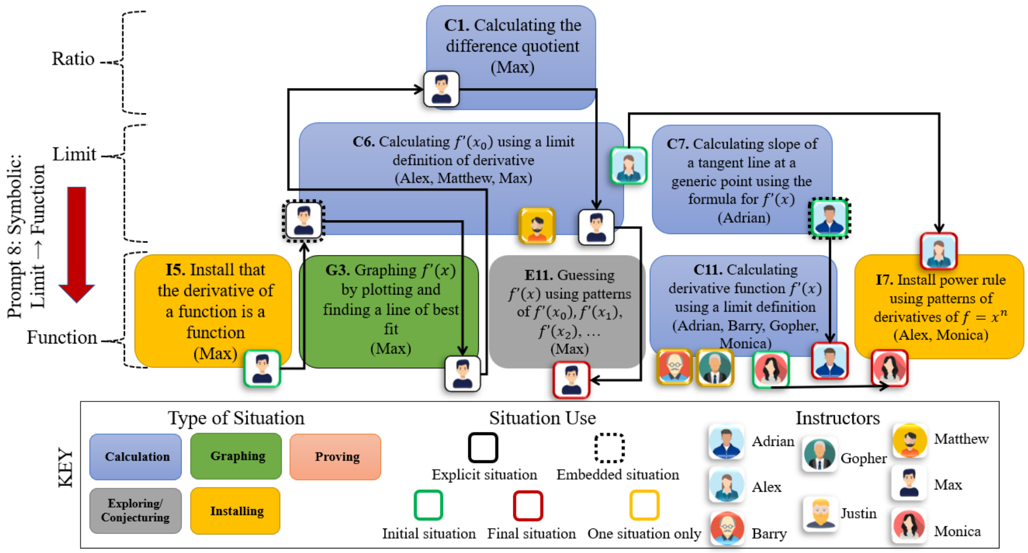
Justin did not propose any tasks for Prompt 7 and 8 (he stated that he does not explicitly talk about the difference quotient in the notation proposed by the prompts or the limit definition of derivative). Monica and Matthew did not propose tasks for Prompt 7, as they did not teach about derivative symbolically as a point, but they did propose tasks for Prompt 8. Next, I provide an overview of how the instructional situations were used in the tasks proposed for each prompt.

Tasks Proposed for Prompt 7: Ratio → Limit

Figure 2a shows the instructional situations that five instructors used to frame their tasks in the order they used them.



(a)



(b)

Figure 2. Calculus-specific instructional situations in the order they appeared in the tasks proposed for (a) Prompt 7 and (b) Prompt 8. The arrows show the order in which the situations were used by each instructor. A situation is explicit if students know what type of problem they are working on after being presented with a task, whereas a situation is embedded within an explicit (larger) situation if, while working on the explicit problem, students find out that they must solve another problem in order to solve the explicit situation.

Max and Gopher started their tasks at the ratio layer, before the limit/target layer, by asking students to: *calculate difference quotients between two points*, x_1 and x_2, or x_0 and $x_0 + h$ (C1). Gopher ended his with the situation of *calculating the derivative at a given point* x_0 at the limit layer (C6), which was the situation that Barry started and ended his task with. Barry, Gopher, and Max expected their students to use formal limit notation to calculate $f'(x_0)$ at a given point x_0 ($\lim\limits_{h\to 0}\frac{f(x_0+h)-f(x_0)}{h}$). Max continued their task with four more situations after calculating difference quotients between two points (x_0 and $x_0 + h$, with decreasing h, the ratio layer; C1). First, Max *installed the limit definition of derivative at a point* ($\lim\limits_{h\to 0}\frac{f(x_0+h)-f(x_0)}{h}$; I3). While other instructors installed the limit definition of derivative at a point *themselves* before the tasks (most probably via lecture), Max expected students to come up with the definition as part of the task by asking them: "What we can do to determine a value at $x = 0$? What concept from calculus helps us analyze questions about arbitrarily small sizes?". Next, they asked their students to: 1) use their newly defined derivatives to *calculate* $f'(x_0)$ *at some given points* (C6), and 2) to show an inequality $f'(x) < f'(x+h)$ for $h > 0$ (*P1. Proving an inequality is true for a specific function*). The proving situation has embedded calculating situations—*calculating* $f'(x)$ *and* $f'(x+h)$ *using the limit definition of derivative* (C11).

Alex started their task at the target/limit layer with the same situation that Barry, Gopher, and Max also used in their tasks: *calculating* $f'(x_0)$ *at some given points* (C6). However, unlike the other instructors, they did not use formal limit notation; instead, they expected their students to assume the denominator goes to zero when calculating the difference quotient $\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x}$. Alex explained that, at this point in their course, the limits are replaced with arrows (→) instead of equal signs ($\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x} \to c$ as $\Delta x \to 0$, instead of $\lim\limits_{\Delta x\to 0}\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x} = c$). To assist students with confirming the value of the difference quotient with Δx going to zero, Alex then asked students to "Describe what happens to the secant lines as Δx gets closer to zero?", which is a situation at the ratio layer: *graphing secant lines* Δx*-units distanced to the right side of a fixed point* x_0*, assuming* Δx *gets closer to zero* (G1).

Adrian approached the task differently than the rest of the instructors by starting his task at the function layer (the layer after the target/limit layer): *calculating* $f'(x)$ *using the limit definition of derivative* $\lim_{h \to 0} \frac{f(x+h)-f(x)}{h}$ (C11). He then asked his students to g*raph a tangent line at a given point* $(x_0, f(x_0))$ (G2) and *find its slope* (i.e., the derivative at a point or $f'(x_0)$; C7), which are two situations at the limit/target layer. I capture the latter situation C7 separately than those used by Barry, Gopher, Max and Alex (*C6. Calculating* $f'(x_0)$ *at a given point* x_0 *using the limit definition of derivative at a point* or *Calculating the difference quotient assuming the denominator goes to zero*) because Adrian expected his students to substitute x_0 in the formula of $f'(x)$ found in his task's initial situation, instead of using the limit definition to calculate derivative at the point.

Tasks Proposed for Prompt 8: Limit → Function

Figure 2b shows the instructional situations that the seven instructors used to frame their tasks in the order they used them. At the function/target layer, *calculating* $f'(x)$ *using the limit definition of derivative* (C11) was the most common situation, used by four instructors—Barry, Gopher, Adrian, and Monica—with Barry and Gopher solely using this situation to frame their tasks. In Adrian's task, the situation was embedded within another—*calculating slope of a tangent line at a point* x_0 (C7), as students were expected to calculate and use the formula for $f'(x)$ to find the slope of the tangent line at x_0. Monica asked her students find $f'(x)$ by calculating the difference quotient, $\frac{f(x+h)-f(x)}{h}$, and assuming that *h* goes to zero. After finding $f'(x)$ for $f = x$, $f = x^2$, and $f = x^3$, she used an installing situation, expecting students to *install the power rule using patterns of derivatives of* $f = x^n$ *for* $n \geq 1$ (I7): "What is the general formula for the derivative of x^n?"

Matthew and Alex started their tasks with a situation within the limit layer, where students were expected to *calculate* $f'(a)$ *for a generic variable (a) either using the limit definition of derivative at a point using the formal or informal definition of derivative with limit of difference quotient* ($\lim_{x \to a} \frac{f(x)-f(a)}{x-a}$ for Matthew, and $\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x} \to c$ *as* $\Delta x \to 0$ for Alex; C6). Although the instructors were prompted to introduce students to the derivative symbolically as a function, Matthew only used the situation of calculating $f'(a)$ for a generic value of a at the limit layer, not $f'(x)$. Because Matthew used a linear function in the task—$f(x) = 5x - 3$, with $f'(x) = 5$ for all values of x, it is possible that he equated finding $f'(a)$ to $f'(x)$, which, mathematically, is true. However, from the task's description, it is not obvious whether students would conclude that the "derivative 5" is in fact a function. Alex continued their task like Monica's by installing the power rule using patterns of derivatives of $f = x^n$ *for* $n \geq 1$ (I7).

To frame their task, Max used five explicit situations across all three layers. Max started the task by asking students to review their work for Task 7, in which students found the derivative at various points. They then encouraged students to *install that derivative of a function is a function* (I5) by asking: "Because we have a derivative value at every function input value, what do we have?". Next, Max asked students to *graph* f' *by plotting derivative values at different points and finding a curve of best fit* (G3). Although students used the derivative values they found at various points in Task 7, I captured *calculating $f'(x)$ using the limit definition of derivative* $\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$ (C6) as an embedded situation before the graphing situation to count for the work students should have done to complete this part. Next, Max used a situation at the ratio layer by asking students to *calculate the difference quotient* $\frac{f(x_0+h)-f(x_0)}{h}$ (C1) for various values of x_0, which was immediately followed by asking students to *calculate $f'(x_0)$ using the limit definition of derivative* $\lim_{h\to 0}\frac{f(x_0+h)-f(x_0)}{h}$ (C6) for their chosen x_0 values. Max ended his task at the function/target layer with an exploring/conjecturing situation: *guessing $f'(x)$ using patterns of $f'(x_0), f'(x_1), f'(x_2), \ldots$* (E11).

Discussion

In this report, I identify the ways seven college Calculus I instructors framed their instructional tasks to introduce the symbolic representations of the derivative at a point and as a function, that is the limit definitions of derivative. While all instructors used calculating derivative at a point and/or calculating $f'(x)$ using a limit definition, four instructors also relied on other types of situations: graphing, exploring/conjecturing, installing, and proving. Although I did not review the findings from the rest of their tasks in this report, the proving situation (P1), the installation of power rule (I7) and installation of the limit definition of derivative at a point (I3) were only used to frame tasks for Prompt 7 and 8. Moreover, the proving situation was the only proving situation used across all tasks, which suggests that the instructors avoided using proving situations when introducing derivatives. More specifically, regarding the installation of power rule (I7), it is noteworthy that two instructors (Alex and Monica) used the symbolic representations to install one specific derivative rule—the power rule. Lastly, although some instructors used similar calculus-specific instructional situations within the three generic problem types, only two instructors proposed the same task consisting of all the same instructional situations (Barry and Gopher for their second tasks). This illustrates instructors' varied ways of shaping students' work when introducing derivatives, which shows that inquiry methods are implemented considerably differently among instructors. Nonetheless, most instructors relied on explicit, rather than implicit situations, which shows their inclinations towards scaffolded inquiry, rather than open-problem or discovery-based inquiry.

Acknowledgement

Funding for this work was provided by the University of Michigan's Rackham Graduate School to the author. I sincerely thank Dr. Vilma Mesa, Dr. Patricio Herbst, and the RTMUS lab for their continuous guidance and feedback.

Student Reasoning and Cooperative Learning while using a Dynamic Geometry Environment in Taxicab Geometry: An APOS Perspective

Aubrey Kemp
California State University, Bakersfield

The goal of this research is to investigate ways a dynamic geometry environment (DGE) and interactions during cooperative learning can leverage student understanding in geometry. Data from 18 students enrolled in a College Geometry course were collected by video recording in-class group work while students explored concepts in Taxicab geometry in a DGE. The textbook from this course and its activities are based on Action-Process-Object-Schema (APOS) Theory. As such, APOS Theory was used as a theoretical framework to analyze student reasoning during these activities. For this report, results are presented for one group of students and their discussion while working on an activity which encouraged the exploration of the mathematical definition of a circle in Taxicab geometry in a DGE. Trends emerged about how group structure while working in DGEs may influence interactions and outcomes for students. Some pedagogical suggestions are provided based on the results of this study.

Keywords: Geometry, Taxicab, Dynamic Geometry Software, Circle, Definitions

Introduction

By exploring concepts and definitions in non-Euclidean geometry, students can better understand Euclidean geometry (Dreiling, 2012; Hollebrands et al., 2010; Jenkins, 1968). One example of a non-Euclidean geometry in which students can explore concepts is Taxicab geometry, which is the geometry that is the result of measuring distance as defined by the L_1 norm. Siegal et al. (1998) and Dreiling (2012) encourage the introduction to Taxicab geometry before other non-Euclidean geometries since the simpler space makes it more accessible for students to reason and abstract concepts. Further, the use of a dynamic geometry environment (DGE) for the teaching and learning of geometry is encouraged (Liljedahl, P., 2020; Hollebrands 2003; Hollebrands et al., 2010; Glass & Deckert, 2001; Contreras, 2013; Kemp, 2018). Since properties of geometric figures are derived from definitions within an axiomatic system, it is important to note that a figure is "controlled by its definition" (Fischbein, 1993, p. 141), rather than a geometric representation influencing the definition. As DGEs offer opportunities for students to interact with accurate constructions rather than drawings on paper, students can explore and focus on relationships between concepts and their definitions. This can guide students to differentiate between drawings and constructions, abstract properties and relationships, and develop a higher level of geometric reasoning and understanding. Cooperative learning, which involves students working in groups to complete a common goal, can help students to maximize their own and each other's learning (Johnson & Johnson, 1999). In cooperative learning settings, students are also more likely to reflect on the procedures they perform (Vidakovic, 1993). Researchers also emphasize the importance of cooperative learning on psychological health and social competence, as this can encourage students to value themselves and increase independence (Johnson & Johnson, 1999).

For this report, results are presented on the following research questions: (a) How do students in a College Geometry course develop their understanding of the definition of a circle in Taxicab geometry using a DGE? (b) How does the use of cooperative learning and DGEs help students to construct knowledge in geometry?

Theoretical Framework

Action-Process-Object-Schema (APOS) Theory is a constructivist framework based on Piaget's *reflective abstraction*. According to this framework, there are four different stages of cognitive development (Action, Process, Object, and Schema) and mechanisms to move between these levels (e.g., interiorization, encapsulation) (Arnon et al., 2014; Dubinsky, 2002; Asiala et al., 1996). In APOS Theory, an *Action* is an externally driven transformation of a mathematical object. For example, an action conception of **Circle** may be exhibited by a student being prompted to identify a point on a circle when given a specific center and radius. Once an individual performs an Action enough and reflects on this, they can *interiorize* this Action into a *Process*. That is, a student demonstrating a process conception of **Circle** can imagine how to draw a circle given any center and radius, understanding that the circle is made up of an infinite number of points that satisfy a property. A Process is *encapsulated* into an *Object* once the individual is aware of it as a totality on which other actions can be performed. As an example of this for **Circle**, a student may exhibit this level of cognitive development when they construct a perpendicular bisector using circles, generally understanding how properties of circles justify why this creates a set of points equidistant from the endpoints of a segment. Once a student constructs an object in APOS Theory, it may be necessary to *de-encapsulate* it. For example, Kemp and Vidakovic (2019) present results of students de-encapsulating their object conception of **Distance** to coordinate their **Euclidean distance** and **Taxicab distance** processes. The entire collection of Actions, Processes, Objects, and other Schemas that are connected to the original concept that form a coherent understanding in the mind of the individual is called a *Schema* and is uniquely formed based on experiences (Dubinsky, 2002). The concepts involved with the *circle schema* are identified to be **Distance, Radius, Center,** and **Locus of points** (Kemp, 2018; Kemp & Vidakovic, 2018, 2019, 2021b, 2023). As a part of these students' developing *circle schemas,* we analyze their conception of the definitions of these concepts as they emerged during a class activity. Detailed descriptions of the levels of cognitive development in APOS Theory associated with these and other concepts in Euclidean and Taxicab geometry are provided in Kemp (2018) and Kemp and Vidakovic (2018, 2019, 2021a, 2021b, 2023).

There is some research that utilize APOS Theory in relation to DGEs (Hollebrands, 2003; Patsiomitou, 2019; Trigueros et al., 2022; Kemp, 2018), but a search in the literature implies a need for more. Further, the vast majority of this research focuses on Euclidean geometry. As exploration in non-Euclidean geometry can offer opportunities for students to refine their understanding of concepts, it is important to investigate how exploration in non-Euclidean geometries in DGEs can also contribute to this refinement. Results presented in Hollebrands (2003), where high schoolers' use of a DGE and how these students reasoned about transformations in geometry was investigated using APOS Theory, is used as a model in this report as the author provides a framework based in APOS Theory for student understanding as it evolves while using DGEs. The author indicated student understanding of the domain of a transformation may have been influenced by their interactions with the computer as the students interiorized the actions they performed on the computer, which contributed to their ability to form explanations of the transformations. Without the opportunity to use a DGE, students in the control group of this study were only able to examine and perform transformations on the limited number of samples provided to them and did not develop as dynamic of an understanding of these transformations. Adapted from Hollebrands (2003) for the context of this study, an action conception of *circle* in Taxicab geometry in a DGE may be exhibited by a student counting units to find a point on a circle given a specific center and radius. Once a student interiorizes this action, they can consider all points on the circle and operate with the theoretical definition of a point on a circle, rather than particular points on the screen. They can also imagine drawing a circle given any center and radius. An object conception of *circle* in Taxicab geometry in a DGE may be demonstrated by a student considering general properties and behaviors of circles in Taxicab geometry without relying on the specific examples in their DGE. As a note from Hollebrands (2003), students with a process conception of a transformation can anticipate the results of a transformation without having to perform the actual transformation on the computer.

Methodology

This study was conducted in a College Geometry course at a large university. There was a prerequisite for the class of an introduction to proofs course, and the enrollment in the class was comprised of seven undergraduate math majors and eleven graduate students who were pre-service or in-service secondary teachers. The textbook used for the course was College Geometry Using the Geometer's Sketchpad (Fenton & Reynolds, 2011) and is based on APOS Theory and the Activities, Classroom discussions, and Exercises (ACE) Teaching Cycle (Asiala et al., 1996). It is noted the course utilized Geometer's Sketchpad (GSP), which is a platform no longer supported for use. As GSP is a DGE and operates similarly to other DGEs, the methodology and results of this study can be transferrable to other DGEs. Concepts learned throughout the course in Euclidean geometry were introduced in Taxicab geometry during the last four 75-minute classes of the semester. All 18 students enrolled in the course volunteered to participate in this study, and audio and video recordings from in-class group work, work completed in GSP, and written work or notes during these class sessions for all 18 students were collected as data. The activity corresponding to the results presented in the current report was intended to guide students through the construction of a circle in Taxicab geometry in GSP and generalize this construction. Examples of a circle in Euclidean geometry and a circle in Taxicab geometry are illustrated in Figure 1. The activity is described below:

1. Plot points at $P(3,4)$, $A(2,2)$, $B(3,7)$, $C(2,5)$, and $D(5,5)$. By counting the number of blocks from P to A, we find that the *taxi-distance* PA is 3 units. Find the taxi-distances PB, PC, and PD. Two of these points are the same taxi-distance from P as A is. Which two?
2. The set of all points that are at the same taxi-distance from P form a *taxi-circle* centered at P. In part (a), three of the points lie on a taxi-circle of radius 3 centered at P. Find several additional points on this taxi-circle. Describe the set of all points that are at a taxi-distance of 3 units from a fixed point P. How is the shape of a taxi-circle different from (or similar to) the shape of an ordinary Euclidean circle?
3. If you are given a point $Q(x_q, y_q)$ and a radius r, how could you quickly sketch a taxi-circle of radius r centered at Q?

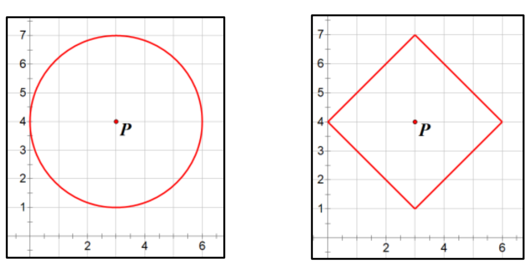

Figure 1. Geometric representations of a Euclidean and Taxicab circle each with center $P(3,4)$ and radius 3.

The design of this activity guides students through performing actions by prompting them to calculate the distance between points in Taxicab geometry to find examples and non-examples of points lying on a circle centered at (3,4) with radius 3. The students are prompted to find additional points that are 3 units away from the center and describe the set of all points that make up this circle. This is intended to guide students to interiorize the actions performed previously in the DGE into a process by focusing on the theoretical definition of a circle rather than the points on their screen. Students are then asked to compare their geometric understanding of a circle in Taxicab geometry to a circle in Euclidean geometry to aid in generalizing properties of a circle (i.e., all points are equidistant from the center, a circle looks different in Taxicab and Euclidean geometry based on how distance is defined), indicative of an object conception of *circle*.

The 18 students enrolled in the course were divided into six groups of three prior to this activity and had already worked through several activities about distance in Taxicab geometry. Students were used to working in groups and in GSP as these were regular and integral parts of the course. The students had access to a class set of laptops that had GSP installed on them and were at liberty to either each use their own laptop or share a laptop to work on the DGE activities in their groups. The classroom was set up with six square tables with two seats on two of the sides opposite one another, and students were free to move chairs around to work together in different ways in their groups. Using the adapted framework from Hollebrands (2003), data was analyzed from each group to investigate their individual understanding in terms of APOS Theory, their use of the DGE, and how their interactions within the group influenced both of these things. This report focuses on data collected from one of the groups, comprised of one undergraduate student, Ally, and two graduate students who were pre-service secondary teachers, Amy and Brianna, during the activity described above. This group was chosen in this report as they were representative of groups that worked cooperatively towards a shared goal and demonstrated various levels of cognitive development of the concept of **Circle**.

Results

As the prompts for this activity were intended to guide students through various levels of cognitive development, the data collected during this activity provided a rich understanding of how these levels can be exhibited by students while working in a group in a DGE. Ally, Amy, and Brianna all worked on their own laptops while communicating regularly with one another and often talking out loud to themselves to try and articulate their thinking. Ally's work in GSP for this activity is shown in Figure 2 below as a representative of the group. It is noted that students had access to a tool in GSP that was designed to measure the distance between two points in Taxicab geometry. This tool would also display the algebraic representation of the Taxicab distance between two points, seen in the top left of Figure 2.

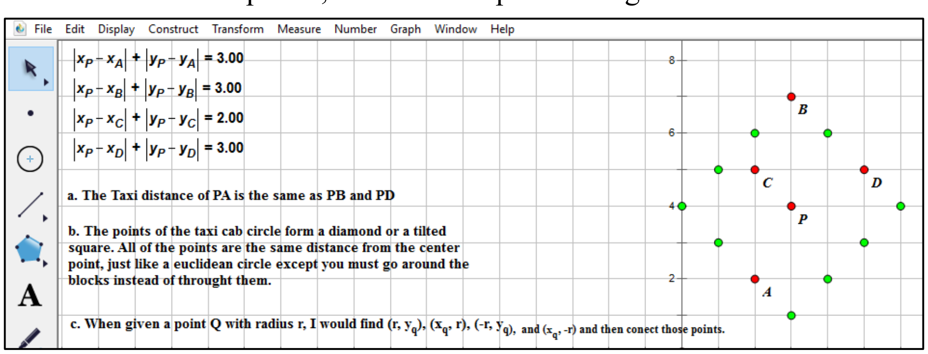

Figure 2. Work in GSP submitted by Ally.

After they read part (2) of the problem which asked students to plot several other points that are three units away from P, Brianna was looking at her graphical representation of the problem and said, "wait, why is PB the same?... Just cause it's three straight up?" to which Amy replied, "'Cause it's like the radius, yeah... of that circle." Shortly after this exchange, Amy began to investigate why the distance from P to A was three and the following interaction occurred:

Amy: 'Cause if that was a triangle, then the length of that hypotenuse be… wait, because PA is like… sides one and two.

Brianna: But we're just finding other like… how many points?

Ally: So, we just need to form like a taxi-circle.

Brianna: But I think we're trying to find other points that we think lie on the taxi-circle.

Ally: (4, 6), umm…

Brianna: Wouldn't $(3,1)$? 'Cause it's the same as PB, just the opposite direction? Like that's the radius, right?

Here, Amy had imagined a right triangle with PA as a hypotenuse and was expressing a comparison between the distance between P and A in Euclidean geometry ("hypotenuse") and in Taxicab geometry ("sides one and two"). This is evidence that Amy was exhibited a process conception of **Distance** by imagining this triangle and comparing the geometric representations of Euclidean and Taxicab distance between P and A, consistent with Kemp and Vidakovic (2023). Ally seemed to indicate she understood they were constructing a circle ("just need to form…a taxi-circle") and used this theoretical definition to anticipate all the points they were finding on the circle they were constructing, indicative of a process conception of **Circle** based on our framework adapted from Hollebrands (2003). Ally also seemed to recognize Brianna was not processing her comment that they are forming a circle and began to list specific points to help the group move into this reasoning. Brianna visualized the vertical distance PB as a radius and essentially reflected this distance ("the opposite direction") over the horizontal line through $(3,4)$ to obtain the point $(3,1)$. Aligning with Hollebrands (2003), since she anticipated the results and implications of a transformation on this radius without having to perform the actual transformation, we interpret this as her exhibiting evidence of a process conception of **Distance** and **Radius**.

As the group continued to explore in GSP while working on the activity, they began to anticipate the shape of the object they were constructing.

Ally: It forms a diamond.

Amy: So, it's not a circle.

Ally: This radius is the same…Well, an ordinary circle is round…I mean they're similar because… the radius is always the same.

Brianna: It's like the distance from…they're all the same distance from the center?

Amy: Well, this is the same distance too, but it's the same taxi-distance.

Brianna: But they're like a different type of distance cause you can go like up, you can move different ways, it's not like straight to it… like a clock.

Ally: They're similar cause its…the radius is all the way around [makes a circular motion with pointer finger].

Brianna: But it's like different.

Amy: They all are like… the same distance.

Brianna: The same distance, but it's like a different type of distance. I'm going to say it's a different type of distance than the radius of a circle.

In this cooperative learning exchange, the group seemed to be maximizing their own and each other's learning as described by Johnson and Johnson (1999) and were all reflecting on the procedures they had performed, consistent with Vidakovic (1993). All three students were working to articulate their thinking, bouncing phrasing and ideas off one another. At first, Amy implied that because this object was a "diamond" [instead of round as in Euclidean geometry], it was not a circle. As the conversation progressed, she heard what her groupmates said and indicated she processed their comments by referring to "the same taxi-distance" in her construction in the DGE. Brianna used a metaphor to explain that a circle in Euclidean geometry is round as a result of using a radius that is a straight segment, like the hand of a round clock. This is evidence Brianna was operating at a process conception of **Circle**, at least within Euclidean geometry, as she was able to generalize properties of the construction of a circle. Amy and Brianna ended up writing extremely similar responses in GSP for this prompt. Seen in Figure 3, Amy [and Brianna] wrote "they are all the same distance from the center, but it's a different type of distance than the radius of a circle." In other words, they seemed to agree that the way distance is measured is the cause of the difference in appearance of a circle in Euclidean geometry and in Taxicab geometry, but indicated they equated the radius of a circle with its representation as distance between two points in Euclidean geometry and that the distance between the same two points in Taxicab geometry is different than a radius.

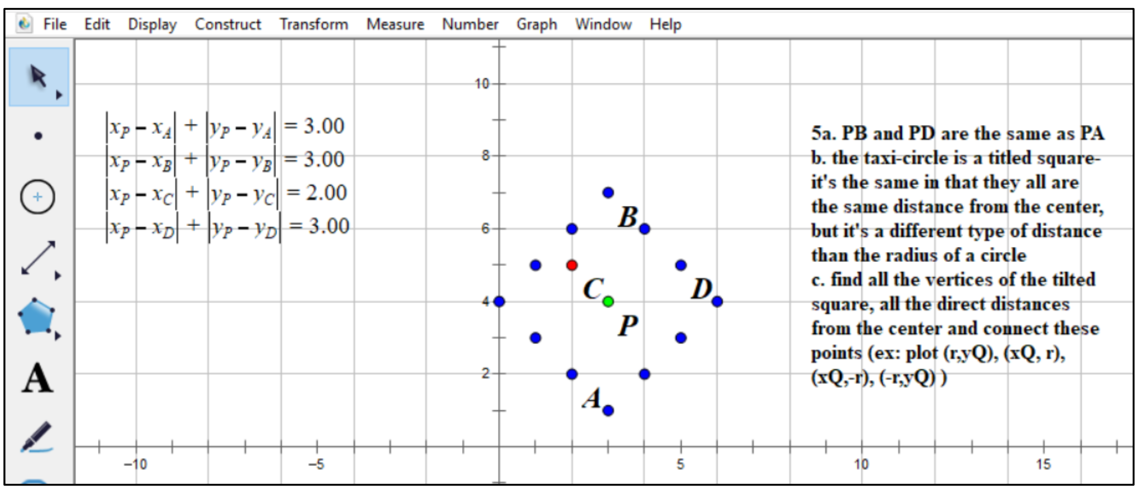

Figure 3. Work in GSP submitted by Amy.

Ally explained that a Euclidean and Taxicab circle were similar in the way they are constructed and compared these constructions across geometries ("they're similar because…the radius is the same…the radius is all the way around.") As she motioned with her pointer finger in a smooth, circular motion it is possible she was imagining a continuous, dynamic procedure defining the locus of points of a generalized circle by rotating a radius 360 degrees. Note she was speaking about an arbitrary circle in both Euclidean and Taxicab geometry at the same time. This is reiterated in her GSP work in Figure 2, where she writes, "All of the points are the same distance from the center point, just like a euclidean circle except you must go around the blocks instead of throught (*sic*) them." It is interpreted that by "go around the blocks," Ally was talking about distance in Taxicab geometry and by "through them," she was talking about distance in Euclidean geometry. As Hollebrands (2003) describes an object conception as a student considering general properties and behaviors rather than relying on the images on their screen, Ally demonstrated here she was exhibiting an object conception of **Circle**.

In the third prompt which asked students how they might quickly sketch an arbitrary circle in Taxicab geometry, the group began discussing geometrically how they would do so. While attempting to articulate this, they shifted over to attempting to write an algebraic explanation for this process. Specifically, for a circle in Taxicab geometry centered at $Q(x_q, y_q)$ with radius r, they determined the points (r, y_q), (x_q, r), $(-r, y_q)$ and $(x_q, -r)$ would be on the circle and by connecting these points, they will have constructed the entire circle. Brianna wrote in GSP, "I would find the 4 vertices (or points that are a straight/direct distance from the center) and then connect them to find the other points that lie on the taxi-circle." Brianna indicated here that she could imagine and understood all the points she would draw would be on the circle, indicating she was operating with at least a process conception of **Circle**. Amy wrote, "find all the vertices of the tiled square…and connect these points." This is notable because it may be the case that Amy was uncomfortable with calling the object a circle, perhaps an example of the tendency to neglect the definition of a concept under the pressure of [assumed] figural constraints, described by Fischbein (1993). Although the procedure determined by the group would only be true for a circle centered at the origin, this indicates a conceptual understanding in terms of identifying the intended points. Right after they wrote these coordinates, the class period ended. If they had more time, it is possible that they would have been able to test their conjecture of these coordinates and adjust them.

Discussion

As they worked to abstract properties, Amy, Brianna, and Ally bounced reasoning off one another. Ally demonstrated operating at a variety of levels of conception of **Circle**, moving between these levels during conversations to either explain a concept to a group member or try and abstract an idea. Brianna and Amy both provided evidence of operating at the action and process levels of conception of **Circle** and made connections through their conversation and explorations in the DGE. In this cooperative learning setting, all three students provided evidence that they were working toward a shared goal. They leveraged their exploration individually on their own laptops in their discussion and used comments from one another to help guide their exploration. When one group member was confused, they tended to try and clarify or help explain something. In this way, the group seemed to support the notion that the activity encouraged them to help one another as it would also benefit themselves, maximizing their own and each other's learning, while increasing their independence (Johnson & Johnson, 1999). As this group all explored on their own laptops, they often were not looking at the same screen while referencing the same objects. While this did not seem to hinder their conversation, it is possible this could deter some groups from conversing meaningfully about the activity. Some pedagogical suggestions based on this research include structuring DGE work in groups to encourage individual exploration while explicitly working toward a shared goal. By doing this, it is possible students will leverage their understanding to help explain concepts to one another and maximize the entire group's understanding, as the participants in this study did. Further, offering more opportunities for students in College Geometry courses to explore non-Euclidean geometry earlier in the course and in DGEs may be beneficial to their understanding of Euclidean concepts as they study them. Future research may investigate different types of structure in DGE group work and how this affects individual understanding. For example, what affordances or hindrances might arise if students all shared one laptop and were looking at the same screen rather than exploring individually? As this study utilized APOS Theory, DGEs, and cooperative learning, it may help fill a gap in the literature of undergraduate mathematics education.

Instructors’ Grounding Metaphors for Quotient Groups

Holly Zolt — Texas State University
Kate Melhuish — Texas State University

In this report, we examine the use of grounding metaphors across three abstract algebra instructors in their discussion of quotient group instruction. We identified three primary categories: construction metaphors, equivalence metaphors, and positional metaphors. The construct metaphors were further refined into building metaphors and demolition metaphors. In this paper, we provide an overview of the types of grounding metaphors in usage and provide insight into how the different instructors took on these metaphors when describing quotient groups and their instruction. We conclude with some considerations as to how these metaphors provide insight into quotient structure and considerations for future research.

Keywords: Metaphorical Thinking, Abstract Algebra, Instruction, Quotient Groups

Quotient groups have been identified as one of the most important, but also one of the most difficult topics in Abstract Algebra (Melhuish, 2019). Most of the research conducted regarding quotient groups has focused on how students think about quotient groups (e.g., Asiala et al., 1997; Melhuish et al., 2023). This literature base suggests students might develop only partial understandings such as relying on coset generation procedures (Hazzan, 1999) or seeing elements of quotient groups as sets and elements but not both (Asiala et al., 1997; Siebert & Williams, 2003). Some researchers have suggested that meanings related to partitioning are more productive as they are compatible with viewing quotient groups as the preimage of a homomorphism (Melhuish et al., 2023) and can support a richer understanding of why only certain subgroups can form quotient groups (Larsen & Lockwood, 2013). This work suggests that partitioning might serve as one important grounding metaphor for quotient groups. However, there is significantly less known about the way in which instructors conceptualize quotient group, what other metaphors may exist, and how they are taught. The goal of this proposal is to contribute to the literature on the teaching of quotient groups by addressing the use of metaphors in instruction. The research questions being addressed is:

What grounding metaphors about quotient groups are used during abstract algebra instructors’ descriptions of their teaching?

Literature Review

There is a great deal of consistency in the teaching of proof-based courses with the genre of chalk-talk dominating the way in which most of the courses are taught (Melhuish et al., 2022). That is, instructors lecture, writing formal mathematics on the boards, verbalize what is written and provide additional, often informal, insights, and ask students some form of questions (e.g., Artemeva & Fox, 2011; Paoletti et al., 2018). This consistency may mask important variations in instruction. For example, Pinto (2019) compared two mathematicians teaching a real analysis course using the same lesson plans. Despite this common material, they differed in the general enactment of the lesson including the timing of when parts were enacted and relevant to this paper, with their use of metaphorical imagery.

Pinto (2019) discussed how one of the mathematicians, Amit, used metaphorical language and imagery to unpack the definition of the derivative. It was stated that Amit wanted to help the students “obtain a picture of it” (p. 10). Thus, there was use of visual images and colloquial language including phrases such as “line”, “swing,” and “trap.” This contrasted with Yoav, who, rather than using imagery-based language approached the definition of a derivative term by term.

Rupnow (2021) similarly found a range of conceptual metaphors used by the mathematicians in their discussion of homomorphisms and isomorphisms. These metaphors spanned ideas of sameness and mappings and specific metaphors used by the mathematicians varied both in when and how often they occurred. Olsen et al. (2020) identified that instructors also use a number of metaphors conveying ideas of what it is to do mathematics during lectures. Oehrtman’s (2009) analysis of students’ calculus metaphors indicated that their experiences likely shaped their metaphors. Works such as Oehrtman (2009), Pinto (2019), and Rupnow (2021) would suggest that as instructors teach similar content – quotient groups in this case – it should be expected that there is variation in the types of metaphors being used. Furthermore, students understanding of concepts can be conjectured to be tied to the metaphors provided during instruction. Although, we caution that the exact mechanism of this link at the undergraduate level is currently understudied.

Theoretical Perspective

In consideration of metaphors, it is often taught that a metaphor is a comparison between two things without using the word that like or as. However, modern linguistics considers this to be an antiquated and incomplete view of metaphor as it treats metaphor as a consequence of language. Rather, they take the view that metaphors involve more than language, but rather are tied to meaning and cognition. Despite disagreement among linguists in what constitutes a metaphor, they tend to agree that metaphor more broadly is a way of viewing one construct or object through the lens of another (Cameron, 1999). For the purposes of this study, in order to understand the concept of metaphor, we are drawing on the work of Lakoff and Núñez (1997, 2000) defining a metaphor to be a “cross-domain conceptual mapping” (Lakoff & Núñez, 1997, p. 32). Additionally, Lakoff & Núñez define two types of conceptual metaphors: grounding metaphors and linking metaphors. In this report, we focus on grounding metaphors. When using a grounding metaphor, a person is taking an experience from everyday life and mapping or projecting the experience onto the concept they are attempting to understand or communicate. We will be using this construct as a means to discuss the types of metaphors being used in teaching quotient groups and examining how quotient groups are understood from a metaphorical point of view.

Methods

The results of this study are a part of a larger dissertation study aimed at exploring quotient group instruction. Data collection took place across seven universities in the United States. The data examined here came from the first of a series of two semi-structured interviews in which the goal of the interview was to examine instructional practices surrounding the teaching and learning of quotient groups. A subset of the participants was purposefully chosen for this analysis based on their professed methods of teaching. Of the instructors selected, one utilized a research-based inquiry curriculum emphasizing partitioning, one primarily lectured and relied on physical manipulates and built up from ideas of cosets, while the last instructor primarily lectured and built quotient groups from more general ideas of equivalence classes.

Data Collection Methods

The goal of the initial interview was to examine instructional practices of those who teach abstract algebra with respect to their instruction on quotient groups. Prior to the discussion of teaching practice, each of the instructors were asked two questions about how they themselves conceptualized quotient groups and how they wanted their students to conceptualize quotient groups. The rest of the questions were focused on how they conducted instruction including questions regarding typical lessons, examples, proofs, assessments, and their view of their role in the learning process. Each of the interviews lasted approximately one hour and was videorecorded and transcribed. These responses were in turn used to inform the design of a follow up interview designed to illicit further discussion on decision making.

Data Analysis Methods

The first research open coded the transcripts (Braun & Clarke, 2006) identifying grounding metaphors. These metaphors were identified based on the participants' the use of "actionable words" or words that evoke a sense of action (i.e., the use of action verbs, gerunds, or participles) or physical classroom experiences that occurred. Once the initial list of grounding metaphors was generated, a second researcher read through each of the transcripts to offer critiques, pushback, and additional metaphors that may have been missed. Any disagreements were discussed between the researchers and worked through. The list of metaphors found in the results section reflects a subset of the agreed upon metaphors.

Results

We identified three overarching categories of metaphors. The first major class was quotient groups through the lens of construction-based metaphors. This metaphor class was further divided into building and demolition metaphors. Additionally, there were equivalence-based metaphors and positional metaphors. Table 1 provides a summary and definition of these metaphors. In the first column the metaphor class is listed along with examples of key phrases that fell into that class. A definition and example of each class is also provided in Table 1.

Table 1. Summary of Grounding Metaphors Class Used to Understand Quotient Groups

Metaphor Class	Class Definition	Class Example
Building Metaphors ● Building ● Clumping ● Sticking Together ● Partitioning*	A class of metaphors that describes the creation of quotient groups through building ideas	"we're doing these things and *building* these, these subsets"
Demolition Metaphors ● Partitioning* ● Collapsing ● Breaking/ Splitting ● Subdividing	A class of metaphors that describes the creation of quotient groups through demolition-based building ideas.	"…think about *collapsing* every one of those parallel lines on to this intersection point."
Equivalence Based Metaphors ● Setting equal to; setting to	A class of metaphors that grounds ideas of treating elements as if they are the same	"you're factoring out by Z mod 3, then you're looking at integers, and you can *ignore.* You can *ignore* multiples of

• Ignoring • Regarding as		three. Any things that differ by a multiple of three are essentially the same thing when you're looking at a quotient group."
Positional Metaphors • Becoming • Going Around • Lying	A class of metaphors rooted in the idea of appearance or location. Often involve type of movement, but it is not necessary	"you think what would happen if you were to collapse every one of those circles to a point, what would you get each of those circles, is going to *become* one point."

In the remainder of the results, we share some examples from three instructors to illustrate how these metaphors are used in their instruction descriptions and how the different types of metaphors support each other in grounding ideas of quotient structures.

Dr. A: Clumping and Collapsing

When explicitly asked how Dr. A wanted their students to think about quotient groups, they stated that they wanted them to understand quotient groups as "clumping." In their explanation of what they meant by clumping, Dr. A stated

> So, this is a clock. So, this is going to be like Z_{12} you start with 0,1,2,3, 4, … ,11 and then you go 12, 1,2,3,4,5 so let's look at a quotient group of Z_{12} Mod four times Z_{12}. So, I start with Z_{12} and then, when I have four, I am back to zero. Go around again when I get to eight if I cut my string correctly to get back to zero. And so, then I've got Z_4, but I can see that all of these things, one I yeah and all of these are one item, and all of these are these are one. […] okay so I'm *grouping* or *clumping,* and I'm setting to zero.

During this illustration, Dr. A conveyed a building metaphor through the use of the word clumping. In this activity, they physically constructed piles of numbers (cosets) through this clumping or gathering action. To further explain this metaphor, they also drew on the positional metaphor of "going around" and equivalence-based metaphors in the use of the language such as "setting to zero" and "these are all one."

As Dr. A continued to explain how they wanted their students to understand quotient groups and the ideas of clumping, they turned to another example and rather than using a building metaphor they instead used, "collapsing", which is a demolition metaphor. Dr. A drew the image that is seen in Figure 1 and stated:

We'll take the cosets of $y = x$ and it's always fun to watch them try to figure out what a coset is but they usually eventually get to the parallel lines which is correct. And so, all the cosets are parallel lines and now, when you think of this every one of those parallel lines is going to get clumped to one point, and so you can draw the counter diagonal and think about *collapsing* every one of those parallel lines on to this intersection point, and so you can see that if I take **R** cross **R** and mod by the diagonal, or, I guess, we do (x, y) such that x equals y. That you get something that is isomorphic to **R.**

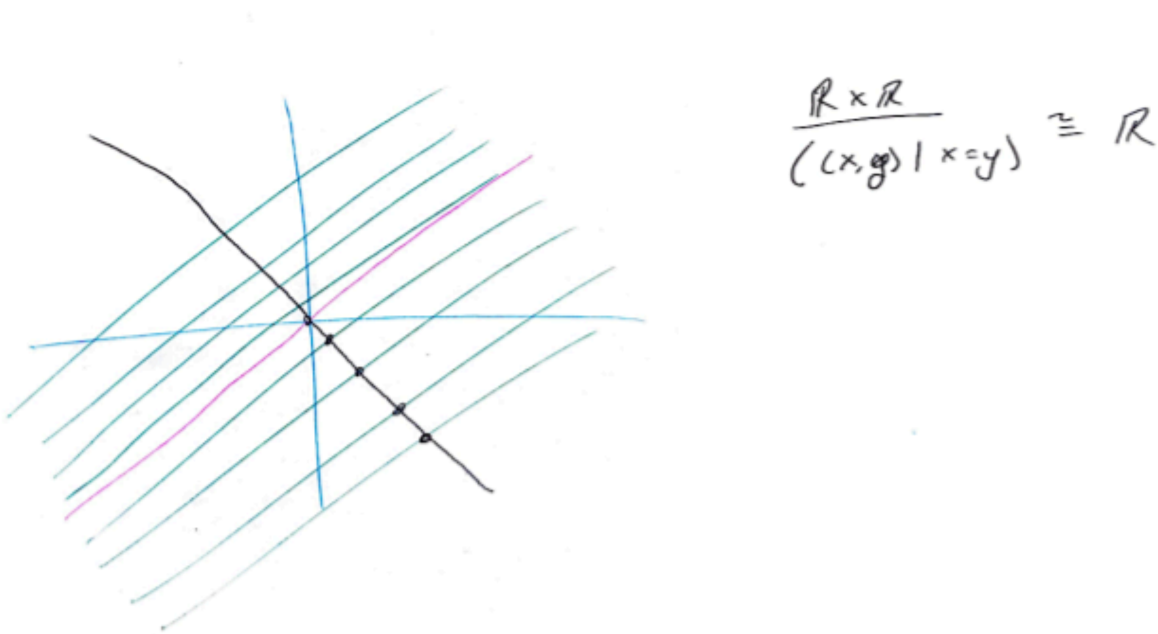

Figure 1

The main imagery that Dr. A utilized in this example is the idea that each of the parallel lines will fall or collapse. However, in this second except, we see that the collapsing is to a specific point thus furthering the metaphor of collapsing by giving a directionality of where the collapsing is going. It is worth noting that in this excerpt, the phrase clumped is used. However, unlike in the previous excerpt, "clumped" appears to describe the state of the parallel lines after they were collapsed rather than the action being applied to the parallel lines. Thus, this metaphor contrasts with the previous example as the mental imagery involved invoked different actions. In the first example, Dr. A invoked imagery of creating piles (and maintaining the subset structure with elements) whereas in this second example the collapsing moves from cosets as collections of elements to their role as single element losing the set structure through the act of setting to zero (emphasizing the representative element).

Dr. B: Partitioning to Build and to Deconstruct

Dr. B was similarly asked how they wanted their students conceptualize quotient groups and they explained that they wanted their students to understand quotient groups as "partitioning" stating "... so this idea of partitioning I think is powerful for thinking about the structure where you're building this, these weird things that are sets and elements kind of at the same time." In this explanation of partitioning, Dr. B communicated that partitioning was a way of building. This class of building continued in their explanation as they made statements such as "building up cosets" and "understanding the machinery involved in building."

In a similar manner to Dr. A, Dr. B also made a transition from building metaphors to demolition construction metaphors. However, unlike Dr. A, the demolition metaphor connected to the same action metaphor: partitioning. While explaining an activity regarding the partitioning of D_4, Dr. B stated

> Is there a way that we could *partition* up this D_4 table into something that acts like evens and odds, right? […] I always expect that the students are going to just *break it up* into like the rotations and the flips. […] I always have groups of students who break it up in other ways, but. They always break up in ways that that work. They're doing something really reasonable, and how they're subdividing these up, and it's now kind of laying this foundation that like one of these subsets has to act kind of like an identity type of thing, like the evens did. We're seeing every element end up somewhere […] This is kind of emphasizing the partitioning into new elements. And that physical color gives you something that you can think of this all as like one object over altogether. So, we spent a lot of time doing that.

In this explanation, Dr. B is described the creation of quotient groups through actions such as "subdividing" or breaking up. However, this is still describing the understanding of partitioning because they first posed the task of partitioning the group D_4, yet they hold the expectation that students will break things up. Thus, this explanation yielded partitioning as a demolition metaphor in this case, but ultimately as both a demolition and building metaphor as it had previously been described as building. Additionally, within this explanation, Dr. B drew on the use of a positional metaphor through the use of the phrase "end up somewhere" as they are discussing this transformation of the elements within the original group structure. In this positional metaphor elements are moving from the original group to their assigned coset.

Dr. K: Equivalence-Based Metaphors

Dr. K emphasized quotient groups as an extension of equivalence classes. In looking at Dr. K's conception of quotient groups, he stated:

> It's when you're factoring out by something. It's that's a factor you can ignore. So simplest examples of course, are modular arithmetic. So, if you're factoring out by *Z* mod 3, then you're looking at integers, and you can ignore -- you can ignore multiples of three. Any things that differ by a multiple of three are essentially the same thing when you're looking at a quotient group.

Within this explanation, Dr. K used primary metaphorical expression: ignore. This expression is used to convey the mathematical idea of equivalence and that "you have a set of objects" in which things are regarded as the same. Dr. K further elaborated on these ideas as they explained one of the examples they liked to use in their practice.

> I do use examples which are not which are not finite examples. Things like the fact that the nonzero complex numbers are a group under multiplication. S^1 is a subgroup, so then what is S^1 this time? Meaning the unit circle, of course. And what is the nonzero complex numbers mod S^1, right? And what is? And also, the positive reals are a subgroup, so what's the nonzero complex numbers mod the positive? These are very geometric things

> for them to think about. And modding out by S^1 really mean it also reinforces this idea. Well, now we're regarding two nonzero complex numbers as the same if they lie on the same circle about the origin and your quotient group, then is effectively the positive risk, so I like to talk about those examples somewhat.

Additionally, in this example, sameness was used in conjunction with the positional metaphor "lie." Unlike the previous positional metaphors, lie takes on a more static nature in that it lacks any type of movement. However, it is an important metaphor to note in that it serves as a justification for how Dr. K judged sameness in this example in that two points were considered to be the same if they were on (*lie)* on the same circle.

Discussion

We shared data from these three instructors because during their description of their teaching of quotient groups, they each seemed to emphasize a different aspect of quotient group understanding. During our analysis, there were four primary classes that emerged as instructors discussed quotient groups: building, demolition, equivalence, and position. As we considered these metaphors and the use of them, we hypothesize that each type of metaphor may reflect different ways of thinking about quotient groups. Dr. A emphasized *clumping* and *collapsing*. These types of actions emphasize an outcome where elements are clumped into sets then collapsed into a single element. These actions may reflect the duality between elements and sets. Dr. B's metaphors were rooted in *partitioning* from original group to quotient group traversing the duality between elements being members of the original (*subdividing)* and these elements now being cosets in the quotient group *(building)*. Finally, Dr. K leveraged ideas of equivalence to emphasize *ignoring* which may reflect the way that a coset can be thought of in terms of its representative element. In some ways these differences may emphasize the different ways of conceptualizing Zn elements as subsets, set with representative element, and representative element only.

For the scope of this paper, we focused on the primary metaphors shared by these instructors. In all three cases the primary metaphors focused on the element and set relationships rather than the group operation. We also note that positional metaphors could be found in all three instructors' language but did not appear as prevalent. Other metaphor classes that appeared in the data but that are not discussed in this report include the personification of normality and its role in "breaking" or "busting" groups or maintaining "machinery." Future research will involve testing this taxonomy with other instructional interviews and expanding classifications to include other elements of quotient groups such as normality. Additionally, future work will also examine the use of a second type of metaphor - linking metaphors - that instructors use as they discuss quotient groups as these were at times used in tandem with some of the grounding metaphors that the instructors were using. Both aspects of this future work will be carried out with the remaining thirteen participants within the larger dissertation study.

At this point, we conjecture that during quotient group instruction there is a lot of imagery that is at play due to the language that instructors use. However, students may or may not be influenced by their instructor's metaphor. Finally, we note that it is unlikely that quotient groups can be conveyed fully with any particular metaphor or class of metaphors. The language used by these instructors reflects attention to a number of salient dualities and therefore grounding metaphors for quotient groups are likely needed in clusters to fully account for the concept.

Instructor-Student Interactions in Geometry Courses for Secondary Teachers: Results from A National Survey

Patricio G. Herbst
University of Michigan

Soobin Jeon
University of Michigan

Inah Ko
University of Michigan

We report preliminary results of selected questions from a national survey of instructors of geometry courses for secondary teachers about the nature of instructor-student interactions. Survey responses (n= 118) are used to indicate six latent constructs describing aspects of instructor-student interaction that in turn quantify hypothesized characteristics of two didactical contracts, which we call inquiry in geometry and study of geometry. We found that instructors whose highest degree is in mathematics education are less likely to rely on a study of geometry contract than instructors whose highest degree is in mathematics. Also, instructors who have previously taught high school geometry are less likely to lecture.

Keywords: geometry, secondary teacher education, survey, didactical contract, instruction

Objectives

The work reported contributes to describing instruction in undergraduate mathematics education. Based on the responses from 118 instructors to 24 survey items, we describe how instructors relate to students in geometry courses taken by prospective secondary mathematics teachers (GeT courses, hereafter), including whether and how they incorporate students' input in lectures, how they handle student difficulties, and how they handle student contributions. After testing a measurement model of constructs that inform the extent to which instructors lead students in the study of geometry or in inquiry in geometry, we report on how indicators of these constructs relate to each other, and whether characteristics of the instructors (including whether their highest degrees are in mathematics or in mathematics education, and whether they have taught high school geometry in the past) predict scores in any of those latent variables.

Literature Review

The mathematical preparation of prospective secondary teachers (PST, hereafter) is an important area for investigation in the RUME community (e.g., Lai et al., 2023; Serbin & Bae, 2023). Whereas scholars and practitioners have written about the mathematics curriculum of teacher preparation for more than a century (Schubring, 1989), the empirical study of mathematics instruction in those courses has lagged for most of our field's history, along with the lag in the study of mathematics instruction at the undergraduate level. Speer et al. (2010) had noted how limited scholarship on mathematics instruction at the undergraduate level had been. Yet, a more recent review by Melhuish et al. (2022) updated that assertion, noting that the study of instruction at the undergraduate level has captured much more interest between 2010 and 2020. A variety of methods have been used in these studies, including, in particular, some instructor surveys of instructional practices (e.g., Johnson, et al., 2018, 2019). Though a main interest in the analysis has been to report on the incidence of lecture in instruction, researchers have also cautioned that the incidence of lecture is not necessarily an indicator of the absence of student-centered instruction (Smith et al., 2014). In advanced mathematics classes such as abstract algebra, however, studies of instructors' beliefs have suggested that mathematicians value lecture as an instructional method to prepare future mathematicians (Melhuish et al, 2022).

For the specific case of the preparation of PST, one might expect instruction could be different, especially considering the emphasis that has been given to inquiry-oriented instruction in the last couple of decades (Abell et al., 2018; Mahavier, 1999). Yoshinobu and Jones (2011) had singled out preservice teachers among those who could benefit the most from inquiry-based learning; and Laursen et al. (2016) documented important gains for PST who had learned mathematics through inquiry. Important questions to ask include: But to what extent do prospective secondary mathematics teachers participate in inquiry-oriented instruction?

GeT courses are salient locations where the incidence of lecture as well as of student-centered instructional practices could be inspected to answer that question. Though small-scale research has been done in GeT classes (e.g., Blanton, 2002), little research has looked at undergraduate geometry instruction at scale thus far. Wong (1970) was an early survey of institutions and the curriculum offered in GeT courses. Grover and Connor (2000) reported on a survey of ~100 GeT course instructors and included one question aimed at pedagogical practices. The responses showed that though only 7.1% of instructors described their courses as consisting of only lectures, only up to 34.3% included classroom discussions facilitated by instructor. Though responses to just one survey question are hardly enough to describe instruction, no other instructor survey has been conducted after Grover and Connor (2000) to expand or update what we know about instructional practice in GeT courses since. The answers from that one question, however, suggested that to understand instructional practice in more detail, we could use an analysis of the components of lecture and inquiry to develop an instrument that more accurately served for instructors to describe what they do in their classrooms.

An important precursor of the work reported here was Shultz's (2020) INQUIRE survey, which explored the extent to which undergraduate mathematics instructors engaged in practices that could be used to describe inquiry. Shultz's (2020) INQUIRE instrument defined latent constructs that could indicate various components of inquiry-oriented instruction described in the literature on inquiry-based learning. Shultz (2020) organized those constructs using the edges of the instructional triangle (Cohen et al., 2003). For example, *interactive lecture* and *hinting without telling* were two constructs identified to measure the extent to which instructor-student relationships (the instructor-student edge of the instructional triangle) were inquiry-oriented. Rather than relying on single questions to indicate a construct, the INQUIRE instrument included 5 items to indicate interactive lecture and 3 to indicate hinting without telling. Among important findings from Shultz (2020) are that the various constructs that can be associated with inquiry-based instruction portray a more complex distribution across instructors who claim to engage in inquiry. Shultz found evidence that lower-division undergraduate mathematics instructors might cluster in four different groups, depending on the scores on various of those constructs. Our GeT Instructor survey also used the instructional triangle to organize various aspects of instruction as latent constructs to be indicated by survey items. In this study we focus on the instructor-student edge of the instructional triangle, and we inquire on the incidence of constructs characteristic of inquiry as well as those which are characteristic of traditional study of geometry.

Theoretical Framework

We build on a theoretical framework about mathematics instruction that combines Cohen et al.'s (2003) instructional triangle and Brousseau's (1997) didactical contract. Specifically, Cohen et al. (2003) conceptualize instruction as a system of relationships among instructor, students, and content that take place in environments. The latter are institutional environments, namely mathematics departments and teacher education programs in colleges and universities. Herbst et al. (2023) further elaborate the content vertex of the instructional triangle to account for the fact that whereas students mainly relate to the content in terms of the work they are asked to do, instructors also relate to the content in terms of the instructional goals that such work is designed to support the acquisition of (Figure 1). This distinction is especially important in inquiry classrooms as the work students are asked to do may not too obviously disclose what the knowledge at stake is (e.g., Hitchman, 2017).

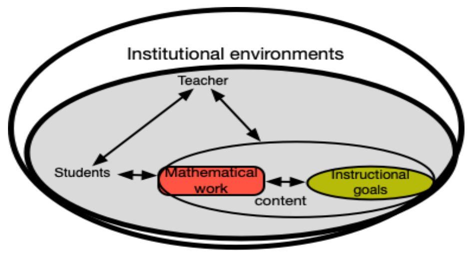

Figure 1. Elaboration of the instructional triangle

The specific ways in which those relationships are entertained call for the use of the notion of didactical contract. The literature has often used holistic names such as “school mathematics” and “inquiry classrooms” (Cobb et al., 1992) or “lecture-based” or “student-centered” to distinguish between types of teaching (Mesa et al., 2020). The notion of didactical contract (Brousseau, 1997), which Herbst et al. (2023) interpret as a system of norms that underpin how relationships among instructor, students, and content take place, serves us to operationalize those nominal distinctions into sets of possible norms that might characterize those relationships. Leading to the development of a survey that could help us elicit descriptive information about GeT instruction, we hypothesized that features of inquiry-oriented instruction could be considered possible norms of a didactical contract (inquiry in geometry) and that features of what often is called traditional or lecture-based instruction could also be identified to characterize a different didactical contract (the study of geometry). We did not expect that the didactical contract in any individual GeT class could be simply classified as either inquiry or study, but rather designed the survey so that we could measure instructors’ recognition of each of the various norms that describe instructor-student relationship in both contracts. The present study reports on instructors’ recognition of the various norms that characterize study and inquiry contracts. We hypothesized that the study contract would rely on norms such as LECTURE (the instructor is expected to introduce any new content), RIGHTANS (the instructor is expected to provide the right answers to students who have difficulties), and STALKTOINS (the instructor is expected to take students’ public comments as directed to the instructor). And we hypothesized that inquiry contracts might rely on other norms including INTLECTURE (students are expected to participate in lectures), HINTNOTELL (the instructor is expected to hint without telling when students have difficulties, and STALKTOCLASS (the instructor is expected to take students public contributions as directed to the whole class). These norms were used to create the items in the survey with which we expected to answer three questions: (1) How likely is it that students participate when new knowledge is being installed? (2) How do instructors respond to individual student difficulties with class work? and (3) How do instructors make use of individual student contributions to the whole class? Further, we expected that constructs that describe a study contract would correlate with each other and the same would happen with variables that describe an inquiry contract. And we wondered the extent to which responses to those questions were predicted by individual characteristics of the instructors, specifically whether their highest degree was in mathematics or mathematics education and whether they had prior experience teaching high school geometry.

Methods

The GeT Instructor Survey

The GeT Instructor survey was designed to describe instruction across geometry courses for secondary teachers taught in mathematics departments across universities in the US. Broadly conceived, it aims to measure the incidence of various instructor-centered and student-centered practices as well as various types of students' engagement with content, including geometry and geometry knowledge for teaching. Some of those items ask instructors to report the extent to which they engage students in tasks of teaching geometry (such as providing feedback on students' written work). Data collection has been ongoing; the present report provides initial gleanings from the analysis of some of the constructs being measured.

Herbst et al. (2024) analyzed the GeT Instructor survey responses concerning students' interaction with content. In that analysis, we estimated the relationship among four factors that capture instructors' descriptions of the nature of their students engagement with content: (1) students *study* geometry (Study), (2) students *inquire* into geometry (Inquiry), (3) students engage in tasks of teaching geometry (ETT), and (4) students engage with dynamic geometry software (DGS). Analysis showed significant correlations between Inquiry and ETT, between Inquiry and DGS, and between ETT and DGS. A structural equation model showed that DGS fully mediates the relationship between Inquiry and ETT. The present report concentrates on another of the instructional triangle's edges: The instructor-student relationship.

In its initial design, the GeT Instructor survey included 24 items to indicate 7 constructs which could be used to describe the instructor-student relationship in the instructional triangle. Each of those items asked participants to indicate their level of agreement using a 6-point Likert scale (ranging from Strongly Disagree to Strongly Agree) in response to provided sets of statements that could describe the respondents' practice in the GeT class. For example, item 811204 presented the statement "While introducing new material, I called upon the students to ask questions about the material being covered" which we hypothesized would indicate the construct interactive lecture (INTLECTURE). Of the seven hypothesized constructs, only six could be measured with the designed items (items for the seventh construct did not meet standard requirements in a confirmatory factor analysis). The six constructs helped provide answers to the three first research questions. Besides, we expected that correlations among the six constructs might align with the different contracts: Study (constructs LECTURE, RIGHTANS and STALKTOINS) and Inquiry (constructs INTLECTURE, HINTNOTELL, and STALKTOCLASS). The GeT Instructor survey hypothesized other constructs as useful to answer questions about the other relationships represented in Cohen et al.'s (2003) instructional triangle. We do not report on those questions and constructs in the present report.

Sample

To reach widely across GeT Instructors in the US, we obtained lists of all the universities and colleges across the US and checked whether they had a secondary teacher preparation program and whether their mathematics departments offered a GeT course required for prospective teachers. This canvassing yielded (n=670) mathematics departments; emails were sent to department heads (or their secretaries) asking them to forward a link to the survey to the instructor who had taught the course last. By the time of this analysis, our effective sample size consisted of 118 GeT instructors who completed all items of a Qualtrics survey, including the GeT Instructor survey and a background questionnaire. Our sample participants confirmed they had taught a geometry course required for secondary mathematics teachers in the last ten years. The participants comprised approximately 55.9% male instructors and 39.8% female instructors. Approximately 72% had their highest degree in mathematics, while 25.4% had their highest degree in mathematics education. And 30.5% had prior teaching experience in high school geometry. A significant 85.6% of participants held either tenure or tenure-track faculty positions, while 10.2% occupied non-tenure roles including lecturers and graduate students.

Results

Descriptives of the raw scores for the seven hypothesized constructs are provided in Table 1. We performed a Confirmatory Factor Analysis (CFA) to evaluate how well the observed items measure each of the seven hypothesized constructs. Notably, items designed to indicate one construct, that instructor functions as an older peer (OLDERPEER), exhibited low correlations among them and small item loadings which we took as evidence that the items did not represent a single latent construct. After excluding these items, we re-evaluated CFA with the remaining items that had item loadings above the threshold of approximately 0.3 onto the six hypothesized constructs. The results indicate an acceptable model fit, with the Root Mean Square Error of Approximation (RMSEA) at 0.080, the Comparative Fit Index (CFI) at 0.854, and the Tucker-Lewis Index (TLI) at 0.818.

Table 1: Descriptive Statistics of the Seven Hypothesized Constructs

	N	Mean	Median	Min.	Max.	Std. Dev.
LECTURE	118	3.997	4.2	1	6	1.287
INTLECTURE	118	4.883	4.8	2.6	6	0.711
OLDERPEER	118	3.547	3.5	1.75	5.75	0.824
RIGHTANS	118	3.031	3	1	6	1.021
HINTNOTELL	118	3.723	3.7	1	6	0.925
STALKTOINS	118	2.989	3	1	4.7	0.879
STALKTOCLASS	118	4.381	4.5	1	6	1.039

The CFA analysis revealed notable patterns of correlation among the constructs, primarily distinguishing between constructs hypothesized as characteristic of the Study contract (LECTURE, RIGHTANS, and STALKTOINS) and those hypothesized as characteristic of the Inquiry contract (INTLECTURE, HINTNOTELL, and STALKTOCLASS). The highest correlations were observed between LECTURE and RIGHTANS (.550), RIGHTANS and STALKTOINS (.240), as well as LECTURE and STALKTOINS (.229). These findings suggest a strong connection between presenting traditional lectures, providing correct answers when students have difficulties, and taking student contributions as a dialogue between the student and the instructor. Conversely, in the realm of the inquiry contract, we observed significant correlations between HINTNOTELL and STALKTOCLASS (.207), and between INTLECTURE and STALKTOCLASS (.119) (see Table 2). These findings indicate relationships among delivering interactive lectures, fostering classroom discussions, and affording students opportunities to solve their own problems. Additionally, the correlation between LECTURE and INTLECTURE was significant (.161, $p < 0.05$). This may indicate instructors' inclination towards utilizing lectures, regardless of the specific type of lecture.

Table 2: Correlation Matrix of the Six Factors in CFA

	811100	811200	812100	812200	813100

We also conducted a comparative analysis of latent variable means (LVM) among instructors from various demographic backgrounds to explore the potential association between these demographics and scores on specific constructs. Specifically, we focused on instructors' highest degree to answer whether having a highest degree in either mathematics (M) or mathematics education (ME) could predict whether the instructor's GeT class might follow more of a study or inquiry contract. To express the between-group differences, we set the LVM in the first group (mathematics) to zero and estimated the LVM in the mathematics education group (see Table 3).

Table 3: Latent Variable Mean (LVM) Difference -Between Demographics Groups

	Highest Degree in Mathematics (M) (N=85) or Mathematics Education (ME) (N=30)		Did Not Teach HS Geometry (N) (N=82) or Taught HS Geometry (Y) (N=36)	
	LVM Difference (LVM in ME after setting M to 0)	p-value	LVM Difference (LVM in Y after setting N to 0)	p-value
LECTURE	- .755***	.0009	-.462*	.04
INTLECTURE	.133	.18	.121	.19
RIGHTANS	-.543**	.002	-.285	.15
HINTNOTELL	.312	.08	.182	.25
STALKTOINS	-.334*	.02	-.171	.10
STALKTOCLASS	.390*	.04	-.054	.81

* p-value < 0.05, **p<0.01, ***p<0.001

A Wald test and chi-square difference test revealed significant differences in latent variable means between groups of instructors according to highest degree for constructs LECTURE, RIGHTANS, and STALKTOINS. Thus, instructors holding their highest degrees in mathematics education are less likely to manage a Study contract, in which traditional lectures are given, correct solutions are offered when students encounter difficulties, and student contributions are seen as one-on-one dialogues with the instructor, as compared to instructors with highest degrees in mathematics. There is some, but not enough evidence to say that instructors whose highest degree is in mathematics education are more likely than instructors with degrees in mathematics to engage in practices aligned with Inquiry. Furthermore, we examined instructors who had or had not taught high school geometry. After setting the LVM in the second group (had not taught high school geometry) to zero and estimating the LVM in the first (had taught) which represent between-group differences, we observed a significant mean difference in the LECTURE construct. Instructors with prior experience teaching high school geometry seem to be less prone to employing traditional lectures in their instruction.

Conclusion

A few observations about the contracts that we call Study and Inquiry can be made as regards how these contracts characterize the instructor-student relationship. The survey successfully deconstructs Study and Inquiry into six constructs (3 for study and 3 for inquiry) that are well indicated by several items. It thus can provide a more nuanced image of what the study and inquiry contracts mean. In particular, as related to the popular conflation of inquiry with no lecturing and the defense that some instructors have offered of the possibility to combine lecturing with inquiry (e.g., Alcock, 2018), the survey provides other well-indicated constructs that can be used to inspect the incidence of inquiry practices. Though the full survey is designed specifically for GeT courses, the specific constructs used to understand the instructor-student relationship are indicated with items that depend very little on the nature of the content being transacted (though they are about mathematics instruction); thus, researchers investigating instruction in other courses of study might be able to use same survey items.

Exploring Graphical Reasoning from Revised Responses to Function Composition Tasks

Students learn about function composition, $(g \circ f)(x)$, in secondary school. From two given equations, one might identify the composite function algebraically via substitution, $g(f(x))$. But what about when functions are given as graphs? This study aims to explore how students reasoned graphically with their revised responses to function composition tasks. We previously identified common types of resultant graphs participants generated in trying to sketch – in a short time period – the composition of various graphically-depicted functions. This paper specifically examines the ways in which students revised their graphs, when given more time to do so and after having engaged in trying to compose functions in a wider variety of contexts, and the reasoning that they provided for these changes. As such, we extend prior work by exploring how students reason about function composition when provided unlimited time constraints on their activity.

Keywords: function composition; graphical reasoning

Students are exposed to function composition in secondary school (cf., CCSSM, 2010). Primarily, they are taught that $(g \circ f)(x) = g(f(x))$ – meaning, for two functions defined by equations, one can procedurally determine the composite function via algebraic substitution. Yet, such algebraic approaches are limited in their ability to develop sufficiently deep mathematical understandings of function composition (e.g., Ayers et al., 1988; Moore & Bowling, 2008). For example, in our prior work we showed how, when given 30 seconds to sketch a graph of the composite of two graphed functions, students did. In this study, we extend our prior work by exploring the ways students reason graphically about the composition of two functions when given time to revise their original sketched graphs, after having sketched graphs to represent the composition of functions represented graphically, algebraically, and tabularly.

Research Question, Background, and Framework

In this study, we seek to answer the following research question: *After having several experiences thinking about function composition, how and why do students revise their responses to graphical function composition tasks?*

Function and Function Composition in Extant Literature

Much literature in mathematics education has been devoted to the function concept (e.g., Breidenbach et al., 1992; Freudenthal, 1983; McCallum, 2019; Mirin et al., 2021; Paoletti et al., 2018). This has included exploring students' conceptions about real-valued functions (from $\mathbb{R}$ to $\mathbb{R}$) through the notion of covariational reasoning (e.g., Paoletti & Moore, 2017). In this context, a deep understanding of function demands students understand how quantities co-vary together – meaning, how changes in one quantity correspond to changes in the other quantity. Studies have shown that students can experience difficulties in understanding the relationship between co-varying quantities and their graphs (e.g., Carlson et al., 2002; Schoenfeld, 1985). More broadly, Dreyfus and Eisenberg (1983) pointed out that without a formula, the graphical representation of function has very little meaning for most students entering calculus.

Yet when it comes to function composition, very little research exists – and what does exist primarily uses algebraic perspectives (e.g., Ayers et al., 1988; Clark et al., 1997; Moore & Bowling, 2008). There is a dearth of literature on function composition, especially through a graphical lens. To address this gap, in a prior analysis (Chen et al., 2023), we identified common types of resultant composite function graphs participants generated in 30 seconds when given graphs, equations, and tables. Although we recognize that students primarily have difficulty with sketching graphs of composite functions given two graphs, in this analysis, we aim to gain further insight into students' reasoning about graphical representations of composite functions. This was done by examining the ways in which students revised their graphs after having further experiences with function composition via equations and tables – which are more familiar ways of thinking about function composition.

Graphical and Algebraic reasoning

A key premise underlying this research is that algebraic and graphical reasonings are different, where each provide distinct conceptions that are complementary for developing deep mathematical meanings. Broadly speaking, algebra is a mathematical field that examines particular structures, based on a set of objects (e.g., $\mathbb{R}$), and a binary operation(s) defined on them (e.g., $+$). Whereas geometry explores spaces that are related with distance, shape, and size (e.g., the Euclidean plane). To highlight this difference, a function, algebraically, is often characterized by its equation, e.g., $f(x) = 2x + 1$ (i.e., the structure of the set of points included in the relation); whereas, graphically, we depict a function with a graph (typically in the Euclidean plane), e.g., $f(x)$ is a line. Moreover, not only do these fields explore different things, but key ways of reasoning differ between them. Driscoll et al. (1999; 2007), for example, differentiated algebraic from geometric "habits of mind." In our context, for simplistic purposes, we use *graphical reasoning* to mean reasoning that relies on figures and shapes in the plane and their properties; *algebraic reasoning*, by contrast, relies on equations.

Methodology and Data Sources

To explore how students reason graphically about function composition, we had university students (n=143) in two mathematics and mathematics education programs (primarily from precalculus classes) sketch the composite function $(g \circ f)(x)$ given two given functions f and g. Participants responded to six tasks (yielding 858 responses), and the task order is important: they went from least familiar to most familiar (in the first four the functions were given as graphs, the next involved two equations, and the last gave a table of values). Students were given the opportunity to revise their original answers after a first attempt at all six tasks – meaning they could sketch a new graph for each of the six tasks after having been refreshed on what were likely more familiar function composition tasks (i.e., the latter using equations and tables).

Task Design

On Desmos, participants were asked to sketch within a limited timeframe (30 seconds, to capture their intuitions and reasonings), the composite function $(g \circ f)(x)$ for six pairs of functions. The majority of these pairs were represented graphically (Figure 1 displays an example Desmos page; Figure 2 displays the other 5 tasks). The purpose in providing participants with somewhat unusual, and non-algebraic forms of the functions, was to deter them from immediately converting to an algebraic equation to complete the composition. Doing so increased the likelihood that students would have to try to reason about function composition graphically based on the shapes of (or relationships represented in) the graphs. In the last two tasks, functions were given in the more familiar forms of an equation and a table. In this paper, we analyze their second attempts – which included either a new composite function graph or a modification of their original graph, as well as a written justification for their changes. Notably, their engagement in these revised tasks happened after participants: i) had more experience with graphing tasks; and ii) had reviewed function composition with – presumably – more familiar modes of reasoning (i.e., equations and tables).

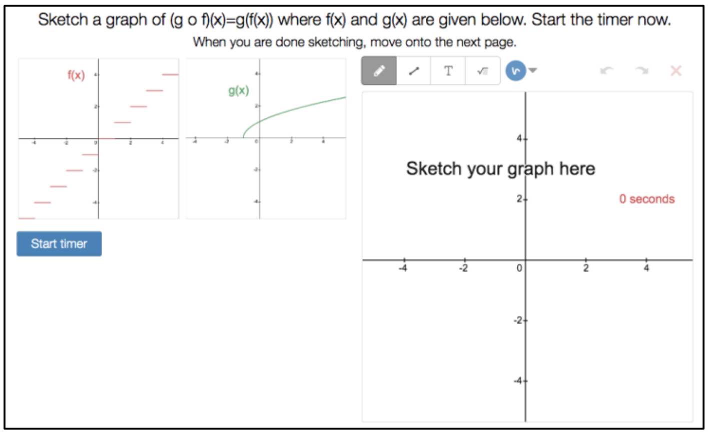

Figure 1. Task 2 in Desmos

Task 1	Task 3	Task 4	Task 5
			$f(x) = x^2$ $g(x) = \sqrt{x}$ Task 6 (Presented in Table form) $f(x) = \{(1,4),(2,3),(3,1),(4,-1)\}$ $g(x) = \{(1,-2),(2,0),(3,1),(4,-1)\}$

Figure 2. Given functions for Tasks 1, 3, 4, 5, 6

Analysis and Coding

This study applied grounded theory as the data analysis technique (Stough & Lee, 2021). Out of 85 altered responses (from the possible 858), our analysis focused on (*n*=73) responses, from 43 distinct participants, in which participants provided (non-blank) justifications. Our analysis identified normative reasoning provided for changes to the initial graphs that were shared across participants. Notably, we aimed to create coding categories that could be applied across the entire set of tasks. We anticipated the revised graphs to include both incorrect and correct graphs of composite functions, and a diverse range of reasoning students may have used. We coded changes between their original and revised graphs as beneficial (+) if they went from incorrect to correct; non-beneficial (-) indicated no progress toward correctness. We generated and refined all categories of coding as a group; when there were uncertainties in how to code a graph, we resolved such cases together and made refinements to categories as needed.

Due to space constraints, we do not include all codes used in our analysis. However, Table 1 provides codes and definitions for the majority of codes – and, in particular, those we report on in this paper. Specifically, these are the codes used to determine students' reasoning for modifying their initial responses. Clarifying examples are given in the results section.

Table 1. Categories of students' reasoning for changing their graph

Code	Description of the reasoning for how or why participants made changes to the composite function $g(f(x))$ sketched
MIXED PROPERTY (MIXED PROP)	One graph put together with the property of the other graph
ALGEBRAIC THINKING (ALG)	Algebraic thinking involving equations or identifying types of functions (e.g., polynomial functions)
DISCRETE POINTS (DP)	Pointwise thinking involving specific points or identifying specific discrete points of the graph (e.g., $f(1)=2$, $g(2)=4$, so $g(f(1))=4$)
TIME	Citing a need for more time on the original tasks

Results

Table 2 provides an overarching summary of the reasoning used by those students who altered their answers after their first attempt. ALGEBRAIC THINKING (ALG) and MIXED PROP were the two dominant responses, so those will be the focus of our results. It is important to note, however, that TIME was also a major factor, with 19 out of 73 responses citing a need for more time on the original tasks as the reason for them altering their original response. Those who ran out of time did not provide any additional reasoning for their answer changes, thus indicating that one reason students revised their graphs was that they needed more time to think about how to compose the two functions. Since a total of 18 out of 73 total changes were beneficial, it reinforces the idea that additional time may provide more opportunities for participants to reason through the challenges and showcase their thinking. There were also a small number of responses (11) that fall under OTHER codes. However, the four most influential categories (ALG, MIXED PROP, DP, and TIME) will be the focus of this report.

Table 2. Summary of data for those with answer changes on Tasks 1-6

Code	Task 1-4	Task 5	Task 6	Total
ALG	4(+)/2(-)	3(+)/6(-)	2(-)	7(+)/10(-)
MIXED PROP	5(+)/14(-)	-	-	5(+)/14(-)
DP	1(+)/2(-)	-	4(+)	5(+)/2(-)
TIME	1(+)/13(-)	2(-)	3(-)	1(+)/18(-)

Note. The symbols (+)/(-) show beneficial/non-beneficial changes in their responses.

Given Graphs

In Tasks 1-4, students were given *graphs* of $f(x)$ and $g(x)$ and asked to sketch the composite function. In these tasks, about 9% of the responses were changed (49 out of 572). See Figures 3 and 4 for (-) and (+) examples (original graph in blue; revised graph in red).

Of those changed responses, 39% of them used MIXED PROP as their reasoning for how they generated their revised graph (19 out of 49). This seems sensible since MIXED PROP implies that students are utilizing and combining physical characteristics of the two graphs – though it was only beneficial in 5 of the 19 cases. On these tasks, 29% (14 out of 49) of responses mentioned timing issues. Perhaps this is because students are accustomed to approaching function composition algebraically, and thus required more time to orient themselves to these graphical representations. Notably, even with the additional time to revise, students still had difficulty – only 1 of the 14 responses that cited time issues made progress toward a correct composite function on these graphical tasks. 12% of students (6 out of 49) still attempted to use ALG to understand these graphical tasks, and this group seemed to make the most progress toward correct graphs. Finally, 6% of students used DP to make sense of the graphical representations (3 out of 49).

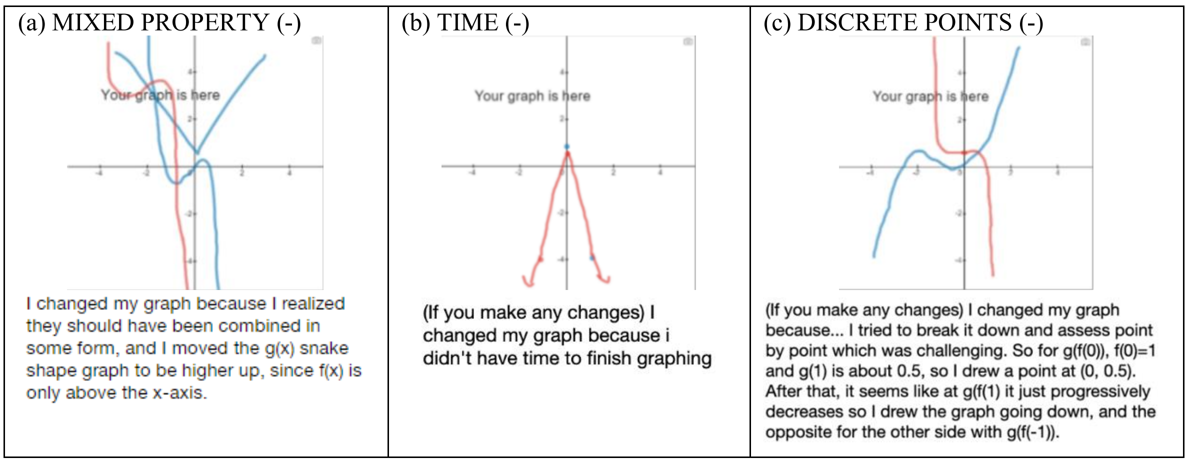

Figure 3. (Still) Incorrect examples from Task 1 of (a) "mixed property" reasoning, (b) "time" reasoning, and (c) "discrete points" reasoning (original graph in blue; revised in red)

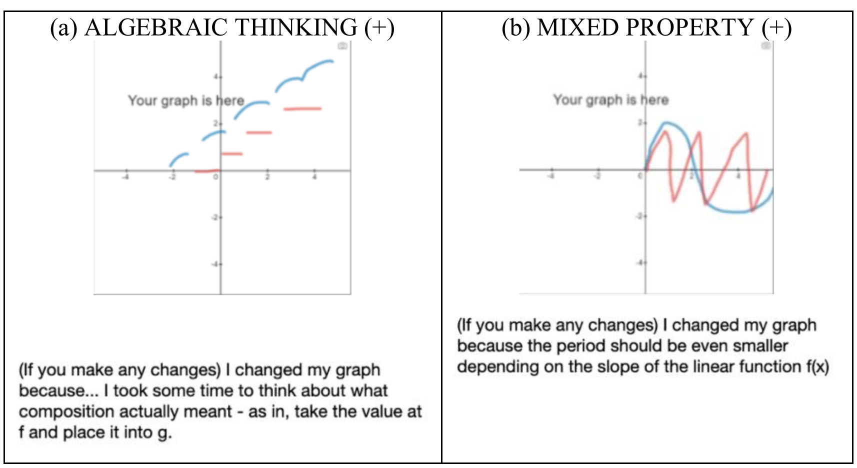

Figure 4. Correct examples from Task 2 of (a) "algebraic thinking" reasoning, and Task 4 of (b) "mixed property" reasoning (original graph in blue; revised in red)

Given Equations

In Task 5, students were given *equations* for $f(x)$ and $g(x)$ and were asked to sketch the composite function. In this task, about 8% of the responses were changed (11 out of 143). See Figure 5 (original in blue; revised in red). Of those changed responses, 82% of them used ALG as their reasoning (9 out of 11), and 18% cited TIME as their reason for changing their response

(2 out of 11). This result is unsurprising, since this task gave students equations, which lends to a more algebraic approach. Of those who changed their answers in Task 5, 27% (3 out of 11) changed their answer so that it improved. All 3 of the improved responses were coded as using ALG for their reasoning, as exemplified in Figure 5a. Interestingly, however, in 4 (of 11) cases students changed their answers from the correct response to the incorrect response. Each was coded as ALG and all were nearly identical to the response in Figure 5c, where x^2 and $\sqrt{x}$ were seen to "cancel" algebraically to x.

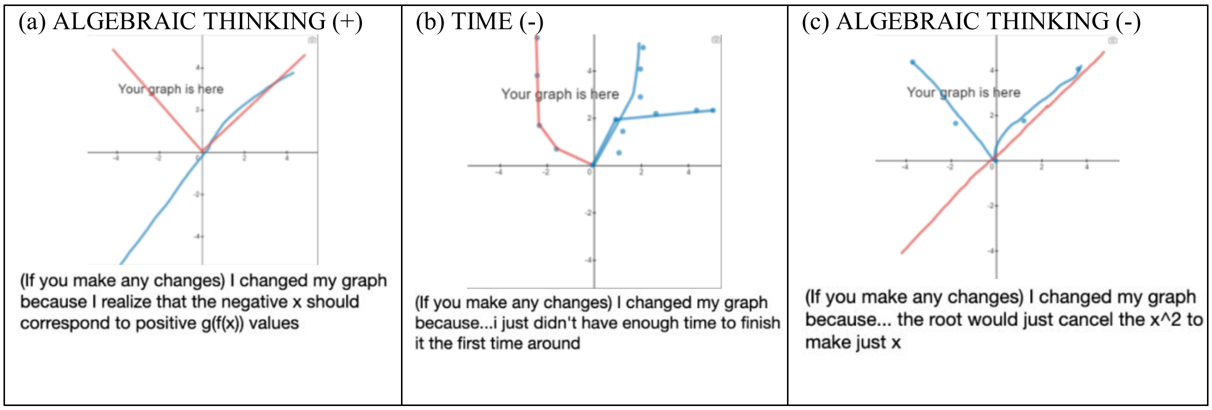

Figure 5. Examples from Task 5 of (a) (c) "algebraic thinking" reasoning, and (b) "time" reasoning (original graph in blue; revised in red)

Given Tables

Task 6 gave students *tables of values* and students were asked to sketch the composite function. In this task, about 9% of the responses were changed when students were given this opportunity (13 out of 143). See Figure 6 for examples (original in blue; revised in red). About 31% of responses (4 out of 13) used DP to explain their changed answers, which makes the most sense based on a table of values. Indeed, all 4 made improvements (see Figure 6a). (Notably, even if students decided to connect the correct set of points with a curve, we considered the composite graph (mostly) correct; the correct graph should just be the discrete set of points.) 23% (3 out of 13) cited an issue with TIME as their reason for changing their answers. 15% (2 out of 13) used ALG to change their answers.

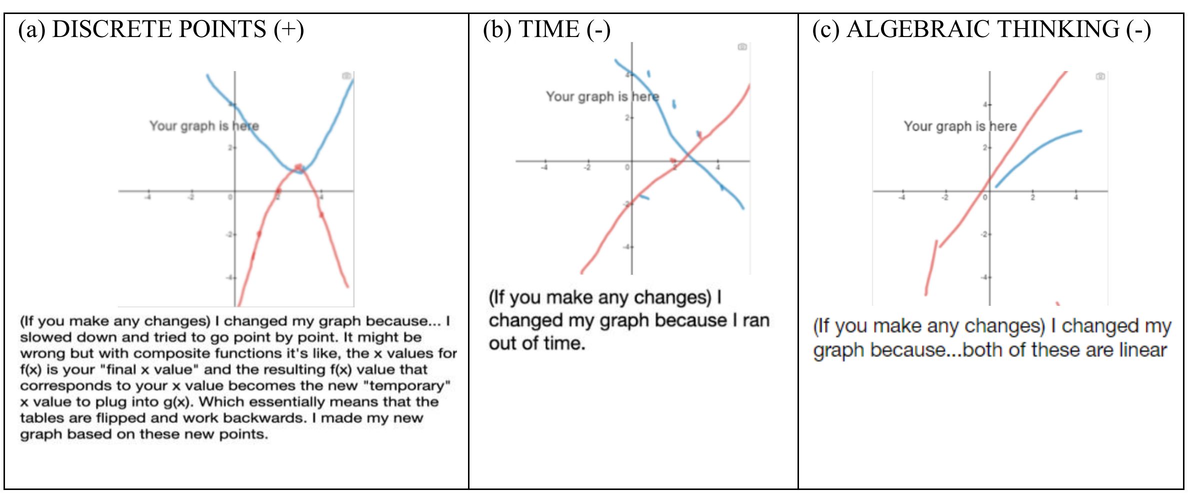

Figure 6. Examples from Task 6 of (a) "discrete points" reasoning, (b) "time" reasoning, and (c) "algebraic thinking" (original graph in blue; revised in red)

Conclusions and Implications

In this section, we highlight four important takeaways for the reader. First, perhaps unsurprisingly, with more time, students performed better. Approximately 25% of the students who edited their responses improved upon their original answer in some way (18 out of 73). This might imply that some students' original wrong responses were due to lack of time rather than lack of ability to perform the composite function task.

Second, when given the opportunity to revise, students seemed to rely primarily on an algebraic approach. Approximately 23% of revised responses cited ALG as their method (17 out of 73). This could imply that more time simply allowed students to rely on the more familiar algebraic manipulations – though, even still, less than half were able to determine the correct composite function. This result seems to suggest that students have not been supported in developing ways of reasoning graphically about function composition, and the extra time serves only to allow for attempts to reason algebraically by identifying approximate equations with which to work.

Third, we also saw that there can be a negative impact to an algebraic approach. All of the students who changed their answers from correct to incorrect (all on Task 5) used algebra in their reasoning for their revisions. This implies that students are using the familiar algebraic approaches even when it actually hinders their natural understanding of the problem! The dual-edged nature of algebraic thinking evident in these revised responses seems to affirm the broad aims of this work – exploring graphical reasoning approaches that support students in developing a richer conception of function composition.

Fourth, overall, the most productive approach in revised responses was based on pointwise thinking (DP) – though most of these were in Task 6. That is, using specific values of x, to evaluate and plot $(x, g(f(x)))$, was helpful reasoning that often led to a correct or mostly correct graphically composed function. Additionally, MIXED PROP seemed to be a promising approach on some "given graphs" (Tasks 1-4) – although identifying which properties of the two functions to combine represents an additional challenge. Both show potential for helping students develop graphical reasoning about function composition.

Collectively, the results presented here along with the results we presented in Chen et al. (2023) highlight that most college students have not been provided opportunities to develop rich meanings for function composition; function composition problems are difficult regardless of if there is a limited time frame and unfamiliar representations (Chen et al., 2023) or if there is an unlimited time frame and students have experienced more familiar representations (this report). Hence, more work is needed to identify further productive intuitions and ways of reasoning students may have that might be helpful to build on. We conjecture novel representations and digital tools might afford learners an opportunity to develop a richer conception of function composition, such as conceiving of function composition graphically or as representing a covariational relationship between multiple quantities. We call for future research to explore this possibility, as well as others, for supporting students in understanding function composition.

Undergraduate instructor's perceptions of barriers to implementing culturally sustaining practices

Megumi Asada
Rutgers University

Undergraduate math education is highly inequitable. One potential strategy to improve the unfair experiences and outcomes of historically marginalized groups in mathematics is to use culturally sustaining practices, which relate math content to student's culture and everyday lives. However, there is limited work exploring the applicability of culturally sustaining practices in the undergraduate mathematics setting. This study interviews seven math undergraduate instructors to better understand their perceived barriers to implementing culturally sustaining practices.

Keywords: undergraduate, equity, culturally sustaining practices

Introduction

Undergraduate mathematics education is highly inequitable. Black and Latin* students are frequently weeded out of introductory undergraduate math courses like calculus, prohibiting access to advanced level mathematics courses (Ellis et al., 2016; Larsen et al., 2017). This disproportionate exclusion of Black and Latin* students can result in isolating experiences for the few students who do persist to upper-level courses, who have diminished access to same-gender, same-race peer support (Borum & Walker, 2012).

One potential strategy to ameliorate the differential experiences and outcomes experienced by minoritized groups in mathematics is to relate math content to students' culture, experiences, and everyday lives (Civil, 2016). The framework of culturally sustaining pedagogy (CSP) (Paris, 2012) proposes a step towards equitable instruction that embeds course content in students' lives while providing them with political consciousness. However, there is limited work exploring the applicability of culturally sustaining practices in the undergraduate mathematics setting, with the exception of Adiredja and Zandieh (2020). Since most existing scholarship on CSP has been in the K-12 context, it is unclear the extent to which the same strategies work in the university setting. Thus, in order to better understand how to implement culturally sustaining practices in college classrooms, we might want to understand the barriers specific to the university context.

Accordingly, this study addresses the following research question: What do instructors of math undergraduates perceive to be the barriers to implementing culturally sustaining practices? Addressing this question presents three contributions. First, this work links the expertise gained from scholarship in K-12 equitable practices in mathematics to the undergraduate setting, where we have not taken up as much of the work from our colleagues in K-12. Second, there is little existing work documenting culturally sustaining practices in undergraduate classrooms. This work will explore instructors perceived barriers to implementing CSP. Finally, as Chazan et al. (2016) note, much of the work in mathematics teaching documents instructors' beliefs without considering the influences that institutions and various stakeholders can have on instructors' choices. This work answers Chazan et al.'s call for greater attention to institutional and greater societal context on the choices teachers make.

Literature Review

An increasing amount of scholarship has documented inequitable experiences in college mathematics experienced by Latin* and Black students and students of under-represented genders in mathematics (for a review, see Adiredja & Andrews-Larson, 2017; Leyva et al., 2021; McGee & Martin, 2011).

Leyva et al. (2021) document instructional practices and broader ideologies of mathematics ability (e.g. mathematics ability as innate; white and Asian people are better at math than Black or Latin* students) that create hostile classroom environments for historically marginalized students. While some work has illustrated cases of successful Black (Borum & Walker, 2012) and Latin* (Leyva, 2016) students, I am not aware of work that considers how more equitable instruction interacts with broader institutional and ideological factors. In other words, given various institutional obligations, how far can an instructor go in implementing culturally sustaining practices?

When done well, culturally sustaining practices can encourage critical dialogue, improve student performance on exams, and promote reflection on previously held social assumptions (for a review, see Aronson & Laughter, 2016). Indeed, Hubert (2014) found that students appreciated seeing their home lives reflected in the classroom, which in turn promoted engagement with mathematics content. However, implementing CSP is far from straightforward. Even for those instructors who would like to adopt CSP practices, some struggle with developing authentic connections between school mathematics and students' everyday lives (McCulloch & Marshall, 2011; Wager, 2012).

Unfortunately, there is still little work documenting supportive practices in undergraduate math education that disrupt commonplace racialized and gendered experiences (Leyva et al., 2022). Leyva et al. (2022) document supportive practices intended "for all" students that are necessary yet insufficient to supporting students of historically under-represented groups in mathematics. While instructional practices such as creating space for questions and mistakes and extending out of class support are important, they are limited in their ability to confront the broader influences of racism and patriarchy on classroom experiences. The limitations inherent to practices that do not explicitly address raced and gendered harm in the classroom calls for further work on practices like CSP that do attempt to directly address these harms.

Theoretical Frameworks

Culturally Sustaining Pedagogy

This study uses the theory of culturally sustaining pedagogy (Paris, 2012), reformulated from Ladson-Billings' culturally relevant pedagogy (1995, 2021). Ladson-Billings developed culturally relevant pedagogy based on her studies of effective instructors of African American students. She found that effective instructors accomplished three key objectives, promoting: student achievement, cultural competence, and critical consciousness.

CSP emerged from an acknowledgement that cultural relevance itself is insufficient. Instead, Paris (2012) noted the importance of going beyond curricula that uncritically cite students' cultures towards one that sustains them. As Ladson-Billings (2021) notes, the wide popularization of culturally relevant pedagogy has led to uses and abuses of the theory. As conceptualizations of culturally relevant pedagogy morph over time, the theory changes and gains new subtleties. Culturally sustaining pedagogy combines students' cultural knowledge with the aim of critical consciousness, or an understanding of current sociopolitical realities. In this study, I used CSP to identify a set of recommendations to discuss with college instructors.

Theory of Practical Rationality

To make sense of why my participants would or would not adapt elements of CSP in their teaching, I used Herbst and Chazan's (2003) theory of Practical Rationality of Teaching. The theory considers the different societal and institutional obligations that affect instructors' choices. Chazan et al. (2016) contend that instructors cannot simply do as they please, identifying various obligations instructors must consider: professional obligations, obligations to the discipline of mathematics, obligations to students as individuals, and obligations to society and its imperatives. In this study, I use Practical Rationality to identify instances when different obligations conflict with or support CSP. Like Herbst and Chazan, I make no moral judgments about the choices instructors make in prioritizing certain instructional commitments over others. The theory also does not make any normative judgments about whether an instructor's perceived obligations are truly obligatory. Instead, it is sufficient that an instructor perceives an obligation as relevant to the instructional choices they make.

Methods

Participants were selected among current doctoral students in a mathematics department at a medium-sized public university in the northeast. My participants were PhD students in Mathematics with at least one semester of undergraduate teaching experience as an instructional teaching assistant (TA). I excluded participants who only had experience as grading TAs or whose only teaching experience was prior to starting their PhD. The choice of target population of mathematics PhD students as opposed to current mathematics professors was intentional. First, mathematics PhD students represent the cohort of future college-level mathematics educators. Additionally, as a younger cohort, current mathematics PhD students may be more amenable to CSP practices. While general support of equitable practices is not a requirement to participate in the study, I anticipated that participants would provide far richer insights about the possibilities of equitable instruction if they themselves were invested in such practices.

Data Collection

I invited participants to engage in a single one-hour semi-structured interview about how they might adapt various culturally sustaining practices from the K-12 mathematics context to the undergraduate classroom. The interview was divided into roughly two parts. In each section, I asked the participant to consider a recommendation from New York State Education Department's (NYSED) Culturally Responsive-Sustaining Education Framework. The first section reviewed a selection of the recommendations for making a welcoming and inclusive environment. The second half of the interview discussed practices related to identifying inclusive curriculum and assessment. I picked these themes as they seemed the most relevant and potentially challenging for the undergraduate math context. The remaining themes were: fostering high expectations and rigorous instruction and engaging in ongoing professional learning and support. While there is no agreed set of recommendations for what constitutes CSP in mathematics education (Thomas & Berry III, 2019) the NYSED recommendations provide actionable recommendations constructed by reputable scholars in the field.

Each question opened with an elicitation in which I read one of the NYSED recommendations for culturally sustaining practices in K-12 mathematics to the participant. The participant was then asked the following questions:

1. What are some of the ways you do or could adapt these recommendations to your classroom?
2. Are there any constraints that would make it hard to adapt this recommendation?

3. What kind of resources would you need to implement this recommendation?
4. What factors get in the way of implementing this practice? OR What supports have made these practices possible for you?

Throughout data collection, I engaged in preliminary data analysis via in-process memos in which I pre-coded (Saldaña, 2009) data, documenting any initial impressions or findings.

Coding

Data analysis merged inductive analyses in first cycle coding and deductive methods in the second and third cycles. During the data collection and pre-coding stage, I observed that participants frequently noted moments of conflict in which it became difficult to reconcile certain CSP recommendations with other obligations that they held. I decided to use Herbst and Chazan's theory of Practical Rationality to foreground instructional obligations. To capture these moments of tension and the underlying values that were in conflict, I blended versus and values coding methods (Saldaña, 2009) for my first cycle of coding. I also coded for the various institutional obligations that participants indicated in response to my follow-up questions about barriers to their practice. In summary, the first cycle yielded two categories of codes: codes indicating participants' values, some of which were paired as versus codes, and codes indicating barriers towards CSP practices.

After first cycle coding, I reanalyzed the data using sensitizing concepts (Charmaz, 2014) from the theory of culturally sustaining pedagogy and aligned asset pedagogies. I categorized the values and barrier codes from the first cycle of coding based on their alignment with CSP. By the third cycle of coding, the code corpus consisted of: versus codes indicating tensions between different instructional commitments, values codes that justified instructional moves, and codes aligned with the literature on culturally sustaining practices. However, there were notable tendencies in the ways in which these coding schemes overlapped. Frequently the versus codes contained two different values codes. Furthermore, the values codes could be roughly organized on whether they aligned with culturally sustaining practices. I then used concepts from broader critical theory (e.g. asset-based pedagogies, resource pedagogies) as parent codes to organize the values codes into those that were broadly aligned with CSP and those that were not.

Findings

Conflicting Commitments

In some cases, participants indicated commitments that conflicted with a desire to implement practices that were culturally sustaining. One of the NYSED recommendations advised instructors to implement restorative justice circles to address harm done in the classroom. Restorative justice is an alternative that focuses on redressing harms caused instead of punishing the offender. I provided a brief description of restorative justice and offered academic dishonesty as an example of a potential harm. I then asked how participants could make sense of this recommendation in their own practice and any supports they would require. In response, one participant, Michael, indicated:

> Going along the lines of the example that you gave, the professor needs the flexibility to be able to adjudicate these things on their own. At [this university], we have a great bit of discretion, as TAs or as professors, about how we handle instances of academic integrity. So at [this university], the structure is actually pretty fertile for us to do this sort of thing. But at other institutions, they are very, very, very strict. To give an example, [at other university] … I am pretty sure that if you cheat on the exam, they just expel you. […] So in order to allow [for restorative approaches], you need to have this discretion, because

> otherwise it's simply impossible. You don't want to be in a situation where common sense or sympathy as a human being is telling you, “look, I can handle this in a better way.” But you have your own job to be concerned with, and, unfortunately, if they're going to come after you if you do something, regrettably, you're gonna have to do what's in the interest of your job.

Michael indicated that professor discretion was necessary in order to implement a restorative approach to academic dishonesty. Ultimately, even if an instructor’s “common sense or sympathy” led them to favoring a restorative approach, the possibility of institutional repercussions could require one to “do what’s in the best interest of [their] job.” I interpreted Michael’s reference to common sense or sympathy as his perceived obligation to the student conflicting with his professional obligations to abide by institutional rules. From Michael’s perspective, attempting to adopt the culturally sustaining pedagogical practice of restorative justice may be rendered an impossibility depending on institutional factors.

Like Michael, Owen described institutional obligations that impeded his ability to implement CSP. In reference to the recommendation to build rapport with students and elicit their opinions and concerns, I asked Owen what constraints he felt in adopting the recommendation. He noted that the institutional requirement of having to escort students to the bathroom during exams and practice of failing 30-40% of business students taking calculus make it difficult to build rapport with students. He mentioned apologizing to students to push back against these constraints. He empathized with the business students and recalled attempting to push back against institutional practices:

> And I think I did do that one day. I think I do try to bring this up sometimes like, “I don't want you to be judging yourself over what happens in the classroom. Because that's sort of what's going on. You're getting grades and you're going to get into this school or not and be allowed to go on or not. And that's stupid and frustrating. I don't believe in it.” I don't think that's a huge affront to the system. I think it'd be much more dangerous to start criticizing the professor. I mean, not that I'm opposed to that, but I'm just saying. You can get fucked up for that. And the other thing is also, in terms of like maintaining rapport, you don't want to tell somebody what they're doing is pointless or stupid…

Owen felt it was hard to build rapport with his students if he had to patronise them by walking to the bathroom or punishing them with bad grades. Interestingly, one of Owen’s perceived commitments appears to be the disruption of the very institutional practices that hinder student autonomy and obstruct CSP. While following his professional obligation to follow the professor’s instructions and escort the student to the bathroom, he also attempted to abide by his obligation toward the student by making a joke about the situation and apologizing to them.

In Michael’s case, he felt that institutional barriers could obstruct his attempts to follow CSP practices. If it came down to choosing between making the best professional decision or acting out of sympathy towards the student, he felt that one must choose what’s in the best interest of their job. On the other hand, Owen, by apologizing to students or directly calling institutional practices “stupid and frustrating,” described methods for subverting institutional barriers in favor of aligning with more CSP-like practice. For Owen, the presence of constraints against student agency seemed to generate novel obligations to acknowledge the constraints and be candid with students.

Limited knowledge of how to implement culturally sustaining practices

In some cases, participants indicated that their lack of knowledge of how to properly implement certain culturally sustaining practices served as a barrier. One of the presented recommendations is to "feature and highlight resources written and developed by traditionally marginalized voices that offer diverse perspectives on … identities traditionally silenced or omitted from curriculum" (New York State Education Department, n.d.) In response, Max commented:

> The main thing that prevents me from doing this is that I don't put enough time into it. If I'm preparing for class, I'm mostly thinking about how to explain—I'm gonna use the example of derivatives again—rather than looking back and saying "can I find a useful historical example of a woman or disabled person who contributed to this area?" and highlight that. I've had a couple of professors who have taken extra time to highlight, for example, women who have contributed to an area of math that we're learning about and I've enjoyed that part. It's always nice when there's a little break in the lemma-lemma-theorem-proof structure to talk about history. That's definitely enjoyable, but it's just extra effort for the professor. […] I try to set pretty high honesty requirements of myself, and I'm not a historian. So one constraint would be I want to tell my students the truth about what happened and what was important in the history of math. I guess that just adds to the amount of time it would take as input to make this work well is that I don't want to just read a BuzzFeed article about Mayan mathematical practices and just quote that without understanding what I'm really talking about. […] If my PhD had a requirement to take a math history class to graduate, then I would love that, and I would know a lot more about that by the time I was teaching it.

Max appears to be supportive of the recommendation, recalling previous "enjoyable" experiences in which professors highlighted historical context in their courses. While he does refer to this work as "extra effort" by the professor, he later indicates that he would appreciate having a requirement embedded in his PhD program to take a math history course. While Max may not view this recommendation as essential, he appears open-minded towards it. However, Max mentions that the amount of time it would take to fully research and understand historical examples of the work of under-represented mathematicians would be substantial. Part of his hesitance stems from wanting to present historical content accurately and his awareness that he may lack the sufficient background knowledge as he is "not a historian."

While Max does open by citing time as a primary constraint, these instances appear to be rooted in the time it would take for Max to prepare and learn any material on his own. He closes by mentioning a previous course in his PhD program would alleviate some of his concerns. It appears that Max's commitment towards presenting material accurately conflicts with the recommendation to include under-represented perspectives in mathematics, given the lack of prior knowledge that PhD students like Max tend to have.

Discussion

The data support two main claims. First, instructors perceive various commitments that may conflict or align with culturally sustaining practices. Second, instructors also indicate that a lack of knowledge of how to properly implement certain CSP practices serves as a barrier to implementation.

In their work documenting the limitations of "for all" practices, Leyva et al. (2022) argue that equitable instruction must also directly confront broader racialized and gendered discourses that permeate mathematics classrooms. If we are to ask instructors to directly subvert institutional ideologies, it would be crucial to understand the various perceived commitments instructors may be balancing as employees of an inequitable institution. Regardless of whether these commitments are commonly perceived or even misplaced, these commitments serve as barriers to instructors who may desire to implement equitable practices but feel unable to.

Previous work described a need for instructors to have deep pedagogical content knowledge (Enyedy & Mukhopadhyay, 2007) as well as knowledge of how students use mathematics in their everyday lives outside of school (Wager, 2012). This data suggests that instructors also felt a lack of historical knowledge about mathematics as a discipline provided a barrier to enacting CSP effectively. The instructors perceived institutional obligations and obstructions even when armored with appropriate training and knowledge would be an interesting direction for future research.

This study explored the question: what do instructors perceive to be barriers to implementing culturally sustaining practices? Interviews with seven math doctoral students who have taught undergraduates, revealed two main findings. Instructors balance conflicting obligations, some in service of culturally sustaining practices and others that directly conflict with CSP. Second, instructors expressed insufficient knowledge and training to implement some CSP practices. Given the need for instructors to disrupt institutional discourses about mathematics, it is important to better understand how instructors may operate and balance conflicting commitments to equitable practices and to the institution to which they are accountable. Furthermore, this work is part of a larger call to situate instruction in its institutional context (Chazan et al., 2016) and potentially understand the possibilities for instructional disruptions given inequitable institutional contexts. Previous literature (e.g. Leyva et al., 2022) has viewed oppressive ideological and institutional influences in tandem with instructional ones. One potential route for further work would be an understanding of the mechanism behind instructional disruptions and how they interact with racialized and gendered institutional and ideological discourses. For example, if an instructor effectively provides counter-narratives against a discourse that mathematics talent is innate, what are the limitations and affordances of a single instructor doing this amidst an institution that continues to perpetuate the dominant discourse?

Limitations

This study presented only a narrow slice of the many perspectives instructors might hold. Of our participants there were: four white men, one Asian man, and two white women. It is possible that the types of responses we would have received would have different had our sample population included more participants of under-represented identities in mathematics. However, generalizing to the population of future professors was not the goal of this study. Additionally, there is a possibility, using a different theoretical lens, that instructors did not truly perceive the obligations they shared with me as legitimate concerns and instead used them as part of a rhetorical strategy to uphold systems of white supremacy in mathematics (e.g. Bonilla-Silva, 2001). While this may have been the case for any of the participants, I argue that it is nonetheless valuable to understand the types of commitments instructors indicate may be in conflict with equitable practices such as culturally sustaining pedagogy.

Resource Use and Student Engagement in Multivariable Calculus

Rafael Martínez-Planell
University of Puerto Rico at Mayagüez

Shelby Stanhope
US Air Force Academy

Stepan Paul
North Carolina State University

This article examines the relations between content, resource use, and the pedagogy of instructors in multivariable calculus. Content included topics that typically appear in multivariable calculus which were grouped into these general areas: introductory ideas, differential calculus, integral calculus, and vector calculus. The resources used included digital resources, 3D-printed models, and other physical resources. Pedagogy practices included both collaborative and individual in-class learning activities, instructor demonstrations, and homework. We also consider the instructor's assessment of the activities they use. Data were obtained from three instructors working at three different types of institutions in the United States: a community college, a small selective undergraduate college, and a large comprehensive research university. The results provide information about instructional needs, as instructors implement resources in multivariable calculus, and about patterns related to the content they cover, the technology they use, and their pedagogical practices.

Keywords: Multivariable calculus, digital resources, TPCK, 3D-printed models

Introduction

Learning multivariable calculus (MVC) is a challenge for students. After operating primarily in two-dimensional worlds to study algebra, pre-calculus, and single-variable functions in calculus, students move to MVC, which typically involves two-variable functions. This introduces a new situation for students, as they must now generalize from the two-dimensional context of their previous studies to the MVC context. Doing so requires students to model and visualize the mathematical objects and their relations in three-dimensional (3D) space. As an instructional aid in this regard, instructors can leverage resources to help students bridge the gap from two to three dimensions, providing learning opportunities that are closer (Parzysz, 1988) to MVC topics than drawing on a chalkboard. To clarify, by resources we mean digital technology, digitally generated technology (e.g., 3D-printed models), or other physical artifacts.

However, the use of resources is not ubiquitous in MVC instruction. This leads to questioning how to best support instructors' use of resources for teaching MVC. In order to provide this support, it is imperative to first try to understand instructors' choices of resources and how resource selection may depend on the topic at hand or a particular pedagogy. One way to initiate this quest is to investigate the relationship between MVC instructors' use of resources for topics in the MVC course and their pedagogical intentions when leveraging resources to engage students in certain types of activities. For this case study, we consider data obtained from three MVC instructors who reported using the digital resource CalcPlot3D, 3D-printed models, as well as other physical resources in their MVC instruction.

To understand the relation between content, resource use, pedagogical practices, and instructor self-assessment of activity quality, we use the following research questions.

- Which topic areas of MVC seem more amenable to resource adoption? What types of resources are adopted?
- Which topic areas of MVC allow for student-centered activities?
- Which topic areas of MVC have activities that instructors assess as being of good or excellent quality?
- Are any patterns noted above that are specific to certain instructors in the sample?

Literature Review

The survey study by Martínez-Planell and Trigueros (2021) shows there is an increasing number of studies dealing with the teaching and learning of multivariable calculus (MVC). However, there is not much research related to the use of digital resources in MVC (Trigueros et al., 2023). There are some studies that report improved learning with the use of physical manipulatives, including tangible surfaces and 3D-printed models (e.g., McGee et al., 2012, 2015; Paul, 2018; Sherer et al., 2013; Wangberg, 2020; Wangberg et al., 2013). A few articles consider the use of digital technology like GeoGebra, Maple, and Mathematica as an aid in visualization, to foment student discussion, and to help bridge the gap between single variable and multivariable calculus (Alves, 2012, Ingar 2014). Some of the studies using digital technologies focus on specific topics or areas of MVC, for example, Trigueros et al. (2023) for basic ideas of two-variable functions, Rojas et al. (2019) for directional derivative, Ingar and Silva (2019) for extrema of two-variable functions, Alves (2014) for using second-order Taylor polynomials for approximating two-variable functions near critical points and relating this to the second derivative test, Henriquez (2006) for multivariable integration, particularly for drawing complex regions and finding limits of integration, and VanDieren et al. (2020) for the cross product. There are also some articles discussing the effect of using digital resources for an entire MVC course (e.g., Carvalho & Pereira, 2011; Gemechu et al., 2018; Habre, 2001). Some more recent articles consider the use of virtual or augmented reality (Cheong, 2023, Jones et al., 2022; Kang et al., 2020; Karabina et al., 2023). Yet, overall, there is much to learn about how resources, especially digital resources, can support the teaching and learning of MVC. Further, all these studies primarily focus on student learning. There is only one published study we know about that considers the use of resources for teaching MVC from the point of view of the instructors' needs (Martínez-Planell & Moore-Russo, 2023). This research is an extension of that previous study, where more data were obtained about the relation between content, pedagogy, and resources for teaching MVC.

Theoretical Framework

We use the Technological Pedagogical Content Knowledge (TPCK) model (Mishra & Koehler, 2006; Koehler & Mishra, 2009) as a theoretical framework for this study. This framework of instructor knowledge builds on the Pedagogical Content Knowledge model initially introduced by Shulman (1986) while also considering the role of technology in instructional decisions and actions. Koehler and Mishra (2009) situate the flexible knowledge needed for teaching as a "complex interaction among three bodies of knowledge: content, pedagogy, and technology" (p. 60). We adopt Mishra and Koehler's (2006) terms "pedagogy" and "content" to mean respectively the "processes and practices or methods of teaching and learning and how [they] encompass educational purposes, values, and aims (p. 1026)" and "the actual subject matter that is to be learned or taught (p. 1025)" respectively. We also adopt their TPCK stance on technologies as being both more traditional items (e.g., pencils and chalkboards) and what they refer to as newer technologies, including digital resources that include computers, tablets, and mobile devices as well as the digital applications they use.

Mishar and Koehler (2006) do not treat technology, pedagogy, and content as mutually exclusive domains. Instead, there is an interplay between the three that is noted in Figure 1 by the overlapping intersections in the TPCK Venn Diagram. In fact, certain resources are more likely to be employed for instructional tasks due to the affordances and capabilities of the resources (Koehler & Mishra, 2008), the fit between the characteristics of the resources and the characteristics of the task at hand (Goodhue & Thompson, 1995), and the instructor's perceptions of how useful and easy-to-use the resources are (Davis, 1989).

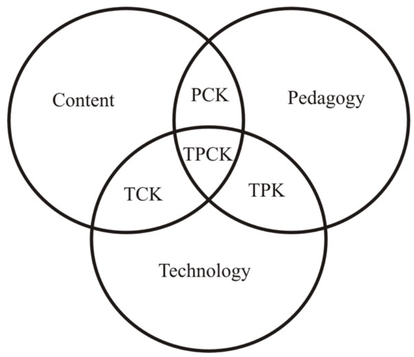

Figure 1. TPCK: Technological pedagogical content knowledge.

Methodology

We used a convenience sample of three MVC professors who employ the CalcPlot3D digital platform, digitally generated 3D-printed models, and other physical artifacts as aids in their MVC instruction. The professors taught at three different universities in three different states in the USA and had taught MVC anywhere from 12 to almost 30 times over their respective academic careers. Professor A teaches at a public community college with over 10,000 students in the Northeast. Professor H teaches at a small selective undergraduate college with about 4,000 students in the Midwest. Professor T teaches at a large public comprehensive research university with over 35,000 students in the East. The three were participating for a second year in a project involving CalcPlot3D and 3D-printed models. The data obtained came directly from the professors, and informal interviews were used to clarify their responses when needed.

The data were instructors' responses to a list of 35 common MVC topics, which was grouped into the following general *content areas* during analysis: introductory information, differential calculus, integral calculus, and vector calculus. The professors were given this list and asked to respond to questions about the types of resources they used in teaching each topic, describe the activities in which the resources were used, and rate the quality of each activity. An activity was the unit of analysis. The professors were asked to self-analyze their instruction using the following codes under each italicized coding category: *resource type* (digital resources, 3D-printed models, other), *pedagogical practice* (instructor demonstration, individual in-class student activity, collaborative in-class student activity, student homework), and *instructor rating* (i.e., evaluation of each activity as excellent, pretty good, needs work, no longer used).

Results

Table 1 displays the counts for several coding categories. However, we will primarily discuss the more qualitative aspects of the data in this section based on the research questions.

Table 1. Activity counts by pedagogical practice, instructor rating, and instructor for each content area and resource type.

Content Area	*Resource Type* Digital Resource	 3D-Printed Model	 Other Physical Resource
Introductory Information	**39 activities** *pedagogical practice* 5 ind act, 37 demos, 10 hwk* *instructor rating* 9 excellent, 30 good	**3 activities** *pedagogical practice* 3 collab *instructor rating* 2 excellent, 1 good	**11 activities** *pedagogical practice* 3 collab, 4 demos *instructor rating* 7 good, 4 not used
Differential Calculus	**19 activities** *pedagogical practice* 2 collab, 1 ind, 18 demos, 4 hwk *instructor rating* 9 excellent, 9 good, 1 needs work	**10 activities** *pedagogical practice* 10 collab *instructor rating* 7 excellent, 2 good, 1 needs work	**4 activities** *pedagogical practice* 1 collab, 3 hwk *instructor rating* 1 excellent, 3 good
Integral Calculus	**21 activities** *pedagogical practice* 21 demos, 1 hwk *instructor rating* 3 excellent, 14 good, 4 needs work	**6 activities** *pedagogical practice* 6 collab *instructor rating* 3 good, 3 not used	**0 activities**
Vector Calculus	**21 activities** *pedagogical practice* 21 demos, 4 hwk *instructor rating* 3 excellent, 15 good 3 needs work	**4 activities** *pedagogical practice* 3 collab, 1 demo *instructor rating* 2 excellent, 2 not used	**0 activities**

* Instructor H allows students to use CalcPlot3D for all homework, but she did not detail how this resource is leveraged. For this reason, we did not count her homework assignments.

We start with the first research question, dealing with TCK, by considering the activities as well as the *content areas* that were more amenable to resource adoption. There were 138 activities reported by the three instructors. Of that total, there are 53 activities dealing with introductory ideas (38%), 33 with differential calculus (24%), 27 with integral calculus (20%), and 25 with vector calculus (18%). Of the 138 activities, 100 (72%) use digital technology (CalcPlot3D), 23 (17%) use 3D-printed models, and 15 (11%) use other resources. This shows there was a clear preference among the participating instructors for using digital technology.

As for *resource type*, the 100 activities that used digital resources were spread across all four *content areas*. The most activities (39%) were employed for introductory ideas with a near even split for differential (19%), integral (21%), and vector (21%) calculus covering every individual topic area except limits and continuity and the chain rule.

Ten of the 23 activities (43%) used with 3D-printed models were for differential calculus. This suggests that instructors find differential calculus more natural or amenable to the design of activities based on 3D-printed models. There are two topics for which the three instructors used 3D-printed models (functions of several variables, partial derivatives), and five topics for which two of the three instructors used 3D-printed models (maxima and minima, Lagrange multipliers, triple integrals in rectangular, cylindrical, and spherical coordinates). There were six other topics for which a single instructor used 3D-printed models. This suggests that the use of 3D-printed models and their implementation should be further explored.

Eleven of the 15 activities were used with resources other than digital or 3D-printed addressed introductory information. The other resources include K'nex rods, a desktop coordinate system, large vector props made from wooden dowels, extendable vectors, a hill outside class, and static images on paper. For the most part, the use of these resources predated the adoption of digital and digitally based resources and attest to instructors' initial TPCK and motivations for engaging in a project to work on using digital and digitally generated resources.

For the second research question, we consider *pedagogical practices* to determine which class activities (by *content area*) allow for more student-centeredness (i.e. individual and collaborative in-class activities). Eleven of the 53 activities for introductory ideas (21%), 14 of the 33 differential calculus activities (42%), 6 of the 27 integral calculus activities (22%), and 3 of the 25 vector calculus activities (12%) were student-centered. All three instructors reported valuing student engagement, but their TPCK allowed them to design more student-centered activities for differential calculus than other areas, especially for vector calculus.

There were only two topics for which all three instructors designed in-class (individual or collaborative) student-centered activities (functions of several variables, partial derivatives) and five topics for which two of the three instructors designed student-centered activities (maxima and minima, Lagrange multipliers, and triple integrals in rectangular, cylindrical, and spherical coordinates). These topics suggest commonalities in instructors' PCK. At the same time, there were 11 topics for which a single instructor designed student-centered activities.

As for homework, which is also student-centered, but not completed in class, Instructor H shared that she allowed students to use CalcPlot3D on all homework, but she did not provide explicit details. There were 6 topics where the other two instructors expected students to leverage digital resources to complete their homework (equations of lines and planes; vector functions and space curves; functions of several variables; tangent plane and linear approximations; maxima and minima; Lagrange multipliers). There were also 13 other topics in which one of the instructors explicitly stated how he expected students to leverage digital resources. Note that none of the six common topics fall under the integral or vector calculus general topic areas.

We now consider the activities that involve instructor demonstrations, which are less student-centered than the other in-class activities just reported, and which also stem from instructors' TPCK. Demonstrations include 41 of the 53 activities for introductory ideas (77%), 18 of the 33 for differential calculus (55%), 21 of the 27 for integral calculus (78%), and 22 of the 25 for vector calculus (88%). So, the activities designed for introductory ideas, integral calculus, and particularly, vector calculus are mainly instructor demonstrations.

There were 13 topics where the three instructors used classroom demonstrations (vectors; equations of lines and planes; cylinders and quadric surfaces; vector functions and space curves; motion in space-velocity and acceleration; functions of several variables; partial derivatives; tangent planes and linear approximations; directional derivatives and the gradient vector; maxima and minima; Lagrange multipliers; vector fields; fundamental theorem of line integrals). There were also 14 other topics in which exactly two of the three instructors used classroom demonstrations. So, there is an ample collection of available demonstrations, as the most common pedagogical practice used with digital technology implementation, which might speak to instructors' TPK.

For the third research question, we consider the topics for which *instructor ratings* were that their activities were of good or excellent quality. Not many activities (only 20%) were self-rated as excellent. Of these, nine dealt with introductory topics (33%), 12 with differential calculus (44%), 3 with integral calculus (11%), and 3 with vector calculus (11%). So, we see that a higher proportion of differential calculus activities rated as "excellent", and there is a lack of highly rated activities in integral and vector calculus.

In examining instructors' PCK, there was only one topic for which all three instructors self-rated their activity as excellent (partial derivatives), and five topics for which two of the three instructors self-rated their activity as excellent (motion in space-velocity and acceleration; functions of several variables; directional derivatives and the gradient vector; maxima and minima; Lagrange multipliers). At the same time, there were 11 other topics for which an activity was self-rated as excellent by a single instructor.

We now move to the fourth research question which considers if any patterns were noted specific to certain instructors in the sample. First, *pedagogical practices*, as determined by student-centeredness (collaborative and individual in-class activities), vary not only by *content area* but also by instructor. For example, in introductory information, only one of the 27 activities of instructor H (4%) was student-centered, while in differential calculus, five of the 13 activities (38%) reported by the same instructor were student-centered. So, the *pedagogical practice* seems to depend on the *content area*. Similarly, in the areas of integral and vector calculus, instructor T designed six of his 13 activities (46%) to be student-centered (collaborative) activities, while none of the nine activities of Instructor A in these areas were student-centered. So, *pedagogical practices* also seem to depend on the instructor.

The choice of *resource type* also seems to be instructor dependent. For example, Instructor H used CalcPlot3D 23 times when discussing introductory ideas, while Instructor T used it only four times. Similarly, Instructor T, when teaching smaller classes, used 3D-printed models in 12 activities, while Instructor A used them for three activities.

Discussion and Summary

Martínez-Planell and Moore-Russo (2023) found that concern for students' learning and the conviction that geometrical understanding is crucial in multivariable calculus motivated their sample of instructors to consider a variety of educational resources. It was found that the instructors were sensitive to students' needs and that over time their teaching shifted from being instructor-centered (demonstrations presented in class) to being more student-centered (activities to engage students often in collaborative group work). The present study examines instructors' TPCK by relating the resources instructors use, the pedagogy employed, and the content at hand.

To answer the first research question, we observed that the area of introductory ideas is more amenable to resource adoption in the sense that it was more frequently the target of activities, mainly for demonstrations using digital technology. This might relate to instructors' TCK. This area of content is also more likely to leverage resources other than digital or 3D-printed for in-class activities. In the case of 3D-printed models, we found that it seems to be more natural for the instructors in our study to use them for differential calculus. For the second research question, mainly focusing on PCK, we observed that all areas allow for student-centered activities through the use of resources. However, there were more student-centered activities for differential calculus followed by the area of introductory ideas. The areas of integral calculus, and particularly vector calculus, are comparatively lacking in the design of student-centered activities. Activities for 3D-printed models, although fewer, tend to be more student-centered than other activities. As regards the third research question, we found that differential calculus has more activities assessed as excellent, followed by the area of introductory ideas. The areas of integral and vector calculus do not show comparable development. For the fourth research question, we found that content addressed, pedagogy used, and resources employed vary by instructor. The general patterns that we found are that digital technology is preferred to other resource use; the use of in-class demonstrations by the instructor vastly outnumbers the use of student-centered activities; there are fewer activities for 3D-printed models, although they tend to be more student-centered; and the area of vector calculus is vastly overlooked in comparison with the others. These patterns suggest that MVC instructors' TPCK is not uniform across content area nor across resource type.

There were six topics for which only one instructor used 3D-printed models, 11 topics for which only one instructor designed student-centered activities, and 11 topics for which an activity was self-rated as excellent by only one instructor. This suggests that sharing materials might help instructors incorporate 3D-printed models into other topics, make the MVC course more student-centered, and disseminate activities that have been rated as excellent. Consistent with Martínez-Planell and Moore-Russo (2023), who argued that instructors could benefit from support on how to teach MVC to engage students by leveraging instructional resources, we found that establishing a means to facilitate instructors sharing student-centered activities, activities they self-rate as excellent, and activities that employ 3D-printed models, could help others and improve MVC teaching. This study makes a case for establishing a means to do so.

In the areas of integral calculus and vector calculus there are fewer activities, very few of which were student-centered or rated as excellent. Correspondingly, most of the relatively few integral and vector calculus activities are instructor demonstrations. This perceived inadequacy or imbalance in these two areas of MVC in comparison with the areas of introductory ideas and differential calculus could be a result of several factors: a consequence of the content itself; a consequence of these areas (integral and vector calculus) being taught towards the end of the course, after instructors have learned to use resources for the introductory and differential calculus areas (so they have yet to get there); or a consequence of a lack of digital capabilities or other tools to properly treat these two areas. More research is needed to better understand this issue. Documenting that these two areas need more work in terms of activities, especially those that are student-centered and of high quality is a contribution of our study.

In the MVC course, there were relatively many activities to address introductory ideas. However, not many of them were student-centered or rated excellent; in fact, classroom demonstrations constituted a large percentage of these activities. While this suggests the possibility of re-examining existing teaching activities in order to increase student engagement with the content, there might be more of a function of time constraint issues exerting pressure on instructional choices more than pedagogical beliefs playing a role. Further study is needed here.

In terms of content, this study suggests that more activities that use resources to improve the teaching of integral and vector calculus are needed. In regard to pedagogy, there is a preference for instructor demonstrations and not enough highly rated student-centered activities. For resources, we observe that more work is needed to explore the pedagogical potential of 3D-printed models. Overall, this study contributes to a better understanding of resource use in MVC, while also contributing to a better understanding of MVC instructors' TPCK.

“I don’t see myself as an expert at all”: Authority in Facilitating Instructional Change

Corinne Mitchell
Virginia Tech

Of the many challenges in shifting towards inquiry-oriented instruction from a lecture-based approach is understanding the role of the teacher in this new paradigm. One aspect of that role involves navigating novel classroom authority dynamics as students bear more authority to create and justify mathematical ideas. Supporting teachers as they navigate this shift is one of the many roles of effective professional development (PD). This study of one PD facilitator’s authority as he worked to support instructors’ inquiry-oriented instruction (IOI) revealed a new type of authority, called pedagogical expertise authority, that may be of particular importance to understanding how to best support IOI. Additionally, the results of this study suggest the impacts of facilitators’ beliefs and teaching experiences on long-term professional development.

Keywords: authority, professional development, inquiry-oriented instruction

Best practices for supporting instructors as they take up student-centered instructional practices have been a central focus in the RUME community in recent years (e.g., Johnson, 2019; Andrews-Larson et al., 2019; Henderson et al., 2011). Due to the shift in authority relations inherent to this change, specific attention must be paid to supporting instructors as they begin to teach in ways that invite students to bear authority in classroom discourse. This study investigates one facilitator’s authority during a semester-long professional development (PD) aimed at supporting instructors’ implementation of the Inquiry Oriented Abstract Algebra (IOAA) curriculum materials (Larsen et al., 2013), with a particular eye toward the potential impacts of the facilitator’s teaching experience on his practice.

Background & Theoretical Framing

Because fostering students' mathematical autonomy is one central goal of inquiry-oriented instruction, PD must support teachers as they adjust their behaviors and roles in the classroom to share authority with students. To create more opportunities for students to autonomously build and justify their own mathematical ideas, as well as develop more productive attitudes and mathematical identities, instructors must move away from a classroom authority tradition based on their own power and mathematical expertise (Langer-Osuna, 2017; Wilson & Lloyd, 2000; Amit & Fried, 2005). Sharing authority among teachers and students is a mutual goal of inquiry pedagogies (Gerson & Bateman, 2010; Hicks et al., 2021), but perspectives differ on what precisely constitutes shared authority. In the most hierarchical sense, a teacher must relinquish authority to students (e.g., Bleiler-Baxter et al., 2023; Fried, 2020), or otherwise minimize his or her authority to create and assess mathematical ideas (e.g., Gerson & Bateman, 2010). More progressive conceptions focus not on the teacher's abdication of authority but rather on how it can be used to promote students' authority (e.g., Bishop et al., 2022; Oyler, 1996). In IOI, teachers are tasked with authoritative roles like guiding discussion and leveraging students' ideas to advance the mathematical agenda of the class while simultaneously bolstering students' authority to create and justify their own mathematics. PD facilitators may become key agents in supporting instructors as they adjust their teaching practices to share authority with students in this way.

Since both facilitators and teachers are tasked with guiding others' learning, the practices of teachers who become PD facilitators are a rich territory for research. To this end, I lift a framework for analyzing classroom authority dynamics to the professional development context. I take specific direction from Gerson and Bateman (2010), viewing authority as an enacted relationship between individuals where an authority bearer makes a claim to legitimacy based on their position within a hierarchy, their expertise, or the norms and practices of the mathematical community, and another receives that authority by changing their behavior, i.e., what is said, what is written, how they are thinking. In addition to Gerson and Bateman's ownership and mathematics expertise authorities (summarized in Table 1), I add the construct of *pedagogical expertise authority.* This construct aims to capture those authority relations arising in PD when instructors' claims about mathematics and pedagogy are legitimized by their expertise as teaching professionals, rather than as mathematicians.

Table 1. Authority types and subtypes with definitions.

Type	Sub-type	Legitimized by . . .
Hierarchical	Institutional	position as instructor of facilitator
	Granted	permission from instructor or facilitator
	Ownership expertise	one's creation of an idea or solution
Expertise	Mathematics expertise	one's mathematical expertise
	Pedagogical expertise	one's pedagogical expertise
Mathematical	Mathematics Community	shared norms, ideas, and practices
	Justification	mathematical & logical reasoning

Context & Methods

The professional development in this study took place in the context of an online working group (OWG) within the TIMES project (Teaching Inquiry-oriented Mathematics: Establishing Supports, NSF Awards: #1431595, #1431641, #1431393). The OWG consisted of three instructors new to teaching IOAA, Elena, Laura, and Roger, and one facilitator, Mickey (all pseudonyms). The instructors were introduced to the curriculum materials in the summer workshop and met synchronously online via Google Hangouts once per week to reflect on the curriculum and their implementation with the facilitator. Participants were regularly asked to share reflections on their instruction and investigate the curriculum tasks from a mathematical perspective. Additionally, the facilitator met with one of the TIMES project's principal investigators (PI) each week in a series of Debrief meetings, wherein the facilitator and PI discussed his goals for facilitation, beliefs about teaching IOAA, and updates on the OWG's proceedings. Both Debrief and OWG meetings were recorded for retrospective analysis.

To identify Mickey's orientations to authority in his facilitation, three sets of video data were analyzed: the OWG meetings, the Debrief meetings, and Mickey's teaching with the IOAA curriculum materials in the previous year. This analysis was guided by iterative thematic analysis (Braun & Clarke, 2021) and had four main phases, summarized in Table 2.

Results & Discussion

Mickey's decision-making practices appear to be influenced by an aim to shift traditional authority relationships in both the online working group and the classroom context. Mickey first demonstrates this intention in an explicit discussion of classroom authority in the early weeks of

Table 2. Summary of analysis phases.

Phase	Description
One	Created analytic notes of OWG meetings; organized into five columns: Video File Name, Timestamp, Quote, Speaker(s), and Notes. Memos focused on Mickey's utterances during and about facilitating discussions regarding IOI.
Two	Created analytic notes of Debrief meetings with identical structure to OWG notes, focusing on subject-matter already prevalent in Phase One data log.
Three	Built descriptive themes of Mickey's prevailing behaviors and attitudes based on commonalities between phase one and two logs.
Four	Analyzed videos of whole-class activities from Mickey's teaching, identifying confirming and conflicting instances of Mickeys previously identified orientations.

the OWG meetings. In the following OWG episode, Elena had been reflecting on her pedagogical choice to give her students the definition of bijection when they could not recall it independently.

Elena: I didn't feel like that was something they could just "inquiry out"' – it wouldn't just happen.
Mickey: Sure, but the thing is is that, holistically, are you doing that more often than not? Because . . . What you're seeing is authority- or power-shift.
Elena: Right.
Mickey: Right. Where is the authority lying? Is it lying with you? Well then, they're only going to do things that satisfy you, instead of doing things that satisfy themselves, you know, for them to learn.

This episode suggests a belief that shifting authority to be shared between teacher and students promotes learning. Mickey's last statement implies that if authority lies with the instructor, then students' engagement will not result in learning. For Mickey, students must take up authority in order to learn. By explicitly motivating participants to attend to these authority dynamics within their own classrooms, Mickey demonstrates his orientation toward authority. This is best characterized as a belief or value in shifting authority structures so that participants, be they students in a classroom or instructors in professional development, rely on their own mathematical or pedagogical expertise to reason about their quandaries, rather than turning to Mickey for his. This practice of shifting authority arises in both the online working group and the classroom when Mickey shares expertise authority with participants while carefully leveraging his authority to advance the agendas in both contexts.

Expertise Authority

Throughout his teaching and his facilitation, Mickey rejects the notion that he is an expert. This refusal to bear expertise authority was displayed in the OWG when Mickey directly discussed his lack of expertise and consistently elicited participants' contributions before making his own, thus sharing pedagogical expertise and ownership expertise authorities among participants. This attitude toward expertise authority is made more apparent in discussions from the debrief meetings and episodes from Mickey's teaching.

In the online working group, Mickey displayed his orientation toward sharing authority by refusing to position himself as the expert in the room, consistently eliciting participant thinking *first* before sharing his own ideas, and sometimes refusing to give advice at all. Often, when a participant asked Mickey a direct question, he would redirect it to the entire group with phrases like, “So that [question] is for everybody, I can answer later,” and “I think this [topic] merits at least a three-to-five-minute discussion. I’ll add a disclaimer that I have no idea how to handle that situation.” In a quintessential episode, Elena has asked Mickey how he would handle the situation of having an exceptionally bright student eager to share all of the answers: “If you're looking at me to be the expert in this situation, I don't have a clue. I have conjectures and thoughts about this, but I want to open it up to everybody in the room.”

Mickey directly states that the participants should not view him as an expert. Furthermore, by choosing to give the opportunity to answer Elena's question to the whole group, Mickey receives the pedagogical expertise authority of the remaining participants. This is a clear invitation for participants to bear pedagogical expertise authority to reason about Elena's quandary, as well as ownership expertise authority to create and discuss possible solutions. It can be inferred that Mickey’s belief about this practice of sharing expertise authority as essential for participants' learning motivates his decision-making as a facilitator.

Mickey's orientation toward avoiding expertise authority is also apparent in discussions from the Debrief meetings, where he overtly describes his relationship to his own expertise. An instance of dialogue that captures this is:

> It’s hard even with them sometimes, because when I ask a question, they're seeking “Is this the answer you wanted?” and like, a colleague of mine introduced me the other day as a pedagogical expert and . . . I am so not that.

Even more explicitly, he says: “I don't consider myself an expert in inquiry-oriented [sic] by any means.” Rather, than viewing himself as an expert in IOI, Mickey is aware that his position as facilitator garners him institutional authority, but chooses to leverage that authority to share pedagogical and ownership expertise authorities with students. This is indicative of Mickey's orientation toward the importance of sharing expertise authorities in professional development.

Likewise, in discussing his own views on assessment during a debrief meeting in Week 8, Mickey mentioned that his OWG seems to struggle consistently with student learning assessments, trying to lean on his experience for guidance. He said, “This keeps coming up over and over and over again, and I keep asking them, ‘What are the goals of your course?’ For me, your assessment should match your goals.” Mickey shared his personal teaching philosophy but rejected any positioning of himself as the arbiter of what kinds of assessments were best. He encouraged his instructors to create their own standards for assessment, rather than to look for the “correct way” to assess their students based on his expertise. This clearly demonstrates Mickey's goal of sharing expertise authorities. His comments about answering participants’ questions based on his expertise authority emphasize his intention to shift traditional authority structures within his facilitation to create dynamics of shared authority.

Mickey's teaching actions provide additional context for these facilitation practices and the authority beliefs that inform them. Because of the contextual differences between the classroom and the online working group, it is no surprise that this orientation arose differently during Mickey's teaching in the year prior. In the classroom, Mickey's orientation toward traditional authority dynamics can be characterized by his intentional and particular distribution of opportunities to bear expertise authorities among his students through a process-over-product value selection of contributions. Additionally, he invites students to bear mathematical authority to evaluate each other’s contributions.

It is often the case that students with correct solutions most consistently bear granted authority to contribute to discussion. Mickey subverts this authority tradition by minimizing the contributions of students with correct solutions and granting authority to students with partial or in-progress solutions to contribute their thinking. In the classroom, this careful distribution of opportunities to bear authority arises when Mickey leverages his institutional authority to prompt students to share their thinking, especially when he asks students to share what he calls “productive failures”. One explanation of productive failures that Mickey gives in class is:

> “Try stuff. In Algebra, you're going to cook a lot of equations up. Some of them may be fruitful, some of them may not be. The biggest thing, though, is to explore. Because, some help, some don't. Learning from your mistakes, having that productivity when you're failing, is a huge part of this.”

Mickey regularly granted students the authority to share these productive failures, and it should be noted that students were expected to discuss these processes as part of their course grade. By granting students authority to contribute their in-progress mathematical ideas, Mickey subverted the tradition that only correct solutions can legitimize a students' mathematics expertise authority, shifting toward a dynamic where students are enculturated into the mathematical community through opportunities to share their informal, in-progress reasoning. In an exemplifying episode, the class is attempting to prove a conjecture about a generating set for a symmetry group. The student who made the conjecture begins to share his completed proof, and Mickey interrupts him to call on a student who is still working on the conjecture, saying, ``Hold on, hold on, let's see, Madison, can you help me out with this?'' Mickey has not received the mathematical authority the student with the correct solution is attempting to bear, and instead grants authority to Madison to share her reasoning about the conjecture so far. In inviting her to bear granted authority, Mickey creates the opportunity for Madison to bear both ownership expertise and mathematics expertise authorities. This is supportive of Madison's, and arguably many other students', mathematical autonomy because it values the process of creating a proof over the final product, which helps students to develop productive beliefs about their position in the mathematical community (see Serbin et al., 2020, p. 4). This support is also created by centering Madison's in-progress thinking, which aids other students in gaining insight into their classmate's reasoning.

Mickey also shifts away from the tradition that the instructor bears the institutional and mathematics expertise authorities to evaluate students' contributions by inviting students to bear authority to evaluate each other’s ideas. Following the episode above where all students have been prompted to share work for task 3 on the whiteboard, Mickey asks, “So, what do we think?

And remember, we're in a non-judgmental phase in our lives right now, so keep your comments very productive, okay?" By empowering his students to evaluate each other's contributions through constructive feedback, Mickey creates opportunities for students to bear mathematical authority to evaluate each other's work and ownership expertise authority to respond to evaluations of their own ideas. This supports their mathematical autonomy by engaging students in reasoning about the contributed solutions and giving them ownership of mathematical ideas.

Mickey's refusal to bear pedagogical expertise authority in the online working group parallels his refusal to bear mathematical expertise authority to evaluate students' contributions in the classroom, instead inviting students to evaluate each other's contributions. Similarly, inviting OWG participants to share their thinking before sharing his own appears in much the same way as his classroom practice; in both instances, Mickey invites participants to share expertise authorities specific to the learning environment. The practice of sharing authority in both settings demonstrates Mickey's intent to shift traditional authority dynamics. This practice arises as an artifact of Mickey's implicit belief that sharing authority supports the development of subject-specific autonomy in participants.

Authority to Advance the Agenda

Although Mickey refused to bear the expertise authority his participants often requested of him, there was tension between Mickey's authority values and his responsibility to advance the agenda of the OWG. Advancing the agenda required Mickey to bear institutional authority both as the facilitator in the OWG and as the instructor in the classroom.

Mickey often prompted participants and guided group discussion to meet the goals of the OWG, bearing institutional authority in order to advance the agenda of the OWG. This is evidenced on the individual level when Mickey directly asks participants for their thoughts on the mathematics, as seen in the following exchange between Mickey and Roger during a group discussion of the Sudoku task (Larsen et al., 2013).

Mickey: Turning toward the content in Lesson 4, why is it, mathematically, that in every group Cayley table, each symmetry appears exactly once in each row and each column?
Roger: It has to do with cancellation?
Mickey: Can you expand on that? Pardon the pun.

When Mickey bears his authority as the facilitator to prompt Roger to share his thinking, he advances the professional development agenda by guiding participants to engage with the curriculum materials from a mathematical perspective. He also directly prompts the participants to reflect aloud on their teaching experiences. After Laura had discussed a difficulty she was having with using one of her student's contributions to formalize a mathematical idea, Mickey prompted her to dig deeper, saying "Now that you can reflect on it, what went through your mind at that moment when you were handling the situation?" and later directing the remaining participants to discuss potential pedagogical moves to apply to Laura's quandary. By exercising his institutional authority as the facilitator in this way, Mickey advances the agenda of the OWG by inviting participants to engage in pedagogical reasoning.

So, while Mickey shares authority often by refusing to be the bearer of expertise authority in the Online Working Group, he is willing to bear the kind of institutional authority associated with the facilitator's responsibility to advance the agenda to meet the OWG's goals. Although these actions do not depart drastically from hierarchical authority relations, they are consistent with a motivation to support participants' pedagogical reasoning and autonomy, which is in line with both Mickey's goals and the intent of the instructional support model.

Similarly, Mickey must bear institutional authority in the classroom to direct students' activity by providing tasks and granting students authority to share their solutions. Similar to the OWG, Mickey's orientation toward his own institutional authority is somewhat unsurprising in the classroom context, but by using it to grant authority to students to contribute, Mickey acts with the goals of supporting the development of his students' mathematical autonomy and advancing the mathematical agenda. What is most striking is the way this agenda informs Mickey's choice of which students are granted authority to contribute. By de-emphasizing the mathematical authority of students with correct answers, Mickey creates more opportunities for a wide range of students to bear ownership and mathematics expertise authorities, thereby promoting their mathematical autonomy.

Conclusions

The results of this case study suggest strong parallels between the teaching and facilitating practices of this PD facilitator: across contexts, Mickey balanced the goal of sharing authority with participants with his responsibility to advance the agenda of the group, pointing to the possibility that teachers' beliefs can transcend the classroom and influence the way they facilitate professional development. Mickey's emphasis on OWG participants bearing pedagogical expertise authority to reason about their instructional practices may have arisen from his experiences with balancing authority in an IOAA classroom, where, unlike in other types of inquiry-based learning, the instructor's responsibility to advance the mathematical agenda demands that they carefully leverage their own authority in ways that encourage, rather than stifle, students' authority.

More broadly, this study speaks to the importance of facilitator's prior teaching experience, attitudes, and beliefs about authority, in creating shared authority dynamics that can support the professional development of new instructors. Viewing both instruction and PD facilitation through this lens of shifting authority dynamics can be useful in future research on both IOI and professional development, especially with the added construct of pedagogical expertise authority. Future work should investigate the effects on teaching when participants are bearers of pedagogical expertise authority in professional development, as well as their affect, attitudes, and conceptualizations of shared authority in IOI.

The Nature of an Online Work Group Reveals the Teaching Knowledge of Inquiry-Oriented Linear Algebra Instructors through Their Goals for Instruction

Minah Kim
Florida State University

Shelby McCrackin
Florida State University

Postsecondary instructors interested in inquiry-oriented instruction of linear algebra participated in a sequence of eight one-hour online work group meetings with other inquiry-oriented linear algebra instructors and facilitators. Recordings were analyzed for how two participants referenced goals for instruction in discussions of implementing a new instructional unit on subspaces. We identified four goals for the instruction of teaching subspaces. We discuss the intersections of several goals that exist due to the tension caused by real-world contexts and abstract mathematical concepts. The instructors presented resolutions to the tension by utilizing varying teaching knowledge. Based on the results, we make suggestions for those who want to transition to inquiry-oriented instructional approaches.

Keywords: teaching knowledge, goals for instruction, inquiry-oriented linear algebra, online work group

Inquiry-Oriented Linear Algebra (IOLA) is a reform-oriented instructional approach that derives from Realistic Mathematics Education (RME). This instructional approach encourages teachers to support students in their reinvention of mathematical concepts through inquiry (Freudenthal, 1991; Kelley & Johnson, 2022). Research has shown that authentic engagement with mathematics through this instructional approach, can benefit student achievement and possibly incite equitable outcomes among students (Burke et al., 2020; Freeman et al., 2014; Haak et al., 2011; Kogan & Larsen, 2014). This instructional practice is difficult to enact, however, because instructors may not fully utilize the teaching knowledge needed to inform their practice. This is especially true for novice instructors implementing inquiry-oriented approaches (Wagner et al., 2007). If long-lasting instructional change is needed for the desirable outcomes available by IOLA, then teachers need to shift their instructional approach (Cohen, 1990; Henderson et al., 2011) by growing teaching knowledge. Thus, researchers have declared "a need for professional development programs that foster the development of undergraduate mathematics instructors' pedagogical reasoning" (Andrews-Larson et al., 2019, p. 129).

This lays the groundwork for the following problems: what is being done to address the professional development gap, what teaching knowledge IOLA instructors possess, and how do we capture it. Thus, an Online Work Group (OWG) for postsecondary mathematics instructors is examined in this study. The OWG was part of the IOLA-X project and was initially created to provide IOLA instructors a chance to collaborate with other instructors who are interested in their continuous pursuit of enacting IOLA. These IOLA instructors are guided by facilitators who are researchers of IOLA-X. Instructors from various universities across the United States joined this OWG for eight sessions across the Spring 2022 semester. They worked on an IOLA task unit "subspace" and discussed their teaching practices with the other researchers, instructors, and facilitators of the OWG. The researchers of the IOLA-X project took their contributions to inform their continual effort to adjust their curriculum and to create teacher notes for other IOLA instructors. The instructors' contributions can be valuable to capture how the OWG makes way for discussion of teacher practice and to also collect teacher knowledge IOLA instructors possess. Here, our research question is "How does the OWG serve opportunities for instructors to exhibit knowledge for teaching in inquiry-oriented ways?"

Literature Review

Linear Algebra is a postsecondary mathematics course that is often a requirement for students in STEM-related majors. As a result, many students at some point enroll in this course. IOLA is one instructional approach to active learning (Freeman et al., 2014) and inquiry-based mathematics education (Laursen & Rasmussen, 2019). Laursen and Rasmussen (2019) discuss this approach to mathematics education as "student engagement in meaningful mathematics, students' collaboration for sensemaking, instructor inquiry into student thinking, and equitable instructional practice to include all in rigorous mathematical learning and mathematical identity-building" (p. 140).

As stated previously, inquiry-oriented instructional approaches are difficult to implement. Mostly because instructors at first may not possess the reasoning and knowledge necessary for enactment (Andrews-Larson et al., 2019). The knowledge we are referring to is mathematical subject matter knowledge (Ball et al., 2008; Hill et al., 2008) and pedagogical content knowledge (Ball et al., 2008; Hill et al., 2008; Shulman, 1986). Shulman in 1986 first introduced the idea of Pedagogical Content Knowledge (PCK) as the subject-matter knowledge for teaching. This includes at the time the unnamed domains of PCK which are knowledge of content and teaching (KCT) and knowledge of content and students (KCS). These domains capture knowledge for teaching such as an instructor's knowledge of the best representation to present to students or knowledge of what ideas or conceptions students will bring to the table. The domains are not restricted to the teaching of a specific content area.

Ball and colleagues (2008) expanded on the work of Shulman in their framework of Mathematical Knowledge for Teaching (MKT). Their framework includes PCK as half of their domains of MKT. The other half is subject-matter knowledge, in other words, mathematical knowledge that is unrelated to the practice of teaching. Teaching knowledge for mathematics instructors has been studied for decades as either declarative or "knowledge-in-use" (Andrews et al., 2022). These studies capture how experienced teachers approach their instruction. Although there is little evidence that more experience means more teaching knowledge (Andrews et al., 2022), there are studies that point to the differences in teaching knowledge between experts and novices (Auerbach et al., 2018). Thus, analyzing the teaching knowledge of experienced IOLA instructors can prove to be worthwhile as they highlight areas of instruction novice IOLA instructors may not consider.

Theoretical Framework

Wagner and colleagues (2007) studied the MKT and PCK regarding the challenges of a novice instructor teaching an inquiry-oriented differential equations course. As a result, Wagner et al. (2007) identified four types of instructional goals in the context of inquiry-oriented instruction at the undergraduate level: classroom orchestration goals, cognitive/learning goals, assessment goals, and content goals. These goals encompass their framework called *goals for instruction.* Each goal is summarized as follows:

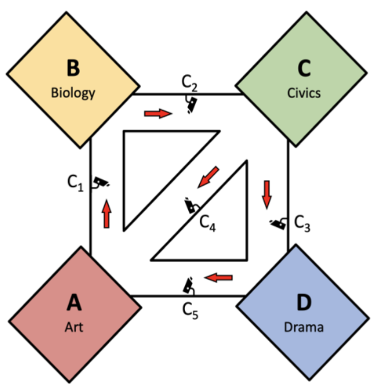
1. Classroom orchestration goals: How instructors orchestrate, intervene, and redirect the discussions and negotiate an agenda with emerging ideas.
2. Cognitive/Learning goals: What student understanding, questions, and activities look like.
3. Assessment goals: How to assess student learning, what the evidence of understanding is, and how to design a pace or curriculum.

4. Content goals: What and how specifically mathematical concepts should be learned.

Using the work from Wagner et al. (2007) as a priori scheme, this proposal identifies how instructional goals were discussed by experienced IOLA instructors in the OWG.

Study Context: Inquiry-Oriented Linear Algebra and Online Work Group

The IOLA-X project focuses on developing student materials composed of challenging and coherent task sequences that facilitate an inquiry-oriented approach to the teaching and learning of linear algebra (Wawro et al., 2013). There are five main phases in the design research spiral: *Task Design*, *Paired Teaching Experiment* (*PTE*), *Classroom Teaching Experiment* (*CTE*), *Online Work Group* (*OWG*), and *Web* (Wawro et al., 2023). The participants of our study come from the OWG in the fourth phase of the research project. The main purpose of the OWG for the IOLA research team is to learn from instructors how IOLA is implemented in various classrooms with various student populations and to gain insights to develop instructor notes and revise tasks (Wawro et al., 2023). At the center of the OWG for this study was the discussion of a unit of tasks about subspaces and Table 1 illustrates the overview of the subspace unit. In this unit, the tasks were contextualized in a problem about students walking in one-way hallways past cameras monitoring their traffic (See Figure 1). To draw out the feedback from the instructors, the facilitators managed mathematical discussions about the tasks as well as facilitated discourse about the preparation and implementation of the tasks. Through examining discussion and input from the experienced undergraduate instructors participating in the OWG, questions, and thoughts about the goals for instruction and challenges with implementation naturally arose.



The hallways in one wing of Ida B. Wells High School were changed to one-way corridors to promote social distancing during a pandemic (red arrows in the diagram). These hallways connect classrooms A-D (the Art room, Biology lab, Civics room, and Drama room) as shown in the diagram. Each hall has a security camera that allows Principal McDaniel to monitor student movement through the hallways (cameras 1-5, as shown in the diagram). As a further precaution, each wing is isolated from the rest, so the students in a wing stay within that wing and no students from any other part of the school will enter the west wing.

SCENARIO ONE: TRACKING MOVEMENT

Before the school year starts, Principal McDaniel goes into the school when it is empty to spend a day learning how to use data from the camera system. Her daughter Ella comes with her, and she asks Ella to help her test the system by walking between rooms – so long as she stays in the building and follows the one-way hallway rules. Ella decides to start in the Art room, passes Camera 1 (C_1) as she walks from the Art room toward the biology lab, and then continues walking past Camera 2 (C_2) as she walks from the biology lab to the Civics room. Afterwards, Principal McDaniel sees that the camera system has recorded the number of people who walked by each camera with the vector $p = \begin{bmatrix} 1 \\ 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$.

Figure 1. The hallway scenario of Tasks 1-2 in the IOLA subspace unit

Methods

Our primary data source was the recorded videos of the OWG meetings—held and recorded via Zoom, and group artifacts such as Google Slides and Jamboards that served as secondary data sources. In this OWG, there were six members: F1 and F2 (facilitators), R1 and R2 (IOLA researchers), and I1 and I2 ("pure" participants who are experienced inquiry-based instructors but not IOLA researchers). This study focuses on the pure participants, so the participation and contributions of I1 and I2 serve as the main data of our study. I1 is an associate professor at a small private college in the Northwestern United States and I2 is a senior instructor at a large public university in the Northeastern United States and they all taught linear algebra at their universities at the time of the OWG sessions. Other than pure participants, this team involves one graduate student (F2), two associate professors (F1 and R1), and one full professor (R2).

Table 1. The IOLA subspace unit overview

Task	Driving Question	Mathematical Formalism
Hallway Task 1: Finding Paths	What are the possible paths from room A to room C and from room C to room C?	Closure (of "inputs")
Hallway Task 2: Managing Populations	What are the possible paths that induce a specific change in room populations? What are the possible paths that leave the room populations unchanged?	Correspondence between ("input" and "output") vectors
Hallway Task 3: New Wings	What are the possible paths for a different wing of Ida B Wells High School (defined by a matrix) that will leave populations unchanged?	Null spaces as a type of closed "input" spaces and column spaces as a type of closed "output" spaces

Each OWG meeting was approximately one hour and there were eight meetings throughout the Spring 2022 semester. Thus, a total of around eight hours of OWG meetings were conducted and recorded over several days. In the first four videos, the OWG members discussed the IOLA subspace tasks, either as if they were students or teachers, so they shared the mathematical progression of an IOLA subspace unit comprised of three tasks. The subspaces unit focused primarily on notions of closure of sets of vectors under vector addition and scalar multiplication, as well as null and column spaces. So, in the first four meetings, participants worked on the mathematical problems as a group and then discussed mathematical goals, approaches, and links to other ideas and topics. The remainder of the meetings took place throughout the participants' implementation of the sequence, with each participant reporting on how the implementation went, what they liked, how their students reasoned about tasks, what they would change or what they would do differently.

We first analyzed all eight videos in terms of goals for instruction. To do so, videos were transcribed by Otter, an online artificially intelligent transcription application. Both authors separately coded all transcripts using Nvivo software. In this analysis, the four goals of instruction were the code schemes. We coded for all the participants of the OWG—even though this report focuses on two pure participants. While coding, we assigned four codes, which mean four goals, at the level of a single turn of talk. Then, we compared codes to reach agreements to build inter-rater reliability. We identified common themes within each code and found out that there were many intersections between two or more goals. We decided to dig into the intersections more precisely—and so analyzed what kinds of pieces of knowledge of IOLA instructors were discussed, considering the goals for instructions and main themes of OWG meetings. For this report, we selected several examples of what I1 and I2 shared and contributed.

Results

Generally, in the OWG meetings, the pure participants discuss how to manage discussions of contextualized tasks about closures and subspaces (classroom orchestration goal), what kinds of discussion topics and communication emerged in engaging in IOLA tasks (cognitive/learning goal), curricular trajectories and mathematical content relevant to subspaces reorganized by instructors (content goal), and pacing, timing, testing, and grading of inquiry-based teaching (assessment goal). Within the findings, the main notable pattern in this OWG is there are many intersections of two or more goals for instruction, except for assessment goals. Also, it is interesting these intersections are rooted in some tensions between RME-based context and abstract mathematical concepts in implementing IOLA tasks. The following examples address those intersections.

I1: Yeah, my only hesitancy in all of this is the fact that you know, in the other task sequences, we have this clear and direct parallel between the intuitive contextual setting and the formal definitions. And this one, we're a little loosey-goosey in a couple of places, and I just, I don't know how that's gonna translate. Like, are they like, are they going to internalize what has been their tendency to think only about scalars that are, you know, positive whole numbers in the first place, right? And so, is this going to somehow reinforce that? Um.

Here, I1 expresses her concern of how students will take up subspaces according to the “loosey-goosey” definition in the task. That it may be difficult to align the abstract with what students would develop intuitively as the formal definition of subspace. This excerpt also is an intersection between classroom orchestration, cognitive/learning, and content goals. This intersection illustrates challenges for the instructor to discern what content ought to be taught (content goal), how those jive with the class activities (classroom orchestration goal) and concerns that students may "think only about scalars that are...positive whole numbers" in the context of the problem and if the task will continue to "somehow reinforce that" knowledge (cognitive/learning goal).

Similarly, another instructor participant, I2 also talks about the transition from the task activity to the introduction to the abstract version of subspace definition.

I2: So, I do want to say like, so it seems like we, the intent or how people have been talking about this is that we're going to use these like non-negative integers for the exploration stuff, but then tell the students to use real numbers for the actual subspace definition.

This is where I2 has the intersection between the classroom orchestration goal and a content goal. In terms of classroom orchestration, I2 anticipates how the task will be used for "exploration stuff" and also plans when there will possibly be direct instruction to then “just tell the students” to use real numbers for the actual subspace definition. Also, in terms of the content goal, I2 discusses what mathematical concept—the actual subspace definition, should be brought up during instruction using the IOLA task. Like above, throughout the overall OWG meetings, I2 expresses some tension in the negotiation between the real-world context of the task and the abstract mathematical concepts.

The intersections between classroom orchestration, cognitive/learning, and content goals stand out in OWG discussions of Task 3, where the concept of subspace is introduced. Task 3 starts from a new 5×7 matrix that represents a new scenario of camera record in another school wing, and the set U is all the possible camera data vectors which leaves the number of students—in each room unchanged. In the last part of Task 3 (See Figure 2), the set U is meant to be connected to the concept of subspace, and then null space. Here, I1 and I2 communicate with each other by discussing their anticipation of implementing Task 3.

I2: Yeah. So, in the previous prompt, they have to, you know, U as defined as, you know, actual students and actual cameras, right? So that means the entries on U are the entries in the vectors and U, I think, have to be non-negative integers. It's then, closed under scalar multiplication for those scalars for non-negative integer scalars. And then we change the scalars in the box definition, but we don't change U. So, our students going to be confused about, I think, "no" is a reasonable answer to C. Right? I think they might say "no", because it is not closed under vector scalar multiplication because I can't scale by a fraction, or a non-negative number, and I'll get something that is not in U because we didn't change U. So, either. So do either. So, I feel like the changes have to be synced, right? Like the change to U. And the change to the scalars needs to be synced, otherwise C turns into false.

I1: I assume that's what we want. Is, is that not what we wanted? like to just point out that like, well, U is closed to being a subspace, but because the scalars need to be any real numbers. It's not? Maybe I misunderstood? The…

I2: I don't know. That was one I thought. I kind of wanted there to be like a thing you found was a subspace, punch line, students like that. I mean, maybe there's used to it.

Recall: Definitions for closure of a set under vector addition and scalar multiplication:

- A set of vectors S is called **closed under vector addition** when $v,u \in S \Rightarrow v + u \in S$.
- A set of vectors S is called **closed under scalar multiplication** when $v \in S \Rightarrow k*v \in S$ for any scalar k.

New Definition: Subspaces

- A non-empty set of vectors in R^n is called a **subspace of** R^n if it is closed under vector addition and scalar multiplication (where, <u>for our purposes, we assume scalars come from the real numbers</u> R).

5. Several statements are written about U and F below. Circle ones that are true, and modify the ones that are false so that they become true statements.

a. U is a sub<u>set</u> of R^7.	a. F is a sub<u>set</u> of R^7.
b. U is closed under vector addition	b. F is closed under vector addition
c. U is closed under scalar multiplication (scalars $\in R$)	c. F is closed under scalar multiplication (scalars $\in R$)

Figure 2. The statements about subspaces in Task 3

I1 and I2 presented contrasting approaches to the IOLA instructions, especially in terms of the tensions between the RME context and formal concepts in the subspace. It seems I1 liked to engage her students in conversation and whole classroom discussions related to the tensions in the subspace tasks. From a previous OWG session, I1 remarked on her experience in a previous "stellar class" with their discussion of span. When her students discussed span, she "...thought it was like, superfluous, but it turned out not to be." As it turned out, there was a tension or confusion caused by the RME-based scenarios in IOLA tasks so students only used positive whole numbers as scalar multiples. She faciliated a classroom discussed where she "freaked out" her students by introducing other real numbers such as e and pi. That led to her students and she having "deeper and deeper" communicatively engaged conversations, and so "that meant content coverage was sacrificed a little. And I decided I was okay with that." On the other hand, I2 seemed to prefer focusing on what may confuse students so he wanted to reduce confusion beforehand. The second instructor wrestles with what content should he bring into discussions in his class between himself on the teacher side and the mathematician side. This wrestling particularly happened when he addressed more formal mathematical concepts such as closure under scalar multiplication, non-emptiness, and dimensions of a subspace—they usually have the potential to conflict with the context of the IOLA tasks. He stated, "I feel it makes me a bad mathematician. Probably a better math teacher to not show them that."

Discussion

The results of this analysis demonstrate several points. Firstly, the goals for the instruction framework can be used as a coding scheme that highlights teaching knowledge instructors utilize as they reflect on their instruction. Secondly, both participants of the study demonstrated often overlapping goals for their instruction. This is most likely due to the varying knowledge they rely on to inform their instruction. We saw from Participant I1 a demonstration of pedagogical knowledge being utilized as she anticipated ways to host a discussion with her students to untangle the difference in the contextualized and abstract definition of subspace. The other participant, I2, mostly relied on his mathematical subject-matter knowledge and his knowledge of students to hypothesize ways to deliver content in the most streamlined manner possible. These insights of teaching knowledge these two instructors possessed were made possible due to the semi-casual nature of the OWG. The instructors participated the most in the work group, yet the facilitators actively engaged in questioning instructors on their decision-making all the while. It is because of the structure a lot of varying teaching knowledge is revealed.

It was through discussion between the participants that revealed tension in implementing the subspace task due to its incomplete definition. The two participants presented different approaches to the IOLA instruction as it related to ironing out this wrinkle. Our two participants highlighted how experienced IOLA instructors will utilize various domains of teaching knowledge while balancing their knowledge of the principles of Realistic Mathematics Education to problem-solve. Thus, we think postsecondary instructors can have different avenues to becoming IOLA instructors so that their approaches to resolving tensions would be different. Therefore, it will be important for both novice and experienced IOLA instructors to have a professional development space—that may look like OWG—to unpack their speculations and approaches and then move forward. After implementation, reflection on instruction is also vital for developing teaching knowledge of oneself and others.

In terms of teacher knowledge—in addition to reflection on teaching practice, the OWG provided an opportunity for instructors to communicate with other instructors and also with the curriculum developers on the insights of the instructional design. This process of examining tasks and reflecting on their implementation is especially vital for IOLA instructors, so the OWG serves the place for them to analyze and reflect on the curriculum they implement in their classrooms. As the instructors examine instructional task designs after listening to what other instructors unpack from their implementation, their approaches can adjust based on their previous examination. As a result, they were able to build their teaching knowledge as it relates to adjusting curriculum to serve their student populations. That demonstrates the importance of reflection for IOLA instructors. Sharing approaches to task implementation and analysis is beneficial, yet it becomes more powerful for other instructors if it sparks reflection on practice.

Availing Orientations and Facilitating Behaviors: An Emerging Framework for Change Leaders

Sandra Laursen
University of Colorado Boulder

Chris Rasmussen
San Diego State University

Scholars and practitioners in higher education recognize that transformational change of organizations—especially departments and institutions—is difficult but essential to achieve needed, national-scale improvements in access, quality and equity in STEM instruction and career development. Based on studies of change projects in college mathematics education and gender equity on STEM faculties, we identify and describe a suite of common leadership approaches among change agents who led these projects. We propose that these approaches function as constructs for an emerging framework about change leadership. By observing how change agents lead complex change projects in higher education, we seek to develop theory about leadership for organizational change and to offer practical guidance to such leaders.

Keywords: institutional change, departmental change, leadership

RUME scholars are well familiar with calls for mathematics departments across the U.S. to improve student success in introductory mathematics courses (PCAST, 2012). Concerns about passing rates in these courses, coupled with student dissatisfaction with an overpacked curriculum that has little connection to their interests, are not new problems (e.g., Seymour & Hewitt, 1997; Seymour & Hunter, 2019). In response to these ongoing problems, professional societies have called for increased uptake of active learning, which is known to improve student outcomes (e.g., Abell et al., 2018; Freeman et al., 2014; Saxe & Braddy, 2015).

Such efforts to improve undergraduate teaching and learning in mathematics are not new. Decades ago a set of major, NSF-funded calculus reform projects sought to create a "lean and lively" calculus (Douglas, 1986). These largely focused on creating and disseminating new curricula and lab activities as the primary lever for change. These materials offered more challenging and relevant problems and often deployed small group work as a primary teaching strategy. Research on college STEM education was in its infancy and researchers were not ready to provide guidance for this kind of work in higher education. In retrospect, we can recognize this approach as insufficient: by focusing on new materials, calculus reform engaged a subset of faculty, but could be largely ignored by many others. High-quality instructional materials are necessary but not sufficient to motivate reform (Henderson et al., 2011).

Today, research-based materials and classroom approaches are widely available for many college courses (Fairweather, 2008). In addition to high quality instructional materials, current innovations are embracing inclusive active learning via sustained professional development. Helping individuals to develop the classroom skills, foundational knowledge of learning, and availing beliefs is essential support for their effective use of research-based curricula (Yoshinobu et al., 2022). Yet relying on individuals to take up innovative materials, one by one, is a slow route to widespread change. The most promising reform approaches today focus on deploying these resources—research-based materials and effective professional development—in a department-wide context with explicit attention to local culture and norms (Laursen et al., 2019).

In this paper we offer some insights derived from our work as scholars examining organizational change in higher education, particularly at the level of departments and institutions. Based on our studies of two quite different sets of change projects that use different interventions to accomplish distinct change goals, we identify a suite of common leadership approaches among change agents who led these projects. We classify these approaches, discuss how they manifest in change projects, and propose that they function as constructs for an emerging framework about change leadership. By asking how change agents lead complex change projects in higher education, we seek to develop theory about leadership for organizational change and to offer practical guidance to those doing such work.

Conceptual Foundations

While leadership and institutional change has long been a focus of scholarly inquiry in higher education (e.g., Eckel et al., 1999; Birnbaum, 1991), this area of research has yet to be broadly taken up in STEM reform contexts (Reinholz et al., 2020). In situating our theory-building contribution to this emerging field of inquiry, we draw on the distinction between a global change theory and a local theory of change (Reinholz & Andrews, 2020). A global change theory is an overarching, meta-level framework of ideas that provide backing or justification for the change process, typically empirically informed and grounded in ideas from fields such as sociology, psychology, or management. Examples include the Four Frames model (Bolman & Deal, 2008), the Networked Improvement Community (Bryk et al., 2015), and the River model (Elrod & Kezar, 2015). Such frameworks offer 10,000-foot views that neither refer to specific change projects nor outline specific interventions but may be used to explain or predict.

In contrast, a local theory of change is a project-specific description that links the overall goals and rationale to desired outcomes, planned activities, and indicators or metrics to explain how the intended local change is expected to come about. Thus, a local theory of change is pragmatic and action-oriented compared to a formal change theory. It may be graphically represented in a logic model or driver diagram (Kinzie & Kuh, 2017), and represents a ground-level view of a particular change plan for a particular place and time.

The framework for change leaders that we begin to develop here takes a 100-foot perspective situated somewhere between a global change theory and a local theory of change. As we detail below, the framework constructs include availing orientations and facilitating behaviors. We use these constructs to characterize change leaders' work, not to prescribe specific interventions or actions. They are aspirational, intended as touch points for decision-making. Local context and goals will drive how they manifest or take shape. In sum, if the local theory of change describes *what* work is to be done, our change leaders' framework offers advice on *how* to accomplish it.

Study Contexts and Data Sources

The authors have separately studied institutional and departmental change in different higher education contexts: efforts to change undergraduate instruction in mathematics departments, and efforts to advance gender equity on STEM faculties. Here we briefly describe these settings and the studies that support our cross-case analysis involving multiple cases of change projects.

Departmental Reform in Mathematics: The SEMINAL Project

The Student Engagement in Mathematics through an Institutional Network for Active Learning (SEMINAL) project was an NSF-funded effort to better understand mechanisms for initiating and sustaining department change focused on implementing active learning in undergraduate mathematics classes. The project began with retrospective case studies of six departments that had implemented active learning in their precalculus and calculus courses (Smith et al., 2021b). The second phase of the project consisted of longitudinal case studies of nine mathematics departments as they rolled out their own change initiatives. Each sought to shift department norms to enable greater uptake of active learning in their precalculus and calculus courses, supported by nominal funding and a networked improvement community to help accelerate their local change efforts. The national call for SEMINAL participants drew 37 proposals, reflecting high interest in departmental approaches to change.

Two overarching themes characterize the change interventions chosen by the nine departments. First, many developed approaches to support instructors as they implemented active learning approaches in their classrooms. They created or adapted active learning instructional materials, offered professional development that met instructors where they are, and nurtured communities of practice. Second, departments created or reimagined the structures and policies that shape instruction from outside classroom walls. For example, departments created curricular structures to organize faculty around thematic groups of courses, developed course coordination policies and practices, and curated a wide range of instructional support materials in an accessible, easy-to-use format. All of these efforts sought to lower barriers that can prevent instructors from implementing the desired classroom changes and to establish norms of coordination and collaboration that help to align multi-section courses.

For this paper, we make use of SEMINAL data about the nine Phase 2 departments. Primary data include project reports that summarized interviews with project change leaders, faculty, administrators, student focus groups, and classroom observations, collected annually over three years. The SEMINAL team also interacted with campus team members via webinars and summer workshops. We conducted secondary analyses of these data and drew on these projects' own writing about their work, published in a special issue of PRIMUS (Smith et al., 2021a).

The ADVANCE Institutional Transformation (IT) program

The U.S. National Science Foundation initiated its ADVANCE program in 2000, calling for systemic approaches to address the persistent problem of women's underrepresentation on STEM faculties. Past programs had supported individual women but left untouched the biased institutional processes and hostile environments that generated the career challenges that women widely faced (Rosser & Lane, 2002). Taking a new tack, ADVANCE supported institutions to identify and remediate those structural and cultural barriers to women's recruitment, retention and advancement, and to share their strategies and tactics widely through both scholarly research and practice-focused dissemination. By 2023, NSF had made nearly 70 awards for Institutional Transformation—sizable ($3M) five-year grants to single institutions—and over 250 awards for adaptation, partnership and research that enable others to adapt and adopt the strategies and tactics developed across the ADVANCE community (Laursen & De Welde, 2019).

As a group, ADVANCE IT grantees have developed a variety of strategic interventions to address core challenges that face women STEM faculty. Laursen and Austin (2014, 2015, 2020) studied the strategies developed and tested by early ADVANCE awardees, and categorized them according to the core problem each addressed and the approach taken to address that problem. Laursen and Austin observed four broad strategies, aimed at (1) interrupting implicit bias in evaluation of faculty for jobs, awards or advancement; (2) improving workplace environments; (3) supporting faculty to fulfill both personal and professional responsibilities; and (4) fostering individual success. Within each broad type of strategy, an array of several specific interventions used in distinct settings is richly described in an online toolkit and book (2014, 2020).

For this paper, we draw on secondary analyses of data and insights gained from over two decades of work with ADVANCE as an evaluator and researcher. Primary data include interviews with 19 principal investigators, focus groups with 18 institutional teams, site visits to five campuses, and two working meetings with 27 change leaders, as well as deep analysis of a large library of documents gathered from over 40 ADVANCE IT projects.

Findings: An Emerging Framework for Change Leaders

It is challenging to shift organizational cultures to make the use of active learning the norm rather than the exception, and SEMINAL departments' progress varied from moderate to substantial. Given the often intransigent nature of departmental change, even moderate progress is a marker of success. The same is true of ADVANCE Institutional Transformation projects: institutions' progress on STEM faculty gender equity was variable, nonlinear, and context-dependent. Though they may seem very different on the surface, what these change projects have in common is that each used a variety of strategies as levers for change (Laursen et al., 2015). No single tactic alone did the job; rather, projects made headway through selecting and combining interventions to build a strategic portfolio that fit their local circumstances and conditions.

Building on the strategic choice of interventions, we noticed that change projects were impactful when the interventions within the portfolio were coordinated, synergistic, and guided by shared language and principles. In this analysis, we focus not on the specific change goals (improving student success in calculus; advancing gender equity) or interventions (shared materials, professional development; implicit bias training, partner hiring policy). Rather, we identify approaches that change leaders used in guiding their projects. Just as each project deployed a mix of interventions to accomplish targeted, local goals, likewise change leaders used a diverse toolkit in leading their group. We identify ten leadership approaches seen in change projects: five availing orientations and five facilitating behaviors (Figure 1). Below we describe these, with examples mainly from ADVANCE, then highlight a case study from SEMINAL.

Availing orientations	Facilitating behaviors
Considers a unit of change beyond the individual	Co-opts or plugs into existing structures
Takes a systems approach to change	Makes new ways of working easier
Attends to context and culture	Foregrounds inclusive practices and equitable outcomes
Leverages a theory of change	Addresses people's needs for a sense of purpose and meaning in their work
Promotes a non-prescriptive, asset-based view of people and system components	Regularly communicates with stakeholders

Figure 1. An Emerging Framework for Change Leaders: Availing Orientations and Facilitating Behaviors

Availing Orientations: Mindsets for Change Leaders

Following Muis' (2004) labeling of students' beliefs about learning, we label change leaders' beliefs as "availing" if they avail or advantage the desired change outcomes. This terminology avoids value judgments of beliefs as 'better' or 'more sophisticated.' We call them "orientations" to recognize that they are not dogmas but mindsets: ways to frame or think about a situation.

The first two orientations are foundational for leaders. In *considering a unit of change beyond the individual*, leaders focus on the goal of changing whole courses, curricula, processes, or programs. This does not mean that everything is upended at once! Rather, it portrays the concern of interest as a shared responsibility. While changes in individuals' knowledge, beliefs, skills and behaviors may be needed, leaders emphasize collective decisions and actions rather than calling out individuals' views and behaviors as the source of a problem or its solution.

Taking a systems approach to change acknowledges that the target course or program is a system of interacting parts. People take actions and enact their beliefs as instructors or advisors; physical structures and infrastructures such as physical spaces and add/drop policies steer or limit perceptions and behaviors; assumptions about the needs of client departments or traditions in assessment influence what topics are highlighted, how they are taught, and what is assumed about the needs of the student audience. A course is in turn embedded in the larger systems of the department, college and institution. Taking a systems approach means recognizing those elements explicitly, probing their functions and interactions, asking why things are this way, and looking for ways to rethink, rebuild, or mitigate the negative impacts of different components.

The next two orientations help leaders translate to their own setting these broad, foundational concepts. In *attending to context and culture*, leaders recognize that every organization has a particular context, based on its mission, history, geography, and role in national, state and local education landscapes. Two-year or four-year, public or private, urban or rural, secular or church-related, historically Black or predominantly white: such factors may reflect real differences in how problems appear and what strategies may work. Outside factors also shape a department, such as its relationships with other departments or with high schools whose students enroll in their courses. And context varies over time. For example, economic trends determine if the department can hire instructors or must tighten its belt; and changes to state policy may shift what courses the institution must provide. Contextual factors shape how a problem presents locally, and they mean that strategies cannot be imported wholesale from other institutions.

Thus it is also important for leaders to *develop and leverage a theory of change,* as described under Conceptual Foundations. Elements of a theory of change may draw on scholarship about how people and organizations change, but often more useful to leaders is a local theory that identifies the specific problems to be addressed, articulates the interventions to be tried, and explains the rationale: why will *these* activities help to solve *this* problem? Developing a theory of change forces leaders to articulate their ideas and assumptions before leaping into action, making visible what may be taken for granted. Sharing it can engage others and build buy-in to the rationale and goals of the project. Leaders can also make use of formal change theory to map out and guide interaction among the components of their local theory of change.

The final orientation emerges in part from the others. By conceiving of issues as arising from larger systems, yet accounting for local particularities, change leaders more readily see problems as shared, systems-embedded challenges rather than pointing fingers toward someone "at fault." They learn to spot local resources that can help them engage others or achieve their change goals. By *adopting a non-prescriptive and asset-based view* of the people, programs, and policies that constitute the system, they depersonalize the problem, invite others to be more curious and less defensive, and welcome multiple ideas and strategies for addressing the challenge.

Facilitating Behaviors: Tactics with Many Uses

We label change leaders' behaviors as "facilitating" if they facilitate or advantage progress on desired change outcomes. These are not specific actions, procedures or interventions, but approaches to leadership that work in concert with the availing orientations. In this way, the framework sits between formal change theory and on-the-ground local theory of change.

One facilitating behavior is to *co-opt or plug into existing structures*, especially entrenched infrastructure, relationships, and policies. Within departments, this may mean introducing course coordination or making teaching assignments that support use of common teaching materials and strategies. Co-opting existing structures may be less work than inventing new ones, and the solutions that emerge are more readily sustained if they are already embedded in the workings of the department. Conceptual structures are often useful too, such as important goals or campus-wide initiatives. Campus ADVANCE leaders met with more whole-hearted support from senior administrators when they articulated their faculty equity goals in language that referenced the institutional mission and mirrored its strategic plan, such as elevating scholarly activity, fostering interdisciplinary research and teaching, or coupling excellence to diversity, as they developed interventions to support women as research leaders or to diversify the faculty body.

Making new ways of working easier is a behavior that helps normalize new or revised ways of working. For example, some ADVANCE teams promoted the use of rubrics to fairly evaluate faculty job candidates, and developed templates and training to help search committees craft and use rubrics. These tools lessened committees' work to develop the rubric; using the rubric in turn lessened the work to filter candidates and negotiate ratings, because standards were clear and already agreed upon. Faculty who had experience with rubrics could then lead other search committees, and the rubric became an anchoring structure for new, normative hiring procedures.

A common way that leaders *foreground inclusive practices and equitable outcomes* is through strategic use of data. ADVANCE leaders used institutional data about faculty retention and promotion, for example, to show that gender inequities known from the literature pervaded their own campus, thus disrupting "Lake Wobegon" narratives that such problems happen elsewhere. They learned how to use social science studies to show the systemic roots of sexism and racism to STEM faculty (who are often unschooled in these fields or methods), and they saw values and behaviors shift as people came to understand gendered and racialized institutional practices as due not to individual "bad apples" but as systems built by and for the historic majority. Other ways to foreground inclusion are inviting diverse voices to the table, interrupting microaggressions, or providing opportunities to learn about inclusive teaching and mentoring.

When leaders *address people's needs for a sense of purpose and meaning in their work,* they are recognizing and harnessing the power of the symbolic frame to elevate certain values and give them cultural meaning (Bolman & Deal, 2008). Mathematics department leaders did this when they celebrated early wins in a long-haul change project or recognized project contributors with teaching awards or callouts in the department newsletter or website. ADVANCE leaders did this when they adapted professional development programs to recognize faculty needs for autonomy, linking individuals' goals to collective goals for leadership and inclusion.

Finally, leaders who *regularly communicate with stakeholders* are thoughtful and persistent in identifying what different constituencies need to know about their change initiative. They consider the clarity, coherence, frequency, and consistency of messaging, and how to use local data to inform and persuade different audiences. ADVANCE teams found that strategically tailored communications could build grassroots support, lessen resistance, and recruit allies who shared some degree of common purpose with their work. Speaking to department chairs, for instance, garnered their support when chairs discovered that ADVANCE could help them with mentoring early-career faculty or supporting associate professors in seeking promotion to full.

The Toolkit in Action: Case Study of a Change Project

California State East Bay (CSUEB) faced historically high DFW rates in precalculus (42% DFW) and calculus courses (36% DFW), especially among students from historically under-represented minority (URM) groups. Like many US mathematics departments, CSUEB relied heavily on part- and full-time lecturers. Because many taught at more than one institution, they often felt isolated or disconnected from the department, and largely relied on traditional lecture. After a multi-year transformation effort, CSUEB created and sustained a strong community of practice that includes lecturers and ladder-rank faculty, initiated a supportive course coordination system, and fostered a culture in which active learning is the new normal. With a keen focus on inclusive practices and equitable outcomes, they also lowered DFW rates to the high teens for all students, and all but eliminated the gap in DFW rates between URM and non-URM students.

Ever mindful of the local cultural value on instructor autonomy, the CSUEB team developed a change portfolio with three primary strategies. First, the team created and curated instructional material focused on "big ideas" and conceptual understanding, all aligned to a master syllabus. All materials were available to all instructors to adopt or adapt, but no one was required to use them. Second, they created a new structure of course coordination, based on a dynamic calendar that offered instructors a pacing guide, suggested group tasks, and helpful comments on content emphasis. Again, these resources were options for instructors to adapt or adopt as they saw best, with change leaders taking an asset-based perspective where instructors were seen as caring and talented, rather than in need of "fixing." Third, and linked to course coordination, they developed a community of practice with monthly meetings that offered instructors a network to support their professional growth, to develop shared understandings, and to build knowledge collectively. This went a long way toward addressing instructors' needs and sense of purpose and belonging.

Together, these three strategies reflect a systems approach to instructional improvement. By offering a variety of resources and embedded professional development opportunities, leaders welcomed all and made the desired change easy, resulting in a "new normal" of equitable active learning. CSUEB's story (Oliver & Olkin, 2022) is not a road map for what others should do, but an example of how leaders' approaches can help a department to succeed in its own context.

Discussion and Implications

In this initial framework, we identify some general ways of thinking and doing change. Observed among leaders of real transformational change projects, they show that meaningful change is possible. That is not to say, however, that leading change is easy. Maintaining the availing orientations may challenge deep-seated beliefs and long-held habits, and enacting the facilitating behaviors requires listening deeply and being open to changing one's mind.

Our focus on leaders shares some commonalities with the empirical investigation of mathematics course coordinators by Martinez et al. (2021), which revealed two orientations to the job (resource/ managerial and humanistic/growth). Knowing these orientations, the authors suggest, can help departments hire and support professional development for these key department personnel. Likewise, our framing of change leaders' availing orientations and facilitating behaviors may help change leaders accomplish their goals and may assist institutions to select and cultivate change leaders whose work will improve the academy.

The availing orientations and facilitating behaviors are neither independent nor linearly related. For example, a change agent's non-deficit view prompts her to seek out data and search for inequities with attention to local concerns about which groups may be privileged or excluded. Moreover, as change agents display these orientations and deploy these behaviors, they can nurture similar mindsets and skills among others, thus broadening or deepening their change coalition. Indeed, recognizing these orientations or behaviors may be a way to identify change leaders whose skills can be further cultivated to share in ongoing work.

At this time the framework is incomplete, as we have identified key constructs but have not specified how they relate to each other. In future work we plan to flesh out these relationships, seeking both to contribute to theory about leading organizational change in higher education and to develop the framework as a practical resource for change leaders.

"More and New Insight": Undergraduate Mathematics Stakeholders See, Imagine, and Evaluate Selves through Collective Poems on Inclusive Teaching

The use of inclusive teaching practices is novel for many instructors; there is a need to support instructors in envisioning what it looks like to teach inclusively. Related to this learning is a focus on reflection—on one's current self as an instructor and envisioning whom one could become as an inclusive teacher. This study explores reflections made possible by reading and responding to collective transcription poetry. Informed by Gutiérrez's conceptualization of equitable teaching as existing across critical and dominant axes, we took undergraduate mathematics program stakeholders' definitions of inclusive teaching practice and created collective transcription poems. We presented the poems to stakeholders, who then reflected on them. We highlight reflections indicative of stakeholders' current selves and possible selves, and the emergent theme of evaluative selves as ways in which to bridge these two dimensions of self with regard to inclusive teaching. We conclude by sharing directions for future work.

Keywords: inclusive teaching practices, critical methodology, reflections, possible selves, networked improvement community

Nationally, undergraduate mathematics courses have significant room for improvement when it comes to equitable and inclusive teaching and learning (e.g., Theobald et al., 2020). The work of moving toward more diverse, equitable, and inclusive undergraduate mathematics teaching and learning is not easy, nor can it be accomplished via a checklist type of approach. Rather, the work is complex and messy and involves people in professional relationships with one another, forming communities, and making sense of their current practices and how those could change for the better. Those involved in instruction in undergraduate environments bring their own identities into the classroom context (Ceglie & Settlage, 2019); identities can evolve as a person considers whom they are currently (current selves) and explores whom they might become (possible selves) (Gee, 2001; Markus & Nurius, 1986). We seek to understand the nature of these considerations with regard to inclusive teaching practices and values.

This study is part of a larger project studying how to support mathematics departments to positively impact diversity, equity, and inclusion. Each department formed a networked improvement community (NIC; Martin et al., 2020) of six to 11 members who met regularly to consider department data and make plans for action. The project brings a critical lens to this equity-focused work. Thus, we chose critical research methodologies that centered the voices of participants and engaged collaboratively with the participants to elicit their feedback and reactions to our research analyses. Here, we explore how NIC members engaged with poetry based on their definitions of inclusive teaching.

[1] Tremaine and Quaisley contributed equally to this work.

Literature Review

We use Gutiérrez's work (2002; 2009; 2012) to conceptualize equity in undergraduate mathematics classrooms. Gutiérrez bifurcates issues of equity along the dominant axis and the critical axis. The dominant axis emphasizes the *access* students have to resources that allow them to participate in mathematics and how this access influences their *achievement*. This axis characterizes an approach to improving equity that focuses on helping students navigate and succeed in existing systems. In contrast, approaches aligned with the critical axis challenge these existing systems. The critical axis foregrounds student *identity* and *power* in mathematics, aiming to transform the system to better serve students, particularly those from marginalized communities. Both axes are necessary for equity-oriented reform, although the dominant axis is often highlighted in change efforts and is more commonly drawn upon by undergraduate mathematics stakeholders to justify enhancing diversity in STEM (Tremaine et al., 2021).

Inclusive teaching incorporates instructor mindset and practices along with the establishment of a classroom community in which students are attuned to hearing the voices of peers. Inclusive classrooms involve ongoing dialogue between instructors and students to develop and nurture a climate in which all participants have a voice, feel their voice is heard, and in which connections between content and students' lived experiences are explicit (Dewsbury & Brame, 2019; Freire, 1970; Nieminen & Pesonen, 2022; Saunders & Kardia, 1997).

Instructors may face barriers to implementing inclusive or equity-focused instructional practices, including their epistemological beliefs about mathematics, hesitance to engage in conversations about student identity, and prior schooling experiences (Dewsbury & Brame, 2019; Shultz et al., 2023). Many current instructors did not experience learning in inclusive classrooms and so may struggle to envision and implement inclusive teaching practices (e.g., Dewsbury & Brame, 2019). However, instructor growth to learn about and effectively adopt inclusive teaching practices is quite possible, given appropriate learning opportunities and support, such as faculty learning communities (Corrales et al., 2021) and departmental action teams (Corbo et al., 2015). A key to instructor growth is for instructors to not just hear about inclusive practices, but to actively engage in reflections on their teaching practices as part of intentional improvement efforts (Dewsbury & Brame, 2019; Schön, 1987).

Conceptual Framing: Possible Selves

Possible selves (Markus & Nurius, 1986) has been used as a conceptual framework to describe identity exploration, evaluation, and development (e.g., Dunkel, 2000), including professional identity in education (e.g., Blaney et al., 2022; Park & Schallert, 2020; Quaisley et al., 2023). We draw from possible selves to describe how instructors engaged with the poetry on an individual level. As individuals think about their potential future they draw from a collection of possible selves—who they might become—to guide their behavior. Possible selves are specific to an individual, representing a "cognitive manifestation of enduring goals, aspirations, motives, fears, and threats" (Markus & Nurius, 1986, p. 954) and emerge from whom one was. Possible selves are also influenced by the sociocultural and historical contexts in which the individual resides. Possible selves are a source of motivation for individuals, functioning as "incentives for future behavior," as individuals endeavor to align themselves with possible selves they consider ideal, or to reject behaviors they connect with possible selves to avoid (Markus & Nurius, 1986, p. 955). In this way, individuals engage in reflection, evaluation, and interpretation of the alignment between possible selves and their current self to analyze how the current self measures up to whom they want to become, could become, or fear becoming. Among the collection of possible selves is an ideal self—the self whom one strives to be. Related to our work, instructors may engage with the poems to evaluate or interpret how their current self aligns with the various possible selves they can be as a teacher, specifically related to an ideal self who uses meaningful inclusive teaching practices.

Using possible selves as a conceptual framing, we aim to better understand the ways in which undergraduate mathematics program stakeholders engage with identities that embody or experiment with inclusive teaching practices and values. We investigate the following research question: *In what ways do stakeholders reflect on current and possible selves in the context of inclusive mathematics teaching through engagement with collective poetry?*

Methods

The work of the NICs began in January 2022, and the larger project is collecting a wide array of data from the NICs. We began with the initial reflective journals from members of the Tau University NIC (TU-NIC) and Kappa University NIC (KU-NIC) (all names are pseudonyms). Among other journal prompts, we asked "*Describe what you think it means to teach with inclusive teaching practices.*" Participants consisted of mathematics instructors (including professors of practice and tenure-track faculty members) and administrators. They were given the option to submit their journals anonymously. We extracted the responses to that prompt from all 16 of the journals and coded them using Gutiérrez's (2002; 2009) dimensions of achievement, access, identity, and power. We then engaged in poetic transcription (Authors, 2022; Clarke, 2017; Prendergast, 2009) to capture the four dimensions. We constructed transcription poetry from the full set of excerpts for each NIC without stratification by participant; in this way, each poem contained excerpts from the words of multiple participants in each NIC. This method of *collective* poetic transcription enables maintenance of participant anonymity (e.g., Thunig & Jones, 2020). For TU-NIC, three researchers each wrote individual poems, and then met and created a set of poems. For KU-NIC, one researcher wrote all of the poems.

The collective poems for each institution were then shared with their respective NICs. We captured written feedback via individual Jamboards[2] containing the poems (two from KU-NIC; nine from TU-NIC) and field notes that captured verbal responses to the TU-NIC poems during a regularly scheduled TU-NIC meeting. Notably, participants responded in other ways; Figure 1 provides an example of an artistic response via drawing. Whereas the opportunities for multimodality of response was an intended strength of using the Jamboards to collect reflection data, we are still learning how to analyze non-textual and non-verbal responses and thus have excluded such arts-based modes of reflection from this particular analysis. We approached our analysis thematically, and used open coding on the written Jamboard reactions. We then met and discussed the codes that arose from each NIC's reactions, collectively combined related codes, and came to agreement.

The initial open codes included general reflections, connections to individual and collective practices (current or desired), challenges, posing questions, emotive responses, and responses to poetry as a form. After open coding, we engaged in axial coding, during which we saw connections in the data to possible selves (Markus & Nurius, 1986). Many of the NIC members responded to the poems in personal ways that compared the poems' collective NIC responses to their own values and teaching. Upon making this connection to possible selves, we revisited the

[2] Scholars have used Google Jamboard as a tool for brainstorming and fostering discussion in participatory research projects (e.g. Huỳnh et al., 2022). This study extends such use by engaging Jamboard as a data collection tool focused on NIC members' perspectives. Benefits of Jamboard include its multimodality of engagement and customizable environment.

data and coded it using current selves and possible selves as primary codes and identified evaluative selves as an emergent code that added nuance to our understanding of how stakeholders conceptualized themselves with respect to inclusive teaching.

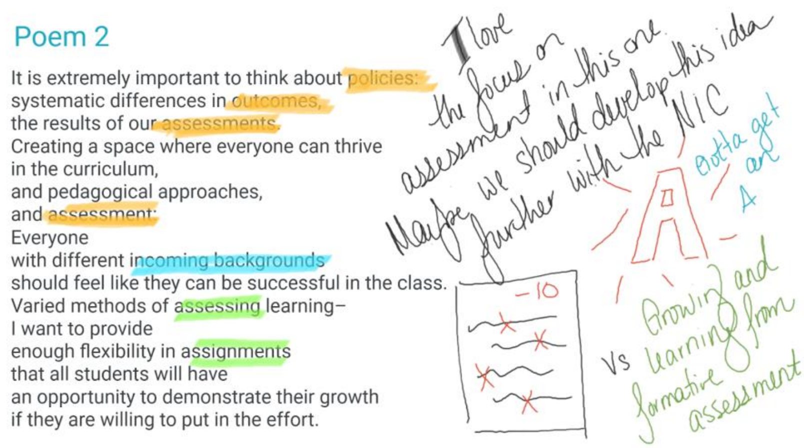

Figure 1. Screenshot of Jamboard response from a NIC participant.

Findings

NIC members engaged in reflections about current and possible selves through their interaction with the poems via the Jamboard platform. We identified three primary shapes taken by the NIC members' reflections—that of the current self, that of the possible self, or that which uses the possible self to evaluate the current self. Below, we detail these shapes, recognizing that all selves are fluid and thus that these reflections represent the specific selves relevant to each participant at the moment in time in which this activity took place (Markus & Nurius, 1986).

Reflections on a Current Self

Reflections on a current self are those in which the individual engaged with the poetry in a way that expressed an awareness of practices that they currently enact in their role as a mathematics instructor or administrator, or asserted a value that they presently hold related to teaching inclusively. Because these poems were constructed through the process of poetic transcription, seeing their colleagues' and their own words about what inclusive teaching can entail prompted moments of resonance or reflection, either with a value or a concrete action, that they currently incorporate into their professional practice. We detail some instances of these reflections below.

Many instances of reflections on current selves were provided in the form of value statements (Seah, 2002), in which an individual connected with the poetry by affirming a value about mathematics education which they read (either explicitly or implicitly) from the poem, or expanding upon the content of the poetry to profess a value which they presently hold in relation to inclusive teaching. For example, in response to the KU poem on Access, Tiersa wrote, "I think it's important to set clear policies, but I want those clear policies to be flexible policies." The poem led them to identify a component of inclusivity that they value: clear policies that maintain a degree of flexibility. In a particularly notable quotation, Connor reflected on the TU Achievement poem by writing that the poem's frequent mention of grading was a "damning perspective," as "learning is more important than grading." This reflection conveys a relativistic value presently held by Connor. In response to the lines, *It is extremely important to think about* *policies: // systematic differences in outcomes*, Skylar agreed and elaborated that this value is "why we have decided to have administrators as part of our NIC membership, because we wanted to examine and change this systemically." In this way, Skylar not only identified a value held by their current self, but connected that current value to a decision.

In some cases, the identification of a resonant value for inclusive teaching was accompanied by a wondering or an experience also embodied by their current self. Kayla, in response to the TU Achievement poem, wrote "understanding experience and barriers is super important—how can we possibly make it equitable?" This statement conveys that Kayla's current self values "understanding experience and barriers," *and* their current self struggles with how *we* on a broader scale might make *it* equitable. Although they did not explicitly define *we* or *it*, they appear to allude to some difficulty or tension associated with the value held by the current self. We see this also from Natalie: they state that "knowing [their] students as individuals is great. But it can become difficult whenever [they] have large class sizes." With this response to the TU Identity poem, they have both identified a value held *and* a barrier faced by their current self. In both of these cases, the ability of their current self to enact a value they hold about mathematics education is tempered by their perception of barriers or lack of agency in achieving it.

Other instances of reflections on current selves took place in the form of an individual directly bringing into their reflection a practice that they currently embody or an experience of their current self which has relevance to the poem. For example, Skylar notes that they "keep trying to build more flexibility into [their] syllabus" while simultaneously juggling continual student requests for "extra grace," a reflection which they wrote next to the lines *Offering exceptions in some cases– \\ a little extra grace?* in the KU Access poem. The question posed by the poem prompted Skylar to reflect on how their efforts to make their classroom—and syllabus—more inclusive do not appear to mitigate the experience of receiving requests for "extra grace" from students.

Reflections on a Possible Self

Reflections on a possible self included those in which the individual imagined or wondered about alternative versions of themselves as an instructor. For instance, some individuals engaged with the poems by contemplating new practices they might try out as instructors who get to know their students despite large class sizes (KU, Skylar) or as "flexible" instructors through the policies they create (KU, Tiersa). Markus and Nurius (1986) also consider past selves—who one was—as a form of possible selves and is another way in which one individual reflected on the poetry. Of the KU poem on Identity, Tiersa wrote: "I feel some shame at the way that I have failed in the past."

Note that these reflections on the possible self sometimes occurred concurrently with reflections on the current self. For example, Taylor reflected on the TU poem on Access: "Structure is important for students in the classroom and this poem makes me see that I need structure too. Note: annotate my stuff for students." Taylor first reflects on their value ("structure is important") and follows up with a new idea for a practice ("annotate my stuff for students") in alignment with a possible self (a more structured or organized instructor).

Individuals also connected with the poetry by describing certain teaching practices as either desirable or incompatible with their current self or practices, or as ones they imagined having difficulty attempting to enact or feeling afraid to enact. For instance, Ethan reacted to the TU poem on Identity by describing a way of engaging with students as incompatible with their personality: "I'm not a social person. It's uncomfortable for me when students are friendly on a personal level. I don't know if I can extend that sort of thing without it seeming fake." Abel reacted to the line "balancing grading policies" in the TU poem on Achievement by revealing a feared possible self; Abel wrote, "This is one of my fears, being fair."

An ideal self was described by multiple individuals as they engaged with the poetry. In response to the lines *Everyone // with different incoming backgrounds // should feel like they can be successful in the class* in the KU poem on Achievement, Skylar identified a desired goal or motivation for instruction: "YES, I really resonate with this goal. It's challenging, but definitely my aim." As these were collective poems, sometimes individuals also described an ideal culture in which each of its members share similar notions of self. For instance, in response to the KU poem on Power, both Skylar and Tiersa expressed their desire for feedback from other instructors and a culture of observation within the department. In this way, Skylar and Tiersa reflected on a personal ideal self—the collegial practitioner self—as well as an alternative community in which each of its members embodied this ideal self.

Evaluative Selves

Evaluative selves are those which exist at a particular intersection of current and possible selves. They took the form of NIC members using notions of a possible self to evaluate the current self, and thus their current values and practices. Markus and Nurius (1986) identify this evaluative bridge between current and possible selves in their work, noting that possible selves provide "a context of additional meaning for the individual's current behavior" (p. 955). In the context of these poetic reflections, we observed participants constructing bridges between possible and current selves by leveraging a possible self to evaluate the actions or values of their current self with regards to inclusive teaching.

For example, we consider Skylar's response to the following lines from the KU Identity poem: *Being attentive // in the problems that I write; // Embedding // culturally relevant examples*. Skylar highlighted these lines and wrote next to them that they "like this idea, and think it's something [they] need to work on." In the same body of text, Skylar reflected on efforts they currently make to incorporate examples that are specific to the KU context, but expressed concern that those examples may still be "exclusionary." Skylar considered two aspects of self—a possible self who is intentional about problem-writing and uses culturally relevant examples, and a current self which tries but may or may not be effectively incorporating these practices. This is a case in which the possible self functioned as an ideal self, utilized as a goal toward which the current self could work. We also saw one example in which a past self was used to evaluate a current self. In reflecting on the TU Achievement poem, Ethan wrote that they recognized from their own reflections the phrase *Hoping // for no disparaging trends // with pass rates or grades* and indicated that they "still really want to know what data from [their] own class would say." By signifying that this experience of the past self remains resonant, a bridge is built through which Ethan frames their current curiosity as something which continues to have value to their current self.

NIC members also engaged in evaluative reflections through the questions they asked in response to their reading of the poetry. These questions called their current self into a place of judgment, without necessarily making a conclusive evaluation of the current self. We view these as equally productive; while they may not have expressed an additional insight into their current values and practices by understanding them through a comparative lens with a possible self, the asking of these questions created space for such evaluation. Tiersa reflected on the KU Identity poem by writing the following questions: "Do I always use the right language? Can students less familiar with English understand my problems?" Implicit in these questions is a possible self which *does* use the "right language" and *does* construct problems understandable by students who are less familiar with English. Also implicit in the nature of questioning is the fact that Tiersa did not equate these attributes with their current self, but rather acknowledged a gap between their current self and this possible self in the context of inclusive teaching. We see something similar from Abel, who reflects on the line *Holding \\ to high standards* by writing "Are my policies applicable and fair to all?" In asking this question, Abel called their current self into a place of judgment—there exists some ideal possible self who *does* have policies which are fair to all, but in asking whether their policies do presently have this quality, they invite into their reflection a comparison of their current self to this ideal possible self.

Conclusion & Implications

Engaging with poetry afforded stakeholders the opportunity to see, imagine, and evaluate themselves with respect to inclusive teaching along Gutiérrez's (2009) dimensions of equity. By seeing the current self within the poems presented to NIC members, individuals felt validation regarding their values, beliefs, and practices surrounding inclusive teaching. Further, imagining possible selves offered individuals the opportunity to grapple with tensions and consider alternative ways of being as practitioners. Some participants also evaluated their current self through comparison to these possible selves, prompting consideration of who an ideal inclusive instructor is and how to become one. This reflection was perhaps a preliminary step toward what Ibarra (1999) describes as trying on a *provisional self*—a self of experimentation, a self that one tries on after observation of and engagement with role models (i.e., people with qualities that align with their ideal self). We found that this dialogue between the current and possible self spring boarded individuals' reflections beyond identifying similar (or dissimilar) values or questioning the feasibility of certain practices and into a problem space for potential experimentation with the current self.

Notably, we also found that the poetry engagement made an impact on some individuals' reflections in unique ways. Consider Taylor's critiques of the TU poem on Access alongside their empathetic connection to students:

> Despite not enjoying the poem as poetry, it did get me to see that doing these things is "easy", but the issue is getting students to make use of our actions. Thank you…If this poem was more structured, more clear, then I wouldn't have made connections for myself and they would have less meaning to me… Structure is important for students in the classroom and this poem makes me see that I need structure too.

Moreover, since this was *collective* poetry, individuals engaged with a variety of different ideas and insights about inclusive teaching. This perhaps gave them a more diverse repertoire of possible selves to construct regarding inclusive teaching. Some individuals expressed that reading collective poetry meant developing a closer understanding of the values of other NIC members, which could perhaps create space for additional community reflection.

Poetic transcription as a critical method highlights not just words or phrases, but also emotions and emphases. Through engaging with collective poetry, participants are invited to reflect on and discuss the ideas *and* feelings of fellow NIC members—and themselves—without placing peers in a vulnerable position. Future work could explore the impact of such reflections on the beliefs, values, and practices of undergraduate mathematics stakeholders. Skylar wrote that the process of reflecting on poetry was "a lot more impactful than [they] expected" and that they "got more and new insight into [their] colleagues' perspectives on inclusive teaching and also [their] own." This insight through novel methodology holds promise for extending our knowledge of how undergraduate mathematics stakeholders see, imagine, and evaluate themselves regarding inclusive teaching practices and values.

Analogical Quotient Structure Sense in Abstract Algebra: An Expansion of University Structure Sense

Michael D. Hicks
Virginia Tech

Kyle Flanagan
Virginia Tech

Despite existing research describing students' understanding of group concepts, little research in undergraduate mathematics education has attended to students' understanding of ring concepts. In this paper, we present an analysis of four students engaged in task-based interviews that provided insights into their understanding of quotient ring when constructed as an analogy to quotient group. Using university structure sense (Novotná & Hoch, 2008) as a foundation, we propose an expansion of structure sense to include attention to various structures (e.g., subgroups and quotient groups), and attention to analogous structure across different contexts (e.g., attending to quotient structure across group theory and ring theory.) Findings suggest that while students uniformly attended to similar structural components when creating the concept of quotient ring, there was variation in the depth of their reasoning about why certain structures exist.

Keywords: Abstract algebra, Analogical reasoning, Quotient groups, Structure sense

Attention to structure is a key component for understanding advanced mathematical concepts. Various studies have investigated students' attention to structure in high school algebra, linear algebra, and abstract algebra. Efforts have also been made to parse students' attention to structure for practical applications to teaching. One approach to parsing students' understanding of and attention to structure is structure sense (Linchevski & Livneh, 1999), which refers to the ability to recognize the same structure flexibly and creatively across various contexts. Although structure sense was originally defined in the context of algebraic equation solving, Novotná and Hoch (2008) extended structure sense to also include university (or abstract) algebra. Specifically, they identified two categories of structure sense: (1) structure sense of elements within a set and their behavior under a binary operation (e.g., understanding closure), and (2) properties of a binary operation (e.g., understanding the relationship between inverses and identities).

The current undergraduate mathematics education literature emphasizes attention to basic aspects of algebraic structure in advanced mathematics, most often with a focus on central algebraic objects (such as group), and the operations associated with them. For instance, Serbin (2023) identified three ways in which secondary pre-service teachers reason about identities and found that a unified understanding of identity could lead to productive reasoning about identities in more abstract contexts. Cook (2014) described students' emerging understanding of ring-theoretic concepts of unit and zero-divisor. Such research has provided a rich understanding of students' sense of basic structure. However, structure sense has not been explicated in the literature for attention to structure in abstract algebra beyond groups, although examples of implicit attention to a wider variety of structure senses exist. For example, Melhuish et al. (2020) presented a case study investigating students' unified understandings of the function and (group) homomorphism concepts and described a variety of understandings, ranging from students who could not recognize homomorphisms as functions at all, to students who could explicitly leverage homomorphisms as functions when approaching tasks.

Given that several important structures exist within abstract algebra (Dubinsky et al., 1994), there is a need to explicate different types of structure sense. However, being that similar structures are also present in many areas across the advanced mathematical curricula (e.g., sub-structures in group theory, ring theory, and topology), there is also a need to describe students' sense of structure *across different contexts.* In this paper, we expand even further upon the proposed extension by Novotná and Hoch of structure sense to abstract algebra to also include structure sense for a wider variety of structures, as well as introducing a mechanism for describing structure sense across contexts. To elucidate this expansion, we pose the following research question: *What are four students' sense of structure associated with quotient groups and quotient rings?*

Theoretical Framing

Expanding on Structure Sense

To describe students' structure sense, we adopt Novotná and Hoch's (2008) structure sense for university (i.e., abstract) algebra as being able to recognize sets of elements together with binary operations and their properties in a range of familiar and non-familiar structures. However, our expansion of structure sense also includes recognizing broader structures found across the advanced mathematics context. For instance, structure sense for 'subgroups' may include the ability to coordinate a subset of a group with the same operation as the parent group. We call the original structure sense in abstract algebra (as discussed by Novotná and Hoch) a *fundamental* structure sense in reference to it being the structure sense for a fundamental object of study in advanced mathematics, such as a group, ring, or topological space. Thus, structure sense need not be constrained to a set and a binary operation, but may be generalized to a set of elements together with some collection of properties that define an object (i.e., a topological space is a set together with a topology defined on the set). In this study, we attended specifically to *quotient structure sense*. Table 1 below summarizes the two types of standard structure senses to be discussed in this paper.

Table 1. Types of Structure Sense in Advanced Mathematics

Fundamental Structure Sense	Recognition of properties inherent to the main object of study (e.g., groups in group theory)	Example: Recognizing the identity element in the dihedral group of a regular polygon.
Quotient Structure Sense	Recognizing properties required to formulate a quotient of a structure, or properties that follow from the definition.	Example: Understanding that the role of a normal subgroup is to allow for well-defined binary operations defined on cosets that respects the original group operation.

As it is central to this paper, we briefly expound upon quotient structure sense. Quotient structures possess a rich and complex structure that involves multiple levels of coordination to grasp in full. For example, there must be a coordination of a parent structure with a particular sub-structure through which an equivalence relation is defined. In the context of abstract algebra, quotient groups and rings require the identification of well-defined binary operations on the quotient structure, thus allowing for the quotient structure to itself be described as an example of the central object of study (e.g., a quotient group is itself a group.)

Analogical Structure Sense

To conceptualize reasoning across different contexts, we view students' comparative activity across contexts as a form of analogical reasoning. We draw upon the Analogical Reasoning in Mathematics (ARM) framework for investigating students' analogical reasoning (Hicks, 2020) which adapts several components of Gentner's (1983) Structure-Mapping Theory to the context of mathematics while also respecting students' potentially idiosyncratic forms of analogical reasoning. Within this framework, analogies are determined by mapping content from a source domain to a target domain. Unlike typical frameworks for analogical reasoning, ARM parses students' reasoning into individual analogical activities, thus allowing for a close examination of one part of a student's analogy (known as an instance of analogical reasoning), followed by a reconstitution of the instances to analyze the student's analogy as a whole. In this way, even if the final result of two students' analogies appear to be the same, their analogies can be distinguished by investigating how the analogy was created.

We introduce *analogical structure sense* to parse students' attention to structure during analogical reasoning across different domains. We define analogical structure sense as the ability to either recognize or create similar structure across two distinct domains. In other words, it is the ability to either (1) reason about which aspects of a known pair of structures are relevant when comparing what is similar and different, or (2) reason about which aspects of a structure in the source domain are crucial to the creation and development of an analogous structure in the target and which aspects of the source are superfluous. Analogical structure sense can be explicated across widely different domains, suggesting that a certain level of abstraction may be required in some cases, such as comparing the subgroup concept and the concept of topological subspace (Hicks, Flanagan & Park, 2022; see also English & Sharry, 1996). In contrast, we refer to a sense of structure as *standard* when it refers to only one domain.

To a degree, standard structure sense already appeals to basic forms of analogical reasoning: a student comparing two examples of groups to identify how they are similar in terms of their structure is reasoning by analogy. When viewed in this way, we recognize that analogical structure sense can be embedded within the original definition. However, for the purposes of this paper, we consider analogical structure in the case where the fundamental structure senses are different between the source and target, such as between groups and rings. Thus, analogical structure sense captures a wider range of structure senses than are possible with the standard definition alone. Table 2 summarizes the two types of analogical structure sense explored in this study.

Table 2. Types of Analogical Structure Sense in Advanced Mathematics

Fundamental Analogical Structure Sense	Recognizing (or creating) similar/different properties inherent to the main objects of study across two domains (e.g., groups and rings).	Example: Articulating that inverses are not necessarily required for multiplication in rings in contrast to inverses always being required for groups operations.
Analogical Quotient Structure Sense	Recognizing (or creating) similar/different properties inherent to quotient structures across two domains.	Example: Considering the need for both additive and multiplicative cosets when defining quotient rings by analogy with quotient groups.

Methods

The data for this study was collected as part of a larger project investigating students' analogical reasoning in abstract algebra. In the Fall of 2019 and the Spring of 2020, emails were sent out to students requesting participation in the study. Four students responded to the request: three advanced undergraduate math majors named Ellen, Nathan, and Brandon (all pseudonyms), and one graduate student in mathematics education named Andrew. Each student was then asked to participate in a series of 5 clinical task-based interviews (Goldin, 2000), with each interview lasting between 60-90 minutes. Each of the interviews was conducted by the first author, who will be referred to throughout as the interviewer. In this paper, we focus our attention on the interview associated with quotient rings in which students were posed the following task: *Make a conjecture for a structure in ring theory that is analogous to quotient groups in group theory.* In addition to this task, students were also asked several questions inquiring into their construction, as well as provided several tasks in which they leveraged their constructed analogue to reason about relevant content, such as generating examples or conjecturing theorems related to the structure.

The analysis of the data occurred in two phases: (1) an analysis of the students' standard structure sense for quotient group, and (2) an analysis of the students' analogical structure sense of quotient structure. The goal was to analyze the students' evoked structure sense, meaning we do not claim that these interviews revealed the full range of the students' structure senses. The video and transcripts of the initial interview were reviewed multiple times, and notes were made whenever any evidence of standard structure sense was present. For example, if the student explicitly mentioned the need for a normal subgroup to describe a quotient group, then evidence of standard structure sense was present. Profiles for each student's senses of structure (totaling 4 profiles) were then written, thus providing a holistic summary of the key points that the student attended to when recalling (or reviewing) the definition of the structure.

To analyze the students' analogical structure sense, the ARM framework was first used to code the students' instances of analogical reasoning while comparing and creating structures in each of the interviews 2-5. Each instance was then scrutinized for evidence of analogical structure sense, meaning whether or not there was evidence that they were reasoning about why certain features of the source should be mapped to the target when comparing or creating structures. In addition, these profiles included descriptions of the concepts that the students attended to while creating the analogous structures. Identifying these concepts often assisted with interpreting the students' analogical reasoning, and these differences revealed a variation in how the students were reasoning by analogy. Following this coding process, a profile was written for each student's sense of analogical structure associated with quotient ring (totaling 4 more profiles overall).

Findings

The four students displayed a range of analogical structure sense, from superficial grasp of the underlying analogous structures to a developing sense of the analogous structure for describing quotient rings. In the section that follows, we describe key holistic observations made about the students' attention to analogical structure for quotient structure. We present these findings in two sections: (1) describing what structures students considered to be relevant to their analogical construction of a quotient structure in ring theory, and (2) describing the variation of depth of the students' reasoning about quotient structure.

Attention to Existence of Analogical Structure: Normal Subrings and Cosets

All students acknowledged that a "normal subring" should be present when constructing the ring-theoretic analogy to quotient groups. Rather than immediately copy over the definition of normal subgroup to the ring context, each participant reflected upon what differences might be present when considering the definition of a normal subring. For example, Figure 1 below exhibits Andrew's constructed definition of a normal subring. Here, Andrew is attempting to reconcile the property of normality for subgroups as a property within the context of rings.

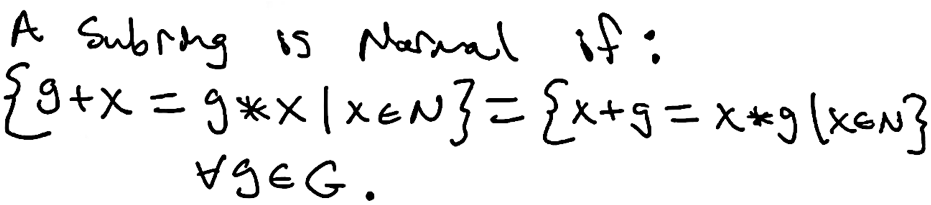

Figure 1. Andrew's definition of a "normal subring."

In the above example, Andrew is exhibiting two important features: (a) he is describing normality as a set of cosets being equivalent, and (b) he is appealing to the existence of two operations by expressing equivalence between additive and multiplicative cosets. This suggests that Andrew's sense of analogical structure included the existence of cosets and the manner in which binary operations were defined on those cosets. Such observations were present across each of the other students as well, meaning that all of the participants uniformly attended to the existence of normal subring, cosets, and adapting binary operations to the quotient ring context in some way.

Although analogical inferences related to the existence of structure across the contexts of group and ring theory may appear superficial on the surface, we contend that our participants' attention to the existence of these structures indicated a productive sense of analogical structure. Furthermore, as we discuss in the next section, the attention to the existence of analogous structure proved to be fertile ground for reasoning deeply about the meaning of those structures.

Variation in Students' Depth of Reasoning: Attending to Meaning of Structure

The students' sense of analogical structure not only entailed the existence of certain components related to quotient structure, but also included the underlying reasons for the existence of those components. However, the depth of reasoning varied from one student to another, thus distinguishing students' analogical structure senses in our analysis. Although all students identified the existence of a normal subring, only some students also investigated further by inquiring into why the normal subring concept was needed at all. In particular, Brandon's proposed description for the structure of a quotient ring was focused on describing a mapping from an element to the equivalence class of the element. Based upon evidence from the initial group interview, Brandon was presumably referring to an analogue for the canonical homomorphism defined for groups wherein every element in the domain is mapped to its coset in the quotient group. When asked what constituted normality in the context of his ring-theoretic analogue for quotient groups, Brandon responded: "I really only remember why we did it for groups." Although he was unable to expound further, he explained that if R' was normal, then the quotient R/R' would be a ring. Thus, Brandon's sense of analogical structure included attention to a quotient structure in fact being an example of the fundamental structure, and thus the normal subring would have to be carefully selected to make this happen.

While Brandon asserted that a normal subring was needed to form a quotient ring, he struggled to provide a description of normality. However, reasoning about the definition of normality for rings appeared in other ways across the students. In particular, each student attended to the need for adapting multiple binary operations to the ring-theoretic analogy for quotient groups. In general, the students made the following observations about binary operations and the quotient ring structure: (1) describing what coset operations look like, (2) determining how the existence of two binary operation affected the normal subring concept. Initially, Andrew focused his attention on just one operation at a time. He stated:

> What I would do, is I would literally just add the second operation to both of these. I'll do it in red what I have. I should probably make it clear though… This [digitally points to $x + H = y + \mathrm{H}$] is a plus operation, and… [writes "$x*H = y*H$"].

He then attempted to reconcile the meaning of normality when using the multiplicative operation: "Oh man, this is gonna be trickier. Because would they be the same? That's harder, let's think about this. I feel like this would be so hard to make happen [digitally points to $x*H = y*H$]." Returning to Andrew's construction of normal subring in Figure 1 above, we see this attention to multiple operations on display as Andrew eventually conjectured that the desired property for a normal subring was that $x + g = x * g$ and $g + x = g * x$

In contrast to Brandon and Andrew, Ellen did not attempt to describe the meaning of normality, nor did she ever formally define a coset in the context of rings. However, Ellen spent significant time reflecting upon how operations would be defined on cosets, thus attending to the need for a set of cosets to form a ring. She proposed the description seen in Figure 2 below. Of particular note was Ellen's attention to a "general" coset of the form aH as seen in the figure. Attention to this general coset included reasoning about a general coset operation, suggesting that Ellen was attending to more than just two operations for the specific context of rings. When asked to explain, Ellen stated: "I'm saying what operation specifically does this need to work for. For rings it's addition and multiplication. So, if you use addition, will that work, and if you use multiplication, will that work."

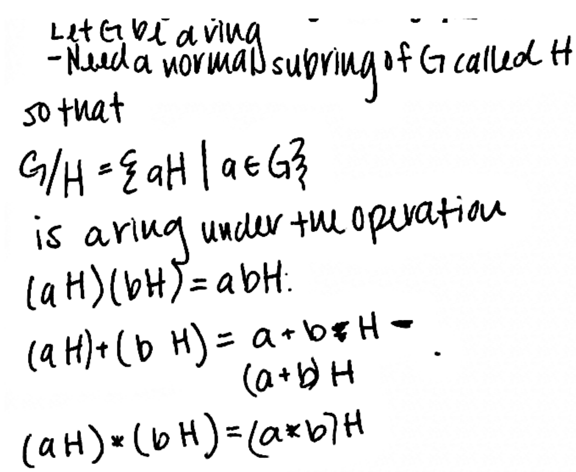

Figure 2. Ellen's proposed quotient ring definition and coset operations.

Summary of Findings

The findings presented above reveal that although all students in this study possessed a strong sense of analogical structure for the *existence* of structural analogies between quotient group and ring, their sense of analogical structure differed greatly in how they attended to the meaning of those structural analogies. Specifically, all students recognized ring-theoretic analogies to normal subgroups, cosets, and the role of binary operations within quotient groups. However, the students' sense of underlying meaning of those structures ranged from deep considerations about the purpose and definition of the structure, to a complete lack of attention to purpose or definition at all.

Discussion and Implications

Our proposed expansion of structure sense, to accommodate a wider variety of structures as well as structures across different contexts, allows for deeper explorations of students' attention to advanced mathematical structures. In this study, we elucidated this framework by investigating students' understanding of a particularly difficult concept: quotient ring. Findings indicate that students do indeed productively attend to several aspects of analogical structure when developing a ring-theoretic analogy to quotient groups, including attention to the need for a "normal subring," and attention to adapting multiple binary operations to the ring context. Overall, while all students were successfully able to make headway into describing a ring-theoretic analogy to quotient groups by spontaneously identifying the so-called "normal subring" concept, the notion of constructing a ring-theoretic analogy to normal subgroups proved to be a difficult task for students.

In contrast to structural similarity, semantic similarity (Holyoak & Thagard, 1989) refers to the degree of similarity between the meanings of objects within a domain rather than the global similarity of the structures as a whole. By investigating students' sense of analogical structure, we discovered that our participants uniformly attended to structural similarity, but varied in terms of their attention to semantic similarity. Although high semantic similarity exists between structures in group and ring theory due to their historical development (see Hausberger, 2018), only a subset of our participants spontaneously inquired into potential semantic similarities, focusing instead on structural similarity.

Our findings warrant suggestions for teaching abstract algebra concepts as well as considerations about the guided reinvention (Gravemeijer, 1999) of ring-theoretic concepts by analogy. The existence of a "normal subring" appeared to be a natural first step for students' construction of the quotient ring concept; however, their understanding of the analogous role that a normal subring should play appeared to be impeded by their understanding of the normal subgroup concept. Thus, our investigation of students' analogical structure sense suggests that, if analogies are to be used during instruction to compare quotient groups and rings, then there is a need to not only emphasize the coordination of structures on their own (e.g., describing quotient groups as a group together with a normal subgroup), but to also emphasize the conceptual underpinnings as to *why* normality is an important component of establishing quotient groups. We assert that this approach could establish an effective first step toward developing curricula for the guided reinvention of the concept of ideal. Furthermore, effectively leveraging of student analogical reasoning could promote productive instances of backward transfer (Hohensee, Willoughby & Gartland, 2022) in which students' understanding of quotient group and normal subgroup could be enriched by attending to the underlying relationship between quotient rings and ideals and making comparisons between the domains. Future research can investigate these matters in greater detail.

Graduate Students' Pedagogical Mathematical Practices
Used in Approximations of Teaching Practice Tasks

Ashly Olusanya	Kaitlyn Stephens Serbin	Younggon Bae
The University of Texas, Rio Grande Valley	The University of Texas, Rio Grande Valley	The University of Texas, Rio Grande Valley

This research design uses Approximations of Practice (AoPs), simulated practices of responsive pedagogy for prospective teachers to respond to, which lead them to make relevant connections between advanced mathematics courses and teaching practices. Data were collected from students in a Master's level Mathematics for Teachers course. The curriculum and interviews focused on three mathematical content domains: probability, algebra, and analysis. The AoPs were written into a semi-structured interview to demonstrate real-world examples of how teachers may see this material arise in the classroom. The AoPs prompted the participants to interpret and respond to student thinking and structure whole class discussions about students' strategies. Their responses were analyzed using Wasserman's (2022) pedagogical mathematical practices (PMPs). We examined each response to the AoPs to identify the participants' PMPs.

Keywords: Pedagogical Mathematical Practices, Advanced Math, Approximations of Practice

Learning advanced mathematics is an essential part of teachers' preparation, as it can help them understand relations among mathematical concepts and refine their mathematical practices, which can inform various pedagogical practices (e.g., Baldinger, 2018; Serbin, 2021; Zazkis & Kontorovich, 2016; Zazkis & Marmur, 2018; Zbiek & Heid, 2018). The Conference Board of the Mathematical Sciences (2012) recommended that there be opportunities in mathematics courses for prospective teachers to make explicit connections between advanced mathematics and the teaching of secondary mathematics. However, these connections between the curricula and teaching are often left unstated (Wasserman & Weber, 2017), so it is essential to make them more explicit. Researchers and educators have made such explicit connections between advanced and secondary content in their innovative curricula (e.g., Álvarez et al., 2020; Burroughs et al., 2023; Fukawa-Connelly et al., 2020; Goar & Lai, 2022; Wasserman et al., 2017).

Following these efforts, we designed a Master's-level Mathematics for Teachers course on connections from abstract algebra, real analysis, and probability to the teaching and learning of secondary / college mathematics. In this course, we implemented Approximations of Practice (AoPs; Grossman et al., 2009), in which the students, who were preservice or in-service teachers, simulated teaching practices of noticing students' mathematical thinking (Jacobs et al., 2010) and orchestrating class discussions about students' ideas (Smith & Stein, 2018). AoPs are productive in supporting prospective teachers in using their *knowledge* of advanced mathematics in their teaching practices (e.g., Álvarez et al., 2020; Burroughs et al., 2023; Serbin, 2021). AoPs can also be productive for supporting prospective teachers in connecting the *mathematical practices* developed in their mathematics courses to their teaching. Wasserman (2022) intersected mathematical practices (Rasmussen et al., 2005) with pedagogical practices (National Council of Teachers of Mathematics, NCTM, 2014) to develop the theoretical construct of *Pedagogical Mathematical Practices* (PMPs), which are the disciplinary practices common to mathematicians and teachers. There is a need for researchers to identify PMPs that can be enacted in the classroom and AoPs. We address this need with this research question: *What PMPs do graduate prospective and in-service teachers engage in as they work on AoPs?*

Literature Review

AoPs are a valuable tool for engaging prospective teachers in pedagogical situations before entering the classroom. *AoPs* are "opportunities to engage in practices that are more or less proximal to the practices of a profession" (Grossman et al., 2009, p. 2056). AoPs can be enacted by teachers acting out classroom scenarios, interacting with simulated students in mixed reality simulations, interpreting written student work, or writing scripts for a class scenario. AoPs tend to require teachers to simulate a response to student thinking using pedagogical practices, such as noticing students' mathematical thinking (Jacobs et al., 2010), responding to hypothetical class situations (Zazkis & Marmur, 2018), and scripting discussions (e.g., Zazkis et al., 2013).

Instructors can use AoPs in their mathematics content courses and teaching methods courses for future teachers. For instance, Tyminski et al. (2014) used AoPs to support prospective elementary teachers' practice of organizing discussions around the different students' strategies. Campbell and Elliott (2015) created an AoP simulating a class discussion to define trigonometric ratios in a high school geometry class by introducing a problematic mathematical situation. These studies illustrate how engaging prospective teachers in AoPs can give them experience using certain pedagogical practices before they teach.

AoPs can bridge teachers' learning of advanced mathematics to their teaching (e.g., Álvarez et al., 2022; Burroughs et al., 2023; Lischka et al., 2021). Álvarez et al. (2020) suggested that teaching is a form of applied mathematics, so teaching applications should be incorporated into undergraduate mathematics courses' curricula, just as engineering and physics applications often are. Other researchers have used scripting tasks as simulations of practice to help students develop productive mathematical understandings (e.g., Marmur & Zazkis, 2022; Zazkis & Cook, 2018) and make connections between advanced mathematics and the teaching of secondary mathematics (e.g., Fukawa-Connelly et al., 2020; Serbin & Bae, 2023; Wasserman et al., 2017). Other researchers have used noticing tasks (Jacobs et al., 2010) to connect advanced and secondary mathematics. For example, Serbin (2021) demonstrated how prospective teachers used their abstract algebra knowledge as they interpreted and decided how to respond to hypothetical students' mathematical thinking in noticing tasks. Overall, researchers have documented the value of AoPs when embedded in the study of advanced mathematical topics. In this study, we further contribute to the research based on AoPs by analyzing the PMPs of graduate students, who are prospective or in-service mathematics teachers, as they engage in AoPs.

Theoretical Background

"Teaching relies on more than just knowledge" (Wasserman, 2022, p. 29); it also relies on practices. Just as researchers have explicated the intersection of mathematical knowledge and pedagogical knowledge (e.g., Shulman, 1987), Wasserman (2022) conceptualized the construct of Pedagogical Mathematical Practices (PMPs) as an intersection of mathematics and pedagogy with respect to practice. Practices of the discipline are the "regular actions, activities, habits, behaviors, processes, norms, etc. that one engages in while 'doing' that activity" (Wasserman, 2022, p. 5). Wasserman explored this domain of practice through the intersectional lens of mathematical practices (MPs) and pedagogical practices (PPs). MPs are the practices or mathematical habits of mind (Cuoco et al., 1996) that mathematicians engage in, such as identifying patterns, proving, conjecturing, problem-solving, and defining (e.g., Heid et al., 2015; Polya, 1945; Rasmussen et al., 2005). PPs are the practices teachers engage in as they teach mathematics, such as those outlined by NCTM (2014) and Hunter et al. (2016). The intersection of MPs and PPs are *PMPs:* "the regular actions, activities, habits, behaviors, processes, norms, etc., that are productive both as a mathematical practice and as a pedagogical practice for teaching mathematics" (Wasserman, 2022, p. 30). Examples include:

> Acknowledge and revisit assumptions and mathematical limitations; consider and use boundary cases to test and illustrate mathematical ideas; expose logic as underpinning mathematical interpretation; use simpler objects to study more complex objects; avoid giving rules without accompanying mathematical explanations; and seek out and use multiple explanations. (p. 30)

In addition to the utility of this construct for analyzing mathematics teachers' practices, the PMP construct also has useful implications for mathematics teacher preparation. PMPs have the potential for integrating pedagogy into advanced mathematics courses and for integrating advanced mathematics into pedagogy methods courses. This can contribute to preservice and in-service mathematics teachers perceiving more connections between advanced mathematics and the teaching of school mathematics. Given the need for researchers and mathematics teacher educators to support teachers in making such meaningful connections between advanced mathematics and the teaching of school mathematics, there is a need for researchers to identify additional PMPs and explore the contexts in which teachers use them. Our study contributes to this need through our identification of PMPs used by teachers as they engage in AoPs.

Methods

We recruited six participants from a large public research university in the southern US, Jessica, Roberto, Amy, Selena, Linda, and Eduardo (pseudonyms), who were enrolled in an MS in Mathematics program with a Math Education concentration. Jessica and Roberto were in-service teachers with multiple years of mathematics teaching experience. The others were preservice teachers who intended to teach high school or college. All participants had recently completed a Master's-level Mathematics for Teaching course, which addressed content from abstract algebra, real analysis, and probability with connections to the teaching of secondary/ college mathematics. The course instructors often assigned AoPs in class work and assignments.

The second and third authors conducted semi-structured task-based clinical interviews (Drever, 1995; Clement, 2000) with each participant two weeks after they completed their course. The interviews were conducted over Zoom and were recorded and transcribed for retrospective analysis. The participants performed the AoPs shown in Figure 1. These tasks were designed to simulate the practices of noticing/ attending to, interpreting, and deciding how to respond to students' mathematical thinking and leading class discussions about students' work. The four AoPs were each related to the mathematical content that the participants had learned during the Mathematics for Teachers course: conditional probability, the differentiability of functions, the zero-product property, and inverse functions. We designed the interview tasks to elicit evidence of the participants' PMPs used in their responses. We asked the participants questions related to what they noticed in the students' responses, what they interpreted about the students' understandings, how they would respond to the students as their teacher, and how they would facilitate a class discussion about the students' approaches. The first and second authors performed inductive coding on the interview transcripts (Miles et al., 2014), in which we open-coded PMPs that were evident in the responses to the AoP tasks. A participant's response was indicative of a PMP when it satisfied Wasserman's (2022) criteria: the practice was common to mathematicians and mathematics teachers. We used Wasserman's (2022; 2023) PMPs as a list of potential a priori codes to begin the creation of our codebook, and we added newly found PMPs to the codebook. We recoded each response to the AoP tasks in two rounds of deductive coding (Miles et al., 2014). We identified patterns among the coded PMPs across the responses, which provided insight into their similar or varied usage of PMPs.

a. AoP Task 1

In an introductory probability class, your students are discussing the following problem on a coin toss game.

> In this game, two players toss a fair coin 4 times each and compare who gets the most heads to determine the winner. Player A tossed the coin 4 times and got 2 heads. Suppose Player B tossed the coin 2 times and got 2 heads. Player B will toss the coin 2 more times and needs one more head to win the game. What do you think about the probability that Player B will win the game?

Read the following discussion between three students.

Student 1: Well, Player B already got two heads in a row. So, I guess it is much less likely to get a head in the remaining two attempts, because, you know, you would expect two heads on average out of four tossing in anyways, right?

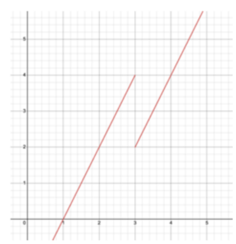
Student 2: We should think about all possible outcomes for tossing the coin four times. Each time, we have two possible outcomes of heads or tails, and repeat it four times, so there are $2 \times 2 \times 2 \times 2 = 16$ possible outcomes in total. These 16 outcomes are all equally likely, so the probability to get each is exactly $1/16$. Player B already got two heads and needs at least one more heads, so the only possible cases are $HHHT$, $HHTH$, $HHHH$. Since we have only 3 cases to win and each has the probability of $1/16$, the probability of winning the game is $3/16$.

Student 3: We know Player B will need at least one head in the remaining two attempts. Since the coin is fair, there will be 25% chance of getting two tails (TT) and 75% chance of getting one or two heads (HT, TH, HH). So, the chance of winning for Player B at this point is 75%.

b. AoP Task 2

In the discussion, three students explained whether the function is differentiable or not and why they think so.

$$f(x) = \begin{cases} 2x - 4 & (x \geq 3) \\ 2x - 2 & (x < 3) \end{cases}$$



Student A: This function is differentiable because I can see the two lines of its graph are parallel, so this function has the same slope everywhere including the point $x = 3$.

Student B: This function is differentiable because I can take the derivative of $2x - 4$, which will be 2 and then it's the same for the derivative of $2x - 2$. You just take the coefficient of the x. So, the derivative of this function is 2.

Student C: This function is not differentiable because its graph is not connected. We know continuous functions are differentiable.

c. AoP Task 3

Suppose you are teaching an Algebra II class on solving quadratic equations. While students work on the task of solving $x^2 + x - 6 = -4$, you see different students use these three approaches.

Student 1	Student 2	Student 3
$x^2 + x - 6 = -4$ $(x-2)(x+3) = -4$ $x - 2 = -4, \quad x + 3 = -4$ $x = -2, \quad x = -7$	$x^2 + x - 6 = -4$ $x^2 + x - 6 + 4 = -4 + 4$ $x^2 + x - 2 = 0$ $(x+2)(x-1) = 0$ $x + 2 = 0, \quad x - 1 = 0$ $x = -2, \quad x = 1$	$x^2 + x - 6 = -4$ $(x-2)(x+3) = -4$ $x - 2 = 2, \quad x + 3 = -2$ $x = 4, \quad x = -5$

d. AoP Task 4

Suppose you are teaching a Calculus I class on derivatives of trigonometric and inverse trigonometric functions. Your students are working on the task of finding the critical points of $f(x) = \cos^{-1}(x)$. You see different students use these two approaches for finding the critical points of $f(x) = \cos^{-1}(x)$.

Student 1	Student 2
$f(x) = \cos^{-1}(x)$ Use the power rule and chain rule: $f'(x) = -1 \cdot \cos^{-1-1}(x) \cdot -sin(x)$ $f'(x) = \cos^{-2}(x) \cdot sin(x)$ $f'(x) = \frac{sin(x)}{\cos^2(x)}$ Set this equal to 0. $\frac{sin(x)}{\cos^2(x)} = 0$ $sin(x) = 0$ Critical points: $x = 0 + k\pi$ for $k \in \mathbb{Z}$	$f(x) = \cos^{-1}(x) = \frac{1}{\cos(x)} = \sec(x)$ $f'(x) = \frac{d}{dx}\sec(x)$ $f'(x) = \sec(x)\tan(x)$ Set this equal to 0. $\sec(x)\tan(x) = 0$ $\sec(x) = 0$ or $\tan(x) = 0$ $\sec(x) = 0$ has no solution. $\tan(x) = \sin(x)/\cos(x) = 0$ Critical points are anything that makes $\sin(x) = 0$ but $\cos(x) \neq 0$ Critical points: $x = 0 + k\pi$ for $k \in \mathbb{Z}$

Figure 1. AoP Tasks Used in Interviews

Results

Overview and Examples of the Preservice and In-Service Teachers' PMPs

In the four AoPs, 15 PMPs were elicited (see Figure 2). PMP 1 was modified from Wasserman's (2022) PMP, "Acknowledge and revisit assumptions and mathematical limitations" (p. 8), and PMP 9 came directly from Wasserman's (2022) findings. We identified 13 new PMPs using inductive coding (see Figure 2). PMPs 1, 2, 3, and 7 were used the most frequently by all participants. PMPs 1, 2, and 3 rely on participants noticing and attending to student thinking. After noticing student thinking, participants frequently validated the mathematical procedure by identifying a mathematical concept that made the work correct or incorrect (PMP 7). An example of using these four PMPs in one AoP can be seen in Roberto's response to AoP 2 (see Figure 1b). The interviewer asked what Roberto noticed about the students' reasoning, and he said:

> Student A says that it has the same slope. I don't know if he's talking about the tangent, but that has nothing to do with this case. It's not really helping to answer the question if it's differentiable. The second student is just taking the derivatives of the piecewise function for each part and getting two, so he's just assuming that this is the same for the derivative, then it's going to be differentiable… differentiable functions are continuous, but the converse of that is not always true.

Roberto acknowledged assumptions (PMP 1) made by the students regarding slope and then invalidated the logic of that claim (PMP 2) by stating it did not answer the question about differentiability. The participant interpreted what the second student was doing in their work (PMP 3) and finally identified the concept of continuous and differentiable functions to invalidate Student C's assumption about differentiability (PMP 7).

Linda used PMP 11 regarding simplifying mathematical definitions into their own words when responding to AoP 2 (see Figure 1b). The interviewer asked if she would ask the students any specific questions to relate it back to the definition. She said,

> I would ask the class to maybe put the definition in their own words because I think sometimes definitions are a little bit fancy. To kind of reason them putting them into their own words would maybe help them connect what they're trying to say to the definition.

Simplifying a mathematical definition in your own words is a valuable tool mathematicians use to better understand a definition. Linda leveraged that PMP in her pedagogical techniques.

An example of PMP 15 was used in Roberto's response to AoP 3 (see Figure 1c). When asked how he would have the students recognize which one was wrong, he responded, "Probably put them in groups and work it out and see what the majority of the group gets or the class gets. If they get it right, I will use that definitely as the answer." PMP 15 was used seven times, mostly in response to the probability group discussion in AoP 1 (see Figure 1a).

Jessica shows an example of using PMP 12 in response to AoP 3, which asked her what she could tell about the students' mathematical understanding (see Figure 1c). Jessica said:

> Student 1 doesn't understand the clear definition of the product. If two things multiplied together, they can't each be -4, because that would be positive 16 there. While Student 3 understands the definition of a product, I feel like they don't understand while $2 \times (-2)$ does work, there's not a value of x that's the same that will work to give you that -4.

Jessica's response identified the procedural error in the student's work (PMP 12), which is a practice that both mathematicians and teachers would do when looking at their own or others' work. Jessica also interpreted the student's thinking (PMP 3), identified errors in their mathematical logic (PMP 2), recognized the concepts that validate a student's use of multiplication and factorization (PMP 7), and checked the student's work (PMP 6). This example shows how multiple PMPs can be used in a short response.

1. Acknowledge assumptions and/or mathematical limitations.
2. (In)validating the logic of a mathematical claim.
3. Interpreting details in someone's mathematical claim.
4. Referencing definition/formulas to verify a mathematical argument.
5. Using multiple representations to make sense of a concept.
6. Check work.
7. Identifying the mathematical concept that validates a mathematical procedure.
8. When multiple mathematical procedures are available choose the most efficient and accurate procedure.
9. Use simpler objects to study more complex objects.
10. Finding a counterexample to a mathematical claim.
11. Simplifying a mathematical definition in your own words to demonstrate understanding.
12. Identifying procedural errors in mathematical work.
13. Interpreting and understanding mathematical symbols and language.
14. Comparing and contrasting mathematical objects or concepts.
15. Combining multiple people's explanations to find a valid mathematical approach.

Figure 2. List of PMPs identified in the data.

Table 1. PMPs Used by Each Participant in Each AoP

	Probability AoP	Differentiability AoP	Equation AoP	Inverse AoP
Amy	1, 2, 3, 4, 5, 6, 7, 11, 12, 14, 15	1, 2, 3, 4, 5, 6, 7, 10, 11, 14	1, 2, 3, 4, 6, 7, 8, 9, 10, 12	1, 2, 3, 4, 5, 6, 7, 9, 10, 12, 13, 14
Eduardo	1, 2, 3, 7, 14, 15	1, 2, 3, 4, 7, 10, 14	1, 2, 3, 5, 6, 7, 10, 11, 12, 14	1, 2, 3, 5, 7, 9, 12, 13, 14
Jessica	1, 2, 3, 5, 6, 7, 11, 14	1, 2, 3, 4, 5, 10	1, 2, 3, 6, 7, 8, 12, 14	1, 2, 3, 5, 6, 7, 12, 13, 14
Linda	1, 2, 3, 7, 10, 15	1, 2, 3, 4, 7, 11	1, 2, 3, 6, 7, 8, 9, 12, 14	1, 2, 3, 5, 6, 7, 9, 14, 15
Roberto	None	1, 2, 3, 4, 7	1, 2, 3, 6, 7, 12, 14	1, 2, 3, 5, 7, 9, 10, 13, 14
Selena	1, 2, 3, 4, 7, 14, 15	1, 2, 3, 4, 5, 7, 10, 11, 14	1, 3, 6, 7, 12, 14, 15	1, 2, 3, 4, 5, 7, 13, 14

All participants used at least 13 of the 15 identified PMPs throughout the four AoPs, but each participant had some nuances in their use of PMPs. The PMPs used by each participant in each AoP are presented in Table 1. Amy consistently drew on multiple PMPs throughout the whole interview. She used 84 PMPs to answer 11 interview questions. In comparison, Roberto only used 33 PMPs. The lower number of PMPs used could be partly attributed to his uncertainty in his ability to solve the probability problem, which led him to not respond to the probability related AoP. Roberto focused heavily on the PMPs 1, 2, 3, and 7 that involved attending to student thinking and validating the mathematical procedures with the correct mathematical concept. Although he could use other various PMPs, he only leveraged a small subset of PMPs in the interview setting. There are common PMPs, such as 1, 3, and 7, that were used by each participant to respond to all class discussion tasks. Some PMPs were more prevalent in certain AoPs; for example, on the Probability AoP, the participants commonly used PMP 14 and PMP 15. They compared the students' approaches and combined their responses to lead a productive classroom discussion. For the analysis task, PMP 4 was elicited by 5 of the participants. Participants found it helpful to use the definition to answer the discussion task. That analysis-related AoP 2 also showed the highest use of PMP 10, where the participants used a counterexample to prove the student response was incorrect. We can see the highest use of PMP 6 for the algebra-related AoP 3 where 4 teachers used it to respond to the discussion task. This task asked students to find the zeros of a quadratic equation, and checking work was the most used PMP by the participants. PMPs 13 and 14 were the most frequently used for the algebra and analysis calculus-based task, in which students misinterpreted the meaning of the -1 superscript. PMP 13 involved interpreting and understanding mathematical symbols, and PMP 14 involved comparing the students' work as a tool to have a classroom discussion. Thus, certain PMPs were used more frequently depending on the mathematical content addressed in the task.

Participants' Use of Certain PMPs Seemed to Depend on the Type of Pedagogical Task

Each subsequent AoP question was intended to prompt the participants to use the information they identified in a previous task to inform their decision-making for the subsequent class discussion AoP. In the initial questions, where the interviewer asked the participant to identify what the students were doing in their work, the participants relied heavily on PMPs 1, 2, 3, and 7. These PMPs require noticing and interpreting student work. As the tasks progressed to the questions regarding how they would respond to the students or lead a classroom discussion about the students' ideas, the participants drew on their decisions from the prior tasks and utilized more PMPs. This is evident in Amy's response to AoP 1. Her response to the question about what she noticed about students' thinking used PMPs 1, 2, 3, 7, and 14. Her response to a question about how she would respond to the students involved her additional use of PMPs 4 and 10. In her response to the question about how she would facilitate a class discussion about the students' ideas, Amy used PMPs 1, 2, 3, 4, 5, 6, 7, 11, 12, 14, and 15. The subsequent addition of different PMPs used as the questions in each AoP task progressed gives evidence to the effectiveness of the task design in eliciting teachers' use of PMPs. Wasserman (2022) claimed, PMPs "can be used to structure discussions of, and give insight into, observed episodes of teaching and practicum experiences" (p. 13). Our research suggests that PMPs are a tool to help teachers structure their classroom discussions and attend to student thinking. As the tasks progressed, participants made decisions on the information presented in the earlier part of the AoP and used PMPs to structure a productive classroom discussion. The participants frequently used five PMPs for these discussion tasks, PMPs 1, 2, 3, 7, and 14. These PMPs may be particularly conducive for teachers leading classroom discussions about students' mathematical thinking.

Discussion and Conclusion

This study showed how the participating teachers used PMPs in AoP tasks where they engaged in hypothetical classroom situations. The use of PMPs implies that their experience in the course encouraged them to connect their advanced MPs with AoPs in the classroom. Prior to this study, the teachers learned advanced topics in real analysis, abstract algebra, and probability by engaging in MPs like defining concepts in abstract algebra and examining special examples of functions to understand the relationship between continuous functions and differentiable functions in real analysis. They applied those practices in the AoP tasks in this course. Their use of PMPs in the interviews conducted two weeks after the semester indicates that the design of the course contributed to preparing the teachers to carry over their practices from advanced mathematics into their future classroom teaching, which could be further examined by following their classroom teaching as shown in prior studies (e.g., Wasserman & McGuffey, 2021). These findings support the participating teachers' perceived changes in their views on the relevance of learning advanced mathematics to mathematics teaching by providing evidence of their demonstration of PMPs in the AoPs. This study gives evidence of their applications of practices in advanced mathematics to hypothetical classroom scenarios. Future studies are needed to examine how teachers use PMPs in actual classroom settings and to further investigate different patterns of using PMPs by content areas and by individual teachers.

Oregon State University

Equivalence is a foundational idea in mathematics and a key fixture in the K-16 curriculum. There is considerable evidence, however, that students at all levels experience difficulties with it. A prevailing explanation is that students rely too much on transformations; and yet, transformational activity is absolutely essential: it is the primary means by which one generates more tractable representations that are better suited to the situation at hand. Strikingly, we found no studies that directly examine students' productive uses of transformational activity. To this end, we conducted a series of task-based interviews with undergraduate students in order to illustrate and account for productive instances of transformational activity across undergraduate mathematics. Our findings affirm a hypothesis from the literature that supplementing one's transformational activity with notions of equivalence can support productive reasoning. Additionally, we extend this idea by providing detailed analyses of what these supplementary notions of equivalence entail.

Keywords: equivalence, task-based clinical interviews, conceptual analysis, student thinking

Equivalence is one of the most fundamental notions in all of mathematics and, as such, is prevalent throughout the K-16 curriculum. Despite this importance, research suggests that students at all levels have difficulty leveraging equivalence to solve mathematical tasks (e.g., Chick, 2003; Chesney et al., 2013; Kieran, 1981). Researchers have argued that many of these difficulties are attributable to an overreliance on *transformations*–that is, operations that change a mathematical object into a new (equivalent) form. The prevailing explanation is that attending to transformations can preclude attending to underlying notions of equivalence (e.g., Alibali et al., 2007; Carpenter et al., 2003; Kieran, 1981). That is, "an overemphasis on change overshadows an emphasis on sameness" (Cook et al., 2022, p. 5).

We observe that much of the literature on transformational activity focuses on its role in students' difficulties (e.g., Cook, 2018; Pomerantsev & Korosteleva, 2003; Tall et al., 2014). And yet, transformational activity is absolutely essential in mathematics: it is the primary means by which one generates equivalent representations of an object that are more well-suited to the problem at hand. Clearly, then, transformational activity can–and should–be productive for students, but we found no empirical studies that feature and analyze productive instances of transformational activity. We infer from the literature that supplementing with other ways of reasoning about equivalence can support productive transformational activity, but what these ways of reasoning are and how they might emerge in students' activity is a question that has not yet been examined. To this end, in this study we aim to provide a "positive counterpoint" (Bagley & Rabin, 2016, p. 84) to the large body of work that primarily associates transformational activity with students' difficulties by analyzing episodes in which students use it productively. In doing so, we aim to answer the following research question: *What cross-domain ways of reasoning about equivalence do students demonstrate when engaging in productive transformational activity?*

Literature

This study addresses two gaps in the literature. First, we observe that most of the literature on students' reasoning about equivalence has taken place *within* particular mathematical contexts. At the K-12 level, for example, research has examined equivalence of fractions (e.g., Smith, 1995), numerical expressions (e.g., McNeil, 2008), algebraic expressions (e.g., Solares & Kieran, 2013), and algebraic equations (Knuth et al., 2006). At the undergraduate level, research has included, for example, examinations within the domains of combinatorial equivalence (Lockwood & Reed, 2020), isomorphism (Larsen, 2013), and modular equivalence (Smith, 2006). There is, however, a scarcity of research that has examined how students might reason about equivalence *across* various contexts.

We note that though the literature on students' transformational activity is expansive, it has almost exclusively been associated with students' difficulties (e.g., Godfrey & Thomas, 2008; Kieran, 1981; Pomerantsev & Korosteleva, 2003; Stephens, 2006). Other studies have pointed out how difficulties with transformations can constrain students' abilities to learn about subsequent ideas (e.g., Cook, 2018; Tall et al., 2014). To be clear, this body of literature establishes an important point about transformational activity: an overreliance on it can constrain students' reasoning. We do wish to call attention to the fact that even though the importance of transformational activity is difficult to understate, research that illustrates and analyzes empirical instances of productive transformational activity and what it might entail is scarce. The literature overwhelmingly focuses on students' difficulties. Our efforts here were inspired by Bagley and Rabin (2016), who, upon observing that computational activity has been oft maligned in the linear algebra literature, illustrated how it can be a very useful tool in certain situations. In the same vein, we aim to provide a "positive counterpoint" (Bagley & Rabin, 2016, p. 84) to the treatment of transformational activity in the equivalence literature.

The literature does, however, contain some provisional theoretical suggestions in this respect that shaped the current study. Alibali and colleagues (2007) argued that attending to the equivalence of equations involves "recognition that the transformation preserves the equivalence relation expressed in the first equation" (p. 223). Similarly, Harel (2008) argued that it is important for students to recognize that "algebraic expressions are not manipulated haphazardly but with the purpose of arriving at a desired form and maintaining certain properties of the expression invariant" (p. 14); other researchers have made similar recommendations (e.g., Kieran, 1981; Steinberg et al., 1991). We interpret these comments to suggest that a key component of engaging productively with transformations involves attending to the reasons that the objects being generated by the transformations are equivalent. In the current study, we examine this initial hypothesis by examining the ways of reasoning about equivalence that students demonstrate in conjunction with their transformational activity.

Theoretical Framework

We adopted Cook and colleagues' (2022) framework for analyzing students' cross-domain ways of reasoning about equivalence. The framework is a *conceptual analysis* because it articulates "what students might understand when they know a particular idea in various ways" (Thompson, 2008, p. 57). Specifically, it outlines ways of reasoning that the authors hypothesize capture meaningful aspects of equivalence as it manifests across mathematical contexts. These include:

- *Common characteristic*: involves attending to equivalence in terms of "a perceived attribute that the objects in question have in common" (Cook et al., 2022, p. 3).
- *Descriptive*: involves attending to the fact that objects "describe the same quantity or serve the same purpose with respect to a given situation" (Cook et al., 2022, p. 3).
- *Transformational*: transformational activity is defined as "a sequence of actions (either already performed or imagined) by which one object might or can be changed into another is enacted or described" (Cook et al., 2022, p. 3).

For example, consider how one might multiply the numerator and denominator of 1/2 by 3 to obtain 3/6. One might supplement this example of transformational activity by explaining that 1/2 and 3/6 are equivalent because they both correspond to the same real number: 0.5 (an example of a *common characteristic* way of reasoning). One might also reason that 1/2 and 3/6 are equivalent by imagining two different ways of shading a circle: both of these fractions correspond to the same amount of shaded area in relation to the area of the whole circle (an example of a *descriptive* way of reasoning because both fractions describe the same quantity of shaded area).

We primarily use Cook and colleagues' (2022) conceptual analysis as a lens through which to build and articulate models of students' ways of reasoning. We note that Cook and colleagues (2022) positioned their framework as their own articulation of key features of the equivalence concept that might be advantageous for students to attend to across contexts. It therefore remains unclear if and how these ideas might emerge when working with students. Put another way, the *first order model* (Steffe et al., 1983) developed by Cook and colleagues (2022) has not yet been used to construct *second order models* (Steffe et al., 1983) of students' reasoning.

Methods

In order to examine students' transformational activity and their associated ways of reasoning about equivalence, we conducted individual task-based clinical interviews (Clement, 2000) with 12 students (due to space constraints, in this proposal we focus only on two interviews). All participants had recently completed a three-course Calculus sequence; each student participated in a single interview ranging from one to two hours in length. Interviews were conducted by the second author. The tasks administered are shown in Figure 1. Students' written work was recorded on an iPad application and was synced to an audio recording.

After completing each task, students were asked to explain their reasoning, particularly how they came to (a) produce one mathematical object from another, and (b) replace one form of a mathematical object with another. For example, students who used row operations to transform the linear system in Task 2 to row echelon form were asked how the new system is related to the original and why it is an acceptable replacement for the original. Interviews were transcribed verbatim and enhanced with screenshots of the students' written work.

We classified an instance of transformational activity as "productive" if the (a) the student successfully used transformations to complete the task, and (b) their answers to these follow-up questions about the objects generated by their transformations involved a description of justification of why they are equivalent. Each enhanced transcript was then independently coded by the first, fourth, and fifth authors using Clement's (2000) interpretive analysis cycles; Cook and colleagues' (2022) framework provided an initial basis for coding. Though the framework was refined as coding progressed, due to space constraints we focus here only on illustrating instances of how students productively supplemented their transformational activity with *common characteristic* and *descriptive* ways of reasoning. The codes for each transcript were then compiled, and coding discrepancies were discussed and revised until a state of negotiated agreement was reached.

Task 1:	Solve the following equation: $3(3x + 1/9) - 2(x - 1/4) = 6(x - 1/36)$
Task 2:	Solve the following system of linear equations: $x_1 + 5x_2 + 2x_3 = 8$ $2x_1 + 4x_2 + 2x_3 = 8$ $x_1 + 5x_2 + x_3 = 7$
Task 3:	Evaluate the following definite integral: $\int_0^1 2xe^{x^2}dx$
Task 4.1:	Consider how we add hours of time on a 12-hour clock. For example, 4 hours from 9:00 is 1:00. We can represent this as $4 \oplus 9 = 1$. Evaluate the following sums: a) $7 \oplus 8$; b) $9 \oplus 9$; c) $10 \oplus 5$; d) $11 \oplus 4$.
Task 4.2:	Consider now how we might multiply hours of time on a 12-hour clock. For example, $3 \odot 7 = 7 \oplus 7 \oplus 7 = 9$. Evaluate the following: a) $2 \odot 10$; b) $3 \odot 11$; c) $4 \odot 8$; d) $5 \odot 9$.
Task 4.3:	Evaluate the following: a) $7 \odot 7$; b) $11 \odot 11$; c) $9 \odot 11$; d) $8 \odot 7$; e) $10 \odot 8$.

Figure 1. Tasks administered during the interviews.

Results

Here we present the results of our analysis of the students' cross-domain ways of reasoning about equivalence. In each subsection, we begin by summarizing the student's relevant *transformational* activity to provide context. We focus on Ethan's demonstration of a *common characteristic* way of reasoning (across linear systems and the integers modulo 12) and Molly's demonstration of a *descriptive* way of reasoning (across fractions and the integers modulo 12).

Transformational Activity with a Common Characteristic Way of Reasoning

Ethan's transformational activity on Task 2 (solving a system of linear equations) and Task 4 (modular arithmetic) was supported by a *common characteristic* way of reasoning about equivalence. Using row operations to transform the augmented matrix for the given linear system into reduced row echelon form (Task 2), Ethan explained that "you do it systematically, […] you want the triangle effect…" and that "…the goal is to get it to reduced row echelon…" (see Figure 2). This action of "reduction" into reduced row echelon (RRE) form is indicative of transformational activity, whereby Ethan translated the system of equations into an augmented matrix, and further produced equivalent augmented matrices.

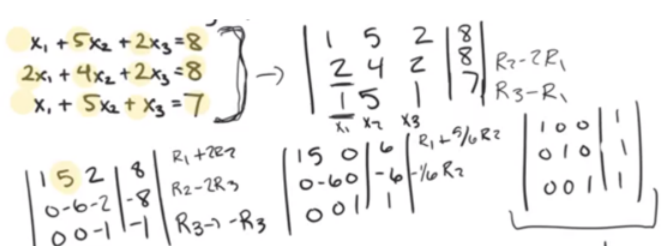

Figure 2. Ethan's written response to Task 2.

The interviewer then asked how the solution to the system represented by the RRE augmented matrix related to the system given in the task. Ethan's response suggested a *common characteristic* way of reasoning:

Ethan: This [RRE] helps complete the original task because […] if you plug these values in [1, 1, 1], they [the equations] would all come out as true. Like $1 + 5 + 2$, that equals 8. […] And then, if you went into that for every single one, you would see that the values would be true. […]

Interviewer: So this solution $x_1 = 1$, $x_2 = 1$, $x_3 = 1$ is not just a solution to this last augmented matrix with the 0s and 1s?

Ethan: No. […] It's a solution for all of them throughout the whole time. If you went back through and made equations with these variables, they would all end up being true. So […] every single step of the way, […] these values would make those equations true.

Interviewer: So, […] even though you're changing-

Ethan: The coefficients?

Interviewer: You're changing the coefficients […],

Ethan: Right. […] So, even though you're changing the system, the values, the corresponding values will still be the same.

Ethan identified a shared attribute among the objects he produced–i.e., the solution of $(x_1, x_2, x_3) = (1,1,1)$–indicating a *common characteristic* way of reasoning about equivalence. More specifically, Ethan was aware that the result of his transformational activity preserved an attribute of the objects he was transforming.

Ethan's initial activity in response to Task 4 (modular arithmetic) centered on multiplying the two integers using the typical multiplication and then repeatedly adding or subtracting 12 until he obtained an integer less than 12 (see Figure 3).

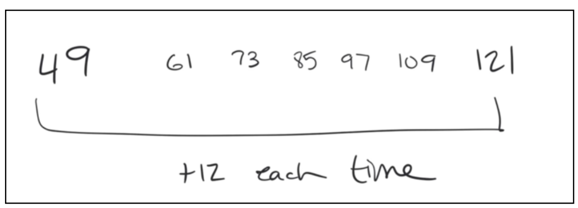

Figure 3. Part of Ethan's written response to Task 4.3.

On Task 4.2, after pointing out that $3 \odot 7$ and $5 \odot 9$ are both 9, the interviewer asked Ethan about the relationship between 21 and 45. Ethan explained that "if you add 12 to 21 you get 33" and "if you add 12 to 33 you get 45." He concluded, "so they are equivalent." On Task 4.3, similarly relating 49 and 121, Ethan said, "we have 49. We want to get to 121, and then […] I'm trying to add 12 to each interval, […] you're adding 12 each time" (see Figure 3). Ethan's transformational activity entailed adding 12 to one integer to produce another equivalent integer.

Ethan eventually pointed out a connection between division and his strategy of repeatedly adding/subtracting 12. He explained that "the reason that it's okay to subtract 12 is because that's basically what you do in division. […] It was how many times can 12 actually go into it, and it came out as, hey, let me just keep subtracting off of it." Shortly thereafter, the interviewer asked Ethan if he could characterize the integers that are equivalent to 4. He initially used his strategy of repeatedly adding 12, yielding 16, 28, and 40, before pivoting to the notion of remainder he had previously described:

Ethan: Their corresponding remainder will always be the original number you were wanting.
Interviewer: And in this case that's …
Ethan: Is 4.
Interviewer: I see. Okay. Even though you're adding 12 repeatedly?
Ethan: Correct. The remainder will always stay constant at that number.

Ethan demonstrated a *common characteristic* way of reasoning by identifying a shared attribute of the equivalent objects he was producing: their remainder after division by 12. Again, Ethan demonstrated awareness that his transformational activity (in this case, adding/subtracting 12) preserved the common characteristic (remainder after division by 12) of the objects in question.

A Descriptive Way of Reasoning about Equivalence

Molly demonstrated evidence of pairing transformational activity with a *descriptive* way of reasoning on Tasks 1 and 4. In her response to Task 1 (solving a linear equation), Molly transformed each fraction into an equivalent fraction with denominator of 36 in order to combine like terms (see Figure 4). The interviewer prompted Molly to explain why she made such replacements:

Interviewer: You rewrote […] -2/4 as -18/36. Can you talk about what you see as the relationship between those two?
Molly: Yeah. So, um, if you multiply -2/4 by 9/9 […] you get -18/36, but it doesn't change the value of the fraction. The fraction stays the same. It's just being written in a different way.
Interviewer: Okay. So, when you say, "The value of the fraction," what do you mean?
Molly: Um ... I mean, it's like if you take a circle and you cut it into 4 and shade 2, and then you cut another circle into 36 parts and shade 18, you'll see the exact same amount is shaded on both circles. […] So, that's how I know that's gonna be the same value.

The interviewer then prompted Molly to draw a picture to accompany her explanation, noting that she could choose another fraction to compare to 2/4 instead of 18/36 for ease of drawing (see Figure 4).

Molly: Like, if you do a circle that has 4, and you shade that, and then you have a circle that has 8, the same amount will be shaded in.
Interviewer: I see. And so, the relationship between 2/4 and 4/8 you're saying is similar to the relationship between 2/4 and 18/36 in here?
Molly: Yeah.

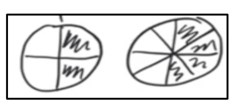

Figure 4. Part of Molly's written response to Task 1 to explain why 2/4 is equivalent to 4/8.

Molly's statement that "if you multiply -2/4 by 9/9 […] you get -18/36, but it doesn't change the value of the fraction" indicates transformational activity because she described a process ("multiply […] by 9/9") by which one fraction (-2/4) could be transformed into another (-18/36).

This transformational activity was supported by a *descriptive* way of reasoning when explaining *why* the transformation was valid. In particular, when describing why these fractions had the same value, Molly appealed to two circles having the same shaded region. This interpretation is further evidenced by Molly's drawing (see Figure 4) to show that 2/4 and 4/8 had the same value, explaining that "the same amount [i.e., the same area] will be shaded in" on both circles.

On Task 4, Molly produced integers she identified as "related" by repeatedly subtracting 12 until obtaining an integer between 1 and 12. Molly wrote" $n = N + x(12)$", where N represented the integer she was starting with, $x(12)$ signified adding a multiple of 12, and n represented the resulting integer. That is, Molly's transformational activity entailed a procedure by which one object could be obtained from a "related" one. The interviewer asked Molly to describe how she would use this process to determine if two given integers were equivalent:

Interviewer: So if I give you... two integers, let's say, um... 412 and 378... and asked you if they are related in the same way that you've been talking about these other numbers, how would you go about figuring that out?

Molly: … I would subtract both by, um, a multiple of 12, and I'll get a number. And then I'll see if n is equal. And if n is equal then I'll know that they, um... are related.

Molly then enacted her procedure of subtracting multiples of 12 from 412 and 378 until she obtained the numbers 4 and 6, respectively.

Interviewer: Okay. Now, what are 4 and 6? ... how are you thinking about those...

Molly: These are what their position on the clock would be.

Interviewer: Okay.

Molly: Um, and since 4 and 6 are not the same position, then, um, 412, um, and 378 are not related.

Here, Molly viewed the resulting objects of her transformational activity in *descriptive* terms: "what their position on the clock would be." Molly was able to judge the equivalence of 412 and 378 by reasoning that since the objects resulting from her transformational activity did not serve the same purpose with regards to telling time (i.e., their positions on a 12-hour clock), the objects were not equivalent.

Discussion

The analysis demonstrated here contributes to the literature in two ways. First, we have expanded the theoretical scope of the framework that we used to execute these objectives. That is, we used Cook and colleagues' (2022) first-order conceptual analysis of equivalence to construct second-order models of students' reasoning, demonstrating that these ways of reasoning can, in fact, account for students' reasoning. Second, our analysis establishes a counterpoint to well-documented difficulties associated with transformational activity in the literature. Previously, analyses of productive instances of students' transformational activity across domains had not yet been documented. In doing so, we affirmed a provisional hypothesis we inferred from the literature (that a key to reasoning productively with transformations includes supplementing with notions of how the objects being generated by these transformations are equivalent), and also explicated what these notions might entail (e.g., demonstrating *common characteristic* and *descriptive* ways of reasoning).

The Evolution of Two Undergraduates' Example and Set Use During Conjecturing and Proving

Kristen Vroom
Michigan State University

Abigail Lippert
Michigan State University

Jose Saul Barbosa
Michigan State University

To better understand how students' example and set use might evolve during their conjecturing and proving activity, we engaged two students in guided reinvention of mathematical statements relating sequence properties during an 11-week teaching experiment. We characterized the students' evolving example/set use in three categories: (1) classifying examples from the initial set of sequences, (2) seeking diversity and using lack of examples from an expanded initial set of sequences, and (3) attending to properties, searching for structure, and building formality with the set of all sequences. We exemplify these categories and then discuss some guidance that could explain the students' example/set use.

Keywords: Examples, sets, conjecturing, proving, sequences

Studies show that students find conviction and justify conjectures by using examples (Coe & Ruthven, 1994; Healy & Hoyles, 2000) and some suggest that students need to be supported to recognize limitations of examples (Knuth, 2002; Martin & Harel, 1989; Stylianides & Stylianides, 2009). More recent research examines how example-based reasoning can support deductive reasoning (Aricha-Metzer & Zaslavsky, 2019; Iannone et al., 2011; Komatsu et al., 2017; Ozgur et al., 2019; Pedemonte & Buchbinder, 2011; Sandefur et al., 2013), including how mathematicians and students use examples in their proving activity (Alcock & Inglis, 2008; Ellis et al., 2019; Inglis et al., 2007; Lockwood et al., 2016; Lynch & Lockwood, 2019; Weber, 2008). Furthermore, researchers have drawn on cognitive unity to explore how the development of students' conjectures based on their work with examples is reflected in the students' respective proving activities and proofs (Lin & Wu, 2007; Pedemonte & Buchbinder, 2011). Additionally, Fiallo and Gutiérrez (2017) studied what types of conjectures and corresponding proofs students developed after experimenting with Dynamic Geometry Software. This research points to the potential usefulness of examples for students in their conjecturing and proving activities.

Additionally, a growing amount of literature shows the usefulness of sets for students as they make sense of mathematical statements and engage in proving activities (Dawkins, 2017; Dawkins & Cook, 2017; Hub & Dawkins, 2018). For instance, Dawkins (2017) explained that it can be productive to consider a subset relation when making sense of a mathematical statement in the form *if p, then q*; that is, the set of all objects that fit property *p* is a subset of all the objects that fit property *q*. However, little research has explored how students can use sets to author and prove their conjectures.

To better understand how students' example and set use might evolve during their conjecturing and proving activity, we engaged two students in guided reinvention (Freudenthal, 2005; Gravemeijer, 1999; Gravemeijer & Doorman, 1999) of mathematical statements relating sequence properties during an 11-week teaching experiment (Steffe & Thompson, 2000). In this study, we examined the evolution of two calculus students' example/set use in response to an intervention we crafted for supporting students' conjecturing and proving activity. We investigated: How can students use examples and sets to support conjecturing and proving? Specifically, how did a pair of students use sets and examples as they were guided to reinvent mathematical statements relating sequence properties?

Theoretical Perspective

We investigated how two calculus students' example and set use evolved as they engaged in conjecturing and proving. By conjecturing, we mean developing a statement that relates mathematical concepts the student suspects are true but does not yet know are true (Lannin et al., 2011). In this study, we are particularly interested in students' conjectures from observing consistent patterns in a finite number of cases (Cañadas et al., 2007) and the generality of the students' conjectures (that is, whether the conjectures were specific to an initial set of finite cases or made a claim about additional cases). The cases that the students in our study observed were instances of sequences (e.g., $x_n = n^2$). Additionally, we use proving to mean conveying a general argument, from the students' perspective, for the statement's truth.

Throughout our data, students organized (and re-organized) examples of sequences into sets. We attended to different sets and set operations to better understand the students' set use. The students' universal set was key to understanding the generality of students' conjectures. By *universal set* we mean the set of all elements under consideration. The students' universal set began as an initial (finite) set of sequences, later expanded to include additional examples, and eventually included all sequences, where the specific examples were just representative members of this infinite set. Additionally, we determined whether students seemed to attend to a union, intersection, subset, complement, and difference (as typically defined in mathematics). For the sake of a relevant example, consider a universal set as the set of all sequences (represented by the shaded region in Figure 1A), which includes all the sequences that are bounded above (purple set in Figure 1), bounded below (green set in Figure 1), or unbounded. The shaded region in Figure 1B represents the *union* of the set of bounded above sequences and the set of bounded below sequences, whereas the shaded region in figure 1C depicts the *intersection* of these two sets. The shaded region in Figure 1D represents the set of sequences bounded below, which is a *subset* of the set of all sequences. The shaded region in Figure 1E represents the *complement* of the set of sequences that are bounded below. The *difference* between the set of bounded above sequences and the set of bounded below sequences is represented by the shaded region in Figure 1F. Finally, Figure 1G highlights that the set of convergent sequences (yellow set) and the set of sequences that are bounded above and not bounded below are *mutually exclusive*. We continue to denote sequences that are bounded above, bounded below, and convergent in this way (i.e., with green, purple, and yellow outlined sets, respectively) throughout our results.

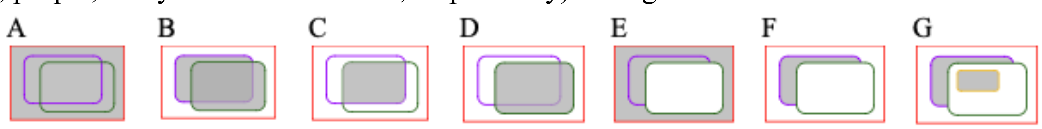

Figure 1. Representation of sets and set operations.

To further understand students' example use, we drew on Ellis et al.'s (2019) Criteria, Affordances, Purposes, and Strategies (CAPS) framework, which offers a way to describe students' example-based activity while investigating and proving conjectures. Specifically, we attended to Purposes and Strategies to understand how students' example-based reasoning supported their conjecturing and proving activity. *Purposes* are the reasons students use examples. For instance, a student might use the example(s) to: form a connection between two concepts (*conjecture development*), confirm their belief in a conjecture's truth (*belief confirmation*), determine a conjecture's truth (*test the truth*), reject a conjecture as true (*refute*), illustrate their claim that a conjecture is true or false (*convey claim*), identify the causal mechanism behind a conjecture (*understand why*), convey an argument supporting their claim that generalizes across cases (*convey a general argument*), and/or respond to a request or prompt (*respond to teacher-researcher*[1]). Strategies are "the range of deliberately strategic approaches students employ both in choosing and using examples" (p. 265). A student can deliberately create a new example that features different properties than previous examples (*seek diversity*), select examples based on particular properties of interest (*attend to properties*), or repurpose an existing example by varying one or more elements (*create systematic variation*). A student can deliberately use examples by searching for a pattern or a mathematical structure to identify general features (*searching for structure*) or developing a formal representation to express what is the same across all examples (*building formality*).

Methods

Data Collection

We conducted a teaching experiment (Steffe & Thompson, 2000) with two students, Lara and Stella (pseudonyms), recruited from a Calculus 1 course at a large university the semester before the experiment. We aimed to experience the students' mathematical learning of and reasoning about sequences and series as they formed conjectures about sequence and series properties, defined related terms, and proved their conjectures. Both students indicated they were freshmen at the time of the experiment, and both used she/her pronouns. Lara was majoring in Biological Chemistry, and Stella was double-majoring in Psychology and Neurosciences. Lara earned a 2.5 (on a 4.0 scale) in her Calculus 1 course, and Stella earned a 4.0. The experiment consisted of eleven 1.5-hour sessions in which the students' collaborative digital work was audio and video recorded. In these sessions, the first author was the teacher-researcher and the third author was the observer.

Realistic Mathematics Education, especially the heuristic of guided reinvention (Freudenthal, 2005; Gravemeijer, 1999; Gravemeijer & Doorman, 1999), framed the instruction during the teaching experiment (similar to Lockwood & Purdy, 2019 and Swinyard & Larsen, 2012). We describe the general task design of the teaching experiment since the details are beyond the scope of this paper. The overarching design goal of the experiment was to guide students to conjecture and prove mathematical statements that relate sequence properties (e.g., all convergent sequences are bounded) and statements about series convergence (e.g., the comparison test). To do so, we engaged the students in context problems (Gravemeijer & Doorman, 1999) with sequences (sessions 1-7) and then with series (sessions 8-11). For this report, we analyzed data from Sessions 4-7, when we asked the students to sort sequences based on different properties (increasing, bounded above, bound below, and converging), make conjectures about sequence properties, and justify these conjectures. The first three sessions mainly focused on the students generating and defining sequences. We refer to these sequences as the students' initial set.

Data Analysis

We transcribed all teaching episodes and enhanced the transcripts that we analyzed for this study with embedded pictures of the students' work. We first identified instances of the students discussing connections between bounded, increasing, and/or convergence by reading the transcript and watching the corresponding video. Once we identified these instances, at least two of the three authors participated in coding the data, with any disagreements resolved through

[1] Ellis et al. (2019) refer to this as "placate the interviewer." We used this different phrasing since it better fit our teaching experiment setting.

discussion. In particular, we investigated the students' example use by identifying purposes and strategies using Ellis et al.'s (2019) framework (see previous section). We also identified additional strategies that we did not think were captured by the framework: *classifying* and *using lack of examples*. We coded data as *classifying* when it featured the student checking whether a sequence fit their concept definition and/or concept image (Tall & Vinner, 1981), which often occurred when students considered moving or adding sequences inside (or outside) a category. We coded data as *using lack of examples* when the students reflected on their inability to create an example with specific properties given the properties' parameters. During this pass of the data, we also considered how the students used sets, looking for evidence of the students considering an *intersection*, *subset*, *complement*, *difference*, and/or if sets were *mutually exclusive* (see previous section). Note that the students did not necessarily (if ever) use words like the "union;" instead, these were our way of denoting the sets that the students seemed to consider. We also searched for evidence of what the students considered their universal set (i.e., the students' initial set of sequences, some other finite set of sequences that expanded their initial set, or the set of all sequences). After we coded each episode, we wrote a vignette of the students' example/set use and compiled the vignettes into one document, organizing them chronologically. We then re-read the vignettes, noting changes in the students' example/set use (asking ourselves how the students' example/set use differed from/similar to the previous episode). Through this constant comparison, we noticed three categories that characterize the students' evolving example/set use, which we exemplify next.

Results

We characterized the students' evolving example/set use in three categories: (1) classifying examples from the initial set of sequences, (2) seeking diversity and using lack of examples from an expanded initial set of sequences, and (3) attending to properties, searching for structure, and building formality with the set of all sequences.

Classifying examples from the initial set of sequences

The first example/set use category featured the students classifying sequences to develop, test, or refute a conjecture specific to their initial set of sequences. From our perspective, the students used their initial set of sequences as their universal set while they engaged in classifying; their diagram organized their initial set of sequences, and their discussion pertained to these specific sequences. An instance of this example/set use occurred during the fourth session in which the students were first asked to sort their initial set of sequences as bounded above and/or bounded below, or neither by placing their sequences in a corresponding set. In response, the students checked whether each sequence had an upper and/or lower bound (classifying). As they were classifying, Stella stated, "I feel like all of our a_n, $f(a_n)$, all those from that example, are going to be [bounded] both," referencing a set of sequences generated during a previous task. Here, we see that Stella noticed a pattern (searches for structure) to form a conjecture about the placement of some of their sequences from their initial set (conjecture development). From our perspective, she considered some of their initial set of sequences ("all of our a_n, $f(a_n)$…") as a subset of their bounded below and bounded above sequences. Then, to confirm that the pattern held (belief confirmation), Stella and Lara continued to classify the sequences they generated based on whether there was an upper and lower bound.

After the students finished classifying their sequences as bounded above and/or bounded below, the teacher-researcher requested that the students add a place for increasing sequences.

Lara shared that it should be "somewhere in the middle" because there was a sequence that was increasing, bounded below, and bounded above. Stella then suggested that they place it "hereish" (see the blue category in Figure 2A[2]) because "some of the [only] bounded below are increasing." During this, Lara and Stella selected increasing sequences (attended to properties) and determined whether they were bounded below and/or above (searched for structure) to make conjectures about their initial set of sequences that connected increasing and the other properties (conjecture development). The teacher-researcher then responded, "Let's try it!... With the examples or the sequences that we have so far, we'll try to put them in one of these locations. And then if we find that we need to change that box, then we will do that." To respond to the teacher-researcher and to confirm their suspicion about their increasing sequences (belief confirmation), Lara and Stella considered each sequence to check if it was increasing and rearranged the sequences accordingly (classifying). See Figure 2B for their revised map. From our perspective, we see the students suggested that their increasing sequences were a subset of the union of (a) their bounded below and bounded above sequences and (b) the difference in the set of their bounded below sequences and the set of their bounded above sequences.

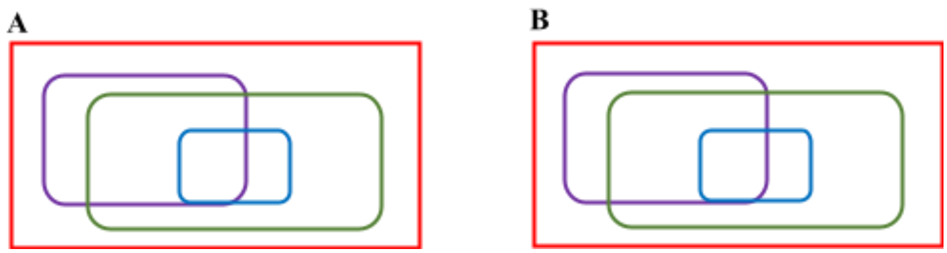

Figure 2. Location of the set of students' increasing sequences (blue set).

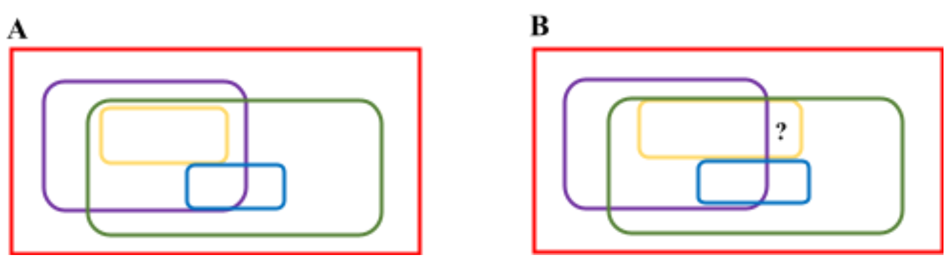
Seeking diversity and using lack of examples from an expanded initial set of sequences

The second category of example/set use featured the students seeking diversity in their initial set of examples and using the lack of examples to confirm their belief and understand why. From our perspective, the students expanded their universal set to include more sequences than their initial set while they sought diversity and used the lack of examples. Their discussion involved more than their initial set of sequences; in particular, they attempted to generate new sequences with different properties, and in doing so, their map transformed from organizing their initial set to potentially organizing additional sequences. An instance of this occurred later in the fourth session after Lara and Stella added a location for convergent sequences, which at the time they referred to as sequences "approaching a number" (see yellow set in Figure 3A). The teacher-researcher then asked, "Should [it] be stretched over?," changing the set's placement and adding a question mark to a new area to consider (see Figure 3B).



[2] We slightly altered these pictures from the students' version for clarity and because of space constraints. The students' version included more sequences with different representations (e.g., graphs).

Figure 3. Location of the set of sequences that approach a number.

To respond to the teacher-researcher and test the truth of the teacher-researcher's implied conjecture that there is a sequence that approaches a number, is unbounded above, and is bounded below, the students iteratively chose or created a new object to consider. In particular, they attempted to create a new sequence with the desired properties (seeking diversity, Figure 4A, Figure 4D, Figure 4E see below), selected ones on their map by paying attention to certain properties (attending to properties, Figure 4B), or created a new sequence based on a previous one (systematic variation, Figure 4C). With each new object, they disregarded it since it did not fit with a desired property (classify). Specifically, Figure 4A was bounded above since the intended domain was natural numbers, Figure 4B was not approaching a number, Figure 4C was bounded above, Figure 4D was bounded above and below, and Figure 4E was not approaching a number. After the students continued attempting to identify a sequence with the properties, Lara stated, "Maybe the answer is just no," meaning that there is not a sequence that is approaching a number, unbounded above, and bounded below. We interpret this as Lara reflecting on their inability to create an example with specific properties (using lack of examples) to confirm their initial placement of the converging set as non-overlapping with the difference of bounded above and bounded below (belief confirmation). From our view, the students suspected that the intersection of all convergent sequences, all bounded below sequences, and the complement of all bounded above sequences was empty (mutually exclusive).

Figure 4. Students' new objects.

After the teacher-researcher asked, "Can you think of a reason why we couldn't find a sequence?," the students began to understand why there was not a sequence that was approaching a number, unbounded above, and bounded below (understand why). To do so, Lara and Stella looked within the approaching sequences (attending to properties) and searched for a pattern, during which Lara noticed "no matter which section you take of the graph, it's bounded above and below" (searched for structure).

Attending to properties, searching for structure, and building formality with the set of all sequences

The third category of example/set use featured the students attending to properties, searching for structure, and building formality with the set of all sequences to convey general claims and general arguments. From our perspective, the students used the set of all sequences as their universal set (not just those depicted and organized on their map) while they attended to properties, searched for structure, and built formality. Students used examples and sets in this way during the fifth and sixth sessions, which began when the teacher-researcher asked the students to make conjectures based on their previous explorations. Stella responded, "I think it's true that a function cannot be both bounded above and increasing." After the teacher-researcher asked why not, Stella considered their increasing set and bounded above set (attended to properties) and seemed to notice that the increasing set intersected some of, but not all, the bounded above set (searched for structure), explaining, "So my thinking is, the blue increasing square does not have a category that's just bounded above. So, like increasing and just bounded above.” She then revised her conjecture (conjecture development), saying, "I guess you could say that it has to be bounded below to be increasing". From our perspective, Stella noticed that the set of increasing sequences was a subset of the set of bounded below sequences. After the teacher-researcher requested that they write this conjecture, the students began developing a formal representation in the form of a statement about what is the same across the increasing sequences (building formality), writing: “sequences that are increasing must be bounded below.” During the following session, the teacher-researcher asked for clarity about whether they considered this statement applicable for all or some increasing sequences. The students confirmed that they intended their conjectures to be about “all” increasing sequences rather than some of them or the specific examples in their map, and revised their conjecture to “all sequences that are increasing must be bounded below.”

The teacher-research then requested that they reflect on whether they thought the statement was true or knew it was true. Stella explained, "So I think we know this is true because all of the values are greater than or equal to the given number which would be… I guess it would have to be x equals one in this case.” Here, she noticed a pattern in that all the increasing sequences were bounded below by a value (searching for structure). She did this to understand what about the increasing sequences made them bounded below (understanding why). The teacher-researcher then questioned what she meant by $x=1$. To respond to the teacher-researcher and convey a general argument, Stella continued building formality to her argument revising her justification to : “all of these sequences [increasing sequences] must have a lower bound at a_n where $n = 1$.”

Discussion

In this study, we investigated how students' example and set use might evolve during their conjecturing and proving activity. Our findings suggest that students' example and set use can evolve over time, and specifically, we identified three categories of our participants’ example/set use: (1) classifying examples from the initial set of sequences, (2) seeking diversity and using lack of examples from an expanded initial set of sequences, and (3) attending to properties, searching for structure, and building formality with the set of all sequences.

Our findings support previous research that indicates students can productively use examples and sets in conjecturing and proving activities. Our study further contributes to this existing literature by shedding light on how students might use examples and sets in tandem during conjecturing and proving. In particular, the sets served as an organizational tool for students’ examples. These sets evolved from organizing their initial set of sequences to a map that depicted general claims of the set of all sequences.

We also gained some insight into guidance that supported the students' example/set use by attending to the *responding to the teacher-researcher* purpose. We found that the first type of example/set use was supported by requests for students to place sequences into their appropriate categories and/or add new categories. The second type was often supported by questioning whether the students' initial placement of the category should be revised by expanding it to include a new category. Moreover, questions like, "Can you think of a reason why we couldn't find a sequence?" further supported students to understand why. The last type of category was supported by requesting that students write their conjectures and then reflect on whether they thought they were true or knew they were true, and in the case that they thought it was true but were not certain, supporting them to further search for structure. In our future work we hope to further explore such guidance and example/set use.

Coloring the Relationship of Frames and Responses in Teacher Noticing

Johan Benedict Cristobal
University of Nebraska-Lincoln

This study builds on Louie, Adiredja, and Jessup's (2021) sociopolitical turn on teacher noticing. In this study, I use graduate student instructors' experiences as students and perceptions of their desirable actions to add nuance to the way Louie and colleagues discuss (anti-)deficit frames and noticing. The study uses a novel analytic framework to organize aspects of frames that begin to hint at a complex relationship between deficit and anti-deficit framing and responding.

Keywords: frames, teacher noticing, responding, graduate student instructors

There have been strides in our understanding of how graduate students develop as instructors (Beisiegel et al., 2019; Miller et al., 2018). However, we still require more nuance in the discussions of the development of teaching skills for graduate student instructors (GSIs), including in instructors' noticing within teaching. Typical descriptions of noticing tend to model instructors who respond to students in deficit-based ways as those who frame mathematics and learning in deficit-based ways; and instructors who respond to students in asset-based ways likewise are those who frame mathematics and learning in asset-based ways (e.g., Louie et al., 2021). Although scholars recognize this conception is idealized, there are few examples in the empirical literature of a more complicated relationship between framing and responding. In this proposal, I share results from an interview-based study of GSIs that provide such examples.

In this study, mathematics GSIs were interviewed before their instructor orientation to recount their experiences as students that I will argue inform the GSIs' noticing. This contributed report stems from a larger study of how GSIs develop their frames of teaching and learning within their first semester of teaching as the instructor of record. With the exploration of graduate students, the conceptual contribution of this study is to build on Louie, Adiredja, & Jessup's (2021) teacher noticing framework by coloring the gray relationship between deficit and anti-deficit phases of noticing and articulate a possible spectrum between deficit and anti-deficit frames and teaching responses. The professional contribution of this study is to clarify the professional development (PD) of GSIs by expanding the PD organizers' training for noticing skills.

These research questions guide the study: (1) *How do pre-PD first-time GSIs discuss student learning and their desired teaching practices?* and (2) *How do these discussions clarify our understanding of frames and noticing?*

Motivation from the Literature

Within the circles of research in undergraduate mathematics education, the development of graduate students as instructors is a shared curiosity. Miller et al. (2018) provided a literature review on the growing literature of GSI development which echoed the need for more understanding of how graduate students develop. In the following years, there have been studies that encompass various avenues of GSI development such as the obstacles of mathematics GSIs face in this development (Beisiegel et al., 2019), factors that influence GSI pedagogical empathy (Uhing, 2020), or the different types of programs that prepare GSIs to be instructors of undergraduate mathematics (Bookman & Braley, 2022; Ellis, 2014).

In a different focus, König and colleagues (2022) conducted a systematic literature review of 182 articles focused on teacher noticing conceptualization, study design, and findings. Within these, they found discussions of comparisons between novice and expert teachers (König et al., 2022, p. 13). However, there was no highlighted discussion of how an instructor develops their noticing skills. In particular, GSI and novice instructors' transition from student to instructor has yet to be explored in research of teacher noticing. Following the call for research of mathematics GSI development and this gap within the literature of noticing, this study continues exploration of the specific skill of noticing within the population of first-time teaching GSIs.

Theoretical Perspective

As discussed in König et al. (2022), teacher noticing has different conceptualizations (p. 8). This study follows from Jacobs et al. (2010) in which they deconstructed and extended the facets of noticing into three interrelated skills: attending, interpreting, and responding (AIR). *Attending* means to identify what is most important in the classroom (van Es & Sherin, 2008). *Interpreting* means to assign meaning to objects, such as students' questions, spoken or written solutions (van Es & Sherin, 2008). Lastly, *responding* alludes to the plan or action of answering the interpreted or attended student contribution in the classroom (Jacobs et al., 2010).

Hill and Chin (2018) provide a recounting of the role AIR has had in instruction. For example in classroom management (Star & Strickland, 2008) and responding to meet students' needs (Barnhard & van Es, 2015; Jacobs et al., 2011). They then investigate the interplay between teacher knowledge, instructional practice, and noticing; namely in the realm of "teacher knowledge of students" (Hill & Chin, 2018, p. 1105).

Relatedly, Louie (2018) continued the conversation of *equitable* noticing (Wager, 2014) in which her participant, Amanda Pepper, illustrates the barriers that caused her to still see students' deficits in spite of her substantial skills in noticing that focused on seeing students' mathematical strengths (p. 67). Years later, Louie and colleagues (2021) took a sociopolitical turn in discussing teacher noticing. They build on previous works, especially of Jacobs et al. (2010), to introduce the presence and influence of frames on the AIR teacher noticing framework, dubbing their proposed framework of teacher noticing FAIR. In short, frames (Goffman, 1986) are the interpretive contexts that participants of a given situation use in order to quickly interpret information, filter the details, and decide how to appropriately proceed. It is the vehicle that allows a person to be able to answer the question "What is it that's going on here?" (Goffman, 1986, p. 8) after attending any current situation.

In Goffman's discussion of frames, there is a strong suggestion that the frames one uses strongly dictate their actions. Louie and colleagues take from Greeno (2009) to understand that "frames provide interpretive contexts that support participants in a given situation to understand what kind of task they are engaged in, what kinds of knowledge are relevant or valuable, and what sort of behavior they and others are expected or entitled to engage in" (Louie et al., 2021, p. 3). In illustrating the utility of the FAIR framework, they acknowledge the gray area between deficit and anti-deficit noticing but chose to use two examples with "sharp contrast" to illustrate how consequential framing can be for noticing (Louie et al., 2021, p. 4).

To build their illustration of deficit framing and noticing, Louie and colleagues discuss how "it makes a great deal of sense" for teachers to attend, interpret, and respond in a deficit manner when teachers frame mathematics learning as "absorption of a universal, objective, and fixed body of knowledge" (Louie et al., 2021, p. 5). Here, deficit noticing involves "attending to accuracy and correctness", "interpreting mathematical work [as only] correct or incorrect", and "responding by affirming correct answers and remediating errors (Louie et al., 2021, p. 5).

In building a parallel illustration of the FAIR framework for anti-deficit contexts, Louie and colleagues began with the "AIR" component and ascertained the "F" that shaped the particular noticing. For example, using Oscar's case, they categorized instances of attending into thematic codes first (students, mathematics, and interactions), and then used literature on deficit or equitable frames to theorize the interrelation between framing and these themes. These two illustrations may suggest the same influence that Goffman had, in that deficit framing leads to deficit noticing or anti-deficit framing leads to anti-deficit noticing.

I understand that the FAIR framework is a model of the relationship between frames and noticing, and their discussion focused on the utility of frames in discussing noticing. This discussion does not do their work justice, as Louie and colleagues discuss more than just these illustrations. The best (or worst) case-scenario illustrations of anti-deficit (or deficit) contexts is a helpful model in accounting for frames in noticing, but frames likely cannot dictate all actions and responses. They have done extensive work in illustrating the complex web between the parts of FAIR as well as how the contexts outside of a classroom has a strong influence on the frames of teachers (Louie et al., 2021, p. 11). For now, this report aims to complicate this FAIR framework by focusing on analytically unpacking frames, which colors the gray area that Louie and colleagues mentioned briefly. This is focused on the framing and the responding parts of the FAIR framework and discuss the research implication for the other parts in the conclusion.

Data and Method

The data used in this report comes from a larger study of mathematics GSIs teaching for the first time as instructors of record. Instructors of record are responsible for the content-delivery and assessments of these undergraduate mathematics courses (Rogers & Yee, 2018). This study took place in a large, public, R1 university. More specifically, the interview data used in this report was collected weeks prior to their first PD and official preparation to teach as instructors of record. These four GSIs will be teaching either an "intermediate algebra" course which cover ideas that "are prerequisites for tackling college-level mathematics" or a "college algebra" course which is not commonly deemed as college-level mathematics, like calculus, differential equations, or linear algebra (Burrill et al., 2023, p. 799). Each GSI chose their own pseudonym.

I am a mathematics GSI myself. While the benefits of rapport and confidence helped in acquiring participants, the relatable experience of being nervous about teaching for the first time has an unavoidable influence on the data collection and analysis. For example, the guiding principle that one's past experience of being lost in a college course influences their future desired actions and expectations as instructors of record is a direct result of the author's experiences as a GSI.

The structure of interviews supports analysis of GSIs' preliminary frames, with the caveat that I am limited to only their perceptions of responses as they have yet to teach. The guiding philosophy of the interview was to orient GSIs into their past experiences. By first asking about a college course that they felt "really lost" in, this reveals their desired expectations and actions better than recounting a time where mastery came naturally. This philosophy stems from the author's experience of better articulating what he wants to do as an instructor when the context is bettering a challenging experience. For example, the question "What expectations should the instructor [of the "really lost" class] have had…?" revealed desires of wanting to break the monotony of lectures to implement student-to-student discussions when confusion arises. This can gather information about how they frame learning as collaborative or how instructors should respond to perceived confusion. Additional questions were asked that allows investigation of frames and responding such as “In your view, how do students learn math?” or “when you think of a skillful teacher, what is that person doing?”.

Analysis proceeded by first giving a descriptive summary for each question immediately after each interview. Then, focusing on individual interviews, each response was analyzed closely to highlight ideas about teaching and student learning. Thus, for each interview, a profile of the GSI was built using the guiding questions: “what attitudes does this person have towards student learning?” and “how does this person’s attitudes compare to the (anti-)deficit frame models from Louie et al. (2021)?” In particular to organize data for the latter, a novel researcher analytic framework organized into a table (Table 1) was used, which the larger study this report stems from is trying to elucidate its viability as a researcher tool for frame analysis.

Table 1. Researcher framework for examining instructional frames

Frames provide interpretive contexts that support participants’ **understanding of**…	Frames of teaching provide interpretive contexts that support GSIs perceptions and enactment of…	Frames of learning provide interpretive contexts that support GSIs perceptions and enactment of…
(1) What role(s) they take up	What their role is in the classroom as novice instructors	What do GSIs have to do for students to learn the intended content, practices, and orientations
(2) What knowledge is relevant or valuable	What professional knowledge is relevant in the act of teaching	What content, practices, and orientations should GSIs attend to in the classroom
(3) What sort of interactions they and others are expected or have the right to engage in	What type of interactions (instructor-student, instructor-group, student-student) are favored or useful in fulfilling their role and achieving the intended learning goals	

Here I discuss the formulation of Table 1. The compartmentalization of frames is motivated by Greeno’s (2009) work, which Louie et al. (2021) also use to discuss frames. Its construction was motivated by asking “how can a researcher establish that one instructor’s frame is different from another?” The change of wording from participants’ “understanding of…” to “perceptions and enactment of…” is key, because this framework addresses the participants’ point of view on the three subdivisions as well as the actions that follow. Professional knowledge (Kunter et al., 2013) refers to the many different facets of knowledge an instructor could have such as content, pedagogical content, organizational, pedagogical/psychological, and counseling knowledge. This functions to clarify what Greeno meant by knowledge in a way that still broadly covers the types of knowledge that instructors draw upon for teaching. Content refers to the curriculum of the course, these are what the instructor must cover according to the department. Practices is a general term to refer to the behaviors one can learn as a mathematician like collaboration or justification. Lastly, orientations cover the abstract such as the attitudes towards the subject like confidence and self-efficacy.

I also want to highlight the combined section row for teaching and learning. While the middle column of Table 1 reads as the instructor’s interactions with the broader profession of teaching and pedagogy, the right column serves as the instructor’s intrapersonal connections to the act of teaching. As such, it felt natural to combine the final row as a sort of bridge between the two sub-definitions of frames. Using the guiding questions, the preliminary frames and perceived ways of responding are organized for each GSI.

Results

In organizing these results, Table 1 was used as a way to organize connections, such as "how have these three framed what it means to learn mathematics?" In the responses to "how do students learn math?", there is a common thread among all four GSIs in framing student learning as learning by doing and highlighting the importance of student-student interactions.

Interviewer: In your view, how do students learn math?

Andy: So like the first part of math, like high school math. You can kind of do, so to speak, on your own in the sense that you can repeat it and see the patterns between examples, and from their branch out into other examples, because you can see the structure better. and knowing that structure, and being able to extrapolate on that structure, is still useful to you, an integral in later parts of math. But I think that in proof math it starts to become more social, because you remember certain things from like true, that stood out to you as elegant and useful, and other people remember different things from the lecture that's been as elegant and useful, and you all have your different preferences on what proofs you like to use.

Paul: The biggest component is doing it yourself, as in like doing problems.

Longboat: They learn by exploring it, trying things out, and more importantly, discussing with people [sitting] behind them, the peers, the other students. That's important.

Past this point, differences start to arise. These three GSIs also discussed how learning starts with an introduction that covers the "big picture" concept which then develops into more intuition and understanding by doing more and more examples. For these three GSIs, the instructor's role is explicitly noted as the person who introduces the concepts and chooses the "right" examples. The fourth GSI, Carlos, discussed learning through the lens of how they learn mathematics which differs from the other GSIs since they take it upon themselves to find more challenging problems to work on.

Carlos: I'll talk like from my point of view, like how I like to learn math… I like to go to lecture, ask as many questions as I can during the lecture, … take notes, go home, read the notes, [and] understand what is going on in the notes. And if I don't understand something, I go to office hours, ask questions there that are like more in depth. And then but oh, before that I try to read the book… It's like very good at supplementing the course. Then, also a lot of problems, or like challenging homework problems that are like more challenging than the stuff that I would see inside the classroom. And so I like to work on the homework like if I have a problem to work on, I work on it for like 30 min to an hour. and then if I don't get anywhere. I stop after an hour like after 30 min to an hour. and then ask classmates. and if we don't figure it out, I ask After 30 min to an hour with a classmate, I ask the instructor. during off hours. And that's in my view how this student [points to themselves] learns math.

Now, compiling the responses to questions that center teaching practices, three common teaching practices arose: (a) having awareness of the climate of the classroom, (b) being well-prepared in content knowledge, and (c) creating a collaborative, supportive environment. These practices are then translated into descriptive codes (Miles, Huberman, & Saldana, 2019): climate, content, and collaboration. Below are representative quotes for each of these themes that demonstrate each theme the best but note that each participant spoke of each theme.

Paul: **(climate)** I noticed I liked a lot about [graduate course] and his instructor style. It felt like he was pretty good at noticing when the class was lost. and sort of pausing to take a break and be like, “Okay, check in with your neighbor, talk about what's going on, where or what's gone wrong.” I think that's an important aspect.

Andy: (**content**) I think a skillful teacher is one who has an understanding of their knowledge base, and also the ways that people can misinterpret it when they first see it.

Carlos: (**collaboration**) One thing that I think any class should have, for example, is to make sure that, like you’re a good classmate, not just like a good student. That definitely, I think, should be verbalized in any classes, especially in that one.

Through Table 1 and these themes, these four GSIs have framed teaching and learning as requiring content knowledge to attend to students doing problems, but also requiring sensitivity to the comfort of the students to create a space conducive to learning from each other.

Since these GSIs have yet to enter the classroom as instructors, the study takes the three themes above to allude to their perception of responding in noticing. For an explicit exploration, Longboat has framed the act of learning as an exploration filled with students asking questions and making conjectures and their responding maneuver during this exploration is to be hands off:

> “I explained a bit of a concept, say the derivative. Maybe I don't give the full story yet. I just give them some precursors to it… Then I say ‘for the next 5 minutes, just to the person behind and next to you, ask what's this good for?’ I think these vague, open questions are good because you've given them an idea the students know it has to do with something you've talked about, right? They don't know exactly where we're heading… You expect students to have this mini research mind, they should be in the head that you explore math. You don't just solve it. So trying things out… They shouldn't discuss it with me, because I know what the answer is… So, give them a safe haven with their peers, where they can say anything… and as always allow students to make mistakes.”

Longboat’s response above provides one of the motivating complications to the FAIR framework. In one interpretation of this response, this was seen as dismissive as it disallows students from seeking answers from their instructor. But, in further exploration, this stems from Longboat's insistence that learning does not happen by having answers "thrown" at students and their belief that mathematics (research) is not given, but is discovered through exploration.

Another example, Andy has framed the act of learning with a skeleton metaphor:

> “You have to get some picture of what you’re looking for, and then see it a lot of times to be able to really see the basic skeleton. And then you can try to fill out that skeleton depending on what problem you're working on.”

For them, the instructor’s role is to give an “introductory picture of what that skeleton might look like” and provide a range of examples (simple to difficult, unambiguous to ambiguous) that allow students to add to the skeleton in different ways during different problems. Longboat and

Andy both share the frame that learning occurs when there is student exploration, but they differ in their way of perception of responding to this frame. While Longboat has a hands-off approach, Andy explores a range of examples alongside their students.

Lastly, as another point of comparison, GSIs also learn through exploration of "more challenging" problems, which is expressed in Carlos' large quote above, however Carlos' perceived role as instructor is to be there for students to approach with questions. This parallels Longboat's students' exploration but contrasts Longboat's instructor role, as students are not disallowed from asking questions.

Discussion

This contributed report set out to build on the work of Louie et al. (2021) bringing frames into the AIR teacher noticing framework. The results of the reported study entangle the relationship between anti-deficit or deficit frames with anti-deficit or deficit responding. With Longboat, Andy, and Carlos, a suggestion of a spectrum rises in the gray area between anti-deficit and deficit ways of responding. Even though these GSIs agreed in framing student learning as including exploration of various problems, their ways of responding branched out in different ways. Similar to Louie et al. (2021), it is reductive to label instructors' noticing as purely anti-deficit or purely deficit as it is rarely the case that noticing is (anti-)deficit in every situation. As in Longboat's situation, their way of responding (not discussing with students during their exploration) could be seen as deficit (when viewed as dismissive) or as anti-deficit (when viewed as a total belief that students are capable of exploring on their own).

Implications and Future Direction

This study was only able to focus on their frames and their perceptions of responding. With that, future research should explore where "switching" happens. Since there is a perceived flow from attending to interpreting to responding, future work can explore where the switch from deficit to anti-deficit happens along this chain.

An implication of this study for professional development organizers is to understand the complicated nature of anti-deficit framing and anti-deficit teacher noticing. On one hand, the author now understands that even if novice instructors are taught the same anti-deficit frame to approach teaching and learning, these can morph into different expressions that could be taken as deficit by their students. On the other hand, this complication of the FAIR framework alludes to a spectrum that can form a pathway from deficit responding to anti-deficit responding that PD leaders can utilize to train instructors to provide more equitable experiences for students.

A consequence of this study is that, even before formal professional development or experience as instructors of record, mathematics graduate students have nuanced perceptions and thoughts about their future teaching and what it means to be a skillful teacher. The larger on-going study this report stems from assumes that these perceptions are continuously shaped during their experiences as students in their mathematics courses. As such, more studies in leveraging graduate students' experiences as students to improve, augment, or re-design aspects of the graduate student professional development and preparation to teach undergraduate mathematics.

Acknowledgments

The author would like to extend thanks to Yvonne Lai for helping outline this contributed report, and to express gratitude to the four graduate student instructors whose interviews helped complicate and extend novel frameworks for better understanding.

Raise Your Hand if You Are Overloaded: The Role of Gestures in Proofs Comprehension

Vladislav Kokushkin
Colorado State University

Activities related to reading and understanding mathematical proofs are notoriously challenging for college students. On top of applying advanced logico-mathematical knowledge, these activities require the reader to process and operate on a substantial amount of information. Failure to successfully navigate the incoming stream of information may result in cognitive overload and impede one's ability to make progress on the task. This case study investigates how an undergraduate student, David, used his hands to overcome the cognitive load he experienced when reading a proof of the Two-Color Theorem. The findings suggest that in the absence of other modes of offloading (e.g., using pen and paper, figurative materials, or technology), hand gesturing may serve as a powerful and convenient offloading mechanism.

Keywords: gestures, working memory, proofs

The ability to read and comprehend proofs is critical for undergraduate students' success in advanced mathematics courses. Students are expected to spend substantial time surveying proofs presented in mathematics textbooks and their instructor's lecture notes (Weber, 2004). However, the activity of reading mathematical proofs differs from reading a literary text and requires developing special experience and particular skills. Unsurprisingly, then, numerous studies have documented that college students struggle to read proofs effectively (e.g., Hodds et al., 2014; Inglis & Alcock, 2012; Mejía-Ramos et al., 2012; Selden & Selden, 2003; Weber & Alcock, 2005; Weber 2004, 2015).

The implementation of certain ineffective reading strategies may be associated with the need to operate on an overwhelming amount of information. For example, Selden and Selden (2003) observed that novice readers spend much time paying attention to surface features of proofs, such as algebraic calculations. In another study, Inglis and Alcock (2012) found that undergraduate students tend to read proofs line-by-line, or, in other words, implement a *zooming in* (Weber & Mejía-Ramos, 2011) strategy. This way of reading proofs is the opposite of a *zooming out* strategy – skimming the proof to grasp the main ideas prior to attending to the details. The tendency to read proofs line-by-line or focus on surface details may pose significant cognitive load (Sweller, 1988, 2010) and impede proofs comprehension.

Cognitive offloading refers to the use of embodied activities to reduce the experienced cognitive load (Risko & Gilbert, 2016). Mathematics education literature has documented the beneficial effects of different modes of cognitive offloading, for example, drawings (Stryker et al., 2022), and hand gesturing (e.g., Cook et al., 2013; Goldin-Meadow et al., 2001). Remarkably, all these studies were conducted in the context of elementary school mathematics, and the role of cognitive offloading as manifested via hand gesturing in the context of undergraduate mathematics has been fundamentally under-researched. Moreover, none of the previous studies investigated the role of gestures in understanding written mathematical texts. As such, the goal of this study is to begin filling the gaps in the RUME literature. Specifically, my chief research question is *What is the role of students' gestures in navigating the cognitive load associated with reading and comprehending mathematical proofs?*

Theoretical Framework

In answering this research question, I adopt Piagetian and embodied perspectives. Embodied theories of cognition (e.g., Barsalou, 2008; Lakoff & Nuñez, 2000; Nemirovsky & Ferrara, 2009) propose that cognitive activities are rooted in sensory-motor processes (Wilson, 2002). Likewise, the idea that sensory-motor operations provide a basis for mathematical learning corresponds to Piagetian theories of mathematical development (Piaget, 1972). Sensory-motor activity is a kinesthetic activity involving muscular movements, including hand gestures. This activity can be further internalized and transformed into mental actions and representations. Although Piagetian and embodied perspectives have certain epistemological disagreements (e.g., on how abstraction takes place), these two theories allow for the integration of the constructs of mathematical proofs, gestures, and working memory (WM) by positioning bodily activities at the core of human cognition.

Working Memory

WM is a psychological model for human's ability to simultaneously store and process limited amount of information over a short period of time (e.g., Baddeley, 1992; Baddeley & Hitch, 1974; Daneman & Carpenter, 1980). Although numerous models of WM have been proposed (e.g., Atkinson & Shiffrin, 1968; Baddeley & Hitch, 1974; Cowan, 2012), Pascual-Leone's (1970) neo-Piagetian approach to WM is of primary relevance to my theoretical framework.

Pascual-Leone (1970, 1987) introduced a mathematical model to account for the development and functioning of WM. The proposed model has two levels. The first level contains cognitive units – schemes in the Piagetian sense. The second level includes cognitive operators, which are responsible for the activation of task-relevant schemes and inhibition of activation of irrelevant schemes. An individual's WM capacity (or *M-capacity*) is characterized in terms of the maximal number of schemes they can activate at a time. The cognitive complexity of the task (its *M-demand*) is defined as the number of schemes the task requires to be activated simultaneously. If the M-demand of the task exceeds an individual's M-capacity, cognitive overload takes place, and student's progress on the task can be impeded.

Gestures

Hostetter and Alibali (2008, 2019) proposed the Gesture as Simulated Action (GSA) framework to provide a theoretical account of how gestures emerge from embodied simulations of motor and perceptual states. In line with neurological and behavioral evidence, the GSA framework asserts that thinking and talking about an action activates neural areas that are responsible for planning the action. This activation may be either inhibited by a human or realized as a sensory-motor output. In the latter case, the hand gesture is born.

Mathematical Proofs

Harel and Sowder (2005, 2007) have proposed the notion of *transformational proof schemes.* According to this view, when students read proofs, their reasoning is transformational in nature, because learners are supposed to perform various transformations of mathematical objects of thought to deduce or keep track of a chain of inferences. Although the authors originally defined transformations only as expressed through written and spoken language, I follow Pier et al. (2019) and extend this definition by including transformations manifested via hand gesturing.

Methods

The data presented here are a subset of data collected for a larger project aimed at understanding the role of gestures in offloading cognitive demands on students' WM when they read, present, and construct proofs of mathematical conjectures. In this paper, I report on David, an undergraduate student enrolled in an introductory proof course, working on the proof of the Two-Color Theorem (see Figure 1).

Theorem: *$n \geq 1$ circles are given in the plane. They divide the plane into regions. Then it is possible to color the plane using two colors, so that no two regions with a common boundary line are assigned the same color.*

Proof: call the proposition $P(n)$. Let the two colors be B and W. We will prove the theorem using proof by mathematical induction.

Base case: for $n = 1$, the result $P(1)$ is clear. If there is only one circle, we may color the inside B and the outside W, and this coloring satisfies the requirements of the theorem.

Inductive hypothesis: assume that $P(k)$ holds for a fixed but arbitrary k. So we know that for any k circles there is a coloring which satisfies the requirements of the theorem.

Inductive step: we need to show that the proposition holds for $k + 1$. Consider $k + 1$ circles $\{C_1, C_2, \ldots, C_{k+1}\}$. Ignoring the circle C_{k+1}, we temporarily have k circles $\{C_1, C_2, \ldots, C_k\}$ By the inductive hypothesis, the regions created by $C_1, ..., C_k$ can be colored according to the requirements of the theorem. We color the plane according to this coloring. Now we add the circle C_{k+1} back and do the following

1. For any region which lies inside C_{k+1}, do not change its color;
2. For any region which lies outside C_{k+1}, recolor it with the opposite color.

Now we may check that the new coloring works:

1. Two neighboring regions whose boundary lies inside C_{k+1} have different colors;
2. Two neighboring regions whose boundary lies outside C_{k+1} have different colors;
3. Two neighboring regions whose boundary lies on C_{k+1} have different colors.

This shows that $P(k + 1)$ is true, and so by the principle of induction, the proof follows. ■

Figure 1. The proof of the Two-Color Theorem (as it was presented to the participant).

Procedures

David participated in two pre-interview WM assessments, a proof-based clinical interview, and a stimulated recall interview (SRI).

WM assessments. The participant's WM capacity was measured using two previously validated procedures – the Figural Intersection Test (Pascual-Leone & Ijaz, 1989) and the Direct Following Task (Pascual-Leone & Johnson, 2005). David's scores on the two tests were averaged and resulted in a WM capacity of 8.25[1].

Proof-based interview. The participant was presented with a proof printed out on the piece of paper as it is shown in Figure 1. The student was told that the proof was correct and that his

[1] Average WM capacity ranges between 5 and 9 (Miller, 1956; Pascual-Leone, 1970).

task was to read the proof and do his best to understand it. The student was not given a pen, scratch paper, a calculator, or any other figurative materials. He was not limited in time and was asked to think aloud while surveying the proof. After David indicated that he fully understood the proof, the interviewer asked a set of comprehension questions (data not reported here). The participant's behavior and mathematical reasoning were video- and audio-recorded.

Stimulated recall interview. On a later date, the student was shown selected video clips with himself working on the proof, and the interviewer asked questions about the participant's reasoning and behavior.

Hypothetical Analysis of the M-demand of the Proof

Prior to collecting data, I conducted a hypothetical analysis of the M-demand of the proof. This analysis is based on identifying a sequence of mental actions that need to be carried out to understand the proof. Specifically, I broke the proof into lines containing one or two mathematical statements. Every line was then coded as A_k. For each line, I identified the set of 1) previous lines A_k logically depends on, and 2) contextual schemes that a participant would hypothetically need to activate when reading the proof. These contextual schemes included extra lemmas, definitions, key concepts (e.g., primality or divisibility), and the essential elements of the proof framework (e.g., inductive hypothesis or proof by cases). For the purposes of this project, I use the word "scheme" in a broad sense to capture the information contained in the text of the proof (lines $A_1, \ldots, A_n$) and contextual mathematical knowledge.

Figure 2 illustrates the hypothetical M-demand of the proof of the Two-Color Theorem. It has been hypothesized that to understand the line A_7, the reader needs to activate the schemes A_3, A_4, and A_5. Also, the reader needs to allocate additional cognitive resources to retain the information contained in A_7 itself and to understand why $\{A_3, A_4, A_5\}$ imply A_7 (indicated as an arrow). Thus, the M-demand of line A_7 was assessed as 5 (one unit per scheme plus an arrow). According to the same methodology the M-demand of the lines $A_9 - A_{11}$ was assessed as 9, which is higher than an average WM capacity.

A_3: By the inductive hypothesis, the regions created by $C_1, ..., C_k$ can be colored according to the requirements of the theorem. $[\{A_2, P, IH\} \rightarrow A_3]$

A_4: We color the plane according to this coloring. $[A_3 \rightarrow A_4]$

A_5: Now we add the circle C_{k+1} back and do the following $[\{A_1, A_2, A_4\} \rightarrow A_5]$

A_6: 1. For any region which lies inside C_{k+1}, do not change its color; $[\{A_3, A_4, A_5\} \rightarrow A_6]$

A_7: 2. For any region which lies outside C_{k+1}, recolor it with the opposite color. $[\{A_3, A_4, A_5\} \rightarrow A_7]$

A_8: Now we may check that the new coloring works: $[\{A_3, A_4, A_5, A_6, A_7\} \rightarrow A_8]$

A_9: 1. Two neighboring regions whose boundary lies inside C_{k+1} have different colors; $[\{A_3, A_4, A_5, A_6, A_7, A_8, Cs\} \rightarrow A_9]$

A_{10}: 2. Two neighboring regions whose boundary lies outside C_{k+1} have different colors; $[\{A_3, A_4, A_5, A_6, A_7, A_8, Cs\} \rightarrow A_{10}]$

A_{11}: 3. Two neighboring regions whose boundary lies on C_{k+1} have different colors. $[\{A_3, A_4, A_5, A_6, A_7, A_8, Cs\} \rightarrow A_{11}]$

Figure 2. A line-by-line analysis of the M-demand of the proof of the Two-Color Theorem. The scheme P denotes the proposition of the theorem, IH – the inductive hypothesis, and Cs – the necessity to coordinate cases.

Data Analysis

The analysis began with creating the transcript of the proof-based interview. The videos in conjunction with the written transcript were used to identify gesturing episodes. Given that gestures oftentimes occurred quickly, I re-watched the video recordings and created codes for all gestures. I did this by looking at each gesture and creating a short description considering physical hand movements, the associated mathematical context, and the corresponding speech (if present). Gestures that did not seem to convey any mathematical meaning, were eliminated from the analysis. The remaining gestures were then labeled as (purely) communicative or offloading. In the latter case, the offloaded schemes were specified. The participant's responses during the SRI were used to triangulate my initial interpretations of his gesturing.

Results

I chose the Two-Color Theorem for two main reasons. First, its proof is mathematically accessible for undergraduate students assuming that they are familiar with the method of mathematical induction. Second, my methodology for measuring the M-demand of the proof predicted significant cognitive overload even for the participants with advanced WM capacity.

As was expected, David did not experience difficulties with the task until he reached the end of the proof. However, when reading lines $A_9 – A_{11}$, the participant demonstrated behavioral indicators of cognitive overload. Specifically, he paused reading and reviewed the details of (re)coloring of the plane (lines $A_4 – A_7$) multiple times, asked for a pen, and eventually started assisting himself with active hand gesturing to represent the circles and the associated regions:

Figure 3. David working on the proof of the Two-Color Theorem.

> So, this is a circle [uses his thumb and a pointing finger to form a circle]. And it has a different color from its outer region [points to the inside and outside of the circle, Figure 3, top left]. C_k [meaning C_{k+1}] is put on top of it [uses another hand to represent a circle, Figure 3, top right]. And now it has an opposite color from the original circle [Figure 3, bottom left]. And it is a neighboring region, with the original outer region, which was opposite of its inside [points to the inside of the original circle and to the outer region. Figure 3, bottom left, then bottom right]. They cannot be both opposite to an inside circle… Oh wait, but they switch the color!

The described sequence of gestures allowed David to offload the activation of a few critical schemes and helped him to make progress in understanding the proof. By placing the first circle and pointing to the inner/outer regions, the student offloaded schemes A_3 and A_4. When using his hand to indicate the action of adding another circle on top of the first one, he transmitted the activation of scheme A_5 into his immediate sensory-motor experience and eventually realized that some recoloring was needed, which is one of the key ideas of the proof. Therefore, offloading schemes A_3, A_4, and A_5 allowed the participant to free up WM resources to operate on other pieces of information, such as scheme A_7.

In the SRI, I showed David the described video episode and asked him what was challenging about the proof and what helped him to overcome these challenges. The participant indicated that it was hard to "remember all the configurations and steps" and discussed some offloading effects of hand gesturing:

> …maybe honestly, the working memory tasks helped me realize that if I could like potentially store some of the memory, like, in my hands, and not move them, and now it helped me like, work on other stuff in my head[2]. So, I just froze that piece of the memory in my hands and then continued to like, think about other configurations… Because, um... it was easier to like visualize different colorings of some regions I can actually see. Because I didn't have to remember both the colors and the region, I just had to remember that.

Although David's reflection could be biased by his prior knowledge about WM, which relates to the context of the study, these data provide an important insight into the nature of the offloading power of hand gestures from the participant's perspective.

Discussion and Implications

My work contributes to the existing literature in multiple ways. First, this case study serves as a starting point for the investigation of the role of students' gestures in navigating the cognitive load associated with activities pertaining to high-level mathematical cognition, such as mathematical proofs. In line with the previous research conducted in the context of elementary mathematics (e.g., Alibali & DiRusso, 1999; Cook et al., 2012; Goldin-Meadow et al., 2001; Ping & Goldin-Meadow, 2010; Wagner et al., 2004), the data presented here provide evidence that, in the absence of other modes of offloading, gesturing may be a convenient and powerful offloading mechanism. Using his hands to offload the activation of task-relevant mental

---

[2] After the WM assessments, David was curious about what constitutes WM and why it is important in learning mathematics. Apparently, he picked up some WM terminology and used it in the SRI.

schemes, David could reduce the experienced cognitive load and free up WM resources that helped him to make progress in proof comprehension.

Second, prior research on gesturing in proofs has revealed the prevalence of so-called dynamic gestures during proving practices (e.g., Nathan & Walkington, 2017; Nathan et al., 2021; Walkington et al., 2014). These gestures depict real-time transformations of either a single object or multiple mathematical entities, related to each. Dynamic gestures were also evident in my data (for example, gestures depicting the transformations of the regions caused by adding the k+1st circle onto the plane). The findings shed light on the cognitive utility of dynamic gestures in terms of their offloading power.

Finally, the proposed analysis of hypothetical M-demands of mathematical proofs was able to model the experienced cognitive load and predict places of cognitive overload by specifying the number of mental schemes the proof requires to be activated line-by-line. Other scholars used alternative approaches for modeling the cognitive load of a mathematical task. For example, Norton et al. (2023) introduced the notion of unit transformation graphs (UTGs) to illustrate the sequence of mental actions students perform when they are engaged in fractional tasks. Although UTGs provide opportunities for measuring the experienced cognitive load and help to explain how it may be reduced (Norton et al., 2023; Stryker et al., 2022), the applicability of this model is limited, and UTGs become impractical in multidimensional tasks, such as mathematical proofs.

As a closing remark, hand gesturing is only one, although outstanding, example of a cognitive offloading mechanism. In another study, Stryker and colleagues (2022) examined the role of student-generated drawings in offloading cognitive demands of fractional tasks. The results indicated that the possibility to rely on drawings helped the students to free up WM resources and complete a cognitively demanding task. Notably, before starting drawing, the participants actively produced hand gestures. However, the use of gesturing did not help the students to overcome the experienced cognitive overload and finish the task without drawing. This gives some anecdotal evidence that drawing can be considered a “more powerful” offloading tool than gesturing. Nevertheless, future research should directly contrast various modes of offloading.

When Cohen's Kappa Is Not Enough: Exploring Methods for Estimating Inter-Rater Reliability for Time Sequential Data

Jennifer Czocher

Texas State University

Alex White
Texas State University

Kathleen Melhuish
Texas State University

We identify a current pragmatic and methodological problem facing RUME researchers who study processes that unfold over time, like classrooms and interviews, with qualitative coding techniques. In many cases, existing methods for estimating agreement between raters fail to account for the properties of this kind of data, are not compatible with how the coding schemes are applied, and fail to properly estimate rater agreement. Despite many peer-reviewers requesting estimates of agreement for coded data, there is often no suitable value to report and researchers must make do with claims about coming to consensus. We review methods found in the literature and evaluate their suitability, strengths, and weaknesses. While each reviewed method is appropriate for some aspect of this kind of data, none satisfies all desired criteria.

Keywords: methods, quantitative, qualitative, inter-rater reliability

Qualitative researchers in RUME often use coding techniques (e.g. Clarke et al., 2015; Saldaña, 2016) to analyze recordings, transcripts, or artifacts like written work from educational settings like classrooms or interviews. Because qualitative analysis typically adopts a subjective, interpretive approach to seeking patterns in rich, complex data sources, one should not expect two raters would exactly agree on how to apply a coding scheme to a given record of an educational setting. Yet, there is still an expectation that multiple raters trained on the same codebook will conduct an inter-rater reliability (IRR) analysis and report an estimate. Miscalculating and inaccurately reporting IRR has been identified as a common methodological issue when reporting observational data (Hallgren, 2012). In our view, these methodological oversights are symptoms of qualitative researchers not having adequate access to suitable IRR measures or a clear mapping of which measures are suitable for different research settings. In this paper, we discuss the limitations of common approaches to IRR within RUME. We focus on observational data with particular attention to time-sequenced data, to illustrate the impact of differing types of disagreements between raters and consider the viability of existing approaches to estimating IRR. We conclude that the field lacks suitable estimates of IRR for addressing questions about time-sequenced interactions between teachers and students' reasoning, questions of particular interest to the RUME community.

Why Should RUME Care about IRR?

Seeking an objective numerical metric, such as IRR, may appear in conflict with interpretive paradigms of qualitative analysis; however, a suitable IRR method can serve an important role in supporting claims about the qualitative codebook and the coding process. First, if a suitable threshold is achieved, IRR can support inferences about the level of intersubjectivity (stability) of the codebook and therefore increase trustworthiness of the data analysis process. Second, a suitable measure may give information about when a rater has been adequately trained to use a coding scheme independently. When raters can reliably work independently, the capacity of the research team increases because researchers' confidence that the coding schemes are being consistently applied increases. Relatedly, some researchers intend to disseminate their coding schemes so that other stakeholders, like teachers and school districts, can use them to target and improve qualities of instruction. Third, researchers may wish to track observer drift (Miller, 2018). As raters code independently, they will begin to favor certain codes over others or introduce examples of codes (or additional codes) in distinct ways. It is important to understand how often raters should check in and re-calibrate their usage of the coding scheme. Additionally, raters' convergence or divergence on specific codebooks could become an object of study in itself. Fourth, IRR is essential to mixed methods research, where the resulting frequencies (how much and how often) of code occurrences serve as the input to quantitative methods.

IRR Methods RUME Researchers Use

To situate our discussion within RUME, we conducted a full-text search of the Boston (2022) RUME proceedings and articles published in *IJRUME* using search terms like "agreement" and "rater/coder reliability." The search returned eight proceedings and 16 articles reporting a value for IRR. Only 2 of 8 proceedings and 7 of 16 *IJRUME* articles reported a statistic such as Cohen's κ. A further two articles reported comparable statistics (Fleiss's κ and Krippendorff's α) and two considered correlations between coders. The remaining papers reported an agreement percentage. This brief search suggests that Cohen's κ is the primary method for estimating IRR appearing in published articles in RUME.

What is Cohen's κ and why is it problematic?

Cohen (1960) introduced κ to measure agreement between two raters using a nominal scale to assign analytic units to categories. Cohen's κ (hereafter: κ) is available in many qualitative data analysis software packages. The requirements are fairly stringent: analytic units must be independent, the coding categories must be independent, the codes must be mutually exclusive and exhaustive (MEE), and the raters must be independent. Imagine a recording of a classroom lesson and a codebook containing n different codes, $\{x_i\}$, which do not have a naturally occurring order. The recording is segmented into analytic units. These could be turns of speech or uniform chunks of time, for example. For each analytic unit, Rater 1 can apply x_i (or not) and Rater 2 can apply x_i (or not). For each x_i, and for each segment, there are two agreement states (both apply code x_i, neither apply code x_i) and two disagreement states (one coder applies x_i and the other does not). The counts for each state can be tallied in a contingency matrix and then Cohen's Kappa computes the ratio between (a) the excess probability that two coders agree compared to the probability agreements are due to chance alone and (b) the probability that agreement is not due to chance alone. It is interpreted as the likelihood that raters are coding the same way, corrected for how often the raters (hypothetically) agree by chance alone. Values closer to 1 correspond to stronger inter-rater reliability. Metrics like κ can be suitable for well-structured qualitative data where codes are applied to well-defined analytic units, like turns in a transcript. However, κ rests on quantitative assumptions (e.g., codes are mutually exclusive and represent independent categories) that are not always met by the outputs of qualitative coding.

Four primary categories of observational data can be distinguished: (a) event sequential data encode only the order of events, but not time information about when they occurred, (b) state sequential data assume that every second of the observational record can be mapped to a unique state in the codebook and thus record transitions between states, (c) interval sequential data consist of equally-segmented intervals and apply codes to each segment, and (d) time sequential data (TSD) allow codable events in the observational record to be identified with a rater-defined time interval (Bakeman & Quera, 1995); codes can be applied to momentary behaviors (e.g., a hand being raised) or to behaviors with a duration (e.g., a teacher engaging in motivational talk). Both the start and stop times of each coded event are relevant in TSD, an aspect which distinguishes it from the other categories and makes it particularly resistant to statistical methods like κ. In TSD data, where one codable event begins is partly constituted by when another one ends (or begins). This means not only that TSD violates independence assumptions, but it also introduces low-level disagreements that researchers may not wish to tally. κ assumes that all types of disagreements between raters are equivalent and should be tallied.

Consider the following three kinds of disagreements: (A) *errors of omission/commission*, where one rater misses (or inserts) a codable event relative to the other rater's analysis, (B) *multiple interpretation problems*, where two raters disagree on what code is appropriate for the analytic unit, but agree that something important relevant to the research question is happening, and (C) *boundary problems*, where two raters agree on what code to use, but choose different times to apply it. The severity of omission/commission depends on whether Rater 1 simply did not perceive the event that Rater 2 conceives as codable, or whether Rater 1 disagrees with Rater 2's interpretation of the event as codable. In the first situation, Rater 1 may simply admit they missed something and adopt Rater 2's code. The second situation should count as a disagreement, but probably not the first. After all, this is a primary reason to have at least two raters reviewing data for mixed-methods work. Multiple interpretations problems will arise when codebooks are detailed and complex. Said plainly, the more choices there are for codes, the more likely two raters will disagree on which code to use even if, at a high level, they agree that a) there is a codable event and b) how to interpret the relevance of the event. Boundary problems are common when using coding schemes that allow for codable events to be selected with a rater-defined time interval instead of uniform time intervals. The raters need to decide when each codable event begins and ends, as well as which code(s) to apply. Each of these types of disagreements is less substantial than two raters fundamentally disagreeing on the nature of what is being observed. The problem is that algorithms vary in their capacity to evaluate what kind of disagreements may have occurred, and therefore whether to count them as "true" disagreements. For these reasons, metrics like κ (and percent agreement) may not properly estimate IRR and thus are limited in their suitability for the kinds of qualitative research common in RUME. In fact, there is growing caution Cohen's kappa should not be considered as a standard for IRR in these cases (Walter et al., 2019).

These problems are exacerbated for projects recording temporally-sequenced observations, like interviews or classroom interactions, and can confront the researcher with distasteful choices. To make the discussion concrete, imagine a cognitive task-based interview setting where the project is interested in studying interviewer-student interactions that lead to successful problem solving. In this example, imagine the research question is about how the interviewer's moves support the student's reasoning. The interviewer's moves might get coded for attributes of the questions she asks or mathematical content of the statements she makes. The student's speech, writing, and gestures might get coded with indicators for phases of problem solving, covariational reasoning, and metacognition – as they occur. These codebooks are very complex and may not be hierarchically organized, thereby resisting simplification efforts.

Due to the nature of mathematical reasoning, multiple codable events may take place during overlapping durations of time. For example, while speaking about a graph, the student may be speaking about two quantities covarying, but doing so to reflect on the adequacy of results from their previous work (metacognition) by considering an analogous situation (problem solving heuristics). Thus, this TSD does not satisfy assumptions about mutual exclusivity. To meet the assumptions for κ, the observational record would need to be artificially segmented (i.e., transformed into a non-TSD type), which would disregard detailed interactional information the qualitative codebooks are designed to capture. For example, coding the teacher and student moves every 30s would (inaccurately) concede that the only important aspect is whether a move occurred during the time interval, and then apply that code to the entire interval, which would wash away any interactional information during that interval. In short, researchers want to retain "when" something happened as a property of the data so that time-dependent interactions can be studied.

Considerations for Evaluating a Method's Capacity to Exclude Low-Level Disagreements

In general, estimates of IRR are very sensitive not only to raters' consistency in applying codes to the data but also to their accuracy in segmenting transcripts of videos into analytic units. Ideally, the coding process supports assignment of "clearly defined, disjunct categories" (Reed et al., 2018, p. 208) to each codable event and there is an "intersubjective, transparent basis for forming coding units" (Bilandzic et al, 2001 as cited in Reed et al., 2018, p. 208). This is easy enough when the codebook corresponds to direct observations, e.g., *student raises their hand*. It becomes much more complicated with research questions that use interpretive coding schemes, like those associated with student reasoning or teacher scaffolding moves. As discussed above, there are three kinds of low-level disagreements that researchers may not wish to tally. In this section, we review existing methods for estimating IRR for TSD that treat two of them: errors of

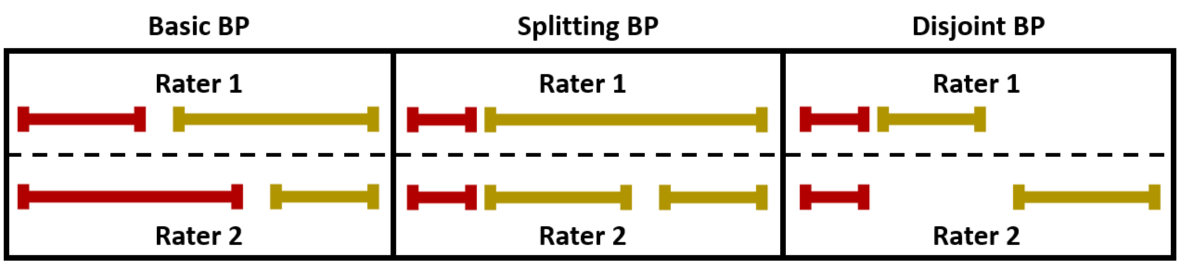

Figure 1 Boundary Problems (BP), which should not count towards disagreements.

omission/commission and boundary problems.

There are three kinds of boundary problems that have implications for the algorithms used to estimate IRR, which we call the basic boundary problem, the splitting boundary problem, and the disjoint boundary problem, diagrammed in Figure 1. The basic boundary problem arises when the raters use non-identical starting or ending boundary points for the codable event. For IRR methods which include some kind of temporal tolerance, a small tolerance can result in false negatives for this kind of boundary disagreement, whereas a large tolerance can result in false positives. The splitting problem occurs when one rater decides to split a code for some non-codable activity that occurred during the interval a codable activity occurs. For example, Rater 1 codes $[t_1, t_2]$ as *quantitative coordination*, but Rater 2 observes that for a duration of time $[t_3, t_4] \subset [t_1, t_2]$ that the student makes a comment about their recent mathematics exam, which is not a codable event, and then goes back to their covariational reasoning activity. Thus Rater 2 produces two codable events, $[t_1, t_3]$ and $[t_4, t_2]$, assigned to *quantitative coordination.* Depending on which IRR method is used, an algorithm could count this as two agreements and one disagreement or as three disagreements. However, the disagreement is closer in nature to deciding the appropriate duration of an analytic unit, which is why we include it as a boundary problem. A suitable method would be sensitive to the splitting problem only in cases where the number of coded events is important to the research question. The disjoint boundary problem happens when a codable event is a very short duration and is couched in an ongoing student activity. For example, the student may exclaim, “wait!”, briefly go silent, and then correct a mistake. Here, the raters may agree on the codable event (*evaluation)*, and which code to apply, but not “when” to give credit for it.

Options for Estimating IRR for Time-Sequenced Data

We sought methods in the literature that aligned with the properties and needs of TSD: (1) they could be modified to accommodate violations of the MEE assumptions (2) the method is properly sensitive to low-level disagreements arising from boundary problems and omission/commission, and (3) the method is adequate to research questions posed about time-dependent interactions. In this section, we review the strengths and weaknesses of three approaches to modifying κ for use with TSD: time-unit kappa, multi-pass, and sequence method. A summary of the methods is provided in Table 1.

Time-unit Kappa. Bakeman et al. (2009) describe the time-unit kappa method as one commonly used in existing IRR literature. This method subdivides the data into very small, uniform, time intervals (typically fractions of a second), and takes the time interval as the analytic unit. As with Cohen’s κ, an agreement matrix is formed by counting agreements and disagreements on the subdivisions and κ is calculated on those matrices. As this approach re-defines the analytic units as small time intervals, disagreement between coders on *number* of coded intervals (as in the splitting boundary problem) are not measured. This method is also often modified with a researcher-specified temporal tolerance, allowing it to potentially be insensitive to disjoint boundary problems. The main drawback of time-unit kappa is that it assumes each tally mark in the matrix corresponds to a codable event, thereby dramatically over-estimating the number of rater decisions. Additionally, long strings of subdivisions would all be (apparently) coded identically, violating the independence assumption of κ. Time-unit kappa may still be useful in some situations. In particular, it addresses the splitting boundary problem, can easily be modified to address the disjoint boundary problem, and would be appropriate for research questions that demand high confidence in code location and duration.

Multi-pass. This family of methods improves upon the time-unit kappa method by identifying agreement between complete coded events instead of breaking them up into time segments. This comes closer to meeting the κ independence requirement. They make multiple passes through the coded data and on each pass they assign agreement or disagreement between raters to each coded event which has not yet been assigned a state. There are three published toolkits that execute multi-pass IRR methods: The Observer (Jansen et al., 2003), Interact (Bakeman et al., 2009), and EasyDIag (Holle & Rein, 2015). The Observer makes two passes to tally agreements based on overlap of coded events (within some researcher-defined tolerance) and then makes two more passes to tally code disagreements. The Interact algorithm works similarly but adds an extra pass to identify errors of commission/omission.

Both The Observer and Interact algorithms state that MEE assumptions should be met and both address the three boundary problems. Both are consistent with research questions that care about the occurrence and order of coded events. These algorithms can still be executed on data which violate the MEE assumption, and so potentially may perform well on data which only minimally violate it (see Jansen et al., 2003). The extent to which they perform well with MEE violations would be testable through simulation methods. However, both algorithms suffer from what Holle and Rein (2015) refer to as the *linking problem*: these methods may produce more entries in the agreement matrix than there are total coded events in the union of the two raters' data. Consider the splitting problem in the middle diagram of Figure 1 from the perspective of Rater 1 and from the perspective of Rater 2. Rater 1's coded event agrees with the first and second events coded by Rater 2 *and* Rater 2's two coded events agree with Rater 1's only coded event. Even though there are only three total coded events, the Observer algorithm would count this as four agreements. Holle and Rein claim that multiple linking can lead to bias towards agreements (2015). Raters who encounter many splitting problems will have artificially inflated reliability.

The EasyDIag algorithm was developed in response to the linking problem in the Observer algorithm (Holle & Rein, 2015). It makes only two passes. In the first pass, it links coded events with sufficient overlap and then removes them from the set. The remaining coded events are considered disagreements. The second pass links the disagreements in order of percent overlap, until the percentage falls below the same threshold. Any remaining coded events are considered errors of omission/commission. While EasyDIag resolves overcounting on the splitting problem, it does not resolve any of the boundary problems. It relies on percent overlap to link coded events and categorize them as (dis)agreements. It would miss boundary problems where the duration of Rater 1's coded event is much longer (or shorter) than Rater 2's coded event. Similarly, it will fail to link coded events with the disjoint boundary problem because it requires some level of overlap between codes. Finally, it will fail to link coded events with the splitting problem because it permits only one link per coded event before removing that coded event from the set of coded events to process. We consider these problems to be potentially resolvable by using a negative threshold, allowing for closely disjoint codes to be associated, which would not be within the range of thresholds (51% to 90%) suggested by the original authors.

Sequence Method. All methods mentioned so far have focused on temporally local agreements between two coders. Bakeman et al. (2009) introduced the GSEQ-DP algorithm which, instead, considers the overall sequence of coded events. This algorithm extends previous work with event sequential data (data viewed as a sequence of coded events, without reference to time stamps). The original algorithm rendered each rater's coded events as a sequence and computed the Levenstein distance between them (Quera et al., 2007). The Levenstein distance measures the minimum number of coded event substitutions, additions, or removals required to transform one sequence of coded events into another. A sequence of transformations is generated in the process and this sequence can be directly mapped to agreements/disagreements (substitutions), commissions (additions), and omissions (removals) in an agreement matrix. κ can then be calculated as usual on the resulting matrix. The GSEQ-DP algorithm connects the sequence-only algorithm to the timing of coded events as follows: Substitutions are free when Rater 1's coded event is temporally close to Rater 2's coded event but a cost is imposed on substitutions that are temporally distant. Imposing the costs ensures the method only identifies agreements between coded events which are temporally close to one another. As with previous methods, the GSEQ-DP algorithm explicitly assume the codebooks satisfies the MEE assumption. Its focus on code sequence resolves the basic and disjoint boundary problems. The splitting boundary problem, though, is still unresolved as the algorithm provides one-to-one mapping between coded events. This method for estimating IRR could be very useful for research questions concerned with the sequencing of coded events, such as, "Does *metacognition* often follow a teacher's *evaluation of response*?" The algorithm could be amended to relax the MEE requirement and to adequately treat the splitting problem by introducing swapping and splitting as valid transformations, bringing in something closer to Damerau-Levenstein distance instead of the Levenstein distance.

Table 1 Summary of methods for estimating IRR for time-sequence data type: criteria not met (✗), met (✓) and could be adapted (!) for requiring codes be mutually exhaustive and exclusive (MEE), the basic boundary problem (BBP), splitting boundary problem (SBP), disjoint boundary problem (DBP), and commission/omission errors (Com/Om)

Observer	!	✓	✓	✓	!	✗
Interact	!	✓	✓	✓	✓	✗
EasyDIag	!	!	!	!	✓	✓
GSEQ-DP	!	✓	!	✓	✓	✓

Conclusions

In this methodological review, we problematized existing methods for estimating inter-rater reliability (IRR) for specific kinds of time-sequenced data common to research programs in RUME. Our discussion distinguished between several kinds of low-level disagreements (errors of omission/commission, multiple interpretation problems, and boundary problems) that can occur when analyzing data qualitatively and what we consider true disagreements – which occur when both raters identify the same event but disagree on which code to apply. True disagreements may have implications for the stability of the coding scheme or speak to the need to re-calibrate the raters. The low-level disagreements should be sorted out through algorithms or quarantined for a reconciliation process between raters. We reviewed Cohen's κ and three methods for extending it for suitability by examining their strengths and weaknesses relative to how they handle the differing kinds of disagreements. While these methods have proven appropriate, and useful, to certain kinds of time-sequenced data, using any of these methods with fidelity would require a shift in research questions, a reduction in complexity of the coding scheme, or modification of procedures for applying the coding scheme.

We agree with Jansen et al. that "how one does reliability analysis depends on what research questions one needs to answer eventually" (2003, p. 394). The metric for estimating IRR should reflect the particularities of how the coding scheme is applied. Unfortunately, many of the measures for IRR make assumptions about the data or coding schemes that do not reflect the kinds of data that the RUME community works with nor the complexity of the coding schemes we develop to study problems of teaching and learning. Instead, researchers are restricted from asking and answering certain kinds of questions because the quantitative tools we have available do not suit the properties of the data. Ultimately, the field needs methods for estimating IRR that respect how the coding schemes are applied to the observational records and thereby comport with the research questions posed.

Students' Treatment of the Negation of Logical Implication

Rachel Arnold
Virginia Tech

Vladislav Kokushkin
Colorado State University

Anderson Norton
Virginia Tech

Joseph Antonides
Virginia Tech

Understanding how students reason about the negation of logical statements is essential in supporting their mathematical development. Prior literature suggests that undergraduate students experience difficulties with the precise negation of logical implications. Many respond with the opposite statement "P implies not Q" when asked for the negation of "P implies Q." We investigate the challenges that introductory proofs' students experience when negating implications, and the reasoning they demonstrate in addressing these challenges. Our findings indicate quantification contributes significantly to their difficulties with negation. Further, nuances in students' quantification may validate an implication's opposite as its negation.

Keywords: logical implication, negation, quantification, transition to proof

Understanding the negation of a statement is an essential skill in logical reasoning. For example, Dubinsky et al. (1988) assert that "in order to understand what something is, it is essential to understand what it is not" (p. 46). Prior research has identified the negation of mathematical statements—particularly logical implications (LIs)—as a persistent challenge for undergraduate students (Barnard, 1995; Griggs & Cox, 1983; Sellers, 2020). The negation of a statement is the statement that contradicts the original statement and excludes any middle ground (Dawkins, 2017). In other words, an LI and its negation have opposite truth values in all cases. However, students will sometimes present a contrary statement as a negation without satisfying the law of excluded middle. In particular, students might argue that the negation of P→Q is the statement P→~Q (Epp, 2003), which we refer to as the *opposite* of P→Q. The primary objective of our study is to understand students' ways of reasoning when negating an LI and the distinctions they make between counterexample, negation, and opposite.

The negation of a universally quantified LI is the assertion that a counterexample exists in the universe. To negate the LI P(x)→Q(x), one must specify the logical properties of a counterexample (P(x) and ~Q(x)) and additionally attend to the quantification of x.

Although students may generate specific counterexamples to statements like "If a number is a multiple of 3, then it is a multiple of 6" (Dawkins & Hub, 2017), there seems to be a significant cognitive gap between identifying a counterexample to an LI and articulating its precise negation. Prior research has documented students' persistent struggles with quantification in general (e.g., Dawkins & Roh, 2020; Dubinsky et al., 1998; Shipman, 2016), which suggests quantification may be a primary source contributing to this gap. However, there may also be other factors influencing the ways they perceive negation, opposite, and counterexample. To understand the nuances of students' treatments of the negation of an LI, we analyzed the reasoning demonstrated by two undergraduates enrolled in a Fall 2022 introductory proofs course taught by the first author. Our research questions were:

1. *Following research-based instruction in an introductory proofs course, what challenges do students experience in negating an LI; and what reasoning do they demonstrate as they address these challenges?*

2. *In particular, how do students experience and address the challenges identified in prior research on treating negation as the opposite statement?*

Framework: Epistemological Obstacles Associated with Negating LIs

Our framework presents the persistent challenges students experience with negating an LI as epistemological obstacles (EOs). The term EO originates in Bachelard (1938), and Brousseau (2002) later described EOs as obstacles that remain in response to best instructional practice. We further characterize EOs as experienced in best instructional interactions, by the student or the teacher. EOs are *persistent*; they cannot be resolved in a single lesson. Here we provide the supporting literature for existing EOs that are pertinent to this study.

Students make meaning of quantified statements in various ways (Sellers et al., 2021). Sometimes, they even interpret the language of quantification in ambiguous ways (Dawkins & Roh 2020; Epp, 1999). Other times, quantification might not be explicitly stated at all, so the intended quantification of a statement remains "hidden" (Shipman, 2016). When expressing LIs, we often say "P→Q" to mean "for all x, P(x)→Q(x)." It may seem that instructors could resolve the issue by consistently and explicitly stating quantification, but subtle differences in meanings of quantification persistently remain hidden for students. Dubinsky et al. (1988) described quantification as an "insurmountable barrier for students in developing a sophisticated understanding of limits and continuity" (p. 44). This description fits our characterization of EOs, and following Shipman (2016), we refer to this EO as hidden quantification.

As we have noted, a statement and its negation have opposite truth values, so negating a statement and generating counterexamples are inherently related (Shipman, 2016). Generating a counterexample for a given statement can be challenging, and when attempting to prove a universally quantified statement false, students will often claim that a single counterexample is insufficient (Zaslavsky & Ron, 1998). Sellers (2020) conjectured that this claim might relate to the recognition that a singular example is insufficient for proving a universally quantified statement is true. It may seem counterintuitive that the negation of a universally quantified statement is an existence statement, and the negation of an existence statement is a universally quantified statement. Thus, we see quantification of the negation as another potential obstacle.

The challenge of quantifying negations sharpens when we consider that the negation of a universally quantified statement encompasses *any* possible counterexample. That is why when proving a universally quantified statement, it is insufficient to show that a particular case is not a counterexample, or to simply modify the statement to bar that case (Shipman, 2016). It is also why the opposite of a statement does not suffice as its negation. Consider the universally quantified (hidden) LI, P→Q. Its opposite would be the universally quantified statement that P→~Q; but both statements could be false because they leave middle ground untouched (Dawkins, 2017). Because students ostensibly conflate the negation of a statement and its opposite—even after instruction in introductory proofs courses (Arnold & Norton, 2017)—we refer to it as another EO. Research suggests relying on Euler diagrams to sort out reasoning with LIs (Hub & Dawkins, 2018), but even Euler diagrams may have their limitations (Antonides et al., in review).

Methodology

The data reported here come from a larger study investigating the EOs that students experience, and ways of addressing them, in transition-to-proof courses. The class was taught by the first author in the Fall 2022 semester. Emphasizing active learning, the class was designed around four main topics: LI, quantification, mathematical induction, and functions. We identified

EOs suggested by existing literature and adopted or created instructional tasks for addressing those EOs head-on. Four students were interviewed three times by Norton and Kokushkin, with each video-recorded interview lasting 30-45 minutes. Students were given a LiveScribe pen and were asked to think aloud. The interview tasks corresponded to the four topics of the course; the third interview included tasks on mathematical induction and functions, as well as a stimulated recall interview (SRI) on a subset of tasks (chosen subjectively) from the first two interviews.

All interview data were coded to capture students' EOs. Our codebook (Figure 1) included codes both from existing literature and emergent codes that could not be explained using existing codes. This paper centers around the NO code, informed by existing literature; emergent codes were NF and LIv (Figure 1). Following the initial round of coding, we engaged in thematic analysis, analyzing contiguity of codes with the NO code.

Code	Description (Source)
LIv	Eliminating the vacuous case (Emerged)
NF	Difficulty with the difference between negation and disproof (Emerged)
NO	Treating the negation as the opposite, e.g., P→~Q (Dawkins & Hub, 2017; Epp, 2003)
Qh	Hidden quantification (Shipman, 2016; Durand-Guerrier, 2003; Ernst, 1984)
Qneg	Uncertainty about quantifying the negation (Dawkins & Roh, 2016; Shipman, 2016)
Reu	Interpreting logic via Euler Diagrams (Hub & Dawkins, 2018; Dawkins & Roh, 2021)

Figure 1. Codes.

We report on interview data from two students, Shivani and Carmen, a sophomore and senior majoring in Computational Modeling and Data Analytics and Aerospace Engineering, respectively. Shivani and Carmen were chosen because of the salience of their data vis-à-vis the negation-opposite conflation, and because their cases represent qualitatively distinct issues that may arise for students as they reason about the negation of an LI.

1. Consider the implication: P(x)→Q(x). What does it mean? How would you quantify it?
2. Consider the statement: "For all x, P(x)→Q(x)." How would you negate it?

Figure 2. Interview task.

Results

In this section, we present the details of Shivani's and Carmen's reasoning about an LI and its negation in response to the interview tasks shown in Figure 2.

Shivani's Treatment of Negation

When first asked what the unquantified LI P(x)→Q(x) meant to her (see Figure 2, Task 1), Shivani did not demonstrate an intellectual need for making the quantification explicit. She responded, "If P, then Q," and then elaborated to say, "So if P, if P is true then Q is true."

When the researcher asked how Shivani might quantify P(x)→Q(x), she drew a correct Euler diagram (Figure 3) and said, "So there exists… an x in the subset P. There exists an x... in... in P if uh... If there exists an x in P then x also exists in Q." Shivani saw $P(x) \rightarrow Q(x)$ as referring to a specific x and therefore quantified it existentially. Moreover, she restricted the universe to consider only those x in the truth set of P. She also seemed to quantify the *hypothesis* rather than the LI itself: "If there exists an x in P."

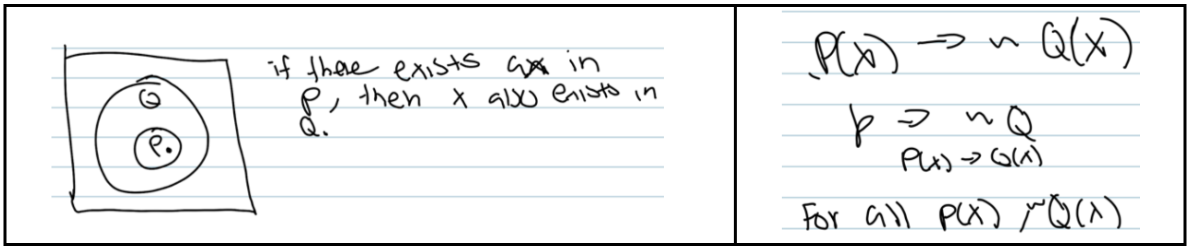

Figure 3. Shivani's Euler Diagram (left) and her corresponding writing (right).

When posed with Task 2 (see Figure 2), Shivani again omitted quantification saying, "So then it would be like P(x) implies ~Q(x) [writing '$P(x) \rightarrow \sim Q(x)$']. That would be a negation because the concl… hypothesis has to be true." Her emphasis on the hypothesis being true coupled with her earlier treatment of x, seems to indicate that, for Shivani, her negation requires x to be in the truth set of P. In an effort to unhide quantification, the researcher asked Shivani how she would quantify x. She responded,

> Since this is for all, then you would have to prove like, there exists one x value that makes this statement true [pointing to her written negation '$P(x) \rightarrow \sim Q(x)$' (Figure 3)]... Because then that would be the counterexample because you wanna disprove it…Because you only need one counterexample to prove that for all x.

For her, the existentially quantified LI $P(x) \rightarrow \sim Q(x)$ represented the existence of a counterexample. When the researcher asked how her negation might be quantified if the original LI was existentially quantified, Shivani adjusted her negation to "For all P(x), ~Q(x)." Shivani demonstrated her understanding of how quantification of the original LI affected the quantification of her negation. And, her use of "for all P(x)" seemed to indicate that Shivani was again requiring x to belong to the truth set of P. Regardless of how the original LI was quantified, when quantifying x in her negation, x belonged to the truth set of P, not simply the universe.

Carmen's Treatment of Negation

Like Shivani, Carmen initially quantified the LI $P(x) \rightarrow Q(x)$ existentially saying, "This means that there is some point in P, some point x in P, that is also in Q." Note that Carmen also restricted the universe to the truth set of P, the values for which she saw the LI as relevant. Then, the researcher asked Carmen to reason about Task 2 (see Figure 2). She responded as follows.

> So we're saying that for every single x, in the set of P... So if... for all values of x, P(x). So this would mean that P would be a subset of Q… [draws an Euler diagram] So I can negate this by saying... what is it? It's P(x)... So we would negate this by keeping the... hypothesis true, saying that P(x) is still true. And then... you can negate this by saying and not Q(x). I think that's how you negate this. Because saying that... um... Yes. And the 'and' is important, because this means that P(x) has to be true, and not Q(x) has to be

true. So you're saying that you are in P(x), but you're not in Q(x), so that would be negating the P(x) and being in Q(x).

Carmen correctly stated the negation as P(x) and ~Q(x), emphasizing the importance of the connective "and." However, she did not explicitly quantify x, so the researcher prompted her.

If we're saying for all x, and you want to negate it... I... think the negation... because you're not trying to find like a counterexample, you're just trying to negate it. I think you could say for every x… in P... and that's what you could say for every like for every x... in this set of, like a universal set, I guess. Maybe not... For every x in P... I'm not good at writing them out. Because I think… that with negations, you're trying to find a way that the original statement, like, not necessarily the opposite, but just like an alteration, I guess, to the original statement, or I don't think you're like looking for a counterexample. Because that would just be proving that the original statement will be false. So if negating it, you… it's still for every x, in... in the universe of... for x is in the universal set.

Carmen struggled to quantify her negation, expressing that negating the LI was different than finding a counterexample or disproving it. She felt that the negation should be a statement about every x (questioning whether x is in P or x is in the universe). Ultimately, Carmen settled on universal quantification, but never stated her full negation. So, the researcher (R) probed Carmen's (C) distinction between disproving the LI and finding its negation.

C: To show that that's false, I would just find one x ...um, that is in P(x), but it's not in Q(x).

R: And that's not necessarily the same as the negation?

C: I don't think so. Because that's just a counterexample. Yes, I think the negation is just kind of like doing the opposite of what it's asking for. It's not necessarily like… it's not asking you to prove that something is false or to make it or it's like asking you to rewrite this statement that would, in a way that would make it false, not asking you to prove that it is false. I guess...

Carmen understood that to disprove the LI, she needed just one counterexample. Unlike disproving, finding the negation for her entailed "rewriting" the statement to "make it false." To understand her emerging distinctions between negation, counterexample, and opposite, the researcher followed up with Carmen two months later during her SRI, presented here.

C: With a counterexample, you choose one specific value. So I think that's the difference between being the opposite and negation. So you have one specific value that you're looking at, but with a negation, you're saying that something is the opposite. You keep it arbitrary, because you kind of want to show like, for all umm so but with like a counterexample, you just say, okay, my k value or whatever equals a specific number. And that's why it's, it's false, because I can show that it doesn't work. Like for this one specific case.

R: Okay. Does that mean that negation and opposite are the same thing?

C: Um, I don't think... I know that they're not the same thing. Because opposite would be like hot and cold, right? ... But, I think a negation... I'm trying to remember...

R: What if I want to negate "hot"? How would I negate "hot"?

C: You can negate it in many ways. You could say warm, cold... or warm, hot, you could say, cold or freezing or stuff like that. So that's a negation because it's not hot. But if you want to just say it's opposite of hot, then you have to go to cold.

R: So if I want to do a counterexample of "hot", I would say, I would find an example of something that's not hot… If I wanted to do the opposite of "hot', I would show everything is cold…And if I wanna show the negation of ‘hot”, I would show everything is “not hot”.

C: Yes.

Carmen used the example “not hot” to explain her distinctions between counterexample, opposite, and negation. In suggesting “you can negate it in many ways,” Carmen seems to be referring to all possible counterexamples. Carmen still universally quantified her negation.

Discussion

The above data suggest that students’ reasoning about the negation of an LI can be influenced by multiple factors, including students’ difficulties with (hidden) quantification, reliance on Euler diagrams, reducing the universal set to the truth set of the hypothesis, and uncertainty about the distinctions between negation and proving false. In what follows, we present the discussion of three main findings that emerged from our thematic analysis.

Difficulty with (Hidden) Quantification

Consistent with prior literature, our participants experienced challenges in recognizing the hidden quantification of $P(x)\rightarrow Q(x)$. Shivani omitted quantification of both the LI and its negation. Carmen explicitly quantified the LI, but neglected the quantification of its negation. This finding confirms that quantification may significantly influence students’ ability to articulate the precise statement of negation.

Ultimately, both Shivani (when prompted) and Carmen existentially quantified $P(x)\rightarrow Q(x)$. Shivani supported her reasoning by drawing an Euler diagram and saying “if there exists an x in P.” Carmen did not rely on drawings. Nevertheless, her language for quantifying x (“there is some point in P, some point x in P, that is also in Q”) referenced an implicit use of an Euler diagram as well. This may indicate that students interpret $P(x)\rightarrow Q(x)$ as referring to a specific x, whereas $P\rightarrow Q$ might be universally quantified. The necessity to refer to a specific x may result in overlooking the vacuous case, which is crucial in distinguishing between the negation and the opposite (Arnold & Norton, 2017). This observation echoes our previous finding that reliance on Euler diagrams may hide the vacuous case (Antonides et al., in review).

Reducing the Universal Set to Only Those Values in Truth Set of the Hypothesis

Prior research has documented students’ struggles with the vacuous case. Hoyles and Küchemann (2002) found that students often view the vacuous case as irrelevant. Dawkins et al. (2023) reported a tendency for students to treat an LI as a statement only about the truth set of its hypothesis. Furthermore, Norton et al. (2022) explicated the nuances of students’ apparent conflation of the truth of an LI with the truth of its hypothesis. Our analysis suggests that students may omit the vacuous case not merely because of an apparent conflation, but rather because they focus only on values for which they view the LI as relevant. Reducing universe to the truth set of the hypothesis yields students’ treatment of the negation as its opposite logically correct—a finding not previously reported.

Both students focused on x values for which P(x) was true (coded as LIv). Shivani said, “if there exists an x in P” and “for all P(x), ~Q(x),” while Carmen stated, “there is some point in P, some point x in P” and “for every x in P.” For us, the LIv code emerged as students’ elimination of the vacuous case. However, in furthering our analysis, this treatment is closely related to the above prior research. Students’ focus on only values for which the hypothesis is true is consistent with their prior experience of using LIs (via *modus ponens*) to deduce new conclusions. This tendency could explain why students seemingly conflate the negation of P→Q with its opposite P→~Q. In fact, when students restrict the universe U to the truth set of P, the negation "∃x ∈ U such that P(x) and ~Q(x)" is logically equivalent to its existentially quantified opposite "∃x ∈ P such that P(x)→~Q(x)." This opposite statement is indeed the negation.

Universal Quantification as a Distinction between Negation and Proving False

Carmen's unquantified negation, P and ~Q, was correct. But, when prompted to quantify it, Carmen chose universal quantification (and further elaborated in her SRI). She consistently made distinctions between negation and proving false. She explained that negation is an "alteration" of the original statement "that would make it false." Perhaps because the original statement was about all values in the universal set and the negation was an "alteration" of this statement, Carmen reasoned that the negation should also be universally quantified. While existential quantification is indeed an assertion about the state of the universe, because Carmen associates "there exists" with a specific x, she may have felt that existential quantification of the negation would not be a broad enough statement about the universe.

When the researcher asked Carmen to distinguish between opposite and negation in her SRI, she gave the example of "not hot," saying "you can negate it in many ways" (e.g. warm or cold). This language may indicate that Carmen sees negating as a collection of all the ways one might say a statement is false. If Carmen was viewing negation as the collection of *all* possible counterexamples, then this might also explain her choice of universal quantification.

Implications and Future Research

We have discussed how EOs related to attending to quantification, treating the vacuous case, and making distinctions between negation and proving false may significantly influence students' treatment of negation. Nevertheless, there are other potential factors that may contribute to students' conception of negation. Such factors include treating an LI as an action (Norton et al., 2023), students' difficulties with transforming LIs (e.g., Durand-Guerrier, 2003), understanding the Principle of Universal Generalization (Norton et al., 2022), and others. Future research should shed light on the effect of these factors on students' reasoning about negation.

Our findings suggest potential instructional interventions. Teachers might draw attention to the distinction between using an LI to draw conclusions (modus ponens) and determining the validity of an LI. In particular, they might emphasize that the latter requires considering all values in the universal set U, not just values in the truth set of P. To make explicit their tendency to narrow their focus to only those values in P, students might compare and contrast the logical difference between "∃x ∈ U such that P(x)→~Q(x)" and "∃x ∈ P, such that P(x)→~Q(x)."

Measuring Mathematical Knowledge for Teaching College Algebra at Community Colleges

Vilma Mesa

Irene Duranczyk
University of Minnesota

Kimberly M. Wingert
RMC Corporation

The VMQI Research Team[1]

We present preliminary findings regarding the dimensionality of a 34-item instrument designed to measure the mathematical knowledge used in teaching college algebra at community colleges and the performance of items within the instrument. The instrument assumed a six-dimension model with two organizers of knowledge, one related to knowledge needed to perform two specific tasks of teaching, choosing problems *and* understanding student work, *and the other related to knowledge of three function types,* linear, exponential, and rational functions*. Multidimensional item response theory models were applied to a sample of 416 community college mathematics instructors. A three-dimension model structured by function types better fitted the data than a unidimensional model. Two- and six-dimensional models, structured by the tasks of teaching or the combination of function types and tasks of teaching, did not converge so they are not discussed. We discuss implications and work to further validate the instrument.*

Keywords: mathematical knowledge for teaching, college algebra, community colleges

Our project (Mesa et al. 2020) sought to develop and validate an instrument to measure community college faculty knowledge of teaching college algebra (MKT-CCA). Theoretical work on teacher knowledge has hypothesized distinct components of such knowledge (e.g., pedagogical, curricular, and content, Shulman, 1986) but empirical support has been elusive (e.g., Copur-Genturk et al., 2019). While there is a consensus that such knowledge should be multidimensional, and multiple efforts that further specify content or pedagogical knowledge according to cognitive level, knowledge type, or mathematical topic have flourished (Ball et al., 2008 [MKT]; König et al., 2011 [COACTIV]; Krauss et al., 2008 [TEDS-M]; Saderholm et al., 2010 [DTAMS]), the question about multidimensionality remains open (Schilling, 2007).

Using an approach that focuses on content-specific teacher decision making (e.g., in high school algebra or geometry), Herbst and colleagues (e.g., Herbst & Chazan, 2012; Ko & Herbst, 2020; Herbst & Ko, 2019) have empirically shown that teachers' mathematical knowledge used in two tasks of teaching are distinguishable via two distinct (albeit correlated) measures for knowledge needed to choose givens for a problem and understanding students' work in geometry. They surmise that the main challenge previous studies had in developing multiple measures is related to their knowledge-type-based framework given that there is no clear boundary among the types (e.g., common and specialized content knowledge) and that teachers need to use multiple dimensions of knowledge simultaneously in the moments of teaching. Grounding their work on the notion of instructional exchanges, they seek to understand, from the teacher's perspective, how knowledge is "transacted" in classrooms. Herbst (2006) notes that in their role as teachers, they are expected to provide students with activities or assignments that

[1] The VMQI Team: Vilma Mesa, Claire Boeck, Inah Ko, University of Michigan; Patrick Kimani, April Ström, Laura Watkins, Maricopa Community Colleges; Irene Duranczyk, Bismark Akoto, Siyad Gedi, Dexter Lim, University of Minnesota; Mary Beisiegel, Oregon State University

would support the development of mathematical ideas and that as students produce work in response to those activities and assignments, teachers must interpret the work to ascertain whether the student has learned or not. These two activities, choosing problems and understanding students' work, require teachers to sort through their own mathematical knowledge to make decisions that are guided by the goal of the instructional situation at stake.

We took this perspective in the design of an instrument that would assess community college instructors' knowledge of college algebra topics for teaching (Mesa et al., 2023). The core tasks of teaching used in this study are choosing problems and understanding student work. We defined *choosing problems* as a task of teaching that requires instructors to select activities or assignments that represent mathematical ideas accurately and give students opportunity to work on a mathematical idea at stake. Further, we defined *understanding student work* as a task of teaching that requires instructors to make sense of the ideas that students produce, either orally or in writing, and evaluate their mathematical correctness. Each task demands knowledge specific to teaching mathematics. Choosing problems requires knowledge about mathematical ideas presented in the problem, and about how to assess if ideas in the problem align with an instructional goal. For understanding student work, an instructor needs to have knowledge about interpreting students' work, typical errors students make, various strategies for solving a problem and how they could be represented, and the mathematically correct answer. We grounded these two tasks of teaching in three different types of functions, linear, rational, and exponential functions, as they are foundational to college algebra and for further work in mathematics. In this paper, we document the process of validating the structure of the instrument, seeking to identify whether there are indeed six distinct dimensions of mathematical knowledge for teaching, through the hypothesized organization along two tasks of teaching and the three function types (see Figure 1).

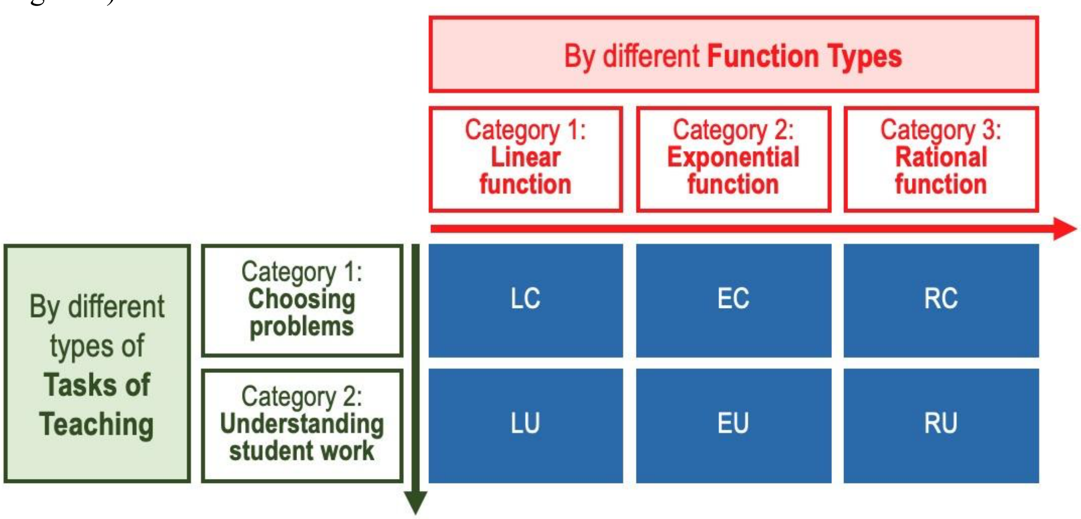

Figure 1. Blueprint for the development of the MKT-CCA instrument. (Mesa et al., 2023)

Methods

The instrument was developed over a two-year period that included an item development camp (13 practitioners, 11 researchers, 240 items), cognitive interviews to improve the items (12 instructors, 36 items), solicitation of situations and student work (15 instructors, 12 items), expert review of the mathematical content (2 mathematicians, 36 items), piloting (120 instructors, 60 items), and further revision of the items (see Figure 2).

Mr. Trevena is creating a lesson about applications of exponential functions. Which of the following news headlines would be the most likely to provoke a discussion about exponential growth patterns? **Choose one option only.**

A. Census data show that the population of the city tripled from 1970 to 1980 then doubled from 1980 to 2000.

B. Prices have increased 7% over the past 5 years, while usage of public transportation has decreased 5% over the same period.

C. Twice as many single people ages 20-25 are living with their parents today as they were 20 years ago and economists predict this trend will continue.

D. The water level of the local river has increased by 13% in the past decade and 35% during the past 30 years.

(a)

Ms. Ucci's class has just finished discussing the notation of $f(t)=a(b)^{rt}$ and the meaning of parameters and variables for exponential functions. To assess her students' understanding she gave them this task:

A radioactive substance decays according to the function $A(t)=100(1/2)^{(1/5)t}$ where t is measured in years and $A(t)$ denotes the amount of the unstable portion of the substance in micrograms at t. What is the meaning of ⅕ in the function?

Which of the following students' responses demonstrates a correct understanding for the meaning of ⅕? **Choose one option only.**

A. ⅕ means that the substance needs to decrease four more times to get to half of its original amount.

B. ⅕ means that ⅕ of the substance *A* is left after half of a year.

C. ⅕ indicates that it will take five years for the substance *A* to reach its half life.

D. ⅕ means that ⅕ of the substance A has decayed in half of a year.

(b)

Figure 2. Sample items in exponential function addressing (a) choosing problems and (b) understanding student work.

The final instrument included 34 items (27 multiple-choice items (MC) and seven testlets (T), resulting in 55 different questions) that were balanced across the six hypothesized dimensions (see Figure 3).

		Function type (#MC, #T)			Total
		Linear	Rational	Exponential	
Task of teaching	Choosing Problems	3, 2	5, 1	3, 3	11, 6
	Understanding Student Work	5, 1	5, 0	6, 0	16, 1
Total		8, 3	10, 1	9, 3	27, 7

Figure 3. Total number of multiple-choice items (MC) and testlets (T) per dimension in the final instrument.

We invited a sample of 4,350 instructors teaching from 752 different institutions to complete the instrument. The sample was constructed to ensure representation of the diversity of the colleges in terms of size, location, and diversity of the student population. The data were collected between October 2022 and March 2023. We obtained responses from 954 participants. Data were excluded if (a) the participant's position as an instructor at a community college could not be verified (n=185), (b) it was a duplicate response (n=85), (c) the participant entered their assigned ID but did not complete any portion of the survey (n=91), (d) the participant indicated that they had never taught college algebra (n=17), or (e) the participant responded to the 34 items in less than 1,200 seconds (*n*=20). There were 556 teachers who responded to some portion of the instrument after these data exclusions were applied. Final analyses focused on the 416 teachers who responded to all 55 questions on the MKT-CCA instrument. Accuracy on each question was submitted to a 2PL multiple item response theory (MIRT) model using maximum likelihood estimation in Mplus (Muthén & Muthén, 1998-2023). The dimensionality of the instrument was tested using likelihood ratio tests comparing alternative models. The six-dimensional model, where each factor represents one task of teaching and one function type, and two-dimensional models, where each factor represents one task of teaching, did not converge. The three-dimensional model included correlated factors, with each factor represented by a set of function-type items (linear, exponential, and rational). In the one-dimensional model all items were loaded onto one factor. Items were considered for deletion when the item did not provide much information and had a low discrimination estimate (less than 0.61, indicating low ability to differentiate teachers).

Results

The sample included faculty from 260 different community colleges in 43 states with 50% enrolling a majority of non-White students; 47% of the colleges were located in a city, about a quarter (26%) in a suburb, and the rest in rural (12%) or small towns (14%); most of the colleges were in the West (37%) or South (36%), with 19% located in the Midwest, and 9% in the Northeast region of the United States. Forty-eight percent of the participants identified as male, and 46% as female; in terms of race, 76% identified as White, 10% as Asian, 4% as Black, 2% as mixed, and 4% chose Other. Seventy-eight percent of the participants held full-time positions; 32% had a temporary appointment, and 9% were on tenure track. The average number of years of teaching experience was close to 17 years (mean=16.76, SD = 9 years; range: 1.5 to 47 years). The majority (63%) held a master's degree in mathematics, mathematics education or another mathematics related field, and 12% held PhDs (about 5% were in Mathematics Education.)

Discrimination and difficulty within the item response theory (IRT) paradigm are indices of item performance. Discrimination gives a measure of the differential capacity of an item, that is the ability of the item to differentiate participants by their ability level. The discrimination is the slope of the item response function graph (i.e., the item characteristic curve); the higher values suggest that the item has a high ability to differentiate examinees. Values of discrimination are reported as positive numbers (i.e., a negative value would be concerning because the probability of getting the answer correct should not decrease as ability increases). Difficulty is defined as the ability level at which we would expect examinees to have a probability of 0.50 (assuming no guessing) of selecting the correct response to the item. The higher the difficulty is, the higher the ability required from an examinee to have a 50% chance of answering an item correctly. Values of item difficulty typically range from –3 to +3; items with difficulty close to –3 are very easy items; items with difficulty close to +3 are very difficult for the pool of examinees. The discrimination values from the 3-dimensional model across the whole set of 55 items ranged from 0.183 to 2.555, whereas the level of difficulty of the full set of items ranged from –4.914 (very easy) to 2.140 (difficult).

The three-dimensional model including all 55 MKT-CCA items fit the data significantly better than the one-dimensional model, $\chi^2(3) = 12.37$, $p < .01$. The Akaike's Information Criterion (AIC) and sample size adjusted Bayesian Information Criterion (BIC) also favored the three-dimensional model. Four items contributing to the linear latent factor, seven items contributing to the exponential latent factor, and six items contributing to the rational latent factor were identified for deletion. The discrimination for all items considered for deletion was less than .61. After removing these 17 items, indicators representing the accuracy on the remaining 38 items were submitted to a final 2PL multidimensional IRT(MIRT) model using maximum likelihood estimation. As before, the three-dimensional model fit the data significantly better than the one-dimensional model, $\chi^2(3) = 9.93$, $p = .02$. The AIC and sample size adjusted BIC also favored the three-dimensional model. All item discrimination parameters were greater than .61 in this final model on the reduced set of items. Examination of the total information curve for each dimension (see Figure 4) revealed that the MKT-CCA instrument provided good coverage of a wide range of latent ability levels, but the test provided the most information about teachers with lower mathematical teaching knowledge. A total of 15 out of 16 of the linear items had negative difficulty parameters (below average MKT-CCA is needed to have a 0.5 probability of getting the item correct), 12 out of 14 of the exponential items had negative difficulty parameters, and all the rational items had negative difficulty parameters. The discrimination across the retained 38 items ranged from 0.612 to 2.472, whereas difficulty level ranged from -3.465 (very easy) to 2.181 (difficult).

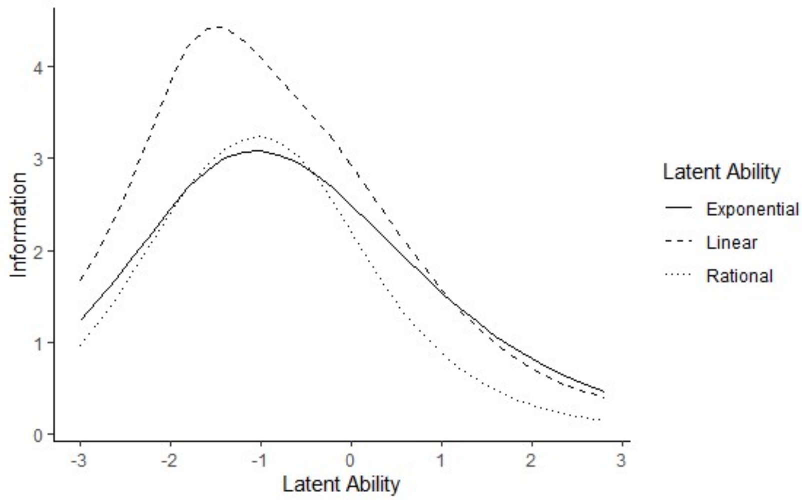

Figure 4: Total information curves for the three dimensions of the final model.

Discussion

The six-dimensional model did not converge, potentially because the sample size was insufficient. While the three-dimensional model fit the data better, we still need to further examine whether the three dimensions do really correspond to distinct function types, given that our hypothesized two-dimensional model was by tasks of teaching, and not about whether the types of functions were distinct. In other words, we need to rule out that the items that are purportedly designed to assess a specific function type, assess that function type and not others.

A two-dimensional model by tasks of teaching did not converge; in other words, it was not possible to differentiate knowledge along the two dimensions associated with choosing problems or understanding student work. We believe that this might be due to how we operationalized the choosing problems dimension, relative to the work by Ko and Herbst (2020) who focused exclusively on choosing givens (set of givens that had enough information for students to solve the problem) for problems in geometry. Such specificity might have contributed to make a clear distinction possible in Ko and Herbst's context. In our study, choosing problems is a task of teaching that requires instructors to select activities or assignments that include much more than specific givens, and thus our broader definition of a task may cause multidimensionality within the choosing problems dimension: that is in crafting items about choosing problems, we may have triggered knowledge related to understanding students' work.

As is apparent in Figure 4, we found that, overall, the instrument was not very difficult even though the instrument allows us to discriminate between high and low scorers. Because of resource limitations, and the need to reach faculty in multiple institutions in the United States, we administered the instrument online (instead of in person), which might have contributed to the test not being as difficult, as we believe that participants might have used resources such as textbooks or online applications to respond to the items, even though this was discouraged. Despite this, we believe that the instrument could be a promising tool to examine community college faculty knowledge for teaching these types of functions and design content-focused faculty professional development.

Next Steps

Our next steps in the validation process include conducting cognitive interviews with participants and testing the model with a population without teaching experience. With the cognitive interviews, we plan to validate our hypotheses about how instructors with or without the hypothesized knowledge would answer a randomly selected set of items. In doing so, we plan to corroborate that instructors who answer the item correctly are doing so because they have the needed knowledge, and that when an item is answered incorrectly, is because the instructor does not possess such knowledge. In randomly selecting the items, we will be able to establish the generalizability of the instrument. Moreover, cognitive interviews will allow us to shed light regarding possible ways in which the two tasks of teaching we hypothesized were intertwined in ways that instructors could not call on one or the other task of teaching independently of each other.

To determine whether there is something special about the instrument as related to community college mathematics faculty, we administered the test to a sample of 100 undergraduate students, who would be knowledgeable of the mathematics, but who did not have any teaching or tutoring experience. We are in the process of analyzing the data to identify whether the samples behave similarly or not. We anticipate major differences in the modeling, which would further confirm that the instrument is useful to assess knowledge for teaching these types of functions at community colleges.

As part of the data collection process, we gathered background information about faculty and their teaching experiences, their history of courses taught, their educational background, engagement in professional development, and their beliefs about mathematics, its teaching, and its learning. Further analysis of these data will shed light about how these characteristics relate to performance on the instrument by different groups of instructors, which would corroborate prior findings relating associations between courses community college faculty teach and performance on instruments assessing teacher knowledge (Ko et al., in press). Such analysis will provide further validation for the dimensionality, difficulty, and discrimination of the instrument.

Guided Reinvention of the Definitions of Reducibles and Irreducibles

Kaitlyn Stephens Serbin Younggon Bae Sthefania Espinosa
The University of Texas Rio Grande Valley

Informed by Realistic Mathematics Education, we designed a hypothetical learning trajectory on graduate students' guided reinvention of reducible and irreducible elements in unique factorization domains. We created experientially real tasks for use in a teaching experiment, in which students used algebra tiles as an emergent model of factoring integers and quadratics in $\mathbb{Z}[x]$. *In students' mathematical activity, this became a model for abstracting the shared structure of (ir)reducible elements in* $\mathbb{Z}$ *and* $\mathbb{Z}[x]$, *which students used as they formally defined (ir)reducibles.*

Keywords: Realistic mathematics education, abstract algebra, hypothetical learning trajectory

Abstract algebra courses that serve in-service and prospective teachers (IPSTs) should guide IPSTs to reason about the advanced content in a way that helps them reshape their understanding of secondary mathematics (Wasserman, 2018). Abstract algebra can be beneficial for helping teachers develop unified understandings of algebraic concepts that span K-16 curricula, such as the factorization of integers and polynomials (e.g., Murray et al., 2017; Novotná & Hoch, 2008; Usiskin, 1974). The Common Core State Standards of Mathematics (National Governors Association & Council of Chief State School Officers, 2010) suggested that teachers should teach students to "understand that polynomials form a system analogous to the integers" (p. 64). An abstract algebra course can support IPSTs in recognizing properties shared by the sets of integers ($\mathbb{Z}$) and polynomials with integer coefficients ($\mathbb{Z}[x]$). $\mathbb{Z}$ and $\mathbb{Z}[x]$ are *unique factorization domains* (UFD), defined as an integral domain R in which every nonzero element $r \in R$ that is not a unit has the following two properties: (i) r can be written as a finite product of irreducibles p_i of R (not necessarily distinct), $r = p_1 p_2 \dots p_n$. (ii) The decomposition in (i) is unique up to associates: namely, if $r = q_1 q_2 \dots q_m$ is another factorization of r into irreducibles, then $m = n$, and there exists some renumbering of factors so that p_i is associate to q_i for $i = 1, \dots, n$ (Dummit & Foote, 2004). Reasoning about UFDs could help IPSTs better understand the properties related to factorization of elements in $\mathbb{Z}$ and $\mathbb{Z}[x]$, e.g., the fundamental theorem of arithmetic and the fundamental theorem of algebra. Before one can understand this structure of UFDs, they need to understand the structure of irreducible and reducible elements. An *irreducible* is a nonzero, non-unit element r of an integral domain R such that if $r = ab$ with $a, b \in R$, then a or b must be a unit in R. A *reducible* is a nonzero, non-unit element r of an integral domain R such that we may write $r = bc$ for $b, c \in R$ and neither b nor c is a unit.

There has not yet been research done on how IPSTs can define the shared structure of factorability of the elements in $\mathbb{Z}$ and $\mathbb{Z}[x]$. We address this by investigating how graduate student IPSTs reinvent the definitions of irreducibles and reducibles. We used the instructional design theory of Realistic Mathematics Education (RME; Freudenthal, 1991; Gravemeijer, 1999; Gravemeijer & Doorman, 1999) to design a hypothetical learning trajectory (Simon, 1995) of how IPSTs can reinvent the definitions of reducibles and irreducibles. This is part of a larger project in which we designed a local instructional theory (Gravemeijer, 2004) guiding IPSTs to reinvent UFDs in connection to their teaching. We address the following research questions: *Which aspects of the task sequence support IPSTs' reinvention of (ir)reducibles? Which ways of reasoning are productive to leverage to guide IPSTs toward reinventing (ir)reducibles?*

Literature Review

Reasoning about the properties of abstract algebraic structures can help IPSTs develop more robust understandings of the secondary algebra content they teach. Researchers have shown how reasoning about the properties of algebraic structures can help students or IPSTs develop unified understandings (Lee & Heid, 2018; Zandieh et al., 2017) of secondary mathematics content. Having a *unified understanding* of a concept involves recognizing the shared overarching structure of the concept among different instantiations of that concept in different contexts and being able to reason about that concept generally without needing to reference a specific context. Cook et al. (2023) identified students' unified ways of reasoning about the structure of inverses shared by different instantiations of that inverse concept. Serbin (2023) showed how reasoning about the group axioms supported IPSTs in recognizing the shared overarching identity structure shared by additive, multiplicative, and compositional identities. Several other researchers have explored students' unified understandings of algebraic concepts, including homomorphisms (Melhuish et al., 2020), linear transformations (Bagley et al., 2015; Zandieh et al., 2017), and binary operations (Wasserman, 2023). These studies illustrate how students and IPSTs reason about the shared structure of various algebraic concepts in different contexts.

We aimed to guide IPSTs to recognize the structure shared by certain types of integers and polynomials, those that are composite or factorable (reducibles) and those that are prime or not factorable (irreducibles). There has been minimal research done on students' understanding of reducible and irreducible elements. Two studies (Lee, 2018; Lee & Heid, 2018) explored the coherence of students' understandings of the factorization of integers and polynomials as instantiations of the decomposition of elements in integral domains. Lee (2018) investigated how students developed a unified understanding of factoring across elementary, secondary, and tertiary contexts. The students who perceived factoring whole numbers and factoring polynomials as disparate procedures could later recognize the shared structure of factorization of elements in integral domains. Juxtaposing integers and polynomials allowed the students to reflect on parallel structures within the sets, such as primes and irreducibles, composites and reducibles, and prime factorization and irreducible factorization. The students developed unified understandings of the shared structure of integers and polynomials as integral domains in which not every element had a multiplicative inverse. Lee and Heid's (2018) study informed our study design that guides IPSTs to identify the shared structure of primes and irreducible polynomials, as well as composites and reducible polynomials, to reinvent irreducibles and reducibles.

Theoretical Background

Design Research (Gravemeijer et al., 2003) involves a cycle of designing sequences of mathematical tasks to be used during instruction, implementing the task sequences, analyzing students' learning, and revising the task sequences based on the student learning outcomes. In designing the task sequence, design researchers develop a Hypothetical Learning Trajectory (HLT), which consists of the learning goal, the learning activities, and the hypothesized thinking and learning that students might engage in as they perform the activities (Simon, 1995). Through the process of designing, implementing, and revising HLTs, researchers can discover students' ways of thinking that anticipate formal mathematics and identify ways to leverage those ways of thinking to guide students' development of formal concepts. Our design of an HLT is guided by the instructional design theory of RME (Gravemeijer, 1999), which conceptualizes mathematics as a human activity. The HLT is designed based on the three RME heuristics: 1) experientially real tasks, 2) emergent model, and 3) guided reinvention. Experientially real tasks allow the students to connect with their informal knowledge, developing an intuitive understanding that will help them create an emergent model for use in that given context, defined as a *model-of* their situated activity. The emergent model shifts from being *model-of* a student's activity to a *model-for* formalizing mathematics as students mathematize their mathematical activity (Zandieh & Rasmussen, 2010). *Horizontal mathematization* involves "describing a context problem in mathematical terms to be able to solve it with mathematical means" (Gravemeijer & Doorman, 1999, p. 117), and *vertical mathematization* involves "mathematizing one's own mathematical activity" (p. 117). Design researchers create experientially real tasks that require horizontal and vertical mathematizing by which students, with guidance, can reinvent mathematical concepts.

Mathematizing occurs as students engage in mathematical activity, such as defining and conjecturing (Rasmussen et al., 2005). Defining is a process of formulating, negotiating, and revising a definition (Zandieh & Rasmussen, 2010). Freudenthal (1973) described two types of defining: descriptive and constructive. In *descriptive defining,* students build a definition by suggesting ideas about an object's properties, and the instructor helps organize and clarify such ideas. *Constructive defining* involves students modeling a new object by using prior examples or ideas. Rasmussen et al. (2005) deemed descriptive defining as horizontal mathematizing, in which the student organizes their ideas into a structured definition, and constructive defining as vertical mathematizing, where students abstract and generalize previously organized activities to create a new concept. Descriptive defining (horizontal mathematizing) grounds the context for students to progressively advance their activity to constructive defining (vertical mathematizing).

Methods

We designed an RME-based HLT with the goal of guiding students to reinvent the definitions of reducibles and irreducibles. We created "experientially real" tasks related to a high school/college algebra context that used algebra tile manipulatives. These tasks were designed to help the IPSTs develop an intuitive understanding of the mathematical concepts and engage in mathematical practices of defining and conjecturing, which would support them in the process of formalizing them. We made conjectures of students' reasoning for each of the designed tasks in our task sequence. We tested this HLT by administering tasks to IPSTs in a teaching experiment (Steffe & Thompson, 2000) conducted in a Hispanic-serving institution in the Southern US. Six mathematics graduate student IPSTs participated in this study. They all took Abstract Algebra courses at the undergraduate or graduate levels but have not learned UFDs in their coursework. They were grouped into three pairs (Group A with Josie and Raul, Group B with Javier and Roberto, and Group C with Kim and Taylor). Groups A and B participated in person, and Group C participated on Zoom. In-person groups were given physical algebra tiles, and the virtual group was provided with an online whiteboard and virtual algebra tile manipulatives.

The research team consisted of a teacher-researcher (TR), secondary instructor, and research assistant. The TR's role was to guide the session, provide students with prompts to work on, and ask follow-up questions to better understand and clarify the students' thinking. The research assistant operated the video camera and took field notes. The secondary instructor observed, took field notes, and asked questions to students when needed. We collected and transcribed the video recordings of fifteen 1.5-hour sessions of the teaching experiment (five sessions per group). The groups' written and virtual whiteboard work was collected. We used inductive coding (Miles et al., 2013) to analyze participants' reasoning, mathematizing, and the development of emergent models as they used algebra tiles in the task sequence. We focused our analysis on students' ways of reasoning that were leveraged by the TR to guide them to reinvent (ir)reducibles. In what follows, we describe the design of each task set in the HLT, how they were informed by RME, and the high-leverage student reasoning (italicized) evident in students' responses.

Results

Task Set 1: Contrasting Composite and Prime Integers

The experientially real tasks in Task Set 1 (see Figure 1a) were designed to help students develop an intuitive understanding of the factorability of integers as they use the emergent model of algebra tiles. The students created a *model of* factoring irreducibles and reducibles as they manipulated algebra tile representations of integers or quadratics in $\mathbb{Z}[x]$. Tasks guided students to see some integers, like 12 represented by 12 one-unit-squared tiles joined together, can be arranged into rectangular arrays where its factors are the side lengths of the rectangle. The first way of reasoning evoked was that *the factors of an integer correspond to the possible side lengths of the rectangular array that represents the integer*. This is evident in group C:

Kim: My thought process is just like, how are all the different ways that…you can factor 12, like with different, with smaller decompositions of numbers.

TR: … how does the factor translate to this rectangle concept here?

Taylor: It's length times width, right? That's what I would think of it. You know, 3 times 4 and 4 times 3, and 1 times 12, and 12 times 1, and 6 times 2, and 2 times 6.

When Kim and Taylor worked on problem 1, they recognized that 12 could be represented in different rectangular arrays that each had side lengths of the different pairs of factors of 12.

This led to their second high-leverage idea was that *the rectangle that was 12 units* $\times 1$ *unit was essentially the same as the rectangle with dimensions of 1 unit* $\times 12$ *units due to the commutativity of integer multiplication*. This is evident in this transcript from group A:

Josie: Do these count as two separate ones?

TR: That's a great question. So you're saying, 1 by 12, is that the same as 12 by 1?

Josie: …Well, I figured…multiplication is commutative, so they're exactly the same.

Josie and Raul thought that two rectangles with dimensions from the same factor pair were essentially the same, so they did not count as two different rectangles. This idea was used in the next task, 2a (see Figure 1), which was designed to help students recognize that prime numbers of square tiles can have only one arrangement that forms a rectangular array. Josie explained:

> Numbers that can only be written in one way would be the prime numbers. They don't have too many factors. They only have that one and itself. And if we're only counting like the- the 1 by 5 as the same as 5 by 1- that's really the only way you can do it.

Josie used the aforementioned way of reasoning that rectangular arrays with the same dimensions counted as the same representation to justify her claim that *numbers that could only be represented in one rectangular array must be prime*. This claim is the third way of reasoning that could be leveraged toward guiding the students to reinvent reducibles and irreducibles. Once the students recognized that those types of integers were prime, they used that way of reasoning in task 2c to identify the difference between the integers that could only be represented in one rectangular array and the integers that could be represented in many rectangular arrays. Josie responded, "The amount of factors that they have. Primes only have 1 and the number itself, and composites have at least 2." This elicited the way of reasoning that *the difference between the integers that could only be represented in one rectangular array and the integers that could be represented in many rectangular arrays was whether they were prime or composite*. This is the first instance where they use the emergent model (the algebra tiles) as a *model for* identifying the differences between irreducible and reducible elements in $\mathbb{Z}$. Overall, these tasks were designed to prompt the students to contrast the primes and composites using the emergent model. We posit that making this contrast is an essential waypoint in guiding students to reinvent (ir)reducibles.

a) Task Set 1	1. Find all the possible ways that the number 12 can be represented using rectangular arrays of squares. 2. Like the number 12, some numbers can be written in many different ways using rectangular arrays of squares. But some numbers can only be written in one way. a) Find several numbers that can only be written using one rectangular array of squares. b) Find several numbers that can written using different rectangular arrays of squares. c) What is the difference between these two kinds of numbers?
b) Task Set 2	1. Try to arrange these quadratics in a rectangular array using algebra tiles. Each side length of a rectangular array cannot be a constant number and must include the variable x. a) $3x^2 + 9x$ b) $x^2 + 3x + 3$ c) $2x^2 + 4x$ d) $x^2 + 4x + 3$ e) $x^2 + 5x + 7$ 2. What is the difference between the quadratics you **can** arrange into a rectangular array and the quadratics you **cannot** arrange into a rectangular array? Make a conjecture. 3. Give 3 examples of quadratics whose algebra tile representations could be arranged into rectangular arrays. 4. Give 3 examples of quadratics whose algebra tile representations could NOT be arranged into rectangular arrays. 5. Does your conjecture from Task 2 about the arrangement of the algebra tiles hold true for these examples? 6. You conjectured that: *A quadratic can be arranged into a rectangular array with algebra tiles if and only if the quadratic is factorable*. Let's test this conjecture with the following quadratics. a) $x^2 - 4$ b) $x^2 - 2$ c) $x^2 + 4$ 7. Refine your conjecture: *Quadratics can be arranged into a rectangular array with algebra tiles iff:*
c) Task Set 3	1. What similarities can you see between the integers that can be represented in different rectangular arrays and the quadratics that can be represented as a rectangular array with algebra tiles? 2. What similarities can you see between the integers that can only be represented in one rectangular array and the quadratics that cannot be represented as a rectangular array with algebra tiles? 3. We can name the first type of integers and quadratics that can be represented as a rectangular array as "**reducibles**." We can name the second type of integers that can only be represented in one rectangular array and quadratics that cannot be represented in any rectangular array as "**irreducibles**." We will formally define these terms soon. When irreducible integers can be arranged into a rectangle, one of its side lengths must be 1 or –1. These numbers are called "**units**." Definition: An element of a ring is called a unit if it has a multiplicative inverse. In a ring, an element is either 0, a unit, an irreducible, or a reducible. What are the units of $\mathbb{Z}[x]$, the ring of polynomials with integer coefficients? 4. We can name the first type of **integers** and **quadratics** that can be represented as a rectangular array as "reducibles." Create a definition for a reducible. 5. We can name the second type of integers that can only be represented in one rectangular array and quadratics that cannot be represented in any rectangular array as "irreducibles." Define irreducible.

Figure 1. The three task sets in the HLT's task sequence.

Task Set 2: Contrasting Reducible and Irreducible Quadratics in $\mathbb{Z}[x]$

The tasks in Set 2 guided students to use the intended emergent model of algebra tiles as a *model of* factoring quadratics in $\mathbb{Z}[x]$ by attempting to arrange quadratics into rectangular arrays. The students recognized $3x^2 + 9x$, $2x^2 + 4x$, and $x^2 + 4x + 3$ can each be arranged into a rectangular array, where each side length of a given array is a factor of the quadratic, whereas $x^2 + 3x + 3$ and $x^2 + 5x + 7$ could not be arranged into a rectangular array (see Figure 2). The tasks had them find the difference between these quadratics and guided students to conjecture *(a) quadratics that can be factored can be arranged into a rectangular array where the factors of the quadratic are the side lengths of the rectangle and (b) the quadratics that cannot be factored cannot be arranged into a rectangular array.* The conjectures are high-leverage ways of reasoning that can be used to support students in reinventing (ir)reducibles. Kim used these:

> For the quadratics that you can arrange in a rectangular array, the quadratic is factorable, … if you have a quadratic you cannot arrange into a rectangular array, then…it is not factorable… if the quadratic is factorable, then you can arrange it in a rectangular array.

This discussion led group C to refine their conjecture to be "A quadratic can be arranged into a rectangular array with algebra tiles if and only if it is factorable." The tasks guided students to consider quadratics that are factorable over $\mathbb{R}$ but not over $\mathbb{Z}$, which cannot be arranged into a rectangle, which led them to revise their conjecture to specify the set over which the quadratic was factorable: *A quadratic can be arranged into a rectangular array with algebra tiles if and only if the quadratic is factorable over the integers*. These tasks guided the students to contrast irreducible and reducible quadratics in $\mathbb{Z}[x]$ to help them develop intuitive understandings of the difference between them in this set. Making this contrast is a high-leverage way of reasoning that is an essential waypoint in guiding students to reinvent the definitions of (ir)reducibles.

Task Set 3: Comparing and Defining Reducibles and Irreducibles in $\mathbb{Z}$ and $\mathbb{Z}[x]$

The tasks in Set 3 (see Figure 3) were designed to guide students to abstract and generalize the structure shared by reducible elements in $\mathbb{Z}$ and $\mathbb{Z}[x]$, as well as the structure shared by irreducible elements in $\mathbb{Z}$ and $\mathbb{Z}[x]$. The tasks prompted students to identify similarities among the modeled representations of the integers and quadratics in $\mathbb{Z}[x]$ that could be arranged into rectangular arrays with non-unit side lengths. Roberto responded, "They're factorable in the integers… one of them is composite, so it can be written in different ways, and the quadratics can be represented as a rectangular array." Prompting students to identify the similar structure of the modeled composite integers and quadratics allowed students to recognize that *integers and polynomials of this type can be factored or reduced into a product of integers or polynomials of lesser degree*. This way of reasoning about the reducibility property of these types of integers and quadratics can be leveraged to guide the students to reinvent the definition of reducibles.

In task 2, the students were asked to identify similarities among the modeled representations of the integers and quadratics in $\mathbb{Z}[x]$ that could not be arranged into rectangular arrays with non-unit side lengths. Javier responded, "Prime integers can be represented in [one] rectangular array. Like when 7 can be 1 times 7… quadratics that cannot be represented as a rectangular array with algebra tiles can be thought of as prime polynomials, such as $x^2 + 4$" (see written work in Figure 3). Prompting students to identify the similar structure of the modeled prime integers and quadratics led them to recognize that *prime integers and quadratics of this type have the same characteristic of not being factorable into a product of integers or polynomials of lesser degree*. This way of reasoning about the irreducibility of these types of integers and quadratics can be leveraged to guide students to reinvent the definition of irreducibles. These tasks intended to evoke a transition in the students' emergent model (i.e., the algebra tiles), provoking the students to use their *model of* factoring integers and quadratics in $\mathbb{Z}[x]$ as a *model for* abstracting the shared structure of reducibles and irreducibles, which could be used to define those concepts.

Before the tasks could guide students to formally define (ir)reducibles, the students needed to understand the concept of a unit in a ring because the definitions refer to a factor being either a unit or not. Task 3 gave the students the definition of a unit and prompted them to identify the units of $\mathbb{Z}$ and $\mathbb{Z}[x]$, which are 1 and -1 in both sets. Once the students had this terminology of "unit" they could use in their definition drafts, tasks 4 and 5 guided students to leverage their prior conjectures to give rough draft definitions of reducibles and irreducibles. The students iteratively refined their definition drafts with support from the TR's pedagogical moves of scaffolding, poking holes in arguments, posing counterexamples, pressing for precision, encouraging the definitions to be nonredundant and generalizable, and making sure any example of the concept satisfied the definition. Josie's five drafts of definitions of reducibles, which progress from using informal to more formal mathematical terminology, are shown in Figure 4. Overall, task set 3 were designed to engage students in constructive defining and vertical mathematizing, i.e., further mathematizing their previous conjectures about properties of reducibles and irreducibles in pursuit of reinventing and defining reducibles and irreducibles.

Discussion and Conclusion

This study shows how the task sequence and TR's pedagogical moves guided the students' reinvention of the definition of reducibles and irreducibles by facilitating their high-leverage reasoning about reducible and irreducible properties of integers and polynomials. The sequence of three task sets prompted students' reasoning in identifying and abstracting the reducibility/ irreducibility of integers (Task Set 1) and quadratics in $\mathbb{Z}[x]$ (Task Set 2). In particular, the experientially real tasks using algebra tiles evoked students' development of emergent models *of* factorizing integers and quadratics, which transitioned to become models *for* identifying and refining their conjectures about the shared structure of integers and quadratics (Task Set 3). In this process, TR's pedagogical moves played an essential role in developing the emergent models and facilitating students' mathematizations (Gravemeijer & Doorman, 1999) by helping them to make sense of their mathematical activities of creating and interpreting algebra tile models (horizontal mathematization) and by guiding them to formalize their conjectures of the shared structure of integer and quadratics in their definitions of reducibles and irreducibles in an integral domain (vertical mathematization). This finding suggests a hypothetical learning trajectory of students' reinvention of definitions in advanced mathematics by eliciting and leveraging students' reasoning in experientially real tasks. Future studies can extend the findings of this study by refining the task design and implementation and by examining different types of high-leverage reasoning that can also guide students in learning trajectories.

We're All Human, So Why Does Equity Matter?

Mary E. Pilgrim

San Diego State University

Charles Wilkes II
San Diego State University

There is a need for mathematics instructors in higher education to have more equitable teaching practices. One way to address this need is through equity-centered professional development (PD). Using interviews across one year of professional development (PD), we describe how three immigrant mathematics instructors grapple with incorporating equity in their teaching practice using Gutiérrez *(2009) four dimensions of equity. We found that the instructors focused primarily on awareness and access with respect to equity but did not understand how to infuse equity in their practice. We also found that three themes, the discipline of mathematics, all students are human, and the identities of the instructors and beliefs seem to serve as barriers for instructors' implementation of equitable practices. Future research might consider how PD could be informed to account for the themes found in this study.*

Keywords: equity, identity, two-year college, community college

"It doesn't matter what my race is. Um, or my gender, because, you know, I'm teaching a subject that I feel is just it's universal. So it really does not matter." This quote came from a two-year college mathematics teacher. The statement is not surprising, and, in some cases might even be expected, as mathematics as a discipline has historically been positioned as universal, unbiased, and politically neutral. The implication being that mathematics is accessible to everyone. While this perspective is common, it is problematic as it removes any accountability or responsibility that the role mathematics as a discipline plays in *what* it means to do mathematics and *who* can do mathematics. This perspective is transmitted to individuals that attain advanced degrees in mathematics and to the students they teach. Having this perception makes it difficult to understand why equity is important in the teaching and learning of mathematics.

In this paper we focus on three two-year college mathematics instructors who are immigrants. We sought to understand how they negotiate their perspective of mathematics, which is closely aligned with the opening quote, when trying to understand and incorporate equity in their classrooms. The research question that guides our paper is: *How do instructors think about their teaching practices while grappling with tensions around self-identities, as well as personal experiences with and beliefs about mathematics as a discipline?*

Literature Review

Even as efforts are being made to advance STEM fields toward a more humanistic and equitable endeavor, mathematics tends to resist transformation more than other fields. One possible explanation can be traced back to how mathematics is perceived in society. Leyva and colleagues (2021) argue that mastery of mathematics is often seen as a precursor to one's social standing and frequently used as a measure for intelligence. Similarly, Moses and Cobb (2002) liken math literacy to civil rights, emphasizing its societal importance. Hence, when discussing mathematics as a discipline, we need to recognize the high esteem in which it is held in society and how it functions as a form of cultural capital.

In the pursuit of equity in mathematics education, it is crucial to examine four key characteristics: the universality of mathematics, the understanding of what it means to engage in mathematical practices, the historical exclusivity of the discipline, and its inherent political nature, especially as these factors relate to the often-understudied context of immigrant instructors in community colleges. First, mathematics is often conceptualized as universal. That is, mathematics is often portrayed as a universal discipline, suggesting its omnipresence and accessibility to all, irrespective of race, gender, or any other identity markers (Baber, 2015). The second characteristic to consider when thinking about equity in math education is understanding what it means to do mathematics. Understanding what it means to do mathematics is critical as there is often a misalignment between what it means to do mathematics and how mathematics is taught (Brown et al, 1989). The contrast between the two – school mathematics and the authentic practice of mathematics outside of the classroom – highlights the tension that exists between what it means to do mathematics and how it is taught in the classroom. The third characteristic is who can do mathematics. Historically the discipline of mathematics has been exclusive, highlighting that only certain individuals can do or are good at mathematics (Ernest, 1989; Martin, 2009; Hottinger, 2016; Nasir & Shah, 2011). The fourth characteristic is recognizing that mathematics is political (Gutierrez, 2013). The classroom is more than just a site for social reproduction and enculturation. Rather, it is a space where power dynamics, identity, and cultural constructs intersect. Indeed, mathematics inherently carries political aspects and power dynamics similar to other human activities. Collectively we argue these four characteristics inform instructor's teaching practices and how they conceptualize equity. Additionally, we build upon the literature by focusing on a population and context that is often understudied in mathematics education, immigrant instructors in mathematics and community colleges.

Theoretical Framing

The four dimensions of equity is a framework as described in Gutiérrez (2009) articulates considerations for equity in mathematics education. The framework highlights four components, access, achievement, identity, and power. The components are divided into two axes—the dominant axis and the critical axis. The dominant axis represents the prevalent emphasis for equity in mathematics education which centers on access and achievement in which access precedes achievement. Access refers to ways in which students can participate in mathematics. This includes students engaging with teachers, curriculum, and resources. Indeed, access may impact achievement. Achievement attends student outcomes such as grades and scores on standardized tests and can highlight ways in which students may demonstrate their mathematical knowledge. While the dominant axis is important, Gutiérrez acknowledges that it is only one half of equity in mathematics education. The second axis which is referred to as the critical axis, includes identity and power, where identity precedes power. Identity refers to the social markers of students and teachers, as well as their lived experiences, and cultural socialization. Understanding and incorporating students' identities is important to attend equity. Power, the last component, highlights the power and agency that both students and teachers have and how teachers can use their power to ensure that classroom instruction is inclusive and attends to the identities of students.

Methods

The Mathematics Persistence through Inquiry (MPIE) project is a five-year NSF-funded project that is using design-based research to build and implement a professional development (PD) program for two-year college mathematics instructors. The focus of the PD program is on supporting the development of inquiry- and equity-focused teaching practices. Goals of the project are to 1) study a two-year college's response to a state-mandated change in gateway mathematics courses (College Algebra, Precalculus, and Trigonometry), 2) use cycles of design research to build the capacity of math instructors in the two-year college to foster student success, and 3) investigate the effects of the capacity-building effort. In this paper we discuss participants' perspectives on equity, which are connected to their own personal experiences and relationships with mathematics, and, in turn, impact their teaching practices.

Setting and Context

The setting of this research project and PD efforts is a two-year Hispanic Serving Institution (HSI) in the Southwestern United States. In this paper we will refer to this institution as Southwestern HSI (SHSI). SHSI serves a student population that includes a majority of students from historically minoritized communities including Latinx students (68%) and students from low-income households (70%). PD participants include SHSI instructors who primarily teach gateway mathematics courses.

The MPIE PD program is a two-semester program running through the fall and spring terms. The participants discussed in this paper participated in the MPIE PD during the fall 2021 and spring 2022 semesters. All were math instructors at the SHSI, most of whom taught a variety of courses including gateway mathematics courses. The fall semester PD focused on inquiry-based teaching and learning with participants meeting six times, two hours each (for a total of 12 hours). In the spring, the PD shifted to an equity and inclusive emphasis, with participants meeting 4 times, 1 hour each (for a total of 4 hours). The reduced PD session time in the spring allowed for individual classroom observation and debrief sessions.

Data

For this paper we present three case studies: Paul, Nhung, and Savana. We selected them as cases because they are all immigrants with unique experiences that seemed to have shaped their beliefs about and ultimately their teaching of mathematics. The beliefs they shared highlighted a tension between their perspectives on what it means to do mathematics, what mathematics affords as a discipline, and the role of equity in disrupting their perspectives. Below is a brief description of each participant.

- Paul is a full-time mathematics instructor who grew up in Tijuana, Mexico and identifies as a Latino who has been perceived by others as white in some spaces and Latino in others, which has created a complex, dual identity for himself. He has taught a variety of courses at SHSI for more than two decades.
- Nhung is a full-time mathematics instructor who spent the first 11 years of his life in Vietnam before coming to the United States as a refugee. He has taught a variety of courses at SHSI for more than a decade.
- Savana is a part-time mathematics instructor who grew up in a large family in Tijuana, Mexico and was in the first generation in her family to attend college. She has taught a variety of courses at SHSI for more than two decades, as well as at other local colleges.

The data examined from the participants are three, one-hour interviews each across two semesters of PD. The first interview occurred after the fall PD, the second interview occurred before the start of the spring PD, and the third interview occurred after the conclusion of spring PD. Each interview was semi-structured and designed to capture information around the instructor's teaching background and style, mathematics experiences, equity beliefs and practice, and inquiry beliefs and practices.

Analysis

Each author on this paper read through a set of three interviews for at least one of the three participants, so that each set of interviews were analyzed by two different researchers. First round of coding involved members of the research team writing memos so that common themes regarding equity and identity could be identified, with Gutiérrez's four dimensions of equity as a guiding framework. After discussion, the themes of *self-identity, math as unbiased/universal, we are all human*, *awareness,* and *access* were identified as themes that appeared in each participant's data. Below we unpack how these themes address our research question.

Findings

These themes all arose across the three interviews from each participant that were used for data analysis. We present them in an order to help provide context for each participant, highlighting how their personal experiences and perspectives show up in their teaching practices.

Identity Impacting Practice

All three participants identified as immigrant teachers - each grew up in another country and then became a teacher in the United States. Their unique experiences growing up and becoming immigrant teachers has played a role in their teaching, impacting their practice and the way in which they interact with their students.

Paul. Paul grew up in Mexico and identifies as biracial. In Mexico he experienced racism and marginalization. Often referred to as "Gringo" or "El Blanco", he struggled to fit in or feel like he belonged in his high school classes. As a 15-year-old, he took a difficult physics class which he ended up failing. During a class period towards the end of the term his Physics teacher stated in front of the class that "The American white boy failed physics. So now he's going to learn what it is to be oppressed and what it is to be privileged." This experience was "hurtful" to Paul and has impacted his choices and values as a teacher. As a teacher at an HSI on the border with Mexico, he knows that there will be students in his class that will likely have an identity or experiences like his own. Having such students in his class is an opportunity for him to connect and provide the support students might need. He is fluent in Spanish and will share his identity with his students to let them know that he also has experienced challenges in his education.

Nhung. Nhung spent his childhood in Vietnam. He was 11 years old when his family moved to the United States (US). Growing up speaking Cantonese, he knew very little English at the time. Thus, as a student in US schools, he struggled in his classes and had multiple uncomfortable experiences when being called on during class. The language barrier made it hard to "verbalize" his thinking and these negative experiences impacted his confidence and learning processes. Mathematics classes usually did not pose the same level of difficulty for him, given the reduced amount of English vocabulary. However, he did struggle to read and interpret contexts presented in mathematical word problems, which made it difficult to apply the appropriate mathematics. These past experiences impact how Nhung teaches. For one, he never wants to put students in a position where they feel singled out and uncomfortable. And second, he wants to be available to help students if they are struggling and need additional support. He goes further to say "I feel like I can relate to students better because…the adjusting to classrooms in the United States is just something that I have a little bit more appreciation maybe for what they have to go through."

Savana. Savana was born and raised in Mexico. She was the youngest of 13 children and grew up in a traditional household. Neither of her parents were formally educated, so learning and writing were unfamiliar to them. Her father believed that the priority for women was to focus on family, children, and the home, but her mother viewed education as important. Savana embraced both values in her own life - family and education. Thus, Savana attended school through community college in her hometown of Tijuana, and then moved to the US to pursue her dream of becoming a teacher. This was not easy. She did not speak English, but she was motivated. She had a "dream…[to] teach math", and even though she did not know the language, noting that it "was really, really challenging", she strived to follow her dream. This aspect of Savana's identity is a big part of who she is and impacts how she interacts with students. She wants students to know and understand that pursuing an education (especially when not in your native language) is "not easy, but it can be done. If we work hard." Savana shares this story with her students, hoping it will motivate them to continue pursuing their education.

Mathematics is Universal and We're All Human

An interesting theme that arose across the interviews was the idea that anyone can do mathematics and that mathematics is a neutral subject. In fact, Nhung felt that mathematics is "unbiased", and that success is achieved with enough "time and effort". He went further to note that that was one of the motivating reasons for joining a PD that had a focus on equity - he wanted to understand how such a neutral subject could have inequities.

The notion that mathematics is a neutral subject was also intertwined with the idea that "we are all human". When asked about how she thought about race, Savana stated that she did not think about race and went further to say: "We are all the same. We're all human beings. We're all the same." While Paul had a similar sentiment, he situated it in the classroom setting about engaging with mathematics and promoting student success. Paul noted the sameness in which he wants to support students while still monitoring biases he may have:

> I'm trying to break the stereotype by, by trying to be okay now we can- no be the same with everybody. Be the example, communicate the same way with everybody, treat everybody with the same level of respect, communicate with the same level of acknowledgement of respect. Don't focus on only a handful of students or one gender. Everybody's the same, everybody's equal. We all belong to one to race the human race. If I, if I make sure that everybody to me is a human, that right there is helping me keep myself in check and avoid falling into those biases, those stereotypes. And if they see that I'm doing that and, and it's encouraging them to succeed.

Throughout PD, Nhung struggle with the idea of inequity existing in the mathematics classroom:

> I just have always seen myself as I'm just a math teacher. Right. It doesn't matter what my race is. Um, or my gender, because, you know, I'm teaching a subject that I feel is just it's universal. So it really does not matter.

Although all participants had this idea of mathematics being universal or we are all human, they each acknowledged the inequities that they themselves had experienced as students or inequities they recognized as being present in mathematics as a discipline. These inequities shaped their identity as mathematics teachers, and, in turn, impacted how they interact with students.

Getting Stuck: Awareness and Access

Throughout the interviews it was clear that Paul, Nhung, and Savana increased their understanding and awareness of classroom equity issues as they progressed through the PD.

Participants seemed to think about equity as access to opportunities. An instance that captures such awareness that was developed early on is when participants were provided with an image, which is now ubiquitous, showing two cartoon panels. In one panel, there are three children trying to look over a fence to see a baseball game. The children are of different heights, and each child is standing on the same type of box to try to look over the fence. Although each has a box to stand on, not all can see over the fence. In a second panel, each child is standing on a different size box that will allow for them each to see over the fence. Although this image does not capture equity as a concept in its entirety, it provides an entry point to a conversation about equity, especially for those who are new to having such discussions. It was this image that gave Paul clarity about equity in the classroom for the first time.

> And they showed the [cartoon description] and I thought to myself, by the way, please forgive me if I if I release a colorful metaphor, because I really get worked up about this. But I was thinking, "God damn w– we've been doing this all along! We've just been giving everybody the same box!" But hey look– there's tutoring, whoopie! Hey look– we have workshops, yee haw! But if students have different needs, how can we bring them up to the same level instead of just giving everybody the exact same opportunity? That's when it clicked, that's how it's done.

Paul realized that giving all students the same opportunities was not what it meant to attend to equity. He worked to meet the students where they are, and part of this process was allowing students to participate in ways that they feel comfortable. This notion of opportunity and comfort was also reflected in Nhung's and Savana's interviews.

Nhung felt that being equitable was giving "students the opportunity to learn" through group activities guided by "leading questions". He believed that each of his students were capable of the same achievement with enough practice, time, and effort. However, Nhung began to struggle with his definition of equitable teaching once he began to realize the varying levels of preparedness in his students, which impacted their ability to take advantage of such opportunities. He noted,

> Well, when you interact with students when you recognize that they are not as prepared to take advantage of those opportunities. Right? And now I see where some of it is falling short. But I don't really know how to address it yet.

While Nhung felt opportunities were important, he recognized that giving students the same opportunities did not address the gap that existed between students. Nhung struggled with this tension stating:

> Right. But it's not just equal opportunity. Right. Because if you start further up than someone else, and both of you are presented with the … same opportunities, you are going to rise or at least you have the opportunity to rise, um, at a greater rate than someone else who started way behind.

This tension caused Nhung to shift his perception of equitable teaching slightly, adding the caveat that students who entered his class with gaps in prerequisite knowledge just needed more chances to work one-on-one with him as the teacher. He further notes that if students "elect to not interact with" him, he will leave them alone and not "bother them". From Nhung's perspective one-on-one attention was a way to elevate students to a level commensurate with their classroom peers. Savana had similar sentiments stating that equity "means being able to provide every student what they need", which may be unique to each student. Ultimately Nhung viewed issues related to equity as access issues and students just needed opportunities to engage with mathematics. Savana, like Nhung, recognized that students were at different ability levels and felt that support needed to be customized based on a student's specific needs. However, while Nhung struggled to attend to students' needs because one-on-one help during class was difficult to accomplish for all students, Savana expressed not knowing how to begin to attend the issue.

> How do I help the student that, um, you know, uh, that has, I don't know, anxiety and, and, and, and just being asked to, to talk in front of the class, you know, makes just asking that person, a question, you know, uh, may block him and, and not be able to, you know, to, to, to follow, you know, what I'm doing. So it's, so it's so, uh, challenging

By the end of the first year of PD not much had changed with perceptions of equity in the classroom. Paul, Nhung, and Savana all discussed increased awareness about equity in their teaching, but little change could be seen in the data across their interviews. All continued to see increasing access to engaging through participation in mathematics as the key piece to attending to equity in the mathematics classroom.

Discussion

Paul, Nhung, and Savana provide an important description for what it means for immigrant mathematics instructors in higher education to grapple with incorporating equity in their teaching practices. Although each instructor had increased awareness with regard to what it meant to attend to equity in the classroom, at the end of their first year in PD that awareness was limited to focusing on increasing access to mathematics. This translated in their practice through their teaching by having more one-on-one interactions with students and encouraging more questions and discussion from students (as they felt comfortable).

There are several factors that might contribute to this limited view of equity in the classroom. Through themes identified across Paul, Nhung, and Savana, one potential barrier seems to be their own personal identities, beliefs, and experiences. The perspective that mathematics is unbiased or universal makes it difficult for the instructors to understand how shifting teaching practices beyond more "opportunities" would help attend to equity. This idea is further validated as Paul, Nghung, and Savana succeeded academically and professionally, in part because they took advantage of opportunities and were motivated. As a result, this view makes it difficult for these instructors to shift their practice beyond creating opportunities and encouraging participation.

Conclusion

Math is political and it is important for instructors to understand their own identity, power, and responsibility when implementing equitable teaching practices. In this paper, instructors highlight a tension that exists between their own identities, beliefs, and experiences, and the common narratives that exist within mathematics (e.g., mathematics is universal). Understanding these tensions and the deep-rooted impact that historical norms and beliefs about mathematics have given us a better understanding of how to reframe aspects of ongoing PD to try to get instructors to move beyond *awareness* and *access* and towards practice that also incorporates Gutiérrez's critical dimension (*identity* and *power*).

Undergraduate Students' Use of Generative Artificial Intelligence in Proving

Jihye Hwang

Seoul National University

Oh Nam Kwon
Seoul National University

In this paper, we explore how undergraduate students use and evaluate generative artificial intelligence (genAI) in proving. We view proving as a human activity and proof as a production of proving, and hence, we believe that students need to be the ones who evaluate the genAI-generated arguments and write their proofs. In the initial phase of research on genAI in proving, we conducted interviews with three undergraduate students to examine how they use genAI in proving and how they write their proofs after their use of genAI. This study revealed that there is a flow in students' use of ChatGPT in proving, and there are factors that impact their use of genAI. We think that the flowchart presented here can serve as a guide for both teaching and research on the use of genAI in the context of proving.

Keywords: Artificial Intelligence (AI), Undergraduate Students, Proving, ChatGPT

Since the end of 2022, when a generative Artificial Intelligence (genAI) tool became public, ongoing discussions about the role of AI in education have accelerated. People started viewing genAI as a tool that can both benefit and hinder students' learning. As the prevalence of the use of genAI in education is inevitable, it is important to consider how educators can help and guide students' responsible use of genAI in education. Based on its affordances (e.g., instant feedback or personalized learning) and limitations (e.g., wrong information or ethical issues), we believe that students should be able to be aware of the pitfalls of AI tools and critically evaluate responses generated by AI tools.

We chose proving as our research context because proving is a context where students need to persuade themselves and convince others (Bieda & Lepak, 2014; Hanna, 2000; Hersh, 1993). Using the feature of genAI that provides instant conversation, it can be used as a good tool to practice convincing each other. Another benefit of using a genAI as a tool in proving can be that it does not necessarily involve negative human interactions with the user. For example, when students ask questions to their instructors or fellow students, power relationships exist between them. Then, some students may take mathematical statements and proofs from the authorities, including instructors, peers, or textbooks, without questioning them (Weber & Mejia-Ramos, 2014). On the contrary, using AI might help students feel more agency and authority by being free from those power dynamics because there is no human behind the tool and their (intentional or unintentional) judgment about the student. Thus, communicating with genAI can become a place where students can have authority in evaluating the argument if used appropriately.

As there have been only a few, if any, studies regarding the use of AI in undergraduate mathematics-level proving tasks, this study initiates exploring this area. We investigated the following research question: *How would undergraduate students use ChatGPT when they are proving a mathematical statement?* Through the study, we call for more conversation about the use of genAI tools in proving by proposing a set of aspects to be considered when using genAI in proving and how those aspects are connected and interact with each other, by revising the IDEE framework by Su and Yang (2023).

Backgrounds and Theoretical Perspectives

In this section, we review 1) the affordances and limitations of genAI, 2) our perspectives on proving, and 3) a framework for using a genAI in proving by modifying the IDEE framework (Su & Yang, 2023).

Affordances and Limitations of GenAI in Education

As emerging of genAI tools was recent, at the end of 2022, which is about a year ago, not much research exists in education in general, and even less in mathematics education. The most common form of current research articles is examining genAI as a tool for education to find affordances and limitations. Researchers viewed that genAI could be of benefit to students' learning, including but not limited to the following: 1) provide personalized and interactive learning environment tailored to individual students' preferences and levels (Baidoo-Anu & Owusu Ansah, 2023; Qadir, 2023; Su & Yang, 2023); 2) provide generate formative assessment tools (Baidoo-Anu & Owusu Ansah, 2023; Qadir, 2023); and 3) provide instant feedback (Baidoo-Anu & Owusu Ansah, 2023). GenAI tools, however, have some limitations and challenges as well. First, several researchers pointed out that genAI can provide wrong information depending on the data set that it was trained in (Baidoo-Anu & Owusu Ansah, 2023; Qadir, 2023; Su & Yang, 2023). Researchers claimed that the accuracy of genAI responses would be lower in complex tasks (Su & Yang, 2023). Second, ethical concerns exist regarding using genAI, such as plagiarism and overreliance (Qadir, 2023), bias in the data set (Baidoo-Anu & Owusu Ansah, 2023), users' privacy (Baidoo-Anu & Owusu Ansah, 2023; Qadir, 2023; Su & Yang, 2023), and equity issues (Cooper, 2023; Qadir, 2023).

Based on this review, as mentioned previously, we view the critical use of genAI as a skill for students to take advantage of the tool, and hence, we aimed to provide a guide for the goal.

Proving and Proofs

In this study, we viewed proving as human activities with the goal of generating proofs. By proof, we adapt the definition of Stylianides (2007). Stylianides defined mathematical proof as

> … a mathematical argument, a connected sequence of assertions against a mathematical claim, with the following characteristics: 1. It uses statements accepted by the classroom community (*set of accepted statements*) that are true and available without further justification; 2. It employs forms of reasoning (*modes of argumentation*) that are valid and known to, or within the conceptual reach of, the classroom community; 3. It is communicated with forms of expression (*modes of argument representation*) that are appropriate and known to, or within the conceptual reach of, the classroom community. (p. 291).

The key point of this definition is that an argument can be referred to as proof when it is approved by the classroom community, which is their mathematical community. It aligns with other researchers' arguments that a mathematical argument becomes proof when a mathematical community agrees on it (Weber & Mejia-Ramos, 2014). From this perspective, what genAI produces is a mathematical argument, but it does not become proof until a mathematical community sanctions it. In other words, students who use genAI become the first person in the line who gets to decide if the generated argument can be qualified as a mathematical proof considering the three components mentioned in the definition of proof before they present this to other people. Thus, the subject who writes and presents mathematical proof should be and is a person, not genAI.

IDEE Framework

Su and Yang (2023) suggested a theoretical framework as a guide to using generative AI in education. The framework has four aspects:

Identify the Desired Outcomes. Identifying the objects of generative AI before using it.

Determine the Appropriate Level of Automation. Automating teaching or learning experiences using generative AI or using it as a supplement to traditional teaching methods, depending on the objectives.

Ensure Ethical Considerations. Considering ethical implications of using generative AI, including potential biases and their impact on teachers and students.

Evaluate the Effectiveness. Evaluating the effectiveness of generative AI in achieving the desired outcomes.

While the IDEE framework (Su & Yang, 2023) is for teaching and learning in general education, this study focuses on students' use of generative AI in the context of mathematical proof. We interpreted the framework by focusing on (1) mathematics education, more specifically for students' proving, and (2) students' use of generative AI for their learning. Thus, the following is our interpretation of the IDEE framework.

Identify the Desired Outcomes. Identifying the objects of generative AI before using it when proving mathematical statements

Determine the Appropriate Level of Automation. Deciding the ways to use generative AI and the extent to which they want to take from what generative AI generates depends on the objectives.

Ensure Ethical Considerations. Students' recognition of potential ethical issues, such as determining whether using generative AI for homework aligns with academic integrity.

Evaluate the Effectiveness. Evaluating the effectiveness of generative AI in achieving the desired outcomes when proving mathematical statements.

Methods

Data Collection

Participants. In July 2023, we conducted individual interviews with three participants, Yuna, Jiho, and Kitae (all pseudonyms), from two different universities in Korea. All of them were freshmen mathematics education majors. Yuna was a woman, and Jiho and Kitae were men. Yuna took a Linear Algebra course, which she described as a proof-based course, as well as Calculus I, and the other two took only Calculus I.

GenAI. We used ChatGPT 3.5 as a genAI in this study because it was the most commonly used genAI in Korea at the time of data collection, July 2023.

Interviews. At the beginning of the interview, students were given six mathematical statements, mostly from number theory and one from advanced calculus. The statements were written both in Korean and English. Students were asked to choose one or two statements they wanted to prove or disprove and allowed to use any resources. We did not ask them to use ChatGPT for this part to see if it occurs naturally for them. However, none of them used the ChatGPT in the first part, so we asked them if they were aware of the tool and had used it. All of them said they had used ChatGPT before, so we asked them to use ChatGPT for proving tasks, observed how they used ChatGPT, and evaluated the argument generated by ChatGPT. During the interviews, a main interviewer led the interview, and a secondary interviewer took notes and asked supplementary questions if needed. Each interview lasted 80 to 100 minutes and was transcribed into Korean after the collection.

Data Analysis

For data analysis, we used the modified IDEE framework. We first coded the transcripts using the four categories: 1) desired outcomes, 2) level of automation, 3) ethical consideration, and 4) effectiveness. In applying the initial categories, we viewed the level of automation as students' decision process to get an argument and effectiveness as students' evaluation of the argument generated by ChatGPT. If students' use of ChatGPT in proving does not fit into one of the four categories, we coded those as others. First, each participant's transcripts were coded by one of the team members; then, different team members did the second round for cross-checking purposes. When the team members detected differences, it was discussed until the team agreed on specific coding. Through this repetitive process, we revised and specified the codes (Table 1).

Table 1 Code Descriptions

Codes	Revised Codes
Desired outcomes	Objectives of using genAI.
Level of automation	Decisions on prompts to ask (differently) to genAI. Decisions on continuing conversation with genAI. Decisions on how much they want to take from the generated arguments by AI.
Ethical consideration	Opinions regarding ethical issues
Evaluation of effectiveness	Evaluations of genAI's argument
Others	GenAI belief Proving belief Proving knowledge

Findings

In this section, we present how Yuna used and understood ChatGPT as a learning resource and how she used ChatGPT in a proving task. We only present Yuna's case here because of the page constraints.

Yuna's Previous Experiences in Using ChatGPT

Yuna was the participant who often used ChatGPT for her undergraduate education in general. She used ChatGPT in mathematics when she had a problem that she did not know how to solve or did not have enough time to complete assignments. Yuna generally noted that ChatGPT was a useful tool that expanded her draft and met the quantity requirement for writing assignments in other contexts. She said ChatGPT was not that useful in studying mathematics because 1) it is not easy to type mathematical symbols into it, and 2) sometimes it generates different answers even if the same problem was typed in. Because of these reasons, she preferred searching online (e.g., Google or MathStackExchange) to ChatGPT for proving tasks. Lastly, despite her negative evaluations for ChatGPT in proving, that she thought using ChatGPT was not cheating and did not have an ethical problem. She thought using ChatGPT did not matter what she used as resources for assignments and said maybe it was even better than copying peers' assignments.

Yuna's Use of ChatGPT in a Proving Task

As she did not use ChatGPT without the interviewer's direction, we asked her to use ChatGPT. In Yuna's use of ChatGPT for a proving task, we found that she had a conversation with ChatGPT by entering prompts several times. We found a repetitive pattern of 1) making decisions on prompts, 2) executing the prompts in ChatGPT, and 3) evaluating the responses until Yuna felt that she was ready to write her proof, which is detailed below (Yuna's pattern of using ChatGPT in proving tasks in Figure 1).

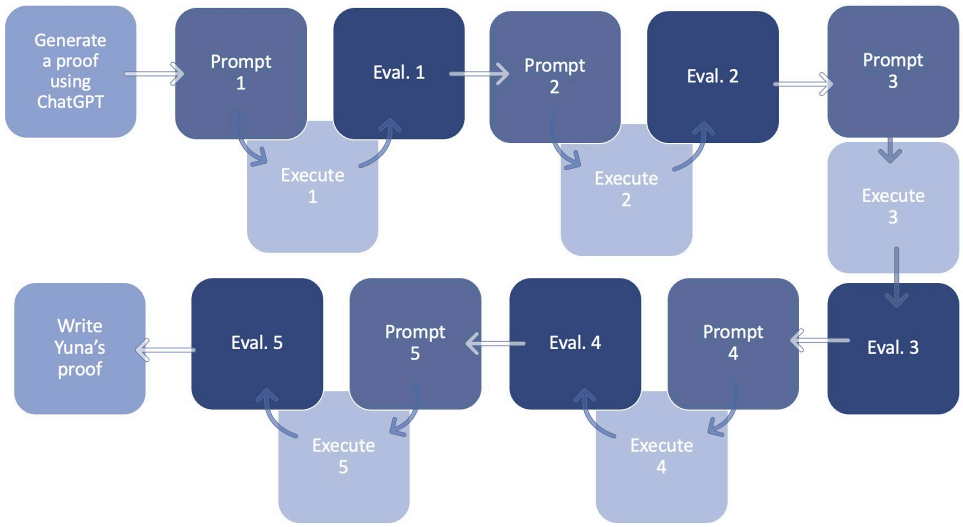

Figure 1 Yuna's pattern of using ChatGPT in proving tasks

Given a set of questions, Yuna selected the following statement to use ChatGPT for proving: *For all integers m and n, if the product mn is odd, then m is odd and n is odd.* As soon as she chose the problem, she copied and pasted the statement directly to prompt ChatGPT (Prompt 1 in Figure 2). ChatGPT provided an argument claiming that the statement was false. When Yuna read the ChatGPT-generated argument, she found the argument was conflicting with her conjecture that the statement was true. Then, she revised the prompt by adding "can you prove this statement:" in front of the previous prompt and typing "m*n" instead of "mn" to clarify that it is about multiplication (Prompt 2 in Figure 2). With Prompt 2, ChatGPT generated an argument using proof by contradiction that discussed the other three cases, except the case when both *m* and *n* are odd. Yuna initially felt that the argument seemed correct but soon questioned:

> It seems like it is saying the right thing… There exist four cases for *m* and *n,* and it used all the cases except when both *m* and *n* are odds, and claiming these cases led to a conclusion that *mn* is even, but I don't know where the remaining case is. [Translated from Korean]

Then, we asked if she knew what the word "proof by contradiction" meant and translated it into Korean. Then she typed Prompt 3 in Figure 2 in Korean, saying: "There are too many English words than mathematical expressions compared to what I am used to, so it is hard to recognize the argument in skimming." When ChatGPT produced the response for Prompt 3, she was not satisfied again and prompted Prompt 4 in Figure 2. Yuna noted that both responses did not include many mathematical expressions, and she did not feel ChatGPT's response was rigorous enough to be considered as proof.

When the interviewer asked if she wanted to prompt further, she typed Prompt 5 (Figure 2), adding "considering cases for m and n," into the prompt because she did not understand why the argument generated by ChatGPT used proof by contradiction. She felt this response was similar to what she was thinking and decided she would not use ChatGPT anymore as she knew what to do. Yuna noted that she probably would not use proof by contradiction to write her final answer. Even though Yuna said that she would not use "proof by contradiction" in her final answer, she used the format of proof by contradiction without the word "proof by contradiction" in her answer.

Prompt	Yuna's Prompts	Translation
1	For all integers m and n, if the product mn is odd, then m is odd and n is odd.	N/A
2	can you prove this statement: For all integers m and n, if the product m*n is odd, then m is odd and n is odd.	N/A
3	모든 정수 m 과 n 에 대하여, 만약 그 곱 mn 이 홀수이면, m 도 홀수이고 n 도 홀수이다.	For all integers m and n, if the product mn is odd, then m is odd and n is odd.

Figure 2 Yuna's prompts used in ChatGPT

Discussions

By combining the analysis of Yuna's and the other students' use of ChatGPT in their proving tasks, we present a flow chart (Figure 3) to illustrate students' process of using ChatGPT in proving by revising IDEE framework (Su & Yang, 2023).

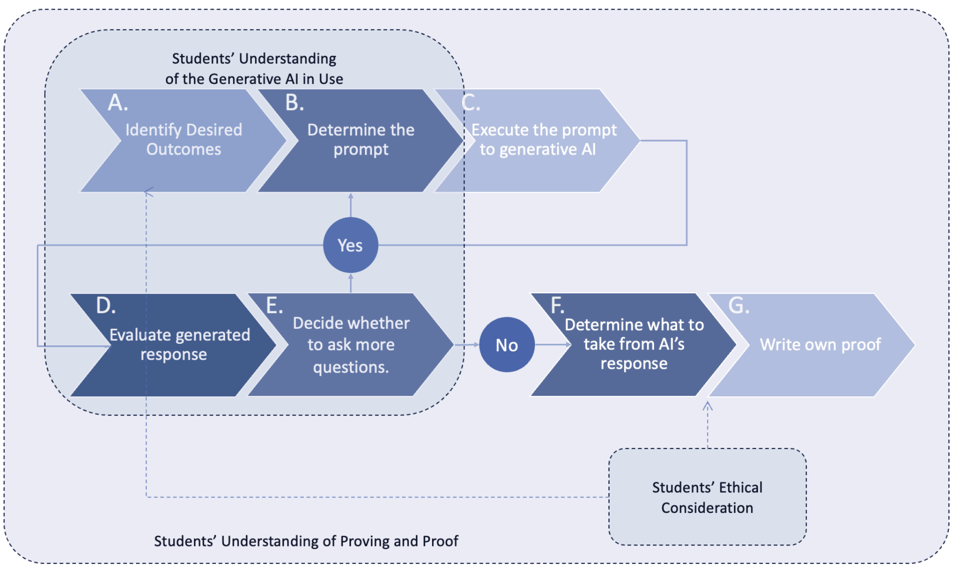

Figure 3 Flowchart of students' use of ChatGPT in proving

A. **Identify desired outcomes.** Students had their objectives by using genAI in proving. The outcomes could be determined by students themselves or given by other people such as an instructor or researcher.
B. **Determine the prompt.** Once students decided on their objectives for using genAI, they decided how they wanted to ask such questions. Yuna's various prompts are in Figure 2.
C. **Execute the prompt to genAI.** As students entered their determined prompts, they received the answers from the ChatGPT immediately.
D. **Evaluate the generated response.** When students evaluated generated responses, their evaluation varied based on the objectives identified in the first stage. As mentioned in the

example, Yuna made several evaluations of the arguments based on her understanding of proofs and mathematical knowledge.

E. **Decide whether to ask more questions.** At this point, students decided if they wanted to use genAI further to get another response based on their evaluation at D. Based on the answer, students could repeat the cycle between B and E as many as they wanted to. In Yuna's case, she repeated the cycle five times until she decided to ask no further questions.
F. **Determine what to take from AI's response.** When they decided to stop using genAI, students made a decision on which part of genAI's responses they would like to take and discard for their proof. It could include a set of accepted arguments, modes of argumentation, and modes of argument representations. For example, Yuna hesitated to use proof by contradiction in her proof because that was not the mode of argumentation she had seen in her mathematics classrooms.
G. **Write their own proof.** As a last step, students wrote their proof as the author of their proof. This stage emphasizes proof is human activity, and what counts as a proof is determined by humans, and in this case, the user of the genAI.

This process underscores that while automation tools like genAI are used, proving remains fundamentally a human activity. In her interactions with genAI, Yuna maintained the authority to critique genAI's arguments and determine their incorporation in her proofs. This finding resonates with the significance of students' agency and autonomous actions in proving (Castle et al., 2022) could critically engage with genAI (Cooper, 2023) by resisting passively accepting arguments from external resources, including gen AI, by giving them the authority (Castle et al., 2022).

In addition to the processes, we identified three other aspects (highlighted in shaded areas of proving Figure 3) considered in their use of genAI for proving:

1. **Students' understanding of proving and proof:** Influences the entire process, including evaluating genAI's suggestions and writing students' final proof. For instance, Yuna believed a mathematical proof should be more equation-heavy and less verbose. She thus modified ChatGPT's verbose argument to a more symbolic form in her proof.
2. **Students' understanding of genAI in use:** Concerns how students perceive the genAI tool they employ. This might include their knowledge about genAI's capabilities based on prior experiences or beliefs. Yuna, believing it cumbersome to type mathematical notations, often refrained from doing so.
3. **Students' ethical considerations:** Relates to students' awareness of potential ethical dilemmas in using genAI. This might be influenced by class norms or personal beliefs about leveraging resources. Yuna, for example, felt using ChatGPT was "better" than copying others' work as at least one tried to type questions and checked the argument by ChatGPT.

We believe these three factors would need to be considered in designing and implementing tasks using genAI. Also, the presented flowchart in this paper could provide a guideline to mathematics instructors to devise their proving activities using genAI in their teaching by suggesting some sequences that should be considered. Also, it means that instructors need to know their students' understanding of proving and proof and genAI and should develop and negotiate the classroom norm with their students. This flow chart could also serve as a tool for analyzing how students use genAI in their proving tasks and the extent to which students critically think about the responses generated by genAI.

Towards Operationalizing What Is Learned During Modeling

Sindura Kularajan
Utah State University

Jennifer A. Czocher
Texas State University

In this theoretical paper we leverage constructivist theories of learning to operationalize what is being learned during modeling. We do this by examining model construction through two theories: (i) schemes and concepts and (ii) abstracted quantitative structure. In addition to operationalizing what is being learned, we illustrate our operationalizations by providing examples from STEM undergraduates' model construction activities.

Keywords: mathematical modeling, learning theories, cognition

Scholars have embraced diverse perspectives on mathematical modeling (hereafter, modeling) to address a variety of research problems within the field (Kaiser, 2017). For example, within the cognitive perspective of modeling, researchers have investigated the ways in which to reduce or mitigate the cognitive obstacles students encounter during modeling. Irrespective of the perspective adopted, the researchers share a common goal: improving modelers' learning outcomes in modeling. In order to do this, it is crucial to understand what exactly is being learned during modeling. This knowledge will shed insight onto the instructional strategies and assessment criteria that educators can employ to guide modeling instruction. Two theoretical lenses have been proposed on how modeling enables the learning of mathematical concepts. The models and modeling perspective puts forward the idea that individuals learn through constructing conceptual systems (models) that are used to "construct, describe, or explain the behaviors of other systems that occur in the world' (Lesh et sl., 2003, p. 213). The emergent perspective describes how learning is occasioned as conceptual models are evolved from one context to the other (Gravemeijer, 1999). While these theories are useful to understand how modeling occasions learning, they do not explicate what exactly is being learned during modeling. In this paper, we draw on two distinct (but related) constructivist theories on knowledge construction: (a) schemes and concepts (von Glasersfeld, 1995), and (b) abstracted quantitative structure (Moore et al., 2022) to operationalize what is being learned during modeling. We support our operationalizations with illuminating data from two undergraduate STEM majors' work on modeling tasks.

Theoretical Framework #1: Applying Schemes and Concepts to Modeling

We take the stance that learning occurs through the change of schemes and formation of concepts. von Glasersfeld (1995) identifies three parts of a scheme: (1) An individual's recognition of a certain situation (S); (2) Specific activity associated with that situation (A); (3) and an anticipated result of that activity (R). When a learner sets a goal, it initiates a scheme (S-A-R) (Simon et al., 2004). That is, the goal triggers similar situations (S) where similar goals were made. This recognition is a result of assimilation. The assimilated situation then triggers the specific activity sequence associated with the situation. In effect, this activity leads to a result (say $R *$). If $R = R^*$ (i.e., the result of the activity turns out to be what the learner anticipated), the learner again assimilates. If $R \neq R^*$ (i.e., the result of the activity is not what the learner anticipated), the learner will experience a *perturbation*, also known as a state of disequilibrium. As individuals desire to stay in a state of equilibrium, the learner will attempt to overcome the perturbation through *accommodation*. An individual can accommodate through either (a) modifying the scheme, or (b) re-organizing the scheme. This results in a change in the scheme. (See Figure 1). Therefore, learning has happened, even if the specific change was unintended by the curriculum or teacher.

Von Glasersfeld (1982) describes concept as following:

> "concept" refers to any structure that has been abstracted from the process of experiential construction as recurrently usable, for instance, for the purpose of relating or classifying experiential situations. To be called "concept" these constructs must be stable enough to be re-presented in the absence of perceptual "input" (p. 194).

Hackenberg (2010) makes the case for concept to be "recurrently usable, for instance, for the purpose of relating or classifying experiential situations," the *abstraction* itself is implemented by the activities of an individual's schemes. Therefore, Hackenberg (2010) operationalizes concepts as "results of schemes that [individuals] have abstracted from their use of the schemes that the [individuals] can take as given prior to operating… [That is, concepts are] results of schemes that have been *interiorized*" (ibid, p.387). In other words, the results of a scheme, and the activities that produced those results can be taken as given during *assimilatio*n of a new situation. We adopt this view on concepts as well.

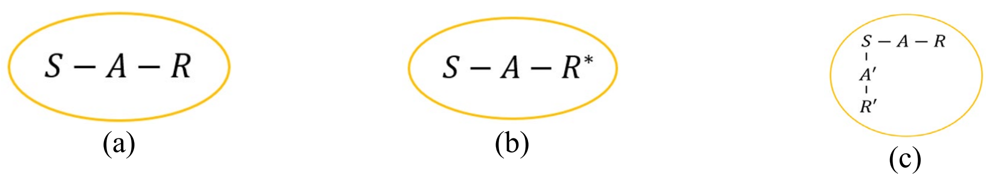

Figure 1. Our Representation for a scheme (a), modification to a scheme (b), and reorganization of a scheme(c)

Object of Validation as Schemes in Use and Standards of Validation as Concepts

Model validation is crucial for mathematical modeling (Czocher, 2018; Zbiek & Connor, 2006) because non-viable models are of little use for solving real-world problems. In Kandasamy & Czocher (2020), we argued that looking deeply into model validation would provide insight into how modeling enables learning because (a) the outcome of model validation may lead to the modification of the model, and (b) learners validate both their final model and their evolving models (p. 924).

When a learner engages in model validation, she holds two models in her mind: the one she is constructing (the object of validation) and the one she anticipates constructing (the standard of validation). The model she is constructing resulted from embracing a goal, which triggered a situation, which triggered a sequence of activities. Thus, the object of validation can be seen as a scheme under use. The model she anticipates is the result of an interiorized scheme and the activities that produced the result. Thus, the standard of validation can be seen as a concept. When the object of validation meets the requirements of the standards of validation, the learner assimilates and remains in a state of equilibrium. When the object of validation does not meet the requirements of the standards of validation, the learner is in a state of disequilibrium. To overcome the perturbation, the learner may choose to either (1) revise the object of validation or (2) accommodate the object of validation through modifying the standards of validation. In these terms, we claim that what modelers learn through modeling are the modifications to the standards of validation. We exemplify this claim using Eshonai's work on the Cancerous Mass task.

Eshonai and The Cancerous Mass Task

Eshonai was an undergraduate majoring in electrical engineering with a concentration in computer science. In this section, we present a portion of her work on the cancerous mass task, one of 5 modeling problems she solved in a modeling instructional sequence. The interviewer's goal was for Eshonai to build on her knowledge of absolute and relative change to develop a change equation as a model for exponential growth (rate of change is proportional to value of the function). The full task statement included information about the HeLa cell lines and a table of hourly measurements of the sample's mass.

> *The Cancerous Mass Task (abridged version):* Cancer cells can be grown in a lab, for study in their own right and also as a basis for further medical research. The HeLa cell line has a 24-hour propagation rate of 69% of its current mass. Create an expression that would model how quickly the sample is growing.

Using the table of values, Eshonai computed the hourly percent change in mass for the first, second, and third hourly intervals. She obtained 2.93% for each interval. Eshonai concluded that the hourly percent change in mass remained constant as time passes and had a value of 2.93%. She validated her model by computing the hourly percent change for the 22nd time interval. Next, The following conversation between Eshonai and the interviewer was exchanged.

Interviewer: What is the percent change [in mass] during 2-hour segments? So, if you were to look at a segment of time or an interval of time that ranged for 2 hours, lasts for 2 hours, what do you suspect the percent change in mass is?

Eshonai: My gut instinct is saying that it would just be double.

Interviewer: Okay. Double what?

Eshonai: Double the percent change of one hour.

Interviewer: Okay, and why do you suspect this? What is making you suspect that?

Eshonai: Well, the percent change is going to be fixed throughout each individual hour, so I assume that it would be fixed over 2 hours as well.

[Eshonai validated her answer by computing the percent change in mass during [1, 3] and confirmed its "roughly double," as in Figure 2(a)]

Interviewer: What about for a 3-hour increment? What does your gut say?

Eshonai: It would be 3 times. I'll do the math right now.

Eshonai confirmed her hypothesis by evaluating the percent change in mass during [1,4] as shown in Figure 2 (b). After computing the values, she realized that her hypothesis did not hold true and there was a discrepancy between the "actual' value and the "hypothesized" value (Figure 2). Eshonai nominalized the percent change in mass she evaluated through using the percent-change formula as "actual" and the percent change in mass she evaluated through her hypothesis—3 times the percent change in mass during an hour—as "hypothesized."

For 2-hour intervals:

$$\frac{5.29735-5}{5}=5.9463\%$$

$$0.02930224\cdot 2=0.05860$$

(a)

For 3-hour intervals:

$$\frac{5.452539-5}{5}=9.05088$$ "Actual"

$$0.02930224\cdot 3=0.087906$$ "Hypothesized"

(b)

Figure 2. Eshonai evaluates the percent change in mass during a 2-hour interval (a) and a 3-hour interval.

After computing the "actual" and "hypothesized" values, Eshonai was hesitant to conclude that the percent change in mass during a 3-hour interval was roughly 3 times the percent change in mass during a 1-hour interval. When the interviewer asked her why she thought there was a discrepancy, Eshonai replied, "I'm not sure. I mean, maybe there could be an error in my part. I feel like they should be exactly the same...I have no idea why there is a discrepancy." With the interviewer's guidance, Eshonai realized that as the length of the interval increases, her "hypothesized" values further depart from the "actual values". She modified her claim, asserting that her hypothesis would hold only for small intervals. The interviewer verified, asking if her hypothesis would hold for a half hour interval. Eshonai added, "I would say it is just half [of 2.93%], because if it is straining accuracy with more time [large intervals] then it should be more accurate with smaller of an interval we have."

In this scenario, Eshonai's object of validation was *the precent change in mass during the 3-hour interval that she evaluated using the percent change formula*. Eshonai's standard of validation, the result she was anticipating, was the *percent change in mass during a 3-hour interval is 3 times the percent change in mass during a 1-hour interval*. Her formulation of the standard of validation may have drawn on Eshonai's prior mathematical experiences with linear growth patterns and was re-confirmed when she computed the percent change in mass during a 2-hour interval (for which she got "roughly" 2 times the percent change in mass during a 1-hour interval). That is, she had interiorized that if the percent changes in mass are the same for each time interval of equal length Δt, then the percent change in mass during N such intervals is N times the percent change in mass during Δt. However, while evaluating the percent change in mass during a 3-hour interval using the percent change formula (the object of validation) she obtained a discrepant value, leading to a perturbation. As a result, she modified her standard of validation by limiting the values of Δt to be small. Therefore, we conjecture, Eshonai's modification to the standard of validation—her conjecture holds true for only small values of Δt—was what she learned during this particular modeling scenario.

Theoretical Perspective #2: Applying Abstracted Quantitative Structure to Modeling

Moore et al. (2022) reframed von Glasersfeld's (1982) definition of a concept using quantitative and covariational reasoning theories. Moore et al. (2022) define abstracted quantitative structure as a system of quantitative operations an individual has interiorized. The authors adopt Thomson's view on quantitative reasoning as conceiving a situation consisting of quantities and relationship among those quantities, where quantities are conceptualized as mental constructs of measurable attributes (Thompson, 2011). Quantitative relationships are a result quantitative operation. The authors operationalize quantitative operations as the mental operations involved in constructing new quantities (Thompson, 1990) and the mental operations involved in reasoning about varying quantities (Carlson et al., 2002). For example, within a disease transmission context, an individual may construct the quantity *how many more people got infected on day 2 than day 1* by additively comparing the quantities: *number of infected people on day 1* and *number of infected people on day 2*. Furthermore, an individual may reason "*as the number of infected people increase, the number of susceptible people decrease*," engaging in the directional variation of new quantities. Moore et al. (2022) posit that an abstracted quantitative structure has the following characteristics: (1) is recurrently usable beyond its initial experiential construction; (2) can be re-presented in the absence of available perceptual material including that in which it was initially constructed; (3) can be transformed to accommodate to novel contexts permitting the associated quantitative operations; (4) is anticipated as re-presentable in any figurative material that permits the associated quantitative operations (p.44). We argue that modeling activity constructs abstracted quantitative structures, and therefore they are the outcome of learning. We exemplify this claim below.

Pai's Abstracted Quantitative Structure Associated with Interactions

Using Pai's work on an instructional sequence of modeling tasks, we illustrate abstracted quantitative structures as a result of learning during modeling. Pai was an undergraduate senior majoring in economics and minoring in mathematics. The instructional sequence was built to examine participants' quantitative reasoning as they constructed models for real-world situations. The overarching goal of the instructional sequence was to examine how participants' reason quantitatively as they constructed models for real-world situations. Of the 8 tasks Pai worked on, we draw on Pai's work from the following tasks.

The Speed Networking Task (abridged): Suppose you and your friends attend a job fair organized by your department. Each student will have 5-minute "quickfire dates" with a representative from each firm. Create a mathematical model that would represent the total number of meetings between your friends and the representatives from the various firms.

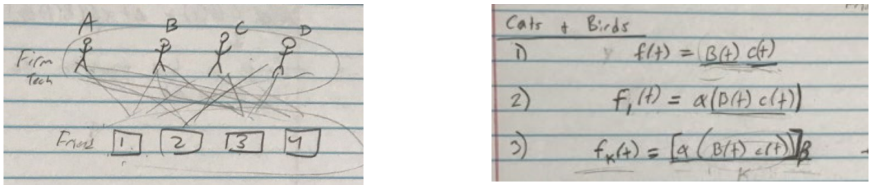
The Cats and Birds Task (abridged): (i) Consider a backyard habitat, where cats are the natural predators of birds. Let $B(t)$ be the number of birds and $C(t)$ be the number of cats at time t. How many potential cat-bird interactions are there at time t? (ii) Not every cat and bird encounter each other. Only some percentage α of potential cat-bird interactions are realized. How would you adapt your model above to account for that fact? (iii) Cats are very good hunters, but they aren't perfect. Sometimes the bird gets away. How would you adapt your model above to represent the number of interactions that results in a bird's death?

The Disease Transmission Task: Suppose a disease is spread by contact between sick and well members of the community. If members of the community move about freely among each other, develop a mathematical model for the dynamics of how the disease would spread through the population.

Below we explain how Pai constructed abstracted quantitative structures associated with interactions between species by providing examples of Pai's initial construction, re-presentation and construction, and finally accommodating to novel contexts.

Initial Construction: The speed networking task. Pai initially modelled this scenario as $y = 5 + 2.5x$, where y represented the total number of meetings between students and representatives and x represented the total number of questions the students may ask from the representative. Pai's model reflects his assumptions about the event's organization: each student would get 5 minutes with each firm, and then an additional 2.5 minutes per question. However, Pai was unsure whether this model satisfied the problem statement. He drew a diagram to represent the meetings between the group of friends and representative from firms (Figure 3a). He counted the number of lines that connected the representatives (A,B,C,D) to the friends (1,2,3,4). Pai then constructed $y = t \cdot f$ to model the number of meetings between friends (f) and representatives (t). Pai used his drawing to justify the model, arguing, "You would simply multiply the number of tech representatives by your number of friends." Pai expressed confidence with the combinatorial model, explicitly qualifying its scope: "every friend talks to every firm, which we cannot know for certain" and "what I have $y = t \cdot f$ is the maximum possible" given that "you cannot have two meetings with the same firm."

In Speed Networking, Pai first constructed an unsatisfactory model. Using his diagram, he was able to construct the quantity *total number of meetings between friends and representatives* as a multiplicative combination of the number of friends and the number of representatives. We argue his activity established a quantitative structure for the total number of possible interactions between two disjoint sets of objects. Next, we argue that he abstracted that structure to carry it to a new scenario.



(a) (b)

Figure 3. Pai's diagram in the Speed Networking task (a) and Pai's models for the Cats & Birds tasks

Re-presenting and constructing: The cats and birds task. After reading the task, Pai immediately wrote the expression $f(t) = B(t)C(t)$ where $f(t)$ represented the total number of potential cat-bird interactions at any time t. Pai stated that the situation was similar to the Speed Networking task. He next modelled the percentage of cat-bird interactions that realized as $f_1(t) = \alpha[B(t)C(t)]$. He justified his expression for the realized cat-bird encounters as "since $f(t)$ is the potential number of cats and birds interactions, assuming they all interact with each other, $f_1(t)$ will be a percentage of that $[B(t)C(t)]$, since not all of them actually interact." He saw a clear link between the subtasks, explaining "I'm assuming each of these models are based on the previous ones."

For the second subtask, Pai first constructed $f_k(t) = \frac{\alpha B(t)C(t)}{K(t)}$ to model the number of cat-bird interactions that resulted in a bird's death. He nominalized $f_k(t)$ as the number of bird-cat interactions that result in a bird's death and $K(t)$ as the number of birds killed at time t. However, he expressed uncertainty around whether $f_1(t)$ should be divided by $K(t)$ or if he should subtract $K(t)$ from $f_1(t)$. The interviewer probed Pai's image of how bird deaths occur, and Pai stated that cats and birds need to meet. He then realized that $f_k(t)$ and $K(t)$ represented the same measurable attribute, number of birds killed due to interaction with cats. Pai then changed his model to $f_k(t) = [\alpha B(t)C(t)]\beta$, where he nominalized β as the "percentage of these interactions [*referring to $\alpha B(t)C(t)$ as he was drawing square brackets, see Figure 3b]* that result in a kill for the cat." Pai justified his revision, arguing that the $B(t)C(t)$ corresponded to total, potential interactions, that $\alpha B(t)C(t)$ corresponded to the actual interactions, and that $[\alpha B(t)C(t)]\beta$ corresponded to the interactions resulting in a dead bird. He concluded, "this makes more sense to me."

Pai wrote $B(t)C(t)$ to model the total number of potential cat-bird interactions without having to draw a diagram, suggesting he re-presented the quantitative structure from Speed Networking in the absence of available perceptual material. The Cats & Birds task presented Pai the opportunity to refine his initial quantitative structure for the total number of interactions between two disjoint sets of objects through removing the assumption that all objects interact exactly once. Pai's model for the number of realized cat-bird interactions, $\alpha B(t)C(t)$, was constructed through shrinking the size of the whole, $B(t)C(t)$, via a scalar α. We interpret that he had constructed a quantitative structure for a subset of the number of interactions. We took Pai's placement of the square brackets in his models (Figure 3(b)) and the excerpt above as evidence that Pai was engaging in shrinking the size of the whole (quantity), in both instances. Next, we show the task that occasioned his accommodation of the quantitative structures.

Accommodating to novel contexts: the disease transmission task. To model the rate of disease spread, Pai introduced the variables $h(t)$ and $I(t)$ to represent the number of healthy people and the number of infected people, respectively. His immediate goal was to model the interaction between healthy and sick people that would result in a healthy person falling sick. He constructed $h(t)I(t)\alpha$, where he defined α to represent "[rate of] successful infections." He justified his model, explaining that "a healthy person interacts with an infected person [gesturing over $h(t)I(t)$], the disease doesn't necessarily spread because they interact. It's going to be some sort of rate, and I have that as α."

In comparison to Speed Networking and Cats & Birds, the Disease Transmission task was a different context, offered less information, and was less scaffolded. Still, Pai set a sub-goal to model the interaction between healthy people and sick people and the interaction that results in a healthy person getting sick. To accomplish this goal, Pai accommodated the quantitative structures he created in the previous task—total number of possible interactions and a subset of the total number of interactions—to this novel context. We take this as indication of Pai having constructed an abstracted quantitative structure associated with the number of interactions between two disjoint set of objects and subsets of those interactions, as it satisfies the characteristics proposed by Moore at al. (2022). Consequently, we claim that through engaging with the instructional sequence of modeling tasks, Pai learned the number of interactions between disjoint set of objects can be constructed via multiplicatively combining the number of each objects and that a subset of interactions can be constructed by scaling the size of the whole.

Discussion

In this paper, we operationalized what is being learned during modeling through (i) schemes and concepts and (ii) abstracted quantitative structures. Through the first lens, we argued that modifications to the standards of validation are what is being learned during modeling. Through the second lens we made the case that learners' construction of abstracted quantitative structures is what is learned during modeling. Our analysis sheds insights into concretizing the end goal of modeling, in terms of learning. This has implications: first, knowing what is learned during modeling will help educators to design modeling tasks that engender that learning. For example, when adopting the view that modifications to the standards are learned during modeling, tasks can be designed to challenge learners' existing standards of validation, providing learners the opportunity for accommodation. Second, the knowledge of what is being learned during modeling is instrumental for educators to be intentional with their instructional goals for modeling and learning environments that support those goals, mitigating some of the inadvertent cognitive obstacles learners may experience during modeling. Finally, it gives educators a sense of what to expect when assessing learners' modeling competencies. We close with two considerations: limitations and future directions. Using the schemes and concepts theoretical orientation, we neither analyzed what reorganizing a standard of validation may look like nor what is learned in the absence of perturbation. Additionally, as standards of validation reside in the mind of the individual, it is not always possible to observe or make predictions about learners' standards of validations nor delineate between the object and standard of validation. To attend to this, future interview protocols can include specific questions regarding learners' model validation such as, *what made you revise your model? Were you anticipating some other result? What was your goal in revising?* However, this theoretical paper is a significant contribution to the field as it initiates a discourse on leveraging established theories of learning to effectively operationalize the learning goal of modeling, and the instructional strategies for nurturing the learning of modeling both as a means and as an end.

Pre-service Teachers Understanding of Commutativity, Associativity and the Challenge of Order

Anna Dellori
Paderborn University, Germany

Lena Wessel
Paderborn University, Germany

Commutativity and associativity are recurring properties in school and university mathematics. In design experiments with pairs of secondary pre-service teachers (PSTs) we investigate what they are focusing when discussing commutativity and associativity, and how they deal with the notion of order. A qualitative discourse analysis shows for commutativity that the focus is on the order of two elements for most PSTs. Few focus on the order of several elements. Regarding associativity, bracketing is a main focus for many PSTs. The order in which operations are computed is sometimes discussed explicitly with also emphasizing the order of elements and sometimes more implicitly. The PSTs struggle with the notion of order so that we suggest coping strategies like "demanding precision in language" and "using alternative terms for order".

Keywords: pre-service teachers, commutativity, associativity, qualitative discourse analysis

Introduction

The arithmetic properties commutativity and associativity are recurring mathematical topics that can be found at various levels in school and university mathematics (Wasserman, 2016). One could assume that dealing with different binary operations and their properties in different settings should have eliminated any difficulties in dealing with the properties. However, according to empirical data, this does not appear to be the case (Melhuish & Fagan, 2018; Zaslavsky & Peled, 1996). When discussing commutativity and associativity, one of the biggest struggles for university students seems to be the notion of order (Larsen, 2010). Larsen (2010) suspects that a lack of precision in the informal language is one cause for this difficulty. Though it is not yet certain what language could be hindering or supportive, and what are possible coping strategies for dealing with the notion of order. This is why the reported study in this paper deals with the following research questions:

1. What do (German) secondary pre-service teachers near the end of their studies focus on when discussing commutativity and associativity?
2. How do secondary pre-service teachers deal with the notion of order concerning the properties commutativity and associativity?

Theoretical Background

In university mathematics, commutativity is defined for an operation $*: M \times M \rightarrow M$ on a set M referring to two elements $a * b = b * a, \forall\, a, b \in M$ and associativity referring to three elements $(a * b) * c = a * (b * c), \forall\, a, b \in M$ (Alcock, 2021). In (German) school textbooks, however, we sometimes find definitions of commutativity that are not based exclusively on two elements anymore, e.g. "The summands of a sum or the factors of a product can be changed in any way" (translated: Braun, 2019, p. 91). For commutativity, the school definition might evoke the idea that the order of several elements may be changed. Whereas the university definition has the idea that the order of two elements may be changed (Larsen, 2010). As a consequence, the understanding of commutativity in school and university mathematics may not match.

One understanding of associativity suggested by the formal definition is that, if the property is valid, brackets may be arbitrarily moved, inserted, or removed (Melhuish & Fagan, 2018). Behind this still rather superficial idea, if bracketing refers to two elements, is the understanding that elements can be grouped differently when computing the operations (Weber & Larsen, 2008). For this, the order in which the operations are computed does not matter (Larsen, 2010) One interesting aspect is, how Cayley formulated associativity as a condition for a group. In general, that commutativity does not hold would not actually need to be explicitly addressed. He postulated "symbols are not in general convertible [commutative], but are associative" (Kleiner, 1986, p. 208 cited in Larsen, 2010). Larsen (2010) observed exactly this phenomenon with his students. They operated with symmetry mappings and addressed (non)commutativity in their definitions for a group even though it is not necessary. To some students it seems inherently important to emphasize that the order of the elements from left to right is not allowed to be changed (Larsen, 2010). Nevertheless, there are also students who have difficulties with keeping the order of the elements when using associativity (Larsen, 2010; Zaslavsky & Peled, 1996). When checking operations for commutativity, one common difficulty is confusing the operation sign with the number sign when changing the order of the elements (Zaslavsky & Peled, 1996). For checking operations for associativity, difficulties can be caused if learners primarily have the understanding that associativity allows brackets to be moved (Melhuish & Fagan, 2018). Students are asked to verify that the operation of the mean $*$: $a * b = \frac{1}{2}(a + b)$ is associative. One given choice to justify that the operation is not associative is based on random shifting of brackets $\left(\frac{1}{2}a\right) + b \neq \frac{1}{2}(a + b)$. This option was chosen by 16.9% of PSTs (Melhuish & Fagan, 2018). More generally, it can be said that the understanding of and checking for commutativity seems to be easier for students than associativity (Findell, 2001).

In comparison of the two properties it becomes evident that the notion of order is apparent in the understanding of commutativity and associativity. However, in the case of commutativity, the order refers to the order in which the elements are arranged. While in the case of associativity, the order refers to the order in which the operations are computed. This similarity entails the risk that students could conflate the two properties when not paying attention to the differences (Larsen, 2010; Zaslavsky & Peled, 1996).

If both properties apply, they could be replaced by a single property (Pinto & Cooper, 2017). For example, if multiplication is considered "it is not clear why these two rules should not be replaced by a simpler multiply in any sequence rule" (ibid. p. 322). It would be sufficient to know that in a multiplication the order may be interchanged arbitrarily without differentiating what the order refers to. Empirically, it also appears that some students combine the two properties into one "order doesn't matter" (Findell, 2001, p. 148) property. This notion can lead students to make statements such as "because it's associative, you can move it all around" (Findell, 2001, p. 148) or "this property [meaning commutativity] allows us to switch around the elements in an expression so that it doesn't matter which elements will operate first" (Findell, 2001, p. 148). The difficulty with order and differentiating what the order refers to could also lead to the misconception that associativity also has something to do with swapping the order of elements (Ding et al., 2013). Furthermore, a common misconception that one property might imply the other property (Melhuish & Fagan, 2018; Tirosh et al., 1991).

Method

Data Collection

This study is part of a design-based research project at a German university with the aim of connecting university mathematics and teaching school mathematics for secondary pre-service teachers (PSTs) (Dellori & Wessel, in press). In this project, three teaching units following the sequencing instruction model (Wasserman et al., 2017) for PSTs algebra learning are developed and tested in laboratory design experiments. The second one addresses learning goals related to associativity and commutativity. At first (*building-up*), the PSTs work with school textbook excerpts about associativity and commutativity. In the second phase (*relearning*), the PSTs deal with commutativity and associativity in different algebraic structures. Finally (*stepping-down*), they reflect on the textbook excerpts with reference to the university mathematics. The data for this paper is situated at the beginning of the relearning phase of the teaching unit about commutativity and associativity. It concerns the following tasks:

1. Let M be a set with the binary operation $*: M \times M \to M$. Write down the definitions for commutativity and associativity.
2. In your own words, describe commutativity and associativity verbally.
3. What are differences and similarities between commutativity and associativity?

For the first two tasks, PSTs first discuss orally and then give a written answer. Task 3. is only discussed orally. Afterwards PSTs are prompted with the statement: "Commutativity implies associativity". Although, some PSTs already mention this claim during task 3.

The design experiments were conducted with pairs of PSTs (N=8x2) by the first author. The PSTs were in their first to third semester of their master's program at a German university and volunteered to participate in the study. At the time of data collection, 15 of the 16 PSTs were enrolled in an Abstract Algebra course. The design experiments were videographed and transcribed. The focus of the analysis is on tasks 2 and 3, as these encourage to reflect on the understanding of the properties.

Data Analysis

To answer the research question about what PSTs focus on when discussing commutativity and associativity, a qualitative content analysis is conducted (Kuckartz & Rädiker, 2022). The main categories are deductively formulated from previous research. For commutativity the two main categories are "order of two elements" and "order of elements" (Braun, 2019; Larsen, 2010). Inductively, the distinction is added as to whether a more general or example-based discussion of the order of the elements took place (examples see Figure 1).

Category	Definition	Example
Commutativity		
Order of elements	There is a focus on the fact that commutativity allows the order of elements to be rearranged.	General: The set under the operation is commutative, if we can say we can change the order around. […] And that for all the elements. Example-based: So, we know that this is commutative, then we can rearrange it as we want. [points to the "a*b*c" on sheet 1]
Order of two elements	There is a focus on the fact that commutativity allows the order of two elements to be rearranged.	General: That it doesn't matter in which order I combine two elements? Example-based: Whether I now combine a with b or combine b with a doesn't matter.
Associativity		
Order of operation	There is a focus on the fact that associativity allows the order in which operations are computed to be interchanged arbitrarily.	First computation: So, it just doesn't matter what we calculate first. Order: Here it is about the operation so to speak. It doesn't matter in which order we compute it. With regard to the operation. Example-based: And it doesn't matter for […] my result, if I, uh, first combine the elements a and b, the result from that with c. Or if I first combine b and c and then again combine what comes out of that with a.
Emphasis on order of elements	There is a focus on the fact that when the associative property is applied, the order of the elements is not changed	The order of the operation pair by pair doesn't matter. […] Whereas maybe … The order of the operation doesn't matter if the order of the elements is the same.
Bracketing	There is a focus on the fact that associativity allows brackets to be set arbitrarily.	When combining more than two elements of a set, brackets may be omitted or set as you like.

Figure 1: Categories for the focus on commutativity and associativity

For associativity the “order of operation”, “emphasis on order of elements” and “bracketing” are the three main categories (Larsen, 2010; Melhuish & Fagan, 2018) (see Figure 1). It has been observed that the order of operations could be addressed explicitly in using the term “order” or more implicitly in describing it on an “example-based” level or focusing on what is “computed first” (see Figure 1).

To answer the second research question (how do the PSTs deal with the notion of order), all passages in which the term “order” occurs were paraphrased and summarized for each pair. These summaries were contrasted and compared in order to identify typical difficulties and coping strategies for the notion of order.

Results

Pre-service teachers’ discussion of commutativity

To answer the first task and give a definition for commutativity and associativity, all PSTs give a symbolic based answer. The definition refers to *two elements* a and b for all pairs. Minor differences between the definitions are the notation of the operation ($*: M \times M \rightarrow M$) or the algebraic structure $(M,*)$. The pair #8 is the only pair that does not specify that $a * b = b * a$ must hold for all elements. The other pairs use the quantifier $\forall$ for this in their definitions. Furthermore, this pair also added $a * b * c = c * a * b$ later, when Sven (#8) talks about switching the elements back and forth. According to their understanding, commutativity is not just about the order of two elements but the *order of elements* in general.

Sven: If I can switch *a* and *b* and have a *c* there as well, then I can also, yes, … switch that back and forth if I want to.

In describing commutativity in their own words, six out of eight pairs clearly focus on the *order of two elements*. For example, pair #3 wrote: “The two combined elements of a set may be interchanged arbitrarily.”. The two pairs #1 and #5 start out with an example-based description of commutativity such as “It doesn't matter whether I combine *a* with *b* or combine *b* with *a*”. During their discussion, passages are also at a general level, for example like “It doesn't matter in which order I combine two elements”. Similarly, pair #8 has a mix of example-based and general passages in their discussion (see Figure 2). Pairs #2 and #4 tend to be almost exclusively at the general level while pairs #3 and #7 engage in discourse solely at this level (see Figure 2).

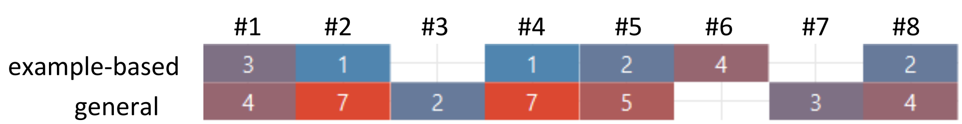

Figure 2: Passages focusing on the order of two elements

Pair #6 was the exception to talk about the *order of two elements* merely on an *example-based* level. On a more general level, this pair only talked about the *order of elements* such as “An operation is commutative if the sequence of elements is freely selectable and may be changed.”. It cannot be said with certainty that they are talking about multiple elements, but as they never explicitly talk about only two elements, it is assumed. The two pairs #6 and #8 are the only ones where the focus is on the *order of elements* rather just two elements. In the discourse of the other pairs we find some passages in which it is not clear from the language whether two or more elements are considered. Since, however, these pairs previously have multiple passages in which they explicitly only refer to two elements, one can assume that the missing explication is only due to an abbreviated form of expression.

Pre-service teachers' discussion of associativity

Like in their definitions of commutativity, all PSTs first state a mainly symbolic definition of associativity. Again, the only differences are in the notation of the operation and the algebraic structure. Pair #8 is the only pair that doesn't express that $(a * b) * c = a * (b * c)$ must hold for all elements.

The understanding that associativity allows *brackets* to be set arbitrarily is coded for six pairs. Pairs #2 and #4 are the only ones that don't discuss brackets in connection with associativity at all. For four pairs (#3, #5, #7, #8), their initial main idea for the verbal description of the property is associated with brackets. For example, in the verbal definition of pair #8: "The result is independent of the bracket placement." Later in the design experiment, these pairs are asked to give an alternative definition without using the idea of bracketing. The other pairs (#1, #6) discuss the notion of bracketing, e.g., see Pia and Nora (#6), but it does not seem to be the focus of their understanding of associativity. For Nora, focusing on the order seems more meaningful than the idea of bracketing.

Pia: Then/ Mhh. Yes, first you are allowed to place the brackets differently somehow. Then, uh, it doesn't matter how the brackets are set.

Nora: Mhh yes but that/ I think that doesn't say much. Because I would just write that/ here the order doesn't matter, right? So, whether I do *a* and *b* first or *b* and c first.

Looking at the discussions about associativity, it can be noted that an *emphasis on the order of the elements* is apparent in six of the pairs while pairs #3 and #8 didn't talk about it all. In some cases, students point out that the order of *a*, *b* and *c* from left to right is not allowed to be changed and explicitly contrast this with the property of commutativity. For two pairs (#4, #7) it was such an integral part of their understanding of associativity that they included it in their verbal definition: "Considering 3 elements from a set, the order of the pairwise composition does not matter if the order of the elements remains the same."

	#1	#2	#3	#4	#5	#6	#7	#8
first computation	5	1	2	1	6	1	1	2
order	2	3	3	5	1	4	8	3
example-based	2		2	1	2	1	6	

Figure 3: Passages focusing on the order of operations

In some way, all PSTs discuss the *order of operations*. Initially, three pairs (#3, #5, #7) consider the order of operations at an *example based-level*. Like Nico and Marcel (#5, see three passages below) these pairs use the specific elements a, b and c to implicitly take the order into consideration (first part). In further discussion, they move away from the three concrete elements and start contemplating that it doesn't matter what is *computed first* (second part). Afterwards, they go further and explicitly interpret "what you do first" as the *order of operations* (third part).

Nico: Yes, well. Um. You could say something like: First *a* with *b* and then with *c* or/

Marcel: First/

Nico: First *b* with *c* and then with *a*.

Marcel: Kind of like … Yeah, you can do it the same way or? Associativity means that it doesn't matter/

Nico: Which operation you do first.

Nico: Mhh. So here we have/ Here it is about the operation. There it doesn't matter in which order we compute it. Referring to the operation.

The other five pairs don't begin their discussion about associativity on an *example-based* level. With two pairs not referring to associativity on this level at all. Some mention the *order of operations* right at the beginning while some start with discussing which operation is *computed first*. Essentially, it can be observed that two pairs (#1, #5) have their biggest focus on which operation is computed first, and two pairs (#4, #6) explicitly on the order of operations. For the other pairs, it's more broadly distributed (see Figure 4).

Pre-service teachers dealing with the notion of order

While for some pairs (#1, #5, #6, #8) the notion of order is only provoked by the third task about similarities and differences between/ of the properties, some pairs (#2, #3, #4, #7) already discuss the notion of order when describing the properties.

The two pairs who manage particularly well to elaborate the similarities and differences always specify what the order refers to when they use the term. Adrian (#3) emphasizes that the order regarding commutativity refers to the elements and the order regarding associativity refers to the computation of the operations. Adrian (#3) has already shown the precise use of the term "order" in the verbal definitions in task 2. Pair #5, on the other hand, was the only one of all pairs that did not use the term order in task 2 at all. Nevertheless, most of the other pairs struggle more to specify what the order refers to. They often simply talk about the "order of operations" and not the "order in which the operations are computed".

Adrian: In both cases, it's about a kind of variable order. Just in one case I may switch the elements and in the other case I may/ It's maybe a bit fare fetched. But there I am also allowed to choose the order, but just which operation I compute first. So that would be a similarity and a difference. So, the similarity is that it's about an order that I'm free to choose. And the difference that it's not about elements, it's about, um, the operation.

The pairs that discuss order at the beginning have in common that they use or wanted to use the term "order" in both their verbal definitions of commutativity and associativity. This causes students to struggle with the notion of order like Anton and Lina (#1, see below). They have a problem using the term "order" for both properties and their way of dealing with it is deciding not to use the term "order" for both properties after all. For commutativity, they prefer to use the alternative term of "direction", which "fits better" to commutativity, according to Lina.

Anton: Because somehow order fits both. That's why I was a bit confused by the term. But somehow… But I mean, it fits more to this [means associativity].

Lina: Maybe it's better to use direction, which is what we said first. So, because you can combine from the left or from the right.

Anton: Yes. I mean/ So I would say both of them are correct. But/

Lina: No, direction fits better. Because that's really, you can look at it from the left and from the right. And with order, there the direction stays the same and then you have *a* and then the bracket or you have first the bracket and then your element.

This approach of resorting to alternative terms - such as direction, placement and position - can be observed in several pairs (#2, #6, #7). In all of these occasions, the alternative terms are used to refer to commutativity. Using alternative terms can lead to rejecting the notion of order for a property, as it is the case for Lina. However, when trying to explain the similarities and differences in task 3, the alternative terms can also be supportive in disentangling the notion of order concerning commutativity and associativity. For example, Anton later used the term "placement order" to clarify what the order is for him in commutativity.

In those pairs (#1, #6, #8) that use the term "order" for only one property in task 2, many of the students tend to associate the term more strongly with that one property even later on. Eva and Mirco (#1) use the term “order” only for commutativity in task 2. In task 3, they quickly give the answer that both properties are in fact about some sort of order. However, Eva is not particularly firm in this view. In the subsequent discussion she is tempted to reject the notion of order for associativity because of her understanding of bracketing. Andreas (#8) behaves like Eva. A similar pattern can be observed for Pia (#6) and Sven (#8). Only that in their case the term “order” originally was used for associativity, and they are inclined to reject order for commutativity.

Eva: Yes, strictly speaking, we don’t switch the order [means associativity]. We just rearrange the brackets.

Mirco: But that is an order in which you compute the operation.

Discussion

In summary, for the majority of the PSTs in this study, the focus of commutativity is on the order of two elements and consequently aligns with the formal definition in university mathematics. For almost all PSTs we found passages in which they just spoke about the “order of elements”. It is assumed that for most students, this is just due to inaccuracy in their language. For associativity, PSTs seem to have a strong focus on the idea of bracketing. Their focus on bracketing leads some students to reject the notion of order for associativity. Just like Larsen (2010), we also observe that the majority of the PSTs emphasize the order of elements when speaking about associativity. The task about finding similarities and differences between commutativity and associativity seems to be very productive in initiating discussions about the notion of order. Those PSTs who lack precision in their language concerning what the order refers to have difficulties with the notion of order. Struggling with using the term “order” for both properties, some PSTs (momentarily) reject the notion of order for one of the properties. To cope, some PSTs develop alternative terms for the term “order” such as “direction”.

The results indicate that a formal symbolic representation of the properties seem not to be particularly challenging for the PSTs. Difficulties arise when explicating the meaning of the properties is concerned. As shown in previous research, symbolic representations and formal vocabulary are not sufficient to explain meanings of mathematical concepts. Thus, meaning-related language is needed “especially for expressing and thinking about abstract relationships” (Post & Prediger, 2020, p. 112). Post and Prediger (2020) suggest providing meaning-related phrases in learning arrangement to support students in understanding the meaning of the part-whole relationship in probability (Post & Prediger, 2020). For understanding the meaning of order regarding commutativity and associativity, our findings suggest that phrases with alternative terms for order seem to be part of the meaning-related language. In line with the theory of scaffolding, we suggest providing students with phrases like that to support them in verbalizing the meaning of order. Besides using meaning-related language, demanding precision in language (in this case to clarify what the term “order” refers to) seems to be productive for explaining the meaning of order as Larsen (2010) already assumed.

The methodological limitations of this study, above all (a) the small sample size, (b) being tied to the specific teaching units, and (c) being situated in a German context (language and university), must be considered when interpreting the empirical findings. Concerning the latter, seeing how the identified language difficulties, coping strategies and proposed supportive means appear and may vary in different languages with other vocabulary could be an interesting aspect for further research.

Student Reasoning in Quantum Mechanics Examined Through Modeling and Sensemaking

A.R. Piña
University of Maine

Zeynep Topdemir
Johannes Kepler University Linz

John R. Thompson
University of Maine

As part of an effort to examine student mathematical and physical reasoning in quantum mechanics, a paired, semi-structured, think-aloud interview was conducted. The students were asked to interpret a quantum mechanical operator expression in a functional (position) representation and to think about an analogous expression in Dirac notation. When the students ceased to make progress on this task, they were given a modeling task in which they constructed an eigenvalue equation for a different operator in quantum mechanics. After examining their newly constructed eigenvalue equation, students were able to determine more precisely the nature of the original expression given in a functional representation. These data were coded in accordance with mathematical modeling and mathematical sensemaking frameworks to examine the intersection of the two frameworks.

Keywords: Quantum Mechanics, Modeling, Sensemaking

Introduction

Due to its prevalence in modern research and applications in industry, quantum mechanics is an essential part of an undergraduate physics curriculum. Research on student understanding of quantum mechanics can be largely differentiated by the instructional methods used with the student populations. Undergraduate quantum mechanics is typically taught with either a functions-first or spins-first approach. In a functions-first approach, instruction first focuses on continuous systems represented in functional notations. This often requires solving differential equations to model (e.g, Griffiths, 2018). In spins-first instruction, students begin with discrete systems represented in Dirac\bra-ket notation (a vector-like notation developed for use in quantum mechanics) before moving onto continuous systems in functional notations (e.g., McIntyre et al., 2012).

One motivation for spins-first quantum mechanics courses is that they tend to fall more in line with graduate instruction. They allow for students to build intuition for and a qualitative understanding of quantum mechanical systems while working with two-state systems, described by relatively simple mathematics, before moving onto the continuous systems that require functional representations (McIntyre et al., 2012). Ideally, students would be able to apply the ideas learned in the context of spins to continuous systems. If this were the case, one could reasonably expect to see evidence of mathematical sensemaking during this transition. Sensemaking in physics is also closely related to modeling frameworks and activities in mathematics education research. The interplay between modeling and sensemaking will be discussed herein. We begin to address these issues by examining students' reasoning and sensemaking while working with multiple representations in the context of quantum mechanics.

Background

We first situate this study among the relevant literature associated with teaching and learning in quantum mechanics. This is followed by a more in-depth discussion of modeling and mathematical sensemaking, which are the two primary frameworks used in analysis.

Teaching and Learning in Quantum Mechanics

Much of the work on student understanding of upper-division quantum mechanics has focused on identifying difficulties students face in engaging with the material. Work has been done at varying levels of specificity ranging from specific concepts, contexts, or calculations to broad overviews of difficulties. Some of the specific concepts include time dependence (Emigh et al., 2015) and measurement (Gire & Manogue, 2008). Others have focused on students' use and understanding of notations (Gire & Price, 2015; Kohnle & Passante, 2017; Schermerhorn et al., 2019). Many of these have been used as the basis for curriculum development projects aimed directly at the identified difficulties (DeVore & Singh, 2015; Emigh et al., 2018; Kohnle & Passante, 2017; Singh, 2016). Others have examined student understanding from the perspective of resources in efforts to determine what may lead to certain lines of unproductive reasoning (Gire & Manogue, 2008, 2011). A variety of studies have addressed how students think about operator and eigenvalue equations in quantum mechanics (Her & Loverude, 2020; Singh, 2008; Singh & Marshman, 2015; Wawro et al., 2020). There is also a growing body of research around representations in quantum mechanics due to their variety and the need for both fluency with and fluidity between them. The three primary representations in quantum mechanics are Dirac, matrix-vector, and functional. The first two are closely related and well suited to modeling discrete systems, while functional representations are well suited to modeling continuous systems. The *resources framework* posits that people have a variety of cognitive resources that are activated in different contexts and utilized in reasoning (Hammer, 2000). Gire and Manogue identified student resources *quantum measurement as agent* and *operator as agent* that could be combined unproductively to lead students to the idea that an operator acting on a state is a representation of making a measurement of the corresponding observable (Gire and Manogue, 2008). This association between operators and measurements is consistent with other findings in the mathematics education community (Wawro et al., 2020).

Mathematical Modeling Frameworks

Modeling activities are commonly implemented in mathematics instruction to present students with opportunities to practice developing their skills in a real-world context, or to demonstrate how different mathematical concepts can manifest in the real world. This has led the mathematics education community to develop several different frameworks for modeling that typically depict cycles (e.g., Blum & Leiß, 2007). Given that modeling tasks often utilize contexts relevant to the natural sciences, the development of frameworks has not been exclusive to mathematics education (e.g., Modir et al., 2017; Redish & Kuo, 2015; Uhden et al., 2012).

Zbiek and Conner (2006) proposed a model consisting of a variety of processes and sub-processes both in the physical context ("real world") and the mathematical context (see Fig. 1). Their distinction between a mathematical entity and real world situation also proved productive for the analysis presented below. Some of the processes are ways one could engage with or think about a real world situation, some are ways one could engage with a mathematical entity, and others are ways that one could go back and forth between a real world situation and mathematical entity. *Exploring* is obtaining more information about the real world situation by questioning, clarifying, or paying special attention to a specific portion of the situation. By exploring one can *observe mathematically*, using mathematical ideas to describe aspects of the situation. Observing allows the interpretations of the physical system to be informed by formal mathematics, addressing a common sentiment that the mathematics and physics concepts are sometimes inextricable. *Specifying* is identifying conditions and assumptions (C&A) relevant to the real world situation. This is also a step where one is likely to come to some conclusion about the relevant conditions of the real world situation or make simplifying assumptions that will inform the *mathematization* of the problem. *Mathematization* in this case is generating a mathematical representation of the real-world situation. *Combining* is identifying that the mathematical entity one is working with has the appropriate properties and parameters (P&P). This checks that the mathematical entity is representative of the C&A. *Analyzing* includes many activities that can be used to manipulate or interpret the mathematical entity and derive one or more new properties. Included in analyzing is formal mathematical reasoning in which one utilizes their understanding of formal mathematics to derive new P&P of the mathematical entity. A subprocess of analyzing is *associating*, which is drawing on real world knowledge not necessarily associated with the real world situation being modeled to determine something about the mathematical entity. Like the way exploring mathematically provides an avenue for addressing how the interpretation of the real world situation is informed by mathematics, associating accounts for the ways in which the mathematics done are informed by physics concepts. *Highlighting* is the selection of specific properties to assist in reasoning that allow for the drawing of a mathematical conclusion. This conclusion can become one about the real world via *interpreting*. *Examining* is determining if the real world conclusions make sense given the real world situation. This could include things like validity checking or special case analysis. *Associating* and *observing mathematically* are significant features of the Zbiek and Conner model that make it well suited to analysis of physics problem solving. In physics problem solving there often processes engaged in that are not explicitly mathematical or physical. The focus on process is a primary reason this was chosen for analysis in this project.

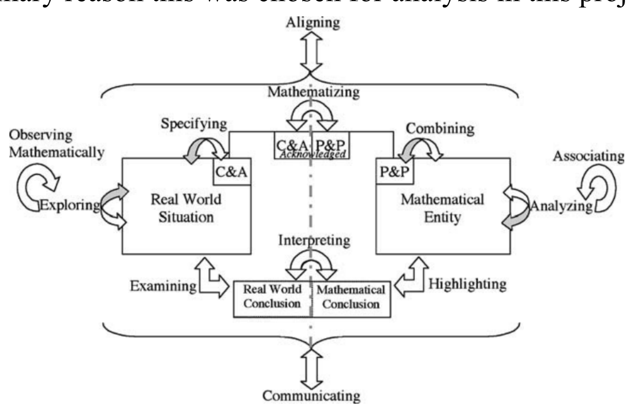

Figure 1. Framework for modeling developed by Zbiek and Conner (Zbiek & Conner, 2006).

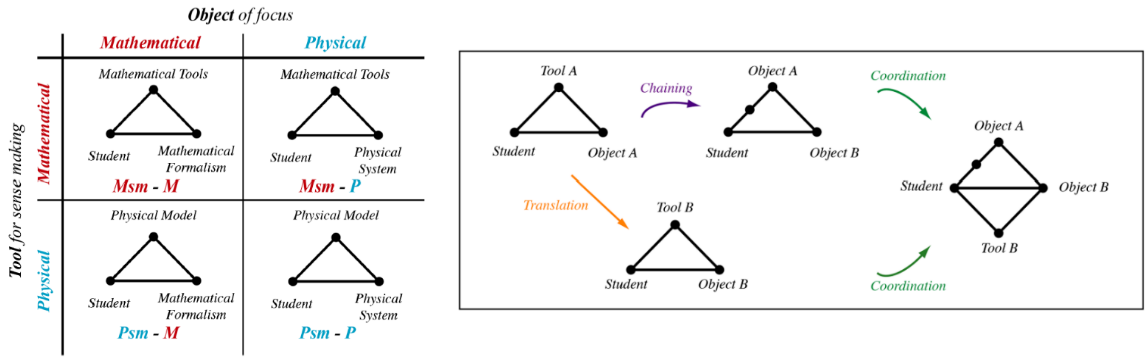
Sensemaking

Broadly, mathematical sensemaking (MSM) can be considered a part of the larger activity of seeking coherence in which students, and even experts, seek connections between conceptual and mathematical understanding in physics (Schoenfeld, 2016). Odden and Russ worked toward building a more operational definition for sensemaking in the sciences (Odden & Russ, 2019). Their definition of sensemaking focuses on the goal – to figure something out – and a threshold, the recognition of an inconsistency. They characterize sensemaking as the work done to figure out or resolve that inconsistency.

With this definition in mind, Gifford and Finklestein developed a categorical framework for analyzing different modes of sensemaking, combining mediated cognition and activity theory (Gifford & Finkelstein, 2020). Mediated cognition is a model for cognition in which a mediator, or tool, is used to help the reasoner's understanding of an object and potentially produce some conclusion (Redish & Bing, 2009)(Vygotsky, 1978). The structure of the model is a result of activity theory, which positions the reasoner (as the subject), the tool being used, and the object being reasoned about amidst a larger context, resulting in an outcome (Engeström et al., 1999). Gifford and Finkelstein focus on the subject, tool, and object; these make up the basis for the model and for the nodes of their sensemaking triangles (see Fig. 2a).



(a) (b)

Figure 2. Categories in Gifford and Finkelstein's framework for (a) mathematical sensemaking in physics and (b) mechanisms for transitions between reasoning spaces (Gifford & Finkelstein, 2020).

For the purposes of analyzing mathematical sensemaking in physics, the tools are either mathematical tools or a physical model. These can be used to engage with either mathematical formalism or a physical system as the object. The different permutations of tools, models, formalism, and system result in four different modes of sensemaking that can be used to model reasoning. The researchers modeled transitions within and between these different modes of reasoning via three different mechanisms, summarized in Figure 2b. Students can "translate" between these modes, reasoning can be "chained" in a multi-step sequence, in which the object of one mode becomes the tool in the next mode, or two different ways of reasoning can be "coordinated" to provide two ways to make sense of the same idea (object).

Methods

The data being discussed in this paper are from a clinical, think-aloud interview with two students from a senior-level, spins-first quantum mechanics course at a mid-sized, research-focused institution in the northeast United States. The first portion of the interview was focused on how the students interpreted, both mathematically and physically, an equation for the momentum operator acting on an energy eigenstate of the infinite square well potential:

$$\hat{p}\sqrt{\frac{2}{L}}\sin\left(\frac{3\pi x}{L}\right) = -i\hbar\frac{3\pi}{L}\sqrt{\frac{2}{L}}\cos\left(\frac{3\pi x}{L}\right). \quad (1)$$

In a functional position representation, the momentum operator is expressed as a derivative with respect to position $(-i\hbar\frac{d}{dx})$, resulting in the additional constants and change in function, making it explicitly not an eigenvalue equation. While this operation is something that students could need to calculate in solving some problems in quantum mechanics, it is not one they are likely to have thought about in the context of eigentheory. When given to students in a previous survey however, it was common for them to label it as an eigenvalue equation, making it of interest and posing the question of the ways in which students determine whether a functional equation was an eigenvalue equation.

The students were then asked to generate an analog of Eq. 1 in Dirac notation. A correct response to this could take any form in which the kets on the left- and right-hand sides of the equation are different (e.g., $\hat{p}|\varphi\rangle = |\xi\rangle$). The students engaged with Eq. 1 until the interviewer deemed that no more progress could be made. In the next portion of the interview, students engaged in a modeling task involving a system consisting of a single particle constrained to exist in one dimension. They were asked to generate an eigenvalue equation for an operator representing the position of the system (e.g., $\hat{x}|x_n\rangle = x_n|x_n\rangle$), identify the different terms in their expression, explain their individual meaning, connections that exist between the terms, and connections between the terms and the physical system. After talking through the eigenvalue equation generated by the students, the original expression (Eq. 1) was revisited, and the students were asked if anything had changed about their interpretation of the equation.

The authors engaged in collaborative qualitative analysis (Richards & Hemphill, 2018) to code student activity into the processes and subprocesses described by Zbiek and Conner. Criteria included which entity students were primarily working with (real world situation or mathematical entity) and whether they were making identifiable conclusions; certain conclusions were associated with specific processes. In the process of interpreting the given expression, students engaged in mathematical sensemaking. The framework for mathematical sensemaking in physics (Gifford & Finkelstein, 2020) was used to analyze student activity when the data reflected students' recognition of an inconsistency. Similar to the modeling analysis, this involved identifying an object and tool utilized in sensemaking. Our aim in using both frameworks is to describe the processes the students go through in reasoning with the given equation more richly than with either framework alone, and to apply that description to student understanding of eigenvalue equations.

Episodes and Outcomes

In the interest of space, we are limiting our discussion to the episodes in which sensemaking occurred. Both frameworks were utilized in the analysis. These sections provide some insight into the interplay of modeling and sensemaking, which is addressed later, in the discussion.

Recognizing Inconsistencies: A Start to Sensemaking

After some initial analysis, the students began trying to rewrite Eq. 1. The explicit manipulation and rewriting of the equation were coded as *analyzing*. The result of their re-writing was, $\hat{p}\varphi_{E_3}(x) = p_{E_3}$, which is incorrect for two reasons: it ignores the fact that there is a function on the RHS of Eq. 1, and it also implies that the energy eigenstate in Eq. 1 is also an eigenstate of the momentum operator, which it is not. The pair continued working with this expression for some time, tweaking different aspects of it before pausing long enough for the interviewer to ask what was causing them to pause. Bob then articulated the inconsistency that led to their sensemaking saying, "Yeah. And my hesitation comes from this, where we say, okay, the thing is we don't have like the, the ket [motions to RHS of $\hat{H}|\varphi_n\rangle = E_n|\varphi_n\rangle$]." The students had previously written the equation they referred to here. The equation is the eigenvalue equation for the Hamiltonian operator which represents energy of a system. It is a very well-known eigenvalue equation which is used repeatedly throughout the course, and so it is likely that the students are attempting to use it as a template in their reasoning.

Bob articulated that while the energy state appears on both sides of the energy eigenvalue equation, their expression did not have a state represented on the RHS. It could be argued that the students noticed that the form of the two equations did not match. If this is the case, then the use of another mathematical entity for the purposes of extracting properties and parameters of eigenvalue equations would be considered *combining*. Bob's leveraging his interpretation of the energy eigenvalue equation as a tool for making sense of Eq. 1 can be modeled as a sensemaking triangle (see Fig. 3). Their sensemaking attempt is unsuccessful since the students are not able to resolve the inconsistency between the forms of the two equations. In their reasoning, the students discuss whether the ket on the RHS of the energy eigenvalue equation is there as a formality.

> *Alice*: Well, you, I think you technically still do, but it, it just, it doesn't, this [motions to $\hat{H}|\varphi_n\rangle = E_n|\varphi_n\rangle$,] is just a representation of it. Right?
>
> *Bob*: A representation of what?
>
> *Alice*: Like when you actually mathematically do this [pointing to $\hat{H}|\varphi_n\rangle = E_n|\varphi_n\rangle$,] and you get your value for energy, like the ket, you wrote there. ... And that's really what you find, but when you write it mathematically and like, to be formal. You include that [points to ket on RHS of $\hat{H}|\varphi_n\rangle = E_n|\varphi_n\rangle$,]. Which might be like not the best way to think about it ...

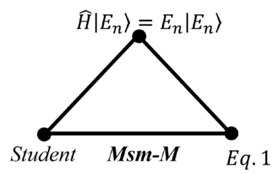


Figure 3. Model of students unsuccessful sensemaking.

Tying Modeling into Sensemaking

After the students' articulation of having essentially hit a wall, the interviewer had them move onto the modeling task, where they immediately wrote, $\hat{x}|\ \rangle = x|\ \rangle$. When asked to explain the terms in their expression, the students identified a position operator ($\hat{x}$), a measured value of position (x), and a state ($|\ \rangle$). As their discussion continued, the students made connections between elements of the expression and the real world situation. Similar to above, this was coded as *combining*, as the students were connecting their generated equation to features of the physical system. In their discussion of what label they would like to use for the kets in the expression, the students again compared it to the energy eigenvalue equation, which eventually leads them to both accept the equation $\hat{x}|L_n\rangle = x_n|L_n\rangle$ as an appropriate eigenvalue equation for an operator representing the position of a particle constrained to exist in one dimension.

The interviewer asked the students to think about what makes the equation they generated for a position operator an eigenvalue equation. Alice and Bob focused on the fact that when operating on the state with the position operator, the state does not change.

> *Bob*: … when we operate our operator, which we designate as *x* hat [$\hat{x}$], um, to represent the position on one of our states, which that could be anything, but since when we operate $\hat{x}$ on this state, we get a scalar value times the same state back. It means that we didn't, we didn't, we, it, […] - if we had changed our state, they wouldn't commute.
>
> *Alice*: By measuring, we don't change the state.
>
> *Bob*: Yeah. But by measuring, we don't change the state. We just find the scalar value that represents the state, I guess.

The students' justifications that their equation is indeed an eigenvalue equation was also coded as *combining*: they are ensuring that the mathematical entity they generated has the appropriate properties to describe the real world situation in the prompt. The primary property they reference in this justification is that the state does not change. When asked if their analysis had any impact on their interpretation, the students were able to fully articulate that the state is changed in Eq. 1 and therefore Eq. 1 is not an eigenvalue equation. The students used their general understanding of eigenvalue equations in quantum mechanics as a tool to determine the relevant features of the eigenvalue equation they generated. This reasoning was then chained to make sense of another object, the non-eigenvalue operator equation, resulting in the final conclusion. Figure 4 models the sensemaking process in its entirety including the students' final conclusion.

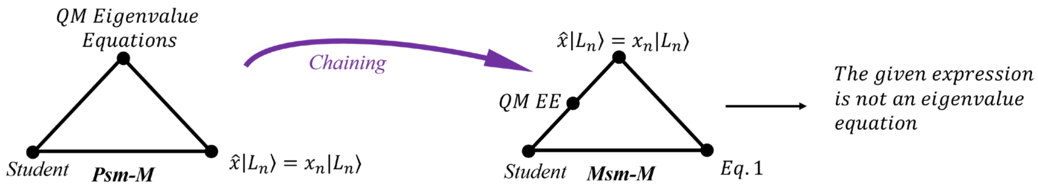

Figure 4. A model of the students sensemaking leading to their final conclusion about Eq. 1.

Discussion

In this study, Zbiek and Conner (2006)'s modeling framework is used to get a fuller picture of the processes students engage in as they work through the tasks, while Gifford and Finkelstein (2020)'s sensemaking framework is utilized to deepen the understanding of how the students resolve an inconsistency in their understanding while working in a modeling frame. When the students recognize an inconsistency in their analysis of Eq. 1, they shift into a sensemaking frame in order to resolve that inconsistency. That is not to say that a modeling frame is requisite for sensemaking, only that the two can coexist, as they do in this case study.

Odden and Russ (Odden & Russ, 2019) claim that sensemaking is often a part of modeling activities, and could potentially occur in parallel with modeling. Our study documents an example of sensemaking within modeling, and explicitly identifies behaviors and strategies students use to resolve an inconsistency. The modeling and sensemaking frameworks come together here to provide insight into the kinds of activities students engage in when given a task that places them in what is typically the middle of a modeling cycle, how they go about trying to resolve an inconsistency, and how analogous modeling tasks can help students refine their reasoning on a task with which they are struggling.

While productive, the Zbiek and Conner (2006) model may not be sufficient to model more advanced physics problem solving. In coding, the authors had several discussions in which they were unable to singularly code some of the students' work because it was difficult to determine whether the object of the students' thinking was a mathematical entity or physical system (e.g., real world situation). We suspect this is due to the blended nature of quantum mechanics content rather than a lack of student articulation thereof. This may suggest a need for modifications to existing frameworks, or a new framework entirely, that accounts for the ways mathematics and physics are blended in physics reasoning and modeling.

The primary limitation of this study is that the data are from a single pair of students so results may not be generalizable. However, these students were articulate and thoughtful, and the ideas they present corroborate previous findings in the literature. We look forward to further empirical and theoretical work in this and other physics topics to provide additional insight.

Believability in Mathematical Conditionals: Generating Items for a Conditional Inference Task

Lara Alcock
Loughborough University

Ben Davies
University of Southampton

This paper describes design issues for a conditional inference task with mathematical content. The task will mirror those used in cognitive psychology to study inferences from everyday causal conditionals: its items will present a conditional premise (if A then B) and a categorical premise (A, not-A, B, or not-B) and ask participants to evaluate whether a conclusion (respectively, B, not-B, A, not-A) necessarily follows. To assemble items, we asked six mathematics education researchers with expertise in conceptual understanding to generate conditionals covering a range of mathematical topics. To mirror the structure of tasks with everyday causal content, we asked that these conditionals should vary in believability. In this paper, we analyze the content and phrasing of the submitted conditionals in order to assess their suitability for use in a conditional inference task, and describe our planned use of this task to investigate the relationship between logical reasoning and mathematical expertise.

Keywords: conditional, inference, logic, reasoning, proof

Introduction

Logical reasoning is central to mathematics, overtly so at the transition to proof (David & Zazkis, 2019). Students must learn to validate inferences that they make during proof construction and inferences that they read during proof comprehension (Hodds, Alcock & Inglis, 2014). This does not mean that every inference must be explicitly justified – demands vary by context (Weber, 2008). It does mean that every inference could in principle be checked, in a process that in experts involves considerable back-and-forth reading (Inglis & Alcock, 2012).

Inference checking can fail for semantic reasons. Alcock and Weber (2005), for instance, reported that some students were willing to accept an inference from the premise that $(\sqrt{n})$ is an increasing sequence to the conclusion that $(\sqrt{n})$ tends to infinity. This inference is deductively invalid (Smith, 2020) because some increasing sequences do not tend to infinity. The argument, however, has the form below. If the conditional premise (interpreted as a generalized conditional per Durand-Guerrier, 2003) were true, then the inference would be valid.

If (a_n) is an increasing sequence, then (a_n) tends to infinity.
$(\sqrt{n})$ is an increasing sequence.
So $(\sqrt{n})$ tends to infinity.

Inference checking can also fail for syntactic reasons. Selden and Selden (2003), for instance, reported that some students were willing to accept a proof of the first claim below as a proof of the second (see also Hoyles & Kuchemann, 2002; Inglis & Alcock, 2012). This is logically invalid (Smith, 2020) because a conditional and its converse are not equivalent.

For any positive integer n, if n is a multiple of 3 then n^2 is a multiple of 3.
For any positive integer n, if n^2 is a multiple of 3 then n is a multiple of 3.

In the semantic case, failure to detect an invalid inference is readily explained by the fact that individuals' example spaces (Sinclair et al., 2011) or concept images (Tall & Vinner, 1981) do not fully 'match' the defined concepts, so that people might overlook counterexamples. In the syntactic case, failure to detect an invalid inference might occur for what amounts to the same reason at a more abstract level: individuals' example spaces or concept images *for conditionals* are unlikely to 'match' the material or truth-functional interpretation used in mathematics (Dawkins & Norton, 2022; Epp, 2003). This occurs because everyday conditionals lend themselves to multiple distinct interpretations: for 'If it is a dog, then it is an animal', a material conditional interpretation is sensible; for 'If you mow the lawn, I will give you $5', a biconditional interpretation is sensible (Cummins et al., 1991). Hence, mathematics students must learn to restrict their interpretations of conditionals just as they must learn to restrict their interpretations of words like 'limit' and 'group'. As they learn, we can expect to see errors in relation to normative validity. Indeed, we might expect errors to persist – maybe mathematical experts reason normatively across all contexts, but maybe they reason normatively in mathematics only, and maybe their reasoning is vulnerable to errors even there.

To investigate these possibilities and thereby to improve knowledge relevant to the teaching of logical reasoning, we plan to build on the extensive research on everyday conditional reasoning in cognitive psychology. Specifically, we plan to construct a mathematical *conditional inference* task and use this, together with a task with everyday causal content, to study whether and how reasoning differs across contents and levels of mathematical expertise. In the present paper, we explain the theoretical background of our work and report first steps in task design.

Theoretical Background

Cognitive psychology has a long history of studying reasoning with and about conditionals (e.g., Evans & Over, 2004; Oaksford & Chater, 2020). Here we focus on conditional inference tasks, as we believe their structure is clearly relevant to proof validation. A typical conditional inference task presents participants with a conditional premise and one of four categorical premises, as illustrated below with everyday causal content (De Neys et al., 2003); participants are asked to evaluate the conclusion in the third line. Normatively, MP and MT inferences are valid, and DA and AC inferences are invalid.

Modus Ponens (MP)
If John studies hard, then he does well on the test.
John studies hard.
John does well on the test.

Affirmation of the Consequent (AC)
If John studies hard, then he does well on the test.
John does well on the test.
John studied hard.

Denial of the Antecedent (DA)
If John studies hard, then he does well on the test.
John does not study hard.
John does not do well on the test.

Modus Tollens (MT)
If John studies hard, then he does well on the test.
John does not do well on the test.
John did not study hard.

The task instructions might emphasise logic, asking participants to assume that the premises are true and state whether the conclusion necessarily follows, or they might seek to elicit everyday reasoning, asking participants to assume that the premises hold and use a scale to express certainty that the conclusion can be drawn (e.g., Evans, Handley, Neilens & Over, 2010). Instructions that emphasise logic mirror the task of proof validation: participants are asked to assume that some premises are true and decide whether a conclusion necessarily follows, which involves recognizing normatively invalid DA and AC inferences.

However, everyday content introduces complexity, because a conditional like 'If John studies hard, then he does well on the test' is not simply true or false. It is a reasonable assertion about a causal relationship, but studying hard is neither necessary nor sufficient for doing well. *Disablers* (Byrne, 1989) might intervene to prevent the antecedent from causing the consequent: John might study hard but not do well if, for example, the test is very difficult or if he studies the wrong subject (De Neys et al., 2003). *Alternative antecedents* (Cummins et al., 1991) might account for the consequent without the stated antecedent: John might study little but still do well if the test is easy or if he is lucky (De Neys et al., 2003). For causal conditionals, disablers highlight the fact that the antecedent might not be sufficient for the consequent and are known to make people less likely to endorse MP and MT inferences; alternative antecedents highlight the fact that the stated antecedent might not be necessary for the consequent and make people less likely to endorse DA and AC inferences (Byrne, 1989; Cummins et al., 1991). Disablers and alternative antecedents can be more or less accessible – for instance, people typically generate few disablers but many alternatives for 'If Alvin read without his glasses, then he got a headache' (Cummins, 1995). Thus, conditionals are more or less believable and support the four inferences to different extents (De Neys et al., 2003). Also, there are individual differences in ability to prioritise logic over believability, though rates do not approach normative perfection. Evans, Handley, Neilens and Over (2010) reported that for participants of higher cognitive ability, acceptance rates under deductive instructions were 93% for MP inferences, 41% for DA, 41% for AC and 47% for MT; these are far from the normative 100%, 0%, 0% and 100%.

In order to study conditional inference across levels of mathematical expertise, we aim to design a mathematical conditional inference task with structure that parallels tasks with everyday content, using all four inference types and conditionals that vary in believability. However, this raises several issues in task design.

One issue is that to parallel everyday tasks, we would like to use simple phrasing as in 'If x is less than 2, then x is less than 5'. However, in mathematics, such a conditional is considered a predicate, not a proposition, so that formally it has no truth value (Durand-Guerrier, 2003). We consider this relatively unproblematic because sensible universal quantification is commonly assumed (Dawkins & Roh, 2022) and because tasks with everyday content have this feature too (Oaksford & Chater, 2007): participants are implicitly invited to consider 'If John studies hard, then he does well on the test' as a generalized conditional applying across multiple situations.

Another issue is that in mathematical proofs, universal instantiation is routine. In the Introduction, the conditional premise 'If (a_n) is an increasing sequence, then (a_n) tends to infinity' appears not with the general categorical premise '(a_n) is an increasing sequence' but with the instantiation '$(\sqrt{n})$ is an increasing sequence'. Premises of both types can appear in proofs, and instantiations have been used in the few studies to investigate conditional inference in mathematics (Case & Speer, 2021; Durand-Guerrier, 2003). However, premises of the general type are used in typical research on everyday causal tasks so, while noting that this would be an interesting variation for the future, we prioritise comparability across contexts.

A third issue is that with assumed universal quantification and no instantiation, mathematical conditionals are either true or false. For any true conditional (that is not a true biconditional), the antecedent is sufficient but not necessary for the consequent. Sufficiency means that and MP and MT inferences are always valid because standard logic is monotonic (Smith, 2020) so there can be no disablers – nothing could 'intervene' to prevent an x less than 2 from being less than 5. Lack of necessity means that DA and AC inferences are always invalid, though counterexamples differ from the alternative antecedents of everyday tasks because they are often singular ('zero') or in classes of a single type ('all negative numbers').

For these reasons, it is impractical in mathematics to follow the typical research approach (e.g., De Neys et al., 2003) of distinguishing more and less believable conditionals using pre-tests in which participants list possible disablers and alternatives. Nevertheless, we suggest that believability for mathematical conditionals does plausibly vary on a continuous scale. For instance, 'If X is a square then X is a parallelogram' is true but perhaps not immediately or wholly believable. While a square is a parallelogram, it would be conversationally uncooperative (Grice, 1989) to call X a parallelogram if one knew that it was a square. In contrast, 'If $x < 3$ then $1/x > 1/3$' is false but definitely not immediately or wholly unbelievable. Negative x values might easily be overlooked – Alcock and Attridge (2023) reported that about one fifth of mathematics undergraduates initially judged this conditional true. We might, in theory, assess believability by asking participants to score it directly (cf. Evans et al., 2010). However, we think that mathematically experienced people would likely balk at assigning a believability score that is not 1 or 0 when they know that a conditional must be true or false.

We therefore take an alternative approach, asking not about disablers/alternatives or believability scores, but instead about *relative* believability. In the work reported here, we asked experts in conceptual understanding to generate five mathematical conditionals each and to rank their conditionals for believability. If believability does vary continuously, this should ensure that we gather conditionals from across the scale. In work to follow, we will use comparative judgement (see, e.g., Davies et al., 2021) with both experts and undergraduates to assess more robustly whether believability is a reliably shared construct.

Method

Participants, Data Collection and Data Processing

We set out to collect conditionals covering a range of mathematical topics, to assess whether believability might vary as anticipated by the theory above, and to refine our understanding of how language around mathematics reflects or differs from that around everyday causal content. We therefore approached six mathematics education researchers with expertise in secondary-school-level conceptual understanding, who would be able to anticipate what undergraduate students would find more and less believable. These participants were informed about the purpose and theoretical background of the study and were each asked to generate five mathematical conditionals that would be familiar to typical students aged 13-14 and therefore basic for mathematics undergraduates, postgraduates, and experts. They were instructed that to parallel those used in tasks with everyday causal content, their conditionals should:

- Cover a range of mathematical topics;
- Have plausibly related antecedent and consequent;
- Not be obviously false;
- Not use additional connectives ('not', 'and', 'or') in the antecedent or consequent;
- Vary in believability (where the most believable could be clearly true).

They were also asked to:

- State whether each of their conditionals was technically true or false;
- Rank their conditionals from 1 (least believable) to 5 (most believable);
- Give a one-sentence explanation of their ranking for each conditional.

Prior to analysis, we requested amendments where participants had included conditionals with extra connectives (often in symbols, for instance '$\leq$' or '$\neq$'). We checked the stated truth values, inviting participants to explain/adjust if there was any doubt about, for example, the set over which universal quantification was assumed. We then ensured that all conditionals were written in the same way, with an explicit 'then' after a comma, and without extra words. For example, '…then it is also convex' became 'then it is convex', and '…then the median must be 7' became '…then the median is 7'. Overall, participants were able to comply with our instructions and generate conditionals with non-obvious truth values, though some observed that ranking was difficult. Naturally, we do not take individual rankings as inherently reliable; the planned comparative judgement will provide more robust measures.

Analysis: Removing Unsuitable Conditionals

Our analysis focused on suitability for use in a conditional inference task. Seven of the 30 submitted conditionals were not suitable because, although they met our criteria, their consequents could not readily be asserted as categorical premises, even with rephrasing (equivalently, the converses could not readily be stated). Not coincidentally, some were long and some invoked an agent 'you' or 'I' or described physical actions as well as abstract relationships. These conditionals, listed below, were therefore removed.

- If I flip a fair coin twice, then the probability of getting two heads is 1/3.
- If you sum the first *n* odd numbers, then you get n^2.
- If a circle is divided into regions by straight lines connecting *n* dots, then the maximum number of regions is 2^n.
- If coin lands on tails 42 times out of 100 flips, then there is not enough information to tell whether it is biased.
- If £12 is shared in the ratio 1:3, then the smaller share is 1/3 of the total.
- If two normal 6-sided dice are thrown and I tell you that one of the dice shows a 2, then the probability of both being a 2 is 1/6.
- If the perimeter of a square is the same as the circumference of a circle, then the area of the square is less than the area of the circle.

Along similar lines, we also removed the conditional 'If $a = -1$, then $|a| = -|1|$' because its consequent is false. We then removed a further four conditionals were not suitable because, although they met our criteria and were phrased in ways better fitted a conditional inference task, they had true converses. This would potentially create a confound because it would mean that DA and AC inferences would be valid for semantic reasons; it also makes these conditionals less 'like' everyday causal conditionals in which there is a clear cause in the antecedent and effect in the consequent. The following conditionals were therefore also removed.

- If $x^3 < x^2$ then $x < 0$.
- If $x = 24$ is the solution to $4x + 9 = 105$, then $x = 12$ is the solution to $8x + 9 = 105$.
- If the diagonals of a quadrilateral bisect each other, then the quadrilateral is a rectangle.
- If *n* is a positive integer, then it can be written as a product of prime factors in exactly one way.

Analysis: Content and Form in Suitable Conditionals

This left 18 conditionals potentially suitable for a conditional inference task. We list these in Table 1, ordered by participants' individual believability rankings (most to least believable) and together with their truth values and mathematical topics. The final column captures the way in which scope of quantification is handled, with codes (discussed further below):

- 'I' where the scope is implicit, usually where a variable is assumed to be a real number;
- 'E' where the scope is explicit, usually where a set is specified in the antecedent;
- 'S' where the antecedent involves a single specific number or situation.

Table 1. Conditionals potentially suitable for a conditional inference task

Conditional	Rank	Truth	Topic	Scope
If a quadrilateral is cyclic, then it is convex.	5	T	geometry	E
If a polygon is a square, then it is a rhombus.	5	T	geometry	E
If $x^2 = y^2$, then $xy = yx$.	5	T	algebra	I
If $x = -4$, then $x^2 + x - 12 = 0$.	5	T	algebra	S
If a quadrilateral has a reflex angle, then it will tesselate.	4	T	geometry	E
If x is positive, then $\tan x > \sin x$.	4	F	trig	E
If $x - 12{,}345 = .67$ then $x > -12{,}345.67$.	4	T	number	S
If a fraction has denominator 7, then it is equivalent to a non-terminating decimal.	4	F	number	E
If $\sin x > 0$ then $\cos x < 1$.	3	T	trig	I
If a number is a multiple of 13, then it has an even number of factors.	3	F	number	E
If a composite number ends in a 3, then it is a multiple of 3.	3	F	number	E
If a rectangle has area 10cm^2, then its perimeter is greater than 10cm.	2	T	geometry	E
If an equation is a quadratic, then it has exactly two roots.	2	F	algebra	E
If $a = 42$, then $a \times b > 42$.	2	F	number	S
If four consecutive numbers are added, then the result is a multiple of four.	2	F	number	E
If the mean of a dataset is 7, then the median is 7.	1	F	statistics	E
If $a > b$, then $ac > bc$.	1	F	number	I
If a rectangle is stretched so that its side lengths double, then its area doubles.	1	F	ratio	E

In terms of topics, truth values, and believability rankings, we find this initial collection satisfactory. Topics are spread across believability rankings. More believable conditionals are more likely to be true but, in line with our suggestion that truth and believability might not align perfectly, there is considerable overlap in the middle of the table. Our removal of unsuitable conditionals did not disproportionately remove those at specific ranks, so there is no evidence of a problematic interaction between believability and phrasing challenges or truth of the converse.

The scope codes highlight new issues in designing a task to parallel those involving everyday causal content, in terms of substance, phrasing and the interactions between the two.

Conditionals with scope code I are most straightforwardly like those used in everyday causal tasks. Their ‘making sense’ without explicit scope means that they lend themselves to presentation with all four corresponding categorical premises. For instance, for the conditional ‘If $x^2 = y^2$ then $xy = yx$’, an AC item would appear as follows.

If $x^2 = y^2$ then $xy = yx$.
$xy = yx$.
$x^2 = y^2$.

Conditionals with scope code E usually have a specified set in the antecedent and a deictic ‘it’ or ‘its’ in the consequent, as in ‘If a quadrilateral is cyclic, then it is convex’. In these cases, categorical premises cannot simply use the consequent as is ('It is convex' makes no sense in isolation). We do not want to lose these items, which make up the majority of those submitted and which are clearly natural in mathematics. As a sensible solution, we will likely mirror the phrasing typically used for everyday causal items, naming the object and using the name in both categorical premise and conclusion, as below. Mathematical conditionals are at least simpler in that they do not require manipulating tenses to accommodate the temporal aspects of causality.

If a quadrilateral Q is cyclic, then it is convex.	If John studies hard, then he does well on the test.
Quadrilateral Q is convex.	John does well on the test.
Q is cyclic.	John studied hard.

Conditionals with scope code S – whose antecedents focus on specific objects – have the interesting property that they do not 'feel' like generalized conditionals. We could avoid using such items, but we note that they have interesting properties around phrasing, necessity and sufficiency. For instance, the antecedent of the conditional 'If $a = 42$, then $a \times b > 42$' seems to be about a, when the conditional actually quantifies over b. It is false but invokes the common misconception 'multiplication makes things bigger', and the antecedent is so far from necessary for the consequent that accepting the AC inference from $a \times b > 42$ to $a = 42$ would seem nonsensical. This raises questions about how plausible false conditionals must be in order to work in our task, and we will discuss this further at the conference.

Discussion and Next Steps

The analysis above clarifies design issues for a mathematical conditional inference task. Despite the normative interpretation of conditionals in mathematics, 'natural' uses of if-then to express mathematical relationships vary considerably. Some uses do not lend themselves to a conditional inference task due to length and overall complexity in describing agents and/or actions. Some have true converses, and therefore do not match items used for causal conditionals, where the cause appears in the antecedent and the effect in the consequent (Cummins et al., 1991). For those that are in principle suitable, scope might be fully implicit – commonly in the case of quantification over sets of numbers – or explicit in the sense that a set is specified in the antecedent. In the latter case, rephrasing is necessary to construct an item.

We will use this analysis to inform our ongoing work. We aim to collect a total of approximately 40 suitable conditionals, with a view to constructing a 16-item task using eight conditionals that are more believable and eight that are less believable (should believability turn out not to be a reliable construct, we will simply use a spread of topics). We will therefore ask two more experts to generate five conditionals each, with the additional criterion that the converse of each should be readily articulated and false. We will then collect conditionals from the mathematics education literature and textbooks to complete a set that balances topics, truth and implicit/explicit quantification, and will seek to make phrasing as uniform as is practical. We will report on this work at the conference, together with the comparative judgement study of believability and a first test of the conditional inference task with undergraduates.

The Price Does Not Appear the Same for Everyone: Racial Differences in Students' Perceptions of the Mathematics Graduate School Application Process

Lack of racial diversity has been an ongoing issue in higher education. Recently, the Theory of Racialized Organizations has been used to help explain why, despite many calls for diversity, the demographics of higher education have not changed. Considering this framework, we seek to understand what aspects of the graduate school application process are viewed as barriers by minoritized students for applying. As part of a larger study of undergraduate student knowledge of the graduate school application process, we analyze 515 responses from undergraduate math majors using Mann-Whitney U tests to identify differences in what participants view as a barrier to apply to graduate school by race/ethnicity. We discuss two main results and recommend changes to graduate programs wishing to recruit more minoritized students.

Keywords: Graduate school application, undergraduate mathematics majors, Theory of Racialized Organizations, Minoritized students

On June 29, 2023, the U.S. Supreme Court struck down Affirmative Action on college admissions (Students for Fair Admissions Inc. v. President & Fellows of Harvard College, 2023). This decision has the potential to impact the ability of future minoritized[1] students to enter college both at the undergraduate and graduate levels. This will be especially problematic for the field of mathematics given its lack of racial diversity that becomes more pronounced at higher levels. While 31.9% of the U.S. population identify as Hispanic/Latinx or African American (U.S. Census, 2020), in recent years only 15.9% of mathematics and statistics (mathematics-only data unavailable) bachelor's degrees were earned by minoritized students (National Center for Science and Engineering Statistics, 2019). Finally, only 7.4% of new mathematics doctoral recipients were minoritized (Golbeck, et al., 2020).

Diversity in graduate admissions has become an important topic of research and conflict in the last decade. Recent higher education research has shed light on what faculty think about the role of diversity in final-round decisions in the graduate admissions process (Posselt, 2016). Often, diversity is discussed as a "goal" for institutions of higher education to achieve. Yet, in their admissions processes, the conditionality of diversity comes secondary to the perceived obligation of "protecting well-established standards of conventional achievement," such as high program rankings and competitive test scores (Posselt, 2016). However, it is well-documented that gaps in standardized test scores fall along lines of socio-economic identity and are not adequate indicators of intelligence (Posselt, 2016). If diversity is considered a criterion for

[1] Minoritized is an alternative way of referring to people who are often labeled as "Underrepresented Minorities" in STEM. This alternative phrasing makes it clear that it is power imbalances and systematic oppression that cause these groups to be less represented in STEM (Wingrove-Haugland & McLeod, 2021).

graduate admissions only secondary to traditional quantitative measures, then current admission practices are likely to "perpetuate enrollment inequities" (Posselt, 2016).

While this research provides great insight on the admissions process across multiple disciplines it loses context and insight that can be gained through Discipline-Based Education Research. Physics education researchers have conducted multiple studies of the graduate application process (Chari & Potvin, 2019a, 2019b; Potvin, et al., 2017; Scherr, et al., 2017; Young & Caballero, 2019). Physics departments "express a … demand for greater numbers of students from [minoritized] groups, but simultaneously report a lack of such applicants" (Potvin et al., 2017). This finding mirrors smaller scale research in the field of mathematics which found "low graduate mathematics application rates from historically underrepresented groups" (Gevertz & Wares, 2020). If the U.S. is to increase diversity in STEM graduate programs, we must examine whether minoritized students apply for graduate school at the same rate as their non-minoritized peers and if not, determine how to address the disparity.

Students who want to pursue graduate school in mathematics often face multiple financial barriers. These burdens can include working to support their family (instead of acquiring research experience or studying), rent, transportation, paying off undergraduate debt, GRE costs, and application fees (Cochran et al., 2018). Multiple studies have shown that application fees limit the number of applications from students from low-income backgrounds (Cadena et al., 2023; Cochran et al., 2018; Roberts et al., 2021; Wilson, et al., 2018). Some programs have implemented fee waivers for this reason. However, the effort required to gain fee waivers deters students from applying to graduate school. For example, students may need to complete their application in advance of the normal deadline or achieve a higher GPA (Cadena et al., 2023; Roberts et al., 2021). In some cases, fee waivers require U.S. citizenship, so undocumented or international students may not qualify for waivers. In addition, the application fee may sometimes cost a student an entire month's salary (Cadena et al., 2023). Thus, financial burdens, and application fees in particular, negatively, and significantly impact low-income students applying to graduate school.

The Undergraduate Knowledge of the Mathematics Graduate School Application Process (Knowledge-GAP) project was created to examine undergraduate mathematics majors' knowledge about the graduate school application process and to facilitate an understanding of perceived barriers to applying to graduate school across different demographic groups. This paper focuses on how minoritized students perceive the application process and seeks to answer the following subset of research questions from the Knowledge-GAP project:

1. *Do perceptions of barriers to applying to graduate school differ by race/ethnicity?*
2. *What factors are most important to minoritized students planning to apply to graduate school?*

Theoretical Background

The Theory of Racialized Organizations (TRO) was developed to help explain "consistency of racialized organizational inequality" (Ray, 2019). This framework calls for researchers interested in racial inequality to critically examine how an organization's policies and institutionalized practices (e.g., admissions procedures) uphold racial disparities (Ray, 2019). It has been applied to many fields and types of organizations since its inception including undergraduate mathematics education (Leyva et al., 2021). In a recent study, Poon et al. (2023) applied the TRO framework "to examine the totality of (undergraduate) admissions as racialized organizations". They found that even supposedly "race-neutral" admissions policies can increase racial inequality due to the existing racial wealth gap in America (Poon et al., 2023). To explain this gap, they call upon the concept of racial capitalism (Poon et al., 2023). Melamed (2015) explained racial capitalism by stating: "Racism enshrines the inequalities that capitalism requires . . . by displacing the uneven life chances that are inescapably part of capitalist social relations onto fictions of differing human capacities, historically" along racial lines (p. 77). We extend this framework to graduate admissions to understand differences in perceived barriers to the graduate application process between minoritized and non-minoritized students.

Methods

Instrument Development

The research team created a survey based in part on a survey used to determine undergraduate physics majors' interest in graduate school and how important they believed different aspects of the application process were (Chari & Potvin, 2019b). Nineteen survey items were adapted from that instrument. A notable difference between that survey and ours was that we provided an opportunity for participants to express their lack of knowledge about different parts of the application process. The final survey had 57 items separated into four categories: (a) knowledge about different aspects of the application process, (b) barriers to applying, (c) interest in graduate school and what students look for in programs they apply to, and (d) demographic questions. Most questions were Likert scale or multiple choice, though four were open-ended and some of the multiple-choice items allowed participants to type in a text response. The full survey is available at this link: https://researchrepository.wvu.edu/faculty_publications/3291/.

Data Collection

The research team sent an email with the survey to department chairs and undergraduate program directors at all U.S. undergraduate mathematics programs at colleges and universities with at least 1000 students total ($N = 985$). We requested the survey be sent to all undergraduate mathematics majors. Initial emails were sent Fall 2022 through Spring 2023, via Qualtrics, and follow-up emails were sent to encourage a greater response rate. In addition to direct emails, the survey was also posted on social media, listservs and in newsletters for several professional organizations in mathematics.

Data Analysis

We received 1090 responses from students at 181 colleges and universities, with 519 complete responses. Note that students could miss part of a question and still have their response marked as complete. Thus, the *N*s for different items are not always the same. Statistical tests were run in IBM SPSS.

To address these research questions, we analyzed data collected through two survey items: *To what extent are the following factors a potential barrier to your pursuit of graduate school?* and *How important are the following factors in choosing which schools you apply to?* Both questions were Likert scale items adapted for this study from Chari and Potvin (2019b). The first item had 17 sub-item topics (potential barriers), which students rated on a scale of 1 (not at all a barrier) to 5 (very significant barrier). The second item had 15 sub-item topics (potentially important factors for applying to graduate programs), which students rated on a scale of 1 (not at all important) to 5 (very important).

Results

Participant Demographics

Tables 1 and 2 show annual income for participants while growing up, and racial/ethnic demographics for participants with complete responses. Note that participants were able to select more than one category for racial/ethnic identification.

Table 1. Yearly Income for Participants When They Were Growing Up.

To the best of your knowledge, which category best describes your family's yearly household income while you were growing up?

Income	*N*	Percentage
Less than $60,000	119	22.9%
Between $60,000 and $100,000	128	24.7%
More than $100,000	208	40.1%
Do not know	44	8.5%
Prefer not to say	20	3.9%
Total	519	100%

Table 2. Race/ethnicity of Participants.*

With which racial and ethnic groups do you identify?

Race/Ethnicity	*N*	Percentage
American Indian or Alaskan Native	7	1.4%
Asian or Asian American	80	15.5%
Black or African American	21	4.1%
Hispanic, Latine/Latinx, or Spanish Origin	59	11.4%
South Western Asia and North African (Middle Eastern or North African)	8	1.6%
Native Hawaiian or Other Pacific Islander	5	1.0%
White	381	73.8%
Prefer not to say	10	1.9%
Total	516	

Perceptions of Potential Barriers & Important Factors

Participants were separated into two groups based on their response to the survey item asking for their race and ethnicity. Participants who said they belonged to at least one of the following groups were labeled as "minoritized" in the dataset: American Indian or Alaskan Native, Black or African American, Hispanic, Latine/Latinx, or Spanish origin or Native Hawaiian or Other Pacific Islander. While there are issues with combining different identities that have been historically and through modern times excluded in STEM disciplines, this method provides insight into factors potentially excluding these groups from graduate education. In addition, sample sizes in many of the individual groups were too small to run meaningful statistical analyses.

We report here only on a subset of the sub-item topics for both items, seven for the first item and five for the second item. A one-way analysis of variance (ANOVA) was not employed because for 8 of the 12 sub-item topics, the Homogeneity of Variance assumption was violated. Thus, for ease of comparison and consistency, Mann-Whitney U tests were performed using the minoritized/non-minoritized variables for all sub-item topics. Table 3 contains Mann-Whitney U test results for the minoritized/non-minoritized groups for the 515 participants who responded to the selected sub-item topics from the first survey item.

Table 3. Mann-Whitney U test results for selected items for the question, "To what extent are the following factors a potential barrier to your pursuit of graduate school?" using the minoritized/non-minoritized variable.

Item	Group	*N*	Mean	Mean Rank	*U*	*Z*	*p*	*r*
Graduate application fees	Minoritized	85	3.08	313.68	13542	-3.88	<.001	0.17
	Not	430	2.47	246.99				
Paying for the General GRE Test ($220)	Minoritized	85	3.40	317.02	13003.5	-4.22	<.001	0.19
	Not	427	2.69	244.45				
Paying for the GRE Mathematics Subject Test ($150)	Minoritized	85	3.38	320.90	12843.5	-4.41	<.001	0.19
	Not	429	2.62	244.94				
Sending GRE scores to programs ($30 per program)	Minoritized	85	3.16	311.82	13530.5	-3.83	<.001	0.17
	Not	428	2.50	246.11				
Availability of scholarships/funds or my ability to pay tuition	Minoritized	84	4.19	320.87	12653	-4.47	<.001	0.20
	Not	429	3.55	244.49				
Parenting or family responsibilities	Minoritized	84	2.35	316.92	12901	-4.60	<.001	0.20
	Not	428	1.68	244.64				
A lack of mathematicians/scientists that look like me	Minoritized	83	2.82	322.11	12358	-4.74	<.001	0.21
	Not	429	1.93	243.81				

The output of a Mann-Whitney U test is a Z value on a normal distribution. The Z values in Table 3 indicate that the minoritized group has greater means than the non-minoritized group. These results show there is a statistically significant difference (all p's < .05) between the minoritized/non-minoritized groups in the responses for all seven sub-item topics. In all cases the minoritized participants were more likely to view each sub-item topic as a potential barrier to their pursuit of graduate school than their peers. All of these results had a small effect size (all r's between 0.1 and 0.3).

For the second survey item, "How important are the following factors in choosing which schools you apply to?", it should be noted that not all participants saw this item. Prior to this, participants were asked to state their interest in graduate school in mathematics. Only participants who responded with anything other than "Not interested in graduate school in mathematics" saw this item. Table 4 contains Mann-Whitney U test results for the minoritized/non-minoritized groups for the 435 participants who responded to the selected sub-item topics from the second survey item.

Table 4. Mann-Whitney U test results for selected options for the question, "How important are the following factors in choosing which schools you apply to?" using the minoritized/non-minoritized variable.

Item	Group	N	Mean	Mean Rank	U	Z	p	r
Availability/Amount of assistantships or scholarships	Minoritized	74	4.61	259.74	10194	-3.51	<.001	0.17
	Not	360	4.20	208.82				
Cost of living	Minoritized	74	4.54	278.77	8860	-4.84	<.001	0.23
	Not	361	3.92	205.54				
No GRE General Test requirement or no minimum score requirement	Minoritized	74	3.09	257.91	10329.5	-3.12	.002	0.15
	Not	360	2.52	209.19				
Having peers who are the same race/ethnicity as myself	Minoritized	73	2.52	278.45	8654	-5.52	<.001	0.27
	Not	360	1.51	204.54				
Having a thesis advisor of the same race/ethnicity as myself	Minoritized	73	2.19	274.76	8850.5	-5.62	<.001	0.27
	Not	359	1.34	204.65				

**Note the total N for these tables are strictly less than the previous tables since participants not interested in graduate school did not get this question.*

The Z values in Table 4 indicate that the minoritized group has greater means than the non-minoritized group. These results show there is a statistically significant difference (all p's $< .05$) between the minoritized/non-minoritized groups in the responses for all five sub-item topics. In all cases the minoritized participants were more likely to view each sub-item topic as an important factor in choosing which school to apply to than their peers. All of these results had a small effect size (all r's between 0.1 and 0.3).

These Mann-Whitney U test results show that minoritized participants are more concerned about the cost of different aspects of the graduate school application process compared to their peers. They are also more concerned about being able to afford to attend graduate school. Finally, they are more concerned about having peers and advisors with the same race/ethnicity in the graduate programs to which they apply.

Annual Income

To examine the relationship between family income and minoritized status, participant responses to the item "To the best of your knowledge, which category best describes your family's yearly household income while you were growing up?" were analyzed. A Chi-squared test of association determined that there was an association between ethnicity status and income category $\chi 2(4, N = 512) = 46.44$, $p = <.001$, $V = .30$. This result had a medium effect size. Minoritized participants were more likely to come from lower income families than their peers: half of the minoritized participants were from families that made less than $60,000 dollars a year while only 17.6% of non-minoritized participants were from families that made less than $60,000 dollars a year.

Discussion

These test results show two main threads in which minoritized participants demonstrate different concerns from their peers: finances and a lack of racial diversity in graduate education. The financial concerns are most obvious in results for 7 of the 12 sub-item topics showing that minoritized participants were directly concerned about funding or finances. Results from another two sub-item topics, familial responsibilities and favoring programs with less stringent GRE requirements, may also be caused (at least in part) by financial concerns. We also found that significantly more minoritized participants reported that they were from low-income households than their peers. The Theory of Racialized Organization and racial capitalism explain how the apparently uniform cost of the application process serves as a contextual barrier and thus a gatekeeper, preventing minoritized students from entering mathematics programs at the graduate level. The results from the last three sub-item topics that do not fit under the topic of finances demonstrate minoritized participants' well-grounded concerns that they will be the only person who looks like them in their department. We know from the demographics of mathematics graduate programs that many mathematics departments are likely to have few, if any, minoritized students (Golbeck, et al., 2019). This can have multiple repercussions for the few minoritized students at these programs. The Theory of Racialized Organizations calls into question why programs have so few minoritized students and the impact that could have on students who are applying. Did these programs previously admit minoritized students who either left of their own volition or were forced out? Is the work of minoritized students, both inside and outside of the classroom, systematically undervalued at these programs? The lack of diversity in these programs negatively impacts minoritized students' decisions to apply.

Based on these results we recommend that programs hoping to recruit and support minoritized students seek ways to minimize the cost of applying to, and staying in, the program. For example, consider removing the GRE General and Subject test requirements (for additional reasons to exclude the GRE from admission requirements, see McEldowney et al., 2024, Miller et al., 2019, and Posselt, 2016). Consider allowing unofficial transcripts in the application and only require official transcripts for admitted students. Advocate for the financial well-being of current graduate students. Try to obtain more funding for graduate students either internally or externally. If faculty are eligible for university childcare programs or childcare subsidies, advocate for graduate students to be eligible for those programs.

In terms of research implications, there is still more data to be analyzed from the Knowledge-GAP survey. A clear next step for the project is to test for differences in knowledge of application fees by race or ethnicity. We also need to examine differences in perceptions of the graduate school application process by other demographic information like gender, income, etc. the Knowledge-GAP is only the first step in studying mathematics graduate student application and admissions processes. More work is necessary to fully understand which factors impact students, especially minoritized students, choice of graduate schools and what obstacles they face. We also look forward to seeing future qualitative research can be done in this area.

Factors Influencing Undergraduate Students' Logical (in)Consistency (LinC) in Mathematical Contexts

Kyeong Hah Roh
Arizona State University

Yong Hah Lee
Ewha Womans University

Kate Melhuish
Texas State University

This study delves into undergraduate students' ability to self-monitor and organize their claims coherently to ensure logical consistency when evaluating mathematical statements and validating accompanying arguments. To assess the capacity of undergraduate students to maintain logical consistency in mathematical contexts, we designed an online instrument comprising twenty statement-argument pairs, each rooted in mathematical content. We administered this online instrument to 205 undergraduate students, encompassing various levels of proof experience, across three diverse U.S. higher education institutions, including two large public universities and one small liberal arts college. Our analysis reveals a substantial number of undergraduate students displayed logical inconsistencies. It also appears that students may exhibit different levels of logical inconsistencies when the accompanying argument is framed using proof by contradiction, as opposed to direct proof. This prevalence underscores a critical concern in mathematics education, particularly proof-oriented mathematics.

Keywords: logic, logical (in)consistency, statement evaluation, argument validation, proof by contradiction

Our primary aim of this study is to understand logical consistency as it pertains to students' mathematical reasoning and argumentation when evaluating mathematical statements and validating accompanying arguments. By logical consistency in an individual's mathematical thinking, we refer to a state of having no logical contradiction among their assertions. To uphold logical consistency, it is critical that individuals recognize and address any logical contradictions that might remain unnoticed within their assertions. Logical contradictions in mathematics arise when statements conflict, as in false statements such as "x is a multiple of 2 and x is not a multiple of 2." Fundamental to mathematical logic is the law of non-contradiction, which asserts that a statement and its negation cannot both be true simultaneously. For instance, if a student claims both "x is a multiple of 2" and "an argument properly proves x is not a multiple of 2," a logical contradiction arises since the second assertion negates the first, and vice versa. Overlooking such logical contradiction in their reasoning can lead to creating mathematical arguments that the community will not accept. To achieve our research aim, we pose several research questions that guide our investigation:

1. To what degree do students demonstrate logical consistency across a set of statements and accompanying arguments?
2. Is there a correlation between undergraduate students' logical consistency and their exposure to proof-oriented mathematics courses?
3. Do specific contexts or variables influence the likelihood of undergraduate students exhibiting logical inconsistencies (LinC)?

These questions will serve as the foundation for exploring logical consistency in students' mathematical reasoning.

Review of Literature & Theoretical Perspective

To comprehend the significance of logical consistency in mathematical reasoning, we turn to insights from cognitive psychology and educational theory. Cognitive psychologists have long posited the general tendency of people to maintain cognitive consistency and avoid cognitive dissonance in various contexts (e.g., Abelson et al., 1968; Festinger, 1957). The principle of maintaining cognitive consistency has been applied to interpersonal relations, beliefs, feelings, and actions (Cooper, 1988; Cvencek et al., 2014; Gawronski & Strack, 2008). However, the relevance to mathematical reasoning remains intriguing. Our study extends this notion into the realm of mathematical thinking, which we refer to as logical consistency. It is essential to recognize the unique challenges that mathematical reasoning presents, particularly concerning logical contradiction, while evaluating mathematical statements and validating accompanying arguments (Roh & Lee, 2018).

Our study is grounded in a theoretical framework that draws from cognitive psychology and constructivist learning theory. Cognitive psychologists have argued that individuals naturally strive to maintain cognitive consistency and resolve cognitive conflicts (e.g., Piaget, 1967). In learning, cognitive conflicts are considered essential for individuals to construct new knowledge or modify their existing knowledge structures (Glasersfeld, 1995). This perspective suggests that students actively seek logical consistency in their mathematical reasoning and argumentation. Research showcases that students can also enhance their reasoning by addressing logical inconsistencies in their mathematical arguments (Dawkins & Roh, 2016; Ely, 2010; Roh & Lee, 2011, 2017).

However, can students effectively identify logical contradictions within their mathematical assertions when they exist? Roh and Lee's study (2018) reported that more than 20% of undergraduate students ($n = 47$) who completed introductory proof courses displayed logical inconsistencies in their assertions. This suggests that even with substantial mathematical content knowledge and mathematical proofs, logical inconsistencies (LinC) may persist in students' mathematical reasoning. Building upon Roh and Lee's (2018) research, we extend our investigation to assess the frequency with which students exhibit logical inconsistencies and identify the prevalent types of such inconsistencies when students evaluate mathematical statements and validate accompanying arguments.

Methods

The LinC Instrument

We developed the LinC instrument to assess students' logical (in)consistency when evaluating a statement and validating an accompanying argument. The current version of the LinC instrument focuses on content areas in precalculus and calculus, employing two factors for statements (logical complexity and truth-value) and three factors for accompanying arguments (attempts, validity, and frames). Table 1 presents the characteristics of the final 20 statement-argument pairs derived from these factors.

Table 1 Summary of the LinC items (20 items in total)

Quantifiers in the Statement	Truth-Value of the Statement		An Attempt in the Argument		Validity of the Argument		A Frame of the Argument		
	True (10)	False (10)	Proof (10)	Disproof (10)	Valid (12)	Invalid (8)	Direct (4)	by Contradiction (7)	by Example (9)
∀ (4)	2	2	3	1	2	2	1	1	2
∃ (6)	3	3	2	4	4	2	1	2	3
∀∃ (4)	2	2	2	2	3	1	0	2	2

∃∀ (6)	3	3	3	3	3	3	2	2	2

Each LinC item starts with a statement-argument pair, followed by three questions: (1) evaluate if a given statement is true or false; (2) determine if a given argument is an attempt to prove or an attempt to disprove the given statement; and (3) evaluate if the given argument proves properly what it attempts to prove. Figure 1 illustrates an example of LinC items.

Item 1. Consider the statement and argument below:

Statement: For all $x > 0$, $x^3 - x^2 + x > 0$.
Argument: Suppose there exists $x > 0$ such that $x^3 - x^2 + x \leq 0$. Then, since $x > 0$ and $x^3 - x^2 + x \leq 0$, $x^2 - x + 1 \leq 0$. However,

$$x^2 - x + 1 = \left(x^2 - x + \frac{1}{4}\right) + \frac{3}{4} = \left(x - \frac{1}{2}\right)^2 + \frac{3}{4} > 0.$$

1. Check the most appropriate one about the statement.
   (a) The statement is true.
   (b) The statement is false.
   (c) We cannot determine if the statement is true or false.
2. Check the most appropriate one to describe what this argument attempts to prove.
   (a) This argument attempts to prove the statement is true.
   (b) This argument attempts to prove the statement is false.
   (c) We cannot determine if this argument attempts to prove the statement is true or false.
3. Check the most appropriate one to describe the validity of this argument.
   (a) This argument proves properly what it attempts to prove.
   (b) This argument does not prove properly what it attempts to prove.
   (c) We cannot determine whether or not this argument proves properly what it attempts to prove.

Figure 1 An example of the LinC items

In each LinC item, we first asked students about the truth value of the given statement before asking them to evaluate the accompanying argument. However, students were allowed to change their answers to any of these three questions before moving to the next LinC item. As a result, students could determine or revise their determination of the truth value of the statement after engaging with the second and third questions about the accompanying argument. That is, students had opportunities to self-organize their thinking to have no logical contradiction among their responses to the three questions given in each LinC item. Thus, if there is a logical contradiction among a student's response to the three questions, we interpret the student's response as displaying logical inconsistency.

For example, a student might initially believe that the statement is true. Still, after reading the given argument about the statement, the student might construe and accept that the argument proves properly the statement is false. Suppose the student recognized the logical contradiction between their initial evaluation of the statement as true and their subsequent validation of the argument that proves the statement false. In that case, they may reconsider either their evaluation of the statement as false or their validation of the argument to maintain non-contradiction in their responses to the LinC item.

However, some students may not detect a logical contradiction even if it exists in their responses. Then, they would not experience psychological pressure to self-organize their thinking to have no logical contradiction, and consequently, they would not change their responses. In this case, the presence of logical contradictions in students' responses suggests that the student exhibits logical inconsistency. That is, the students cannot self-organize their thinking to have no logical contradiction. The three questions in each LinC item allow logical inconsistencies in students' responses to manifest if they exist. The LinC instrument's reliability is acceptable with Cronbach's α=0.686 (*n*=205).

Data Collection

In this study, we collected data via an online survey utilizing the LinC instrument. The survey was administered at two large public universities and one small liberal arts college in the United States from fall 2019 to spring 2022. We obtained responses from a total of 205 undergraduate students who dedicated sufficient time to complete the LinC instrument. Among them, 86 participants were recruited from in-person classes during fall 2019, fall 2021, and spring 2022. The rest of the participants (119) were from online classes during spring 2020 and fall 2020, coinciding with the COVID-19 pandemic, during which educational institutions experienced a rapid shift towards remote and online teaching modes.

Data Analysis

Table 2 provides a comprehensive list of all possible logical inconsistencies that could arise from evaluating a statement and validating an argument about the statement. This table serves as a valuable reference tool for analyzing logical inconsistencies in students' responses to the LinC instrument and identifying patterns in students' responses.

Table 2 All instances of responses identified as displaying logical inconsistencies to the LinC items

LinC Type	Response to Question (1)	Response to Question (2)	Response to Question (3)
aba	The statement is **True.**	The argument attempts to prove the statement is **False.**	The argument proves **properly** what it attempts to prove.
aca	The statement is **True.**	We **cannot determine** what it attempts to prove.	The argument proves **properly** what it attempts to prove.
baa	The statement is **False.**	The argument attempts to prove the statement is **True.**	The argument proves **properly** what it attempts to prove.
bca	The statement is **False.**	We **cannot determine** what it attempts to prove.	The argument proves **properly** what it attempts to prove.
caa	We **cannot determine** if the statement is true or false.	The argument attempts to prove the statement is **True.**	The argument proves **properly** what it attempts to prove.
cba	We **cannot determine** if the statement is true or false.	The argument attempts to prove the statement is **False**.	The argument proves **properly** what it attempts to prove.
cca	We **cannot determine** if the statement is true or false.	We **cannot determine** what it attempts to prove.	The argument proves **properly** what it attempts to prove.

In order to examine the first research question, we report descriptive statistics broken down at the item level. To examine the second research question, we considered a level of proof experience (in terms of the number of courses) as a predictor of the LinC overall score. We created a linear model and a hierarchical linear model (students nested within teachers), finding that the nesting added no explanatory power. Finally, for the third research question, our analysis focused on a subset of the data of 86 participants. This subset was drawn from the data collected during which classes were delivered through an in-person teaching mode. Note that the year 2020 coincided with the COVID-19 pandemic, and we acknowledge that the experience, perceptions, and academic performance of participants in online teaching mode during the pandemic may have been influenced by the unique circumstances and challenges posed by the pandemic. Focusing on the subset of participants who experienced in-person teaching, we aimed to mitigate the potential confounding variables influencing the third research question.

Results

RQ1: To what degree do students demonstrate logical consistency across a set of statements and accompanying arguments?

Of the participants ($n = 205$), 81% (187 students) displayed logical inconsistencies at least once while responding to the 20 items in the LinC instrument. Among those who showed logical inconsistencies, 73% displayed them at least twice, 64% at least three times, 53% at least four times, and 40% at least five times. These findings suggest that many undergraduate students in mathematics courses display logical inconsistencies in their thinking. These findings also highlight the need for further research and instructional interventions to address this issue.

RQ2: Is there a correlation between undergraduate students' logical consistency and their exposure to proof-oriented mathematics courses?

In order to explore this relationship, we developed a series of linear models. The first model included both in-person and online semester data. TeachingMode is 1 when online and 0 when in person. ProofExperience takes on a value of 0 for no-proof courses, 1 for one proof course, and 2 for two or more proof courses. We estimated:

$$LinC\ Score = 18.22 - 3.92 * TeachingMode + 0.13 * ProofExperience$$

finding that TeachingMode was significant with $p < .001$, but ProofExperience was not significant, $p = 0.58$. Since TeachingMode plays an unclear role (perhaps relating to modality or pandemic effect), we also ran a model on just the in-person data, finding similar results. The estimated coefficient for proof experience was 0.05 with a $p = 0.89$. These results were rather robust, with proof experience not being significant in any model our team ran. This indicates a surprising result: Logical inconsistency does not appear related to the amount of proof and formal representation system exposure.

RQ3: Do specific contexts or variables influence the likelihood of undergraduate students exhibiting logical inconsistencies (LinC)?

Because the prior analysis showed that teaching mode had a substantial impact on students' performance, we focus this early preliminary exploration of RQ3 on the in-person subset. Of the participants drawn from the in-person teaching mode ($n = 86$), 57% (49 students) displayed logical inconsistencies at least once while responding to the 20 items in the LinC instrument. Among those who showed logical inconsistencies, 40% displayed them at least twice, 30% at least three times, 15% at least four times, and 5% at least five times.

We examined if these students are more likely to display logical inconsistencies with certain types of statements or arguments. In particular, we analyzed the student responses considering the statements' complexity and the frames of the arguments as the factors that might affect students' logical inconsistencies. In Tables 3 and 4, the LinC frequency for each item represents the number of students displaying logical inconsistency in their responses to that specific item.

LinC and Statements' Logical Complexity. We may assume that students would have greater difficulty understanding mathematical statements with more complex logical structures, such as multiply quantified statements. Similarly, we might anticipate students encountering logical inconsistencies more like in statements with greater logical complexity. We might expect more students to display logical inconsistencies when engaging with multiply quantified statements in the LinC items 11-20 than statements involving a single quantifier in the LinC items 1-10. However, our analysis yielded unexpected results. Students' responses to LinC items contained logical inconsistencies, regardless of the logical complexity of the statements. Over 10% of the students displayed logical inconsistencies on each of the LinC items, including those with complex statements involving two quantifiers (items 11, 15, 17, and 20) and even those with relatively simple statements involving one quantifier (items 1, 2, 6, and 9) as detailed in Table 3. This finding suggests the frequency of logical inconsistencies of students does not significantly differ with respect to the logical complexity of the given statements.

LinC and Frames of Arguments. On the other hand, the type of argument frames points to potential differences in the frequency of logical inconsistencies. We observed a higher occurrence of logical inconsistencies when the argument was framed using proof by contradiction instead of direct proofs (see Table 4). To be specific, over 10 % of the students displayed logical inconsistencies on all but one LinC item with the seven arguments framed using proof by contradiction (e.g., LinC item 11), whereas none of the LinC items with the four arguments framed using direct proofs (e.g., LinC item 8). We can conjecture that the contradiction frame may relate to how students attend to logical consistency.

Table 3 LinC Frequency by Statement Types (n=86)

Item	LinC Frequency	Statement	
		T/F	Quantifier
1	10	T	$\forall$
2	13	F	$\forall$
3	0	T	$\forall$
4	5	F	$\forall$
5	1	T	$\exists$
6	9	T	$\exists$
7	4	T	$\exists$
8	4	F	$\exists$

10	5	Disprove	Invalid	Example
17	10	Disprove	Invalid	Example
2	13	Disprove	Valid	Example
13	5	Disprove	Valid	Example

Conclusion & Discussion

Our study investigated the factors influencing logical inconsistencies among undergraduate students while evaluating mathematical statements and validating accompanying arguments. Initially, we expected students to struggle more with mathematical statements with greater logical complexity. However, our findings challenge this assumption. Surprisingly, students exhibited logical inconsistencies regardless of the logical complexity of the statements. On the other hand, students may exhibit different levels of logical inconsistencies when the accompanying argument is framed using proof by contradiction, in contrast to direct proof. The complexities involved in indirect proofs (e.g., Antonini & Mariotti, 2008) may be related to logical inconsistencies.

Mathematical reasoning relies fundamentally on avoiding logical inconsistencies, as even a single logical inconsistency can render an entire argument invalid. Our study reveals that a substantial number of undergraduate students displayed logical inconsistencies. This prevalence underscores a critical concern in mathematics education, particularly proof-oriented mathematics. We believe that identifying and addressing logical inconsistencies in students' thinking should be a top priority for promoting their learning of proof-oriented mathematics. Therefore, it is imperative for mathematics educators and researchers to carefully monitor students to see when logical inconsistencies exist in students' thinking and understand the factors that affect their occurrence.

Our study has limitations, including the specific context (precalculus and calculus) and sample size. Future research could explore logical consistency in diverse mathematical contexts and involve larger and more diverse student populations. Additionally, the high frequency of logical inconsistencies among undergraduate students highlights a potential gap in their mathematical reasoning skills. The frequency of these logical inconsistencies suggests a pressing need for further research and instructional interventions to address this issue. This is especially important as traditional proof courses do not seem to serve our students in developing their logical consistency. Investigating the effectiveness of specific instructional interventions in addressing logical inconsistencies is a promising avenue for future research.

Student Quantitative Understanding of Integration in Single Variable Calculus

Jason Samuels
City University of New York

Student understanding of integration and key concepts from Single Variable Calculus and the role of infinitesimals was investigated. Analysis was done using a framework which highlights quantitative reasoning. Data showed rich understanding of integrals in multiple representations, with some gaps. Also revealed were connections between those concepts expressed over intervals in Algebra and expressed instantaneously in Calculus, and how conceptions of infinitesimals supported those connections. Implications for instruction are considered.

Keywords: Calculus, quantitative reasoning, infinitesimals, integral

Introduction & Literature Review

First semester Calculus is a critical course for all STEM majors, a required course containing foundational ideas for future study. Student success has been below desired levels for a long time, and efforts toward improving student success are extensive and ongoing (Bressoud, Mesa & Rasmussen, 2015). There has been much investigation into student understanding of Single Variable Calculus (SVC), exploring conceptions of limit (Oehrtman, 2009; Tall, 1992), derivative (Zandieh, 2000; Park, 2013), integral (Jones, 2015; Sealey, 2014), and the Fundamental Theorem of Calculus (Carlson, Smith & Persson, 2003; Radmehr & Drake, 2017). Some work has been done to connect those conceptions to a student's related prior conceptions (Thompson, 1994; Pustejovsky, 1999; Samuels, 2011). However, none of these studies investigated these questions for students learning Calculus using infinitesimals.

Recently there has been a growing call to revise Calculus instruction away from an Analysis-based approach using limits and toward a more quantitative approach (Augusto-Milner, Jimenez-Rodriguez, 2021). There have been a handful of documented attempts to do so with infinitesimals (Ely, 2021). Some research has theorized the underlying student thinking in such an approach (Ely & Ellis, 2018). None of these studies of infinitesimal-based Calculus instruction has examined how students conceive of important Calculus ideas. These gaps in the literature suggest the following research questions. (1) What is a characterization of student understanding of integration and key Calculus concepts after one semester of Calculus taught with infinitesimals? (2) How are understandings of Algebra concepts in discrete form used to generate understandings of related Calculus concepts in instantaneous form?

Framework

To analyze student understanding of Calculus, an approach oriented towards quantitative reasoning (Thompson & Carlson, 2017) was used. This mode of reasoning entails "conceptualizing a situation in terms of quantities and relationships among quantities" (Thompson & Carlson, 2017, p425), where a quantity is a measurable attribute combined with a way to measure that attribute. The quantities of SVC and the relationships between them can be described using the ACRA Framework (Samuels, 2022). The framework is summarized here briefly with a delineation of the quantities and some of their relationships. An *amount* is a real value, a *change* is a difference between two amounts, a *rate* is a ratio of two changes, and an *accumulation* is a sum of consecutive changes. One important relationship is that the product of a rate with a change (in the input variable) is a change (in the output variable), the *change equation*. Changes and rates over real intervals are encountered in a typical Algebra course;

changes and rates over arbitrarily small intervals first arise in SVC. A positive infinitesimal is a positive number which is smaller than all positive real numbers. Instead of using limits, one can interpret differentials as infinitesimals to describe the arbitrarily small quantities in Calculus. (For further details, see (Samuels, 2022).) This study was targeted specifically at student conceptions after taking Calculus I. In a previous study (Samuels, 2023), I focused on conceptions of instantaneous rate. In this study, I focused on conceptions of accumulation along with connected ideas and relationships.

Table 1. Part of the ACRA Framework for Quantities in Calculus (from (Samuels, 2022))

QUANTITIES	**Description**	**Real**	**Infinitesimal**
Amount	A magnitude or extensive quantity	x, y	ε
Change	A difference between two amounts	$\Delta y = y_2 - y_1$	dx, dy
Rate	A quotient of two changes (of different quantities)	$m = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$	$f'(x) = \frac{dy}{dx}$
Accumulation	A sum of consecutive changes	$f(b) - f(a) = \Sigma_i \, \Delta y_i$	$f(b) - f(a) = \int_{x=a}^{x=b} dy$
RELATIONSHIPS			
Change Equation	The product of a rate with a change in one quantity is a change in the other	$\Delta y = m \cdot \Delta x$	$dy = f'(x)\, dx$
CONVERSIONS	An equation of amounts converts to one of infinitesimal changes or rates, and those two convert back and forth	$y = f(x)$ ⇒ $dy = f'(x)dx$ ⇕ $\frac{dy}{dx} = f'(x)$	

Methodology

In 2023 Spring the author taught a Calculus I course at a northeastern college designed to use infinitesimals instead of limits. Two months after the end of the course, a clinical semi-structured interview (Hunting, 1997) was conducted with one of the students, who had volunteered. A script was prepared beforehand with questions on change, rate, accumulation, and the relationships between them, in both precalculus and calculus contexts, and in multiple representations (verbal, numerical, graphical, symbolic). Flexibility was allowed for follow-up questions which might be suggested in-the-moment by student responses. The interview was video recorded, transcribed, and coded using the framework.

Results

Travis [a pseudonym] was first asked "without Calculus, what's an example where we could talk about change?" He explained that "you could have two different amounts, and you basically subtract one from the other to get change". He then described an example involving toys produced, made a table of values, calculated various changes, and drew the graph in Figure 1a. When asked about rate, he expressed it as the ratio $\Delta y/\Delta x$ and calculated it over several different intervals (see Figure 1b).

When asked about accumulation, Travis said that "it's the sum of each individual change in x or y value." For the question, "If a plant grows 3in/week for 2 weeks, then 2in/week for 4 weeks, then 1in/week for 6 weeks, how much did it grow?", his calculations are in Figure 2a. He initially wrote the numerical calculations, and when prompted for "a more abstract notation" he

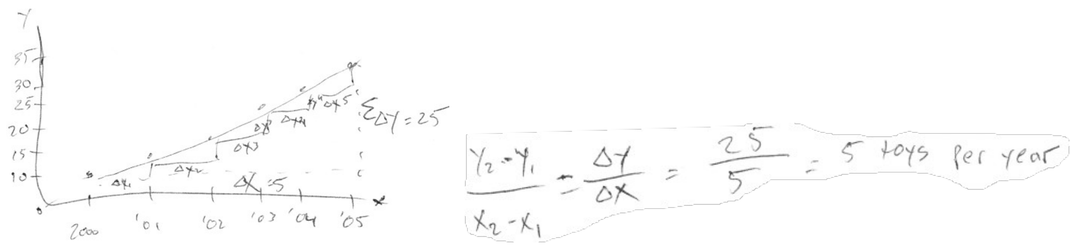

Figure 1. Travis' example to explain change and rate on a real interval (a) Travis' graph (b) Travis' calculations

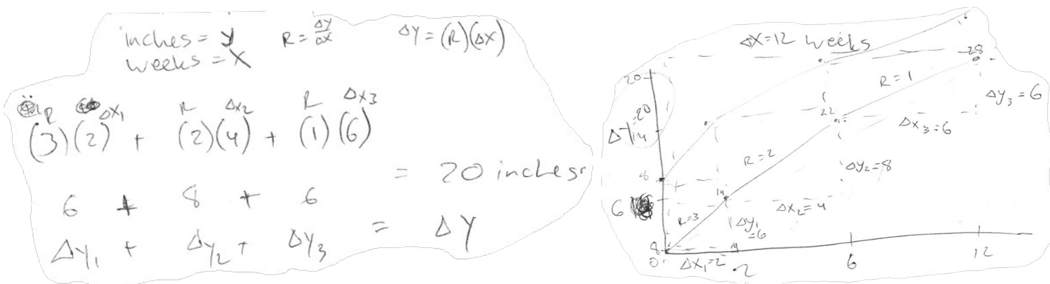

Figure 2. On a question to calculate an accumulation with a finite sum (a) Travis' calculation (b) Travis' graph

added more lines, expressing the accumulation as "$R{\cdot}\Delta x_1$ + $R{\cdot}\Delta x_2$ + $R{\cdot}\Delta x_3$" ("*R* for rate") and "$\Delta y_1 + \Delta y_2 + \Delta y_3 = \Delta y$".

Travis was asked to make a graphical representation of his calculations, and his work is in Figure 2b. It includes changes in *x* (e.g. Δx_1=2), changes in *y* (e.g. Δy_1=6), rates (e.g. R=3), and total changes Δx=12 and Δy=20.

Next, questions involving Calculus were asked. When asked "What is a situation where you would need calculus to talk about the slope or the rate?", Travis replied "You need calculus when you do not have a constant rate on a line, and you want to find the instantaneous rate at a certain point." He elaborated by creating the example $f(x) = x^2$ and then calculating $dy/dx = 2x$, which at the point (4,16) was 8 (see Figure 3b). In the following excerpt, he describes his reasoning.

Interviewer: Can you indicate on this graph [Figure 3a] what a *dx* is?
Travis: Sure. You would have to zoom in really closely on the point [draws a circle], and then you would have a little *dy* and a little *dx*. [draws and labels two line segments]
Int: And what do you mean by little?
T: Infinitely small. ...it's a little hard for me to describe it, but zoomed all the way in on that point, you get a line. The slope of that zoomed-in line is your infinitesimal rate.

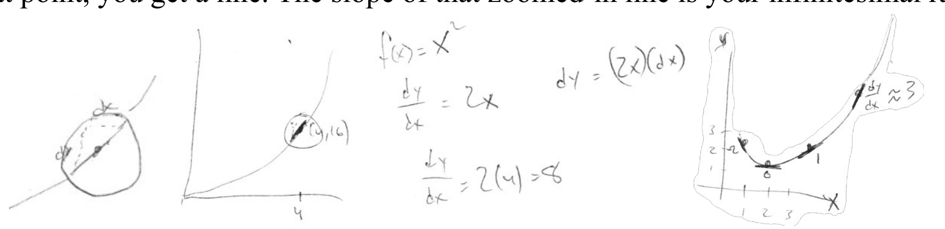

Figure 3.(a) Travis drew dx and dy (b) Travis created a function, graphed it, calculated the derivative and dy (c) Travis drew the graph, marked several points, and for each drew a short tangent line and a slope estimate

Given the graph of a function, Travis was asked to draw tangent lines and estimate the derivative at several points. He did this correctly, as shown in Figure 3c. When asked to solve for *dy* in his example, he wrote "$dy = 2x\ dx$". When asked what it means, he said "It means that the infinitesimal change of *y* equals the infinitesimal change in *x* multiplied by the rate."

When asked about infinitesimals, Travis said "you only have a point to work with, so you need to zoom in so far on that point in order to get a line... And the infinitesimal basically gives you a way to use real numbers to assign values to the changes going on at that infinitely small point." He said it is not possible to write down an infinitesimal number, so we use the symbol ε.

Travis was given an application in which the height of a ball was $h = 27t - 10t^2$. When asked for the rate, he calculated $dh/dt = 27\text{-}20t$; when asked for the units he said "meters per second". When asked to compare Δh and dh, he said "because you're dealing with *dh* and *dt*, these are infinitely... small changes in the ball's height, because you're only doing it in relation to an infinitely small change in the time. If it was going to be Δh and Δt, it would be a bigger change. So your Δt may be 2 seconds, in which case your Δh would be a bigger number."

When asked to compare *dh* versus *dh*/*dt*, he said that "*dh/dt* is a rate, and it is...the rate at which the height of the ball is changing in relation to time... And *dh* by itself is just the change in height of the ball, not the rate at which that height is changing."

When asked about integration, Travis described it as "calculating the sum [of changes] between two points". As to types of accumulation, when asked "is there a notation for doing" the sum in a finite accumulation, Travis responded "the sigma thing". When asked to compare with the "Calculus version of the same thing", Travis responded "this is going to be my integral".

When given a slope field and asked about its meaning, he said "these are all representations of, I guess, instantaneous rates of whatever the function is of these graphs" and each dash "tells you the direction that the function is going to be going at that point."

Travis was asked an application question. "A rope has a certain amount of mass *m* over its length *x*. Suppose it has $2x$ kg/ft at the *x*-foot mark. How much mass does it have between the 1-foot mark and the 4-foot mark?" Travis' correct calculations are in Figure 4a. He was also asked to sketch a graphical representation of the solution, and his inscriptions are in Figure 4b. It includes a slope field, a solution curve, with Δx=3ft and Δm=15kg marked. (He noted that "obviously my scale is all messed up".) He explained his work in the following excerpt.

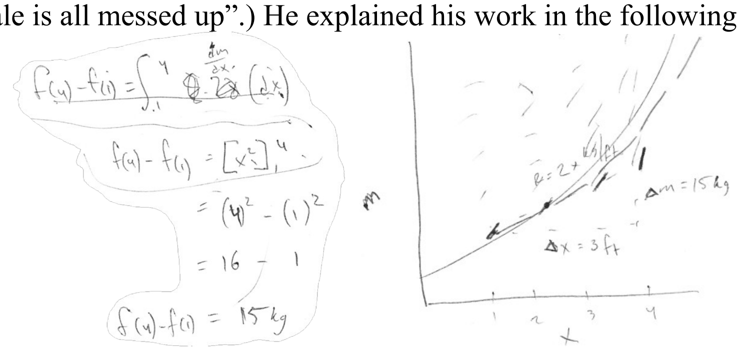

Figure 4. For an application to find mass given density (a) Travis' calculation (b) Travis' graph

Int: The first expression you wrote down, where did that come from?

T: You're asking from the 1 foot to the 4 foot mark. So those are my limits...

Int: ...in the original expression, it's the integral from 1 to 4, $2x\ dx$. So tell me how that's going to give you $f(4) - f(1)$ … Tell me what that means and how that's the thing that you need.

T: This [pointing to $f(4) - f(1)$] is my Δy, for lack of a better phrase. And then this [pointing to the right side] is my rate times my Δx...I know that by multiplying my rate and my *dx* will give me my *dy*... so the $2x$ times the *dx* that gives you a *dy*.

Int: ...what about the actual squiggle, the actual integral mark itself? Is that telling you something specific or is just something that you write down?

T: The squiggle is like the letter S stands for sum.
Int: And what is it that you're adding up? If it's a sum, what are you adding up?
T: The values of the mass between 1ft and 4ft. Yeah, the value of mass at 1ft plus the value of mass at 2ft, or I guess at every infinitesimal increment between 1 foot and 4 foot to give you the amount that it has between those two points.

While explaining his calculation, Travis noted that he was expecting an x to appear in the answer. He explained his confusion about it, eventually sorting it out and referencing the FTC.

> I'm thinking I'm... trying to figure out where this x mark on the rope is, but that's not what you're asking… There would be other times where you would be asking, how much mass does it have between the 1ft mark and the x foot mark? … I would even have been happier having the limitations from 1 to x and be solving for $f(x) - f(1)$ … This is very simple.

In the excerpt below, Travis described some infinitesimals and their quantitative characteristics.

Int: What does *dm* represent?
T: An infinitely small change in the mass of the rope.
Int: Okay. And in the course of doing this calculation or this problem, how many *dm*'s are you going to encounter?
T: Infinitely many.
Int: Okay. And *dm/dx*, what does that represent?
T: That would be my 2*x*. That would be my, that's my *m*'(*x*), my instantaneous rate.

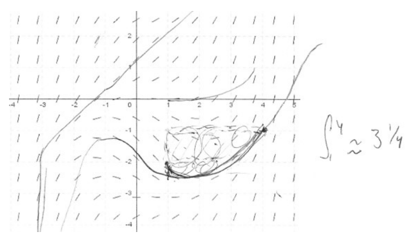

Figure 5. Travis represents the integral on a slope field.

When asked to use a slope field to find the integral from x=1 to x=4, Travis said "If you have an endpoint at four and endpoint of one, you have this little area here of your change in y from one to four and your change in x. I would shade in this and say that's your integral from one to four… your Δy accumulation would be one and a half-ish and your Δx would be three… Basically, you're going to find this area [counting boxes] one, two, three, and like a quarter." His inscriptions are in Figure 5.

In the excerpt below, he discussed two different graphical methods of representing integrals.

> When I was taking the class ... I was going to tutoring, and [he] explained [integration] to me using area…I was like, okay ... but slope field ... at the time I don't remember even linking it to integrals, which obviously now I see how it does. But all I remember was like, wow, this is easy. I just draw a line going along with the other lines... this is simple.

Discussion

Travis demonstrated a detailed understanding of the quantities of Calculus. He gave clear explanations of the concepts of change, rate, and accumulation, and made specific connections between them. For change, he represented a real change numerically as a difference between two real numbers and graphically as a line segment; he represented an infinitesimal change both symbolically (using *dx*) and graphically (using zooming). For rate, he represented discrete rate numerically and symbolically as a ratio of two changes and graphically as the slope of a straight line. For an infinitesimal rate, he calculated one using formulas, represented it graphically as a short tangent line (both on the original graph and after an infinite zoom, and subsequently as a slope field), and described it an instantaneous rate, using both prime and differential notation. (Although he did not explicitly refer to an infinitesimal rate as the ratio of infinitesimal changes, he frequently manipulated it as though it were.)

Travis was able to perform all 3 conversions, from an amount equation to an infinitesimal change or rate equation, and between the last two. From an equation with "y=", in addition to calculating the derivative, he wrote down the infinitesimal change equation with "dy=". Further, he was able to assign a quantitative meaning to each term - the infinitesimal change in x, the infinitesimal change in y, the infinitesimal rate - and interpret the equation as a relationship between those quantities, both in an abstract scenario and an application where he assigned correct units to each. Also, he distinguished between infinitesimal rate and change, in meaning and use. He converted between the instantaneous change and rate equations by multiplying or dividing by dx. In a standard Calculus course, students are told both that one cannot manipulate in that way and individual differentials have no meaning, as well as to manipulate that way and use isolated differentials in the procedure of integration by u-substitution. The inherent contradiction has been noted before (Ely, 2021). After Calculus instruction with infinitesimals, Travis had a coherent concept image (Tall & Vinner, 1981) of these equations, in meaning and in symbolic manipulation.

Travis was able to describe accumulation using the quantities of change and rate. In the finite case, he stated that it was the finite sum of changes; given a piecewise constant rate, he was able to calculate the accumulation using arithmetic, and graph it as a piecewise linear graph. He also stated that the accumulation was a sum of infinitely many infinitesimal changes; given a formula for instantaneous rate he calculated the accumulation with an integral, he graphed it as a solution curve in a slope field. He also (after some confusion) described the calculation both for a constant upper boundary to produce a constant answer and a variable upper boundary to produce a function answer (the FTC).

Travis expressed accumulation as a finite sum of changes in the output variable as well as a sum of rate times input variable change terms ($f(b) - f(a) = \Sigma_i \Delta y_i = \Sigma_i r_i \cdot \Delta x_i$). For integration, he made a parallel infinitesimal statement, $f(b) - f(a) = \int f'(x)\, dx$. Although he did not explicitly write the formula $\int dy$, in one application he did describe the integral which calculated the total mass as a sum of infinitesimal masses, and separately described how dy can be replaced with $f'(x)\, dx$. For integration, previous research has shown that applications are very difficult for students (Wagner, 2018; Jones, 2015), and that quantitative understanding is rare (Jones, 2015; Fisher & Samuels, 2016). Similar quantitative meanings for integration have been discussed in previous studies (Oehrtman & Simmons, 2023; Jones, 2015), but instruction relying on limits results in dx having no rigorous definition.

Travis made strong connections between the real and infinitesimal versions of the same concepts. For change, he indicated Δx as a horizontal segment on the original graph, and he indicated dx as a horizontal segment on the graph visible after you "zoom in really closely… [it's] infinitely small". In the ball problem, he referred to dh and dt as "infinitely small changes" whereas "Δh and Δt, it would be a bigger change". For rate, Travis drew (piecewise) lines for (piecewise) constant slopes, labeling slope values. For instantaneous rate, he described "zooming in" at a point to reveal a straight graph; he drew that straight tangent line on both the original graph and a zoomed-in graph, also marking the slope value at a point. For accumulation, he wrote the formula as a finite sum with Σ, and he used ∫ as an infinite sum of infinitesimals, and integration would be needed when the rate is non-constant. He noted that there would be "infinitely many" *dm*'s and *dx*'s in calculating the integral for mass. He made a direct comparison between Δy and dy in the context of rate, change, and accumulation. In various contexts, Travis made statements about real quantities and incorporated infinities and infinitesimals to express corresponding statements. Thus he exhibited *transfinite thinking* (Samuels, 2023) underpinning his Calculus conceptions. Learner connections between finite and infinite scenarios have been investigated previously (Oehrtman, 2009; Mamolo & Zazkis, 2008), but only recently was this term rigorously defined, or were the connections examined for their contributions to productive conceptions.

One initial point of confusion for Travis concerned whether or not the solution to an integration application should contain a variable. Previous research into the Fundamental Theorem of Calculus (FTC) has shown the extreme difficulty students have in recognizing the upper bound as the variable (Thompson, 1994). In this investigation, Travis eventually remembered the two relevant types of question, a fixed upper bound or a variable upper bound, even commenting that he would be "happier" with the variable problem, exhibiting knowledge of the FTC and the functional nature of its formula.

Another point of confusion was the graphical representation of the integral. Working from a slope field, Travis drew a solution curve, then shaded an area and stated that was the result of the integral. He conflated the two graphical representations, the solution curve in a slope field, and the area under the integrand function. This is a conception not previously documented, partly due to the dearth of research on Calculus instruction with infinitesimals. Travis discussed one possible cause, working with a tutor whose instruction did not align with the approach of the class. Previous research has shown that conflicting instruction can cause productive notions of infinitesimals to erode (Simmons et al., 2022). Having two separate graphical representations for the same situation or calculation is inherently confusing (the integrand plays different roles). One implication for teaching is the need to emphasize this distinction as much as possible. The optimal pedagogy is a topic for future inquiry. Other directions for future research include investigating quantitative conceptions of the rate equation, and the FTC.

It is important to point out that data in this study was drawn from a single student. I cannot claim that any observations generalize to the entire population. Rather, the analysis sheds light on how a student might form conceptions about Calculus and integration using infinitesimals. Due to the relative novelty of the context, this signifies a contribution to the literature.

Conclusion

In this study, I examined an understudied area of student understanding in Single Variable Calculus, conceptions of integration after one semester of Calculus I taught using infinitesimals instead of limits. The data showed rich connected student conceptions of integration, supported by conceptions of change and rate, in multiple representations. These conceptions were expressed both for real quantities and infinitesimal quantities, connected by the student via transfinite thinking.

Calculus instruction using infinitesimals is not typical practice. There is a growing body of evidence that it is a productive approach for students to make quantitative meaning in Calculus, and this study is a contribution in that direction. It also demonstrated how student knowledge of the quantities and relationships within Calculus, and their connection to prior knowledge, can be exhibited by students, and productively analyzed using the ACRA Framework.

Instructors' Use of Student Projects in Postsecondary Quantitative Reasoning Courses in Ohio

Deependra Budhathoki
Defiance College

Student projects in a postsecondary Quantitative Reasoning (QR) course can encourage students to think deeply about connections between a real-world situation and the corresponding mathematical or statistical model. These projects can help students collaborate and improve their 21st-century skills, such as critical thinking and oral and written communication. This paper reports how 13 QR instructors across two studies at 11 public postsecondary institutions in Ohio implemented student projects. We analyzed the course syllabus for each participating instructor, conducted at least one semi-structured interview, and observed their teaching using six Instructional Quality Assessment rubrics. Data revealed substantial variation in the implementation of student projects, resulting in varying opportunities for student learning. Our findings indicate that student projects are a critical variable in Quantitative Reasoning.

Keywords: Quantitative Reasoning, student projects, and project-based learning and assessment.

An entry-level postsecondary (gateway) QR course includes nontraditional mathematical goals for students (e.g., collaboration and oral and written communication using quantitative arguments) that aim to prepare them to solve problems in everyday and professional contexts (Mathematical Association of America [MAA], 1996; Stump, 2017). Policy documents and professional opinions call for methods of instruction and assessment that build the student QR competencies of interpretation, representation, calculation, analysis, assumptions, and communication (e.g., AAC&U, 2009; Boersma et al., 2011). They also emphasize the need for students to think deeply and critically about real-world phenomena and link them to relevant mathematics and statistics (Foley & Wachira, 2021).

QR instruction is relatively common to include projects requiring students to solve real-world problems and construct associated knowledge and skills (Lutsky, 2008; MAA, 1996). Learning via such projects provides constructivist and collaborative opportunities for students to grow academically and nonacademically (Harwood, 2018; Virtue & Hinnant-Crawford, 2019). Traditional mathematics assessments—quizzes, tests, and exams—do not address students' engagement in and learning through the projects and typically do not emphasize bona fide real-world problem-solving, collaboration, or communication. Professionals, including Virtue and Hinnant-Crawford, argue that students' learning in a nontraditional course that relies on projects can only be appropriately assessed through their engagement in similar opportunities, that is, project-based assessment.

Student Projects in Quantitative Reasoning

Project-based learning (PBL) and project-based assessment (PBA) address issues related to implementing several formative assessment strategies in mathematics courses, which may be challenging to implement in a typical mathematics course (Chanpet et al., 2020). PBL and PBA tasks include several nontraditional instructional and assessment tools, such as observation, performance tasks, portfolios, presentations, taxonomies of experts, reflection writing, and peer- and self-assessment in different contexts (Noonan & Duncan, 2005; Tal et al., 2000). These tools also allow students to enhance and demonstrate their understanding of mathematical relationships in several real-world phenomena.

Quantitative Reasoning courses and *project-based learning and assessment* (PBLA) share many things, including implementing real-world tasks to help students solve problems from their everyday contexts. Using rich tasks in projects for instruction and assessment in QR courses can help instructors understand a student's misconceptions and determine a student's learning gaps (Kish, 2017). QR and PBLA constitute a social constructivist approach requiring students' active engagement and critical inquiry into genuine phenomena. Students' coordination, collaboration, and communication are their essential components. Several recent studies have identified group projects as a critical variable for QR instruction and assessment (Budhathoki, 2022; Budhathoki et al., 2024; Foley et al., 2023). Therefore, PBLA can be instrumental in enhancing and assessing student learning in QR courses.

National and state-level recommendations (e.g., Leitzel, 2014; MAA, 1996) emphasize active student engagement and the critical inquiry of real-world phenomena. However, little or nothing is said about assessing student learning or using projects. Moreover, most gateway mathematics instructors lack experience using projects in their teaching. QR instructors in Ohio (the research contexts reported in this paper) and at the national level often say their unawareness about the types of projects to select, the number of projects to implement during a semester, ways to engage students in a project, and learning outcomes to focus on through such projects. Consequently, there are varied QR instructional and assessment practices in Ohio.

This paper reports the combined findings of two studies conducted to explore the formative assessment practices of QR instructors in Ohio public postsecondary institutions; the first was a pilot study, and the second a dissertation study. However, this paper focuses on reporting only QR instructors' implementation of student projects. The findings reported here may be significant to novice and experienced instructors who strive to implement projects in their QR teaching and similar other freshman-level mathematics courses.

Multiple Case Study and Cross-Case Analyses

The Ohio Department of Higher Education (ODHE) created common student learning outcomes and transferability across its 36 public community colleges and universities for all gateway mathematics courses, including QR (ODHE, 2015). Foley and Wachira (2021) and Leitzel (2014) have touted QR as the most appropriate gateway mathematics course for non-STEM majors. To earn transferability, the ODHE (2015) requires that critical thinking be the centerpiece of QR, that a QR course develops the competencies of interpretation, representation, calculation, analysis, assumptions, and communication, and that a QR course focuses on three main content areas: numeracy, probability and statistics, and mathematical modeling. However, the ODHE (2015) does not specify how to assess students' achievement of such learning outcomes. However, this is a part of the process for a given institution to have its QR course certified to be transferable across the state.

The researcher employed a multiple case study in both examinations. He defined a case in the pilot study as an instructor who taught at least one section of QR courses in public postsecondary institutions in Ohio during data collection, which he narrowed to the instructor teaching at least one section of Ohio Transfer 36-approved QR courses for the dissertation study. The researcher employed a purposeful selection of cases to recruit 6 instructors (3 male and 3 female) from 2 universities and 3 two-year colleges during the Spring of 2020 for the pilot study and 8 instructors (2 male and 6 female) from 3 universities and 5 two-year colleges during the Summer and Fall of 2021. However, 1 female instructor from a two-year college dropped off from continuing her participation, still giving consent to use the data thus far. Also, 1 male instructor from a two-year college participated in both studies, totaling 13 QR instructors from 11 public postsecondary institutions in Ohio. The instructors had a wide range of positions and experience; they ranged from graduate students to full professors. Their experiences in QR teaching ranged between one semester and six years. Also, some of them were working as course coordinators at their institutions.

The researcher conducted one qualitative interview with each instructor and analyzed their course syllabus in the pilot study. However, he conducted at least two virtual or in-person interviews for the dissertation study, analyzed course documents including course syllabus and teachers' artifacts, and observed two consecutive classes using 6 IQA rubrics (a) *Rigor of teachers' questions*, (b) *Accountable talk*, (c) *Clarity and detail of expectations*, (d) *Communications of expectations*, (e) *Teachers' press,* and (f) *Students providing* (Boston, 2019).

The data reported in this paper mainly include that obtained from the instructors' course syllabi analyses. The researcher categorized the instructors' project-related data into several categories, like the number of projects implemented during a semester, weights to the total course grade that instructors provided for projects and associated presentations, the content domains covered through the projects, whether the projects were individual or group assignments and the time they assigned the projects to students. The researcher transcribed the verbal data for the interview data and created codes using value coding focusing on the instructors' intrapersonal and interpersonal perceptions and experiences in implementing projects in this course (Saldana, 2016). Then, he developed themes by merging similar and related codes. He used the cross-case analysis technique to explore commonalities and differences in the instructors' actions, activities, and processes regarding project implementation (Stake, 2006).

Results and Discussions

The data analyses revealed exciting information about the instructors' use of student projects in teaching QR. Though all 13 instructors included projects in their course syllabi, they had mixed perceptions about using projects and associated presentations in this course. They also had a great deal of variation in their types, the number of projects, and how to implement them. Table 1 and Table 2 represent information obtained from the analysis of the course syllabi from the pilot study and the dissertation study, respectively. Both tables consist of the instructors' plans

Table 1: Use of Student Projects by Instructors in the Pilot Study

Instructors	Number of Projects	Weights for Projects	Content Domains	Individual or Group	Time of Implementation
Amanda	3	45%	Financial literacy Statistics Modeling	Group	One at each third of the semester
Cole	1	10%	Media literacy	Individual	The second half of the semester
Dani	3	40%	Business math Statistics Modeling	Group	One at each third of the semester
Evan	1	10%	Statistics	Individual	End of the semester
Fawn	1	4%	Comprehensive	Group	End of the semester
Zach	1	10%	Media literacy	Individual	The second half of the semester

for implementing projects, including the frequency of the projects; weights given to projects to determine student grades; content domains emphasized through the projects; nature of the projects; and the implementation time. Zach is included on both tables as he participated in both studies. Still, Zach had different project implementations during the two semesters of his participation; an increment in his number of projects and associated weights to the course grades may indicate QR instructors' increasing use of student projects in public postsecondary institutions in Ohio.

Wide Range of Number, Weights, and Time of Implementation

The instructors provided a wide range of importance to student projects and associated presentations in their course syllabi. The weights of student projects and presentations to the total course grades ranged between 4% and 75% through 1 to 8 projects a semester; the average number of projects a semester was 13, with an average weightage of 33%. However, as discussed above, this data may change based on their implementation; in his dissertation study, the researcher discovered that the average weight for student projects based on the 8 instructors' implementation decreased from 28.8% of total course grades to 27%, but with an increase in student presentation weights, from 12% to 15%. Out of 13 instructors reported in this study, 2 instructors (Evan & Fawn) provided a little weight to their projects to determine the course grades; they employed only one project during the semester and, like a traditional homework problem, required students to solve the given problems with the provided information. On the

Table 2: Use of Student Projects by the Instructors in the Dissertation Study

Instructors	Number of Projects	Weights for Projects	Content Domains	Individual or Group	Time of Implementation
Ashley	1	30%	Student choice	Group	Over the semester
Clara	3	40%	Personal finance, Statistical modeling	Group	One at each third of the semester
Gordon	2	30%	Financial Literacy, Statistical modeling	Group	One in each half of the semester
Julie	8	40%	Recent topics	Individual	Every other week.
Kande	6	75%	Recently topics	Individual	Every other week
Susan	4	50%	Numeracy, Statistics, Modeling, Comprehensive	Group	One in about a month.
Yara	4	60%	Financial literacy, Statistics, Media literacy, Modeling	Two individual, two group	One in about a month.
Zach	2	20%	Media literacy, Personal Finance	Individual	One in each half of the semester.

contrary, the other 2 instructors (Julie & Kande) used 8 and 6 projects in a semester, offering 40% and 75% weights to the total course grades. Still, these two instructors also implemented their projects like a traditional homework problem, emphasizing students' abilities to solve the problem, not the QR competencies like interpretation, representation, analysis, assumptions, and explanation. These 4 instructors did not have firm beliefs about using student projects in this course, but they had to put them in their syllabi as the Ohio Department of Higher Education required. However, some instructors heavily relied on student projects to determine course grades even though they did not have much weight on student projects. For example, Ashley and Susan from the dissertation study heavily relied on student projects. Though they had exams and quizzes in their course syllabi, they implemented such assignments as open, take-home group projects. They stated that they had to put exams and quizzes in their course syllabi as the mathematics departments in their institutions were traditionally required and required them to use exams and quizzes at least in some manner.

The instructors also had variations in the time they implemented the student projects, mainly depending on the number of projects during the semester. The instructors using multiple student projects generally divided the whole semester duration by their number of projects and used the results as the duration for each project. However, Evan and Fawn implemented their only one project at the end of the semester, like a test for a content domain or comprehensive exam. It is worth restating that these two instructors did not rely much on student projects. Likewise, though Julie and Kande implemented one project every other week, they used their projects as different names for their unit homework.

Content Domains

Even though the 13 instructors had variations in the number of, weights to, and time of implementation of their student projects, they had some commonalities in the content domains their projects covered. Notably, only 9 of the 13 instructors required students to work on any given quantitative situation, identify the available quantitative information, choose appropriate mathematical processes to solve the problems, make necessary assumptions, and derive conclusions. They provided open-ended quantitative situations, embracing the three content domains the Ohio Department of Higher Education suggested—*numeracy*, *probability and statistics*, and *mathematical modeling.* Their practices embrace all or any of the six QR competencies—*interpretation, representation, calculation, analysis, assumptions,* and *explanation* in the projects. The commonalities in content domains were more among the instructors who used more than one project during a semester. Notably, 7 instructors used more than one project during a semester, excluding the two who claimed to implement projects in each content domain. They all assigned a project in numeracy, budgeting, or personal finance. The statistical project was another popular choice; 6 of 7 instructors assigned multiple projects and 1 assigned only one project implemented statistical projects, requiring students to calculate and reason with statistics.

Similarly, 4 among the 13 instructors assigned mathematical modeling projects to students. In addition, 4 instructors included media literacy in their projects. In addition, 2 instructors, who had only one project, either let students choose any project they found interesting or provided a comprehensive worksheet; they also had chances to highlight some or all of the content domains discussed above.

The other 4 instructors, who implemented their projects like a traditional worksheet problem, generally emphasized students' ability to use recently learned mathematical knowledge and skills to solve problems. They usually provided all the required information, suggested appropriate mathematical steps, and required students to calculate answers. Their practices mainly emphasized 3 of 6 QR competencies—*interpretation, representation, and calculation.*

Collaboration and Communication

The majority of the 13 QR instructors emphasized student collaboration through their projects. Notably, 8 of the 13 instructors assigned some or all projects in groups and emphasized that students work together to understand quantitative situations, collect data, prepare reports, and present findings and conclusions. The instructors used various innovative approaches to ensure collaboration among students. Some instructors collected effort grade forms from each to determine how the team members contributed to the projects. Likewise, some required each member to submit individual reports, reserving rights to grade only one paper per group and assign grades to the whole group.

All QR instructors required students to submit a written report from their projects, but only 7 incorporated oral presentations. Depending on the nature of their projects, the instructors required students to prepare a detailed report individually or in a group or submit the worksheet. However, Cole and Zach needed students to prepare a report, develop QR activities out of their media literacy projects, and exchange with peers to seek mutual feedback.

The instructors' student presentation implementation was closely related to the nature of their projects, group or individual. Seven instructors implemented student presentations, and they all assigned group projects. Only the instructor who implemented group projects but not student presentations was the one who did not believe much in student projects. Still, there was a significant variation in the instructors' implementation of student presentations. While other instructors required students to present their project findings and conclusions, Gordan allowed students to present any interesting quantitative context. The four instructors who did not require students to present included the 4 instructors using their projects as worksheet problems and the 2 instructors from the same two-year college, Cole and Zach. Many of these 6 instructors argued that adding a presentation would add anxiety to students. They stated that students in QR courses often have low confidence in their mathematical abilities, and requiring them to present on a mathematical topic may adversely affect their learning.

Group Projects as a Critical Variable for Formative Assessment in QR

The dissertation study discovered group projects as a critical variable for formative assessment in Quantitative Reasoning courses. The 8 instructors in this study generally relied on group projects for students' learning with collaborative and collective endeavor; their average weight for group projects was 20.5%, which was 56.5% of their average collaborative assessments. They also had a strong positive association between collaborative assessments and group projects, $r = .87$. Five (5) of the 8 instructors used group projects, highlighting students' holistic development and ability to use the mathematical content in real-world problems through their group projects. They mostly used open-ended, ill-defined, and high cognitively demanding tasks in their group projects, emphasizing the reasoning competencies of QR, like analysis, assumption, and communication. They mostly gave less instruction and support and sought students' collaboration and communication to accomplish the projects. The group projects also had a close connection with student presentations. Only the instructors who assigned group projects required their students to present the findings and conclusions of the projects.

Group projects were also associated with the instructors' formative assessment strategies. Only the instructors using group projects asked a series of checking and advancing questions to check students' understanding, seek clarification, connect ideas, and further their learning and understanding, usually in a whole class setting. Likewise, only such instructors had sophisticated feedback practices; they provided formative feedback while students worked on their group projects and in-class activities, emphasizing clarifying students' misconceptions, furthering understanding, and fostering self-esteem and confidence. Likewise, the instructors generally orchestrated students' peer- and self-assessment only in the group projects and presentations. The peer- and self-assessment also highlighted the students' collaboration, communication, and reflective understanding abilities.

The group projects also connected to the instructors' scores in the IQA rubrics. Instructors who employed group projects scored higher than those who used only individual projects. For the 7 instructors in the dissertation study, the average score on the 6 IQA rubrics was 3.08 out of a possible 4, with at least 3 in each rubric, but the Accountable Talk. This study also suggested collaboration and communication as the premise and results for the group projects.

Conclusions

A Quantitative Reasoning course aims to develop students' quantitative and reasoning abilities to solve problems in their everyday and professional contexts. A typical QR instruction uses projects that include real-world tasks and performs as constructive and collaborative platforms where students work individually or in groups to foster their QR competencies. Therefore, many professional communities and policy documents explicitly or implicitly suggest instructors use projects as both instruction and assessment in QR courses.

Quantitative Reasoning instructors in public postsecondary institutions in Ohio greatly varied their plans for and implementation of student projects. They mainly varied in the number of projects they used in a semester, associated weights to determine course grades, the content domains covered by the projects, and the implementation, individual or in groups. There were significant differences among the instructors who used one project versus multiple projects in the semester. Likewise, in implementation, the instructors varied when they assigned student projects, the nature of such projects, opportunities for students to collaborate while working on projects, instructors and peer feedback practices, and the learning competencies emphasized through the projects. The instructors' student presentation and formative assessment practices mainly depend on the nature of their projects; only the instructors who employed group projects required students to present their findings and conclusions. The instructors' variations in their project implementation provided different learning opportunities for their students. Such variations may challenge the transferability of this course. Ten among 11 institutions represented here offered the *Ohio Transfer-36* approved QR courses. However, the instructors mostly used fermi projects, mainly covering the three content domains the state authority suggested–*numeracy, probability and statistics,* and *mathematical modeling.*

The discussion in this paper restated several findings of the first researcher's dissertation study: (i) a great deal of variation in QR instructors' use of student projects in public institutions in Ohio, (ii) group projects as a critical variable for formative assessment in QR. The group projects, supported by instructor autonomy, create opportunities for students to solve real-world problems, fostering their six QR competencies—*interpretation, representation, calculation, analysis, assumption,* and *communication* (AAC&U, 2009; Boersma et al. 2011), and (iii) collaboration and communication as the premise for and results from the group projects.

Acknowledgments

The researcher is grateful to all participant teachers and their institutions for sharing the information required in this study. He also acknowledges his dissertation supervisor and other committee members, who provided guidance and suggestions to accomplish the two studies. The researcher even thanks his college and graduate student senate for providing financial support to conduct the dissertation study.

Do Instructors Value Examples in Proof?

Jordan Kirby
Francis Marion University

During the transition from procedure-based mathematics courses to proof-based mathematics courses, many students struggle to understand the purpose of examples. A productive use of examples can help both the generation and understanding of proofs. Although recent advances in research have argued the importance of productive uses of examples, there is little research investigating the alignment of research with current practices of instructors or of how the instructors view research on example-use. Findings from this study indicate instructors are aligned with mathematics education research on differing levels of example-use. However, many instructors may be hesitant to see examples be used by their students in written work. Despite this hesitation, instructors still encourage students to use examples to aid their understanding of proof.

Keywords: Proof, Examples, Instructors

Introduction

Student difficulties in understanding and producing proofs are well documented in mathematics education research (e.g., Ellis et al., 2019; Harel & Sowder, 2007; Stylianides, 2007). One such difficulty with proving comes from the effective use of examples to aid proof production and understanding (e.g., Aricha-Metzer & Zaslavsky, 2019; Epp, 2003; Zaslavsky & Knuth, 2019). Although there is much research in understanding how and why students use examples when proving, little research exists studying instruction in proof classes based around examples (Zaslavsky & Knuth, 2019). Zaslavsky and Knuth (2019) noted, "Very little research has focused on the nature and design of instructional practices that facilitate the development of students' abilities to strategically think about and productively use examples as they engage in proving-related activities" (p. 243).

This paper begins the process of addressing Zaslavsky and Knuth's (2019) call for research by investigating the perceptions of students' use of examples held by introduction to proof (ITP) instructors. To develop effective instructional interventions, it is imperative to understand what practitioners currently do in their classrooms (Desimone & Garet, 2015). This study aims to lay groundwork necessary for future research to implement instructional interventions by ascertaining the current perceptions and reactions held by ITP instructors across the United States. To accomplish this goal, I seek to answer the following research question: **How do instructors of ITP classes perceive students' understanding and use of examples when proving?**

Theoretical Framework

I draw upon the work of Aricha-Metzer and Zaslavsky (2019) in distinguishing between productive and unproductive use of examples when proving. Aricha-Metzer and Zaslavsky defined productive examples when the example helped the prover make progress or gain insight into key aspects of the proof. An unproductive use of examples in proof was when the prover used an example but no progress towards developing or understanding a proof was made.

One of the aspects of proof in my work is how examples are used and potentially included in the formal written work provided by students in an ITP course. Balacheff (1987) described categories of example-use in proof; these categories include: naïve empiricism, crucial experiment, and generic example. Table 1 summarizes these categories.

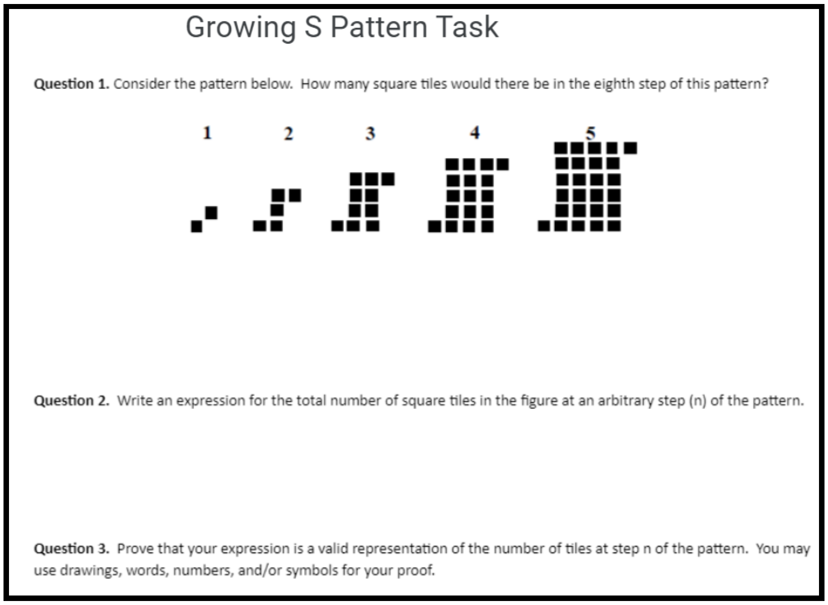
Table 1 Balacheff (1987) example-use categories

Name of Category	Definition (From Balacheff 1987, p. 19-20)
Naïve Empiricism	Drawing from the observation of a small number of cases the certainty of the truth of an assertion
Crucial Experiment	A process of validation of an assertion in which the individual explicitly poses the problem of generalization and solves it by betting on the realization of a case that he recognizes as being as unspecific as possible
Generic Example	Explanation of reasons for the validity of an assertion by carrying out operations or transformations on an object present not for itself, but as a characteristic representative of a class of individuals

Aricha-Metzer and Zaslavsky (2019) explain that when examples are used akin to the generic example level described by Balacheff (1987), the examples used by students were typically classified as productive. In defining generic example, I build on the work provided by Rø and Arnesen (2020) citing Reid and Vallejo Vargas' (2018) two criteria of a generic example: evidence of awareness of generality and mathematical evidence of reasoning. In short, the argument must conclude with a general claim about the original problem to be proven as well as contain reasoning directly linked from the example to be classified as a generic example.

Methodology

Participants of this study include university professors across the Southeastern United States actively teaching their university's version of an ITP course. Eleven professors agreed to participate in the study with varying demographic information such as Carnegie classification of the university, type of Ph.D. received, tenure at the university, and self-described teaching style. One-hour semi-structured interviews were conducted with all participants online through Zoom. Participants were emailed two questions before the study shown in Figure 1.



Question 1. Given the number of vertices in a polygon, find a method to calculate the number of diagonals of the polygon. Explain why your answer is correct.

Figure 1. Growing S pattern task and polygon diagonal task

Participants were not expected to solve these problems before the meeting. The problems were chosen to be easy enough to solve for most faculty members during the interview so time could be spent discussing student use of examples rather than proving the claim. Four participants mentioned they would use or have previously used one or both of the questions shown to them in the interview. Ten of the eleven participants expressed belief these two questions were appropriate for early semester in an ITP course.

During the interview, participants were shown three student work samples for each of the two questions provided. These student work samples were chosen to exemplify the three levels of Balacheff's (1987) framework on example-use. Figure 2 details one of these student work samples: Carla at the crucial experiment level solving the growing S pattern task.

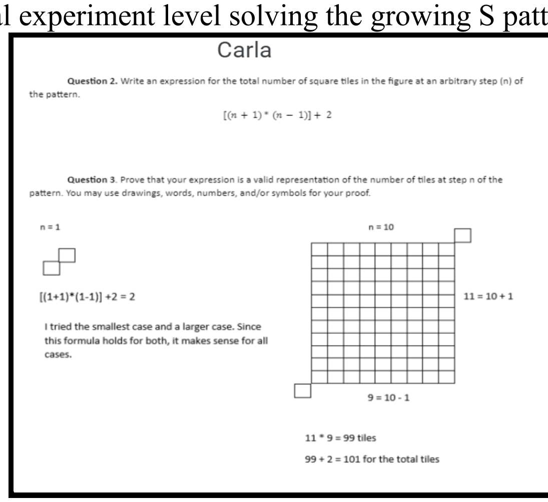


Figure 2. Carla solving the growing S pattern task at the crucial experiment level.

During the interviews, the order of the two questions was randomized as was the order the student work samples were shown. Student work samples were always kept clustered so a participant would either receive the three growing S pattern task solutions first or the three polygon diagonal task solutions first. When presented with student work, participants were asked to mention anything they noticed about the student work sample. Participants were informed this may include if they believe the student is correct, if they liked what the student did, if they had comments on any of the student work, if they had seen something similar to this solution in their classroom, or any questions they would have as instructors if a student in their class presented them with a solution like this as a homework assignment.

After responding to all six student solutions, participants were asked to group the student solutions into as many or as few categories as they deemed appropriate and name each category. Finally, participants were asked to rank the six student responses from 1 to 6 with a response of 1 signaling the best attempt at a proof and a response of a 6 signaling the most work needed to be done for a prof. After finalizing their rankings, participants were asked to provide instructional feedback to advance the students forward whom they ranked best and worst. This manuscript will focus on the ranking task and transcript from across the responses to student solutions.

Analysis

Video data from Zoom interviews with faculty were transcribed by talk turn. I define a talk turn as all utterances spoken by one participant until interrupted by the interviewer. This data was then open coded for common remarks about students' example use among the faculty participants. In order to be considered as a potential code, the code theme had to be included at least twice within the same participants' transcript and across three different participants. For instance, Dr. Amanda's transcript showed a potential code for *mathematical induction*. This was coded when Dr. Amanda remarked discussing Carla's work, "Okay, so here's some induction ideas. You've got the base case. And a small case for the largest." Similarly, Dr. Amanda remarked on Nancy's work (naïve empiricism, growing S pattern task), "[Nancy] tried a smallest case. And the larger case, is suggesting that there's maybe some more idea there of like, maybe I can interim check intermediate cases, which sort of feels like you're building to induction." Dr. Amanda continued to note similar remarks about two other participants' work. This was sufficient within Dr. Amanda's transcript to be a potential code. If this code showed up in another transcript from another participant, I included the code as a theme. For the ranking task, screen captures were taken and compiled to look for common rankings. The rankings were compiled into a table with the feedback given for each participant coded as described earlier.

Results

I will answer my research question in two parts. First, I will list how participants ranked the student responses. Then, I will discuss one of the common themes that emerged from transcribing the data.

Rankings

Participants were asked to rank the six student work samples from a 1, signaling the best attempt at a proof, to a 6, signaling the worst attempt at a proof. The six student work samples were split between the two questions listed in Figure 1 with one student work sample at each of the levels described by Balacheff (1987). Table 2 shows the rankings of each student argument across the 11 faculty participants.

Table 2. Participant rankings of student work samples from 1 to 6

	1st	2nd	3rd	4th	5th	6th
Gina's argument (generic example)	10	1				
Jacob's argument (generic example)	1	9	1			
Carla's argument (crucial experiment)		1	9	1		
Eric's argument (crucial experiment)					8	3
Aaron's argument (naïve empiricism)			1	5		5
Nancy's argument (naïve empiricism)				5	3	3

Table 2 shows how frequently each student was ranked in positions 1 through 6 in the 11 interviews. This table gives evidence to the participant's inclination to rank students' arguments in alignment with the levels of example-use described by Balacheff (1987). Ten of the 11 participants ranked Gina's argument as the best attempt at a proof. Many participants expressed although they similarly liked Jacob's argument, the design of the growing S pattern task led to a seemingly more appealing argument leading to Gina's ranking above Jacob's. Although Eric (crucial experiment – polygon diagonal task) was positioned to exhibit a more robust use of examples than students at the naïve empiricism level, some of the wording used by Eric caused concern for many participants. Eric included statements such as, "This led me to a pattern" and "If my pattern holds," without every explaining what his pattern was. Most participants expressed concern with these phrases when ranking Eric and decided to rank him in the bottom two for lack of clarity.

Theme of Acceptance of Example-Use

A common theme that emerged from the interviews was the theme of acceptance or rejection of example-use. Of the 11 interviews conducted, 5 participants expressed concern with seeing examples of any form included in the written work shown by students. The other six participants alternatively expressed interest and praise for the use of examples to aid proof production and understanding.

The theme of acceptance or rejection was common amongst all 11 participants. A participant was classified as either accepting or rejecting examples entirely based on unprovoked remarks of the first phase of the interview responding to student work samples. All participants expressed their preference of acceptance or rejection of examples at least twice within their interview. The acceptance category included comments promoting student reasoning and praise of the use of examples to aid the understanding or production of the proof. The rejection category instead expressed concern in every instance for the example included in the written work and felt the proof was more lacking with the inclusion of the example. There were no differences in demographic information between the acceptance and rejection groups.

One instance of an acceptance category comes from Dr. Tucker. When responding to Jacob (generic example – polygon diagonal task), Dr. Tucker remarked, "So, I do like the, I guess he kind of start out with, you know, thinking of a fixed number. Just to kind of get an idea of what to do with it." Later, Dr. Tucker similarly commented on both Gina (generic example – growing S pattern task) and Carla's (crucial experiment – growing S pattern task) work praise for the pictures drawn and an interest in having more students use this type of reasoning. These comments were sufficient to include Dr. Tucker in the acceptance of example-use category. Participants in the acceptance category did not accept all forms of examples as sufficient for proof. Five of the six participants in this category expressed concern for both Nancy (naïve empiricism – growing S pattern task) and Aaron's (naïve empiricism – polygon diagonal task) use of examples in their proof. Dr. Tucker commented on both Eric (crucial experiment – polygon diagonal task) and Aaron's work,

> I guess generally, a pitfall I see with students is trying to just do a couple of examples. And then that kind of just, I know this doesn't say prove (referring to the wording of the question given), but kind of thinking that counts as a proof. And yeah, it feels like they just kind of need to bring more justification of why would this work in general.

Although Dr. Tucker and others in the acceptance of example-use category appreciated the work shown by students when proving, this did not mean they accepted incomplete proofs. Participants in the acceptance of example-use category expressed appreciation for the productive uses of examples as described by Aricha-Metzer and Zaslavsky (2019) and concern for the unproductive use of examples.

Participants in the rejection category responded to student work regardless of Balacheff's (1987) associated level with explicit concern for the written inclusion of examples in the product produced. These comments were made for both productive uses of examples as well as unproductive uses of examples. For instance, Dr. Hubert remarked about Gina's work, "I mean, it's reasoning by example. Which is always rough. I would say the n minus one, n plus one part could have helped me earlier on." Dr. Hubert here refers to how Gina starts with a drawing of a specific case. From this case, Gina gathers information about the nature of the problem and correctly answers the problem producing a generic formula to solve the growing S pattern task along with a short algebraic proof. Dr. Hubert expressed concern that Gina left the reasoning with her example in the work instead of removing this first.

Later in the interview, Dr. Hubert again remarked about Gina's work, "So I'm struggling right now with if you can do this (referring to Gina's formal answer at the bottom of the page), how does it not stick? I mean, I ought to be able to just state that part earlier right?" Dr. Hubert was struggling in the interview to understand why if Gina knew the complete answer she could not remove the discussion about how she arrived at the answer and instead state her proof more formally. This idea of formality was raised by Dr. Sarah about Jacob's work with examples commenting, "The fact that Jacob does still have, like the thinking about his example. To me, I would not want to see evidence of it in the proof." The rejection of examples category was largely defined by the difference in how formality was viewed as a necessary condition in an ITP course.

Discussion and Conclusion

This research looks to make progress in answering the call to action from Zaslavsky and Knuth (2019) to include more instructional tools about examples in proving. I set out to answer my research question: How do instructors of ITP classes perceive students' understanding and use of examples? Answering this question will assist future researchers in developing instructional interventions for practitioners of ITP courses by considering the current state of the field. I answered this research question in two ways. I first answered my research question through the participants' rankings of the provided student work based on the completeness of a proof. Second, I showed a theme for common responses to student work involving example-use through the acceptance or rejection of examples in proving.

Through the ranking task, participants are largely aligned with the levels of example-use described by Balacheff (1987). Although there was a discrepancy with Eric, most of the participants still ranked the student work largely by type of example used by the student. This finding can help future instructional interventions find a starting point for helping instructors of ITP courses aid students in using examples more productively as instructors seem to be implicitly aware of the categories of example-use without any background information given. Participants of the study were asked in a short debrief after the interview if they were familiar with any research on generic examples or Balacheff's framework. None of the participants were familiar with any of this research.

Through the coding, a potential theme of acceptance or rejection of example-use came to light. This theme should be considered when designing instructional interventions in the future for example-use in proof. There were no differences in any demographic information collected between the acceptance of example-use group and the rejection of example-use group. For professional development to be most effective, practitioners need to be met at their current level (Desimone & Garet, 2015). This study gives some evidence that for some practitioners, work may need to be done by mathematics educators on convincing their future professional development groups of the effectiveness and usefulness of generic examples. There is a potential conflict with the message sent to students if practitioners value examples to aid a students' understanding while in class but then do not want to see examples in the written work. Finally, the issue of formality of written work in an ITP course was repeatedly seen. Participants in the acceptance of example-use group did not bring up issues with formality of the presentation of a proof. Participants in the rejection of example-use group frequently brought up issues of how including work in a proof detracted from the argument.

I encourage future researchers to investigate this disconnect of example-use and acceptance in other areas of mathematics, other types of proof, and in more detail. The comments taken in this study came unprovoked as the interview protocol did not include questions about acceptance or rejection of example-use. Directed questioning towards types of examples and what a proof should look like would benefit future work in developing instructional interventions for ITP classes. Mathematics education researchers and practitioners should consider the idea of formality of proof and determine how to best approach future research in the field of example-use in proof.

Playful Math, Problem Posing, and Discovered Complexity

Amy B. Ellis
University of Georgia

Anna Bloodworth
University of Georgia

Dru Horne
University of Georgia

Problem posing is an important part of mathematical inquiry, but students can struggle to pose problems that are mathematically relevant. One route for supporting meaningful problem posing is through playful math tasks, which can emphasize agency and exploration. In this paper we report findings from a small-group teaching experiment with five pre-service secondary teachers who explored a variety of tasks, including open tasks, problem-solving tasks, and tasks designed to foster mathematical play. In investigating students' problem posing, we found that developing playful challenges for one another supported instances of discovered complexity, the experience of new conceptual challenges. We discuss examples of discovered complexity and the mathematical ideas students developed when grappling with novel ideas.

Keywords: Problem posing, mathematical play, covariation

Instructional approaches that engage students in experiences that are authentic to disciplinary inquiry should offer opportunities for problem posing, exploring, and conjecturing (Bonotto, 2013). Problem posing can be a particularly powerful activity to support students' mathematical inquiry (Cai et al., 2015), and classrooms that do not include problem posing can curtail students' mathematical exploration (Ellerton, 2013). Collective problem posing activities are one way to build students' autonomy in the development of the mathematics they learn, and they can provide a space for students to develop their creativity and problem-solving skills (Cai, 2012). There are, however, challenges with meaningfully fostering problem-posing skills. Students and teachers can pose a variety of problems when presented with a given set of information (Stickles, 2011), but may struggle to pose problems that are mathematically relevant, appropriate, and solvable (e.g., Cai & Hwang, 2003; Silver & Cai, 1996; Silver et al., 1996). As Cai et al. (2015) noted, more research is needed to understand not only which strategies are needed to pose mathematically interesting problems, but also how to effectively teach for problem posing.

We conjecture that *playful math* could be one way to foster productive problem posing. We have been running a series of studies investigating how to meaningfully incorporate playful elements into task design and instruction, and have found that playful mathematics tasks can emphasize student agency, exploration, and goal selection (e.g., Bloodworth et al., 2023; Horne et al., 2023; Ellis et al., 2022). When crafting playful mathematics tasks, we shift the design role to the student, enabling students to construct challenges for one another. This provides an opportunity to engage in problem posing that may support discovered complexity (Williams, 2001; 2002; 2003), which occurs when problem solvers "perceive *intellectual* and *conceptual* complexities not evidence at the commencement of the task" (p. 378, emphasis original). In this paper we address the following research questions: When does students' problem posing lead to discovered complexity? In particular, how does discovered complexity emerge in different task types, and what mathematical ideas are developed through discovered complexity?

Background Literature and Theoretical Perspectives: Problem Posing and Play

Cai and Hwang (2020) defined Mathematical Problem Posing (MPP) as "the process of formulating and expressing a problem within the domain of mathematics" (p. 2). While some emphasize problem posing in terms of the generation of a new problem from a given set of conditions (e.g., Stoyanova, 1998), others also include in problem posing the activity of reformulating existing problems (e.g., Silver, 1994). Problem-posing tasks, then, are ones that require students (or teachers) to generate new problems based on given situations, expressions, or diagrams (Cai et al., 2020). As an example, Stoyanova (1998) offered the following task: "Last night there was a party and the host's doorbell rang 10 times. The first time the doorbell rang only one guest arrived. Each time the doorbell rang after that, three more guests arrived than had arrived on the previous ring. Ask as many questions as you can" (p. 66). Note that this task, which is typical in the literature, offers a constrained context with specific values, and then asks students to develop problems with the given information. That said, a good problem-posing task should leave room for different interpretations (Kontorovich et al., 2012; Silver & Cai, 1996).

Posing problems can deepen students' understanding of mathematics, as well as their understanding of problem-solving (Brown & Walter, 2004). Indeed, problem posing is an important part of problem-solving competence, and to become successful problem solvers, students need to encounter tasks that require both posing and solving problems (Cai et al., 2015; Kilpatrick, 1987; Niss & Højgaard, 2019). Problem posing can also capture students' interest, foster reasoning and communication abilities, and can help students understand that there is no one right way in mathematics (Cai et al., 2015; Silver, 1994).

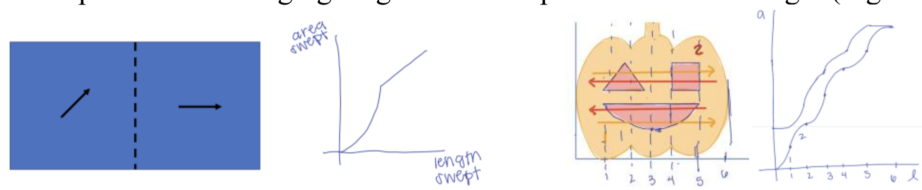
Research on people's abilities to pose problems is largely situated at the K-12 level, and the findings are mixed. Some studies show that both students and teachers can pose interesting and important problems (e.g., Silver & Cai, 1996; 2005; Cai & Hwang, 2020). However, more studies have identified challenges with successful problem posing (e.g., English, 1998). Stickles, for instance, found that secondary teachers could pose problems, but their success was partial and was related to experience and background (2011). Taken as a whole, the studies of students' and teachers' problem posing have identified issues such as a) posing nonmathematical problems, b) posing tasks that were not problems, and c) posing low-quality problems (Cai & Hwang, 2020; Leung & Silver, 1997; Silver et al., 1996).

In investigating strategies for supporting problem posing, researchers have noted the importance of providing opportunities for exploration (Koichu & Kontorovich, 2013). Crespo and Sinclair (2008), for instance, emphasized the need to allow students avenues to explore the limits of the mathematical situations they investigate. Cai and Cifarelli (2005) studied how undergraduate students posed problems, and identified two levels of reasoning strategies, hypothesis-driven and data-driven, that students incorporated into their problem-posing strategies. Brown and Walter (2004) proposed the "what-if-not" strategy, and others have suggested helping students learn to pose problems by extending or revising an existing problem (e.g., Abu-Elwan, 2002; Cai & Brook, 2006). However, as Cai et al. (2015) pointed out, "Much more research is needed to develop a broadly-applicable understanding of the fundamental processes and strategies of problem posing" (p. 17). As we discuss below, we hypothesize that some features of playful math could foster meaningful problem posing.

Mathematical Play and Playful Math. Drawing on five characteristics that recur throughout the literature, we define mathematical play in terms of a person's experiences, behaviors, and affective states during activity. First, mathematical play entails *freedom* and *agency*. It is player-centric, with the player in charge of the process (Holton et al., 2001; Gresalfi et al., 2018). Participation is voluntary (Williams-Pierce & Thevenow-Harrison, 2021) and ludic (Featherstone 2000). Second, mistakes have *low stakes*. When playing, a person is not afraid of failing (Williams-Pierce & Thevenow-Harrison, 2021) and may not even experience anything as "failure" (Barab et al., 2010; Su, 2017). Third, mathematical play entails *engagement and* *immersion* in one's activity (Gresalfi et al., 2018). Learners find pleasure in their experience (e.g., Burghardt, 2011; Sukstrienwong, 2018), and activity is imaginative and creative (e.g., Parks, 2015; Su, 2017). Fourth, mathematical play is *experimental and exploratory* (Mason, 2019). Play often leads to surprises (Su, 2017), and when one plays, one is in a state of openness to unexpected experiences and outcomes (Davis, 1996). Finally, mathematical play is *goal-driven* (Huizinga, 1955). Goals can emerge as play proceeds, and researchers have described instances of goal-directed behavior, such as learners solving challenges in a video game (Williams-Pierce, 2019). Consequently, we consider mathematical play to entail the following three traits: (a) exploration, (b) self-selection of goals, and (c) immersion, investment, and/or enjoyment.

Researchers have identified a number of learning benefits from mathematical play. It can support experimentation, reflection, and persistence (Barab et al., 2010; Gresalfi et al., 2018; Mason, 2019) and can provide a productive route for exploring and conjecturing (Jasien & Horn, 2018; Mason, 2019; Williams-Pierce, 2019). Beyond mathematics, classroom-based play offers a supportive environment for risk-taking and creativity (Barab et al., 2010; Brown, 2009; Radke & Ma, 2018; James & Nerantzi, 2019). It can help students connect theory and practice (Barnett, 2007), it can foster openness to new learning (Forbes, 2021), and it can support classroom engagement (James & Nerantzi, 2019; Whitton & Moseley, 2014). Many of these practices mirror mathematicians' activity, such as detecting patterns (Fernández-León et al., 2021; Melhuish et al., 2021), generalizing (Bass, 2008; Martín-Molina et al., 2018), conjecturing (Fernández-León et al.; 2021; Harel, 2008), and experimenting (Watson, 2008). These similarities have resulted in calls for instruction that encourages playful engagement. For instance, Gresalfi and colleagues (2018) argued that "much of what is considered to be sophisticated disciplinary engagement involves many of the same features as play" (p. 1335).

To study how to foster mathematical play, we used the term "playful math" to describe the elements of classroom activities and environments that can facilitate mathematical play. Drawing on the literature, we have identified five design principles for playful math tasks (Ellis et al., 2022): (1) enable free exploration within constraints; (2) engender anticipation within the task; (3) provide a method for intrinsic feedback; (4) offer meaningful challenge while still being feasible; and (5) allow the student to act as both designer and player. As an example, we created the *Guess My Shape* game, which draws on a set of research-based tasks to support student understanding of function through examining covarying quantities (Ellis et al., 2020; Matthews & Ellis, 2018). In these tasks, students investigate dynamically growing shapes, graphing a shape's area compared to its changing length as it sweeps out from left to right (Figure 1a).



(a) *(b)*

Figure 1. An instructor generated (a) and student generated (b) shape and associated area-length graph.

To playify the tasks, the *Guess My Shape* game prompts students to create shapes of their choice (design principles 1 and 5), construct graphs comparing length and area (principles 2, 4, and 5), then challenge each other to determine the shape or the graph based on what is provided (principles 2, 3, and 4). Figure 1b shows an example of a particularly creative shape and its associated graph created by our participants, which entailed sweeping a pumpkin from left to right, and then sweeping backwards right to left to remove area to create a jack-o'-lantern.

The playful math design principles are consistent with many features of problem-posing tasks. Problem-posing tasks require students to generate new problems (principle 5), and they offer opportunities for exploration (principle 1). However, our tasks shift the design role to students in a manner that is more open-ended than what is seen in the problem-posing literature. For instance, in contrast to Stoyanova's (1998) doorbell task, in which both the situation and the relevant numbers or mathematical expressions are given, we provide fewer constraints and encourage students to design novel challenges.

Discovered Complexity. We draw on Williams' (2001) construct of discovered complexity to examine the consequences of students' problem posing, particularly the spontaneous problem posing that occurred in the course of both designing and solving tasks. Williams (2002) wrote that when students discover a complexity, they spontaneously formulate a question that leads to intellectual and conceptual challenges: "the mathematical ideas in a discovered complexity are new to all students in the group and the teacher does not contribute new mathematical ideas during the interaction" (p. 403). The process of discovered complexity is autonomous, spontaneous, and creative, similar to the activity described by a research mathematician (Williams, 2002). Discovered complexity is associated with high positive affect (Williams, 2003) and meets the conditions for flow (Williams, 2001), as students can work just above their present skill level to meet a challenge almost beyond their reach.

Methods

We conducted a videoed teaching experiment (TE; Steffe & Thompson, 2000) with five secondary pre-service teachers, Phyllis, Meredith, Kelly, Ryan, and Toby (all pseudonyms). The students had all completed their first semester in a secondary mathematics education program, and they were familiar with non-routine covariation and graphing tasks. The students enjoyed a positive rapport with one another and were comfortable questioning each other and themselves.

The TE met for a total of 6 hours. We began with the function growth activities described above, which we call standard tasks, and which addressed polynomial, trigonometric, and piecewise functions. We also incorporated playified tasks in the form of the *Guess My Shape* game, as well as more traditional problem-solving and open tasks (e.g., tasks that were open-ended with many possible solutions, such as "create two growing shapes that could be represented by the same graph"). The problem-solving tasks were ones such as the handshake task: "If there are n people in a room, and they all shake hands with each other exactly once, how many handshakes occurred?" All of the standard, problem-solving, and open tasks were challenging and creative, but only the *Guess My Shape* game adhered to all five playful math design principles. Over the course of the TE we implemented six standard tasks, three problem-solving tasks, two open tasks, and three playified tasks.

Analysis. As part of a larger study investigating the characteristics of students' mathematical play, we developed emergent codes describing students' experiences and behavior. One code that became relevant for this paper was "wonderment", which represented instances of students spontaneously communicating curiosity or interest about a new mathematical idea, problem, or relationship. Wonderment is an instance of spontaneous problem posing. We initially found 23 cases of wonderment, and examined each case to determine: a) did it occur during a standard, open, problem-solving, or playified task; b) did it result in discovered complexity? We identified instances of discovered complexity by seeing whether each wonderment yielded a novel or more complex mathematics challenge, as opposed to simply trying to understand the given question, establish a convention or definition, or wondering how to create a challenging task for someone else (but not actually creating such a task). During this process, we abandoned two of the 23 wonderments as not actual wonderments. In one case, a student was trying to understand how another student's shape was being swept out, and in the second case, a student was curious about the logic another student was using for her solution. We analyzed the remaining 21 wonderments collaboratively, meeting weekly to refine and adjust our meanings and resolve discrepancies.

Results: When Wonderment Leads to Discovered Complexity

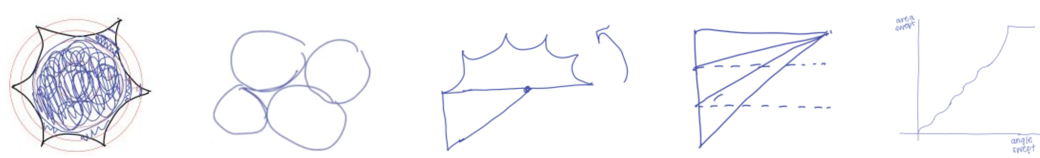
Table 1 shows the number of wonderments per task type and the number of wonderments within each type that led to discovered complexity. Five of the 21 wonderments occurred during the two open tasks, and the remaining 16 occurred during the three playified tasks. We did not find any instances of wonderment in the six standard tasks or the three problem-solving tasks.

Table 1. Number of wonderments and number of resulting discovered complexities by task type.

Task Type	Wonderments	Discovered Complexity
Standard	0	0
Problem Solving	0	0
Open	5	3
Playified	16	9

In examining how discovered complexity emerged, we first identified cases of wonderments that were not discovered complexities. As an example, Toby grappled with an open task in which he had to invent a shape with a monotonically increasing graph that changed concavity. He drew a trapezoid, and a corresponding piecewise area-length graph that had a concave up portion, a linear portion, and a concave down portion. Toby asked himself, "Does that count as a change in concavity? Like, what is the concavity of a straight constant line?" Toby's wonderment did not introduce a new mathematical idea or problem, and it did not count as problem posing. Instead, it was an attempt at a clarification of meaning.

In another example, during the *Guess My Shape* game, Phyllis and Meredith explored a novel way of sweeping. They created a figure that they called a police badge (Figure 2a) and imagined sweeping area from a point in the center moving outward in a circle. Phyllis wondered, "I'm just thinking about, like, now just the geometry stuff. When there's a bunch of circles connected (draws four circles, Figure 2b). You see what I mean, you see spikes here. Is there any relationship with that at all?" Later, she clarifies her wonderment: "How many circles could you fit around one circle of the same size?" Here Phyllis's wonderment posed a problem about circle packing, addressing mathematics that was novel to her. However, before she had an opportunity to attempt a solution, the students were interrupted and told to move back to the whole group, and thus she did not get a chance to engage with intellectual or conceptual complexity.



(a) (b) (c) (d) (e)

Figure 2. Phyllis and Meredith's shape (a), Phyllis's illustration of a circle packing problem (b), Meredith and Toby's shape (c), triangle divided into sub triangles (d), Meredith and Toby's graph (e)

In contrast, we present a case in which a wonderment did lead to discovered complexity. As seen in Table 1, discovered complexity only occurred a little over half the time during students' activity in the playified *Guess My Shape* game. It occurred more often when the students were creating a challenge for their classmates, a formal act of problem posing, than when solving a challenge (discovered complexity occurred during 5 out of 7 wonderments when creating a challenge, but only 4 out of 9 wonderments when solving a challenge). We found that discovered complexity emerged when students either developed curiosity about the nature of covariation, rates of change, or related graphs, or when students became curious about why a particular solution method or strategy was valid.

In the following example, Toby and Meredith posed a problem by creating a shape for their classmates, which they imagined sweeping radially from 0° to 360° (Figure 2c). The students wondered whether the associated graph comparing area and angle swept would be constant once the angle reached 180°:

Toby: So, what happens when we do that? I feel like you're getting more triangle each time you open up, right? Because this length gets longer (points to radial lines in Figure 2d; dotted lines are not yet present), but the base is the same and the height is the same, right? Wait, the base is definitely the same. I don't know about the height, it could also be increasing.

Meredith: I think it –

Toby: – Wait, wait, there's only base and height. So, the base is the same, the height's increasing, so it would get bigger.

Meredith: The base has to be the same.

Figure 2d divides the triangle into three smaller triangles, and Toby and Meredith referred to the vertical portion on the left of each smaller triangle as its base. They erroneously assumed that for each equal angle increment, the base of each small triangle would be the same. Toby and Meredith initially conceived of the height of each triangle differently. Toby assumed the heights would be the solid radial lines in Figure 2d, whereas Meredith realized that they would need to be the dotted horizontal lines, which she drew in: "I think the height has to be perpendicular to the base." The students agreed that the heights of each triangle must be equal, and therefore, they concluded that the amount of area added for each equal angle increment would be equal. Thus, the graph for that portion of the shape should be linear.

Toby remained, however, uncertain about this conclusion. As they worked on an initial graph, he returned to the issue of the triangle's growth, saying, "I still find that hard to believe, but I think it's true. How come this ends up being the same as if we had done that (draws another triangle with the base at a 45° angle, rather than vertical) instead?" Both students, however, believed that it must be linear, because they had justified it based on the belief that the base of each incremental triangle would be equal. Later, a teacher-researcher asked the students about their thinking, and Toby expresses doubt again, but this time with a different outcome:

TR1: How did that triangular part, what was your reasoning there?

Meredith: We were saying that for the bases, we're saying all have to be the same because that's how we're designing the –

Toby: Wait. Are they though? I'm questioning myself again. Just because the angle increases by the same amount, does that mean the base is the distance away, because…(pause). I'll draw a bigger one. There's this angle, and you open it up by the exact same amount. I feel like you're going to have *more* base over here (points to the bottom sector in Figure 2d) than you did up here (points to the top sector). You know what I mean?

Toby drew a much larger triangle, and relying on the grid feature of his notetaking app, then carefully subdivided it into triangles with equal increment angles. In this manner it became apparent that each new triangle had a larger base than the previous triangle. Consequently, the students revised their graph to reflect that the portion of the graph from 180° to 270° would not be constant, but rather would increase at an increasing rate (Figure 2e). Indeed, this can be determined by considering the smaller triangles as each having a swept angle θ, a height of 1, and a base *x*, in which *x* grows as area is swept. The area of each triangle will be $\left(\frac{1}{2}\right)x$. Because $\tan\theta = x$, the area function will be $A = \frac{1}{2}\tan\theta,\ 0 \leq \theta \leq \frac{\pi}{4}$, which yields a graph that increases at an increasing rate.

In posing the radial sweeping problem, Toby and Meredith encountered a discovered complexity. Toby's wonderment about whether the relevant portion of the graph would be linear led to the students perceiving a conceptual complexity, that of how to determine the growth of the triangle. That this was an intellectual challenge for the students was apparent in their discomfort with their initial graph, as well as the need to revisit the question more than once. In resolving the complexity, Toby and Meredith shifted from reasoning only about increasing or decreasing rates, without attending to a way to quantify area amounts, to reasoning geometrically with the triangle area formula to justify why the area had to grow at an increasing rate for each equal-increment angle sweep. In this manner, the problem Meredith and Toby posed for their classmates required them to grapple with a novel conceptual complexity.

Discussion

The *Guess My Shape* game formalizes problem posing by asking students to design problems, but in a manner that is less constrained than what is typically seen in the literature (e.g., Stoyanova, 1998). The primary constraint on the students was that they had to determine how to graph any shape they developed. Because the students were motivated to make their tasks "fun", "tricky", and "unexpected", they pushed themselves to create shape-graph pairs that included novel and creative elements, some that were particularly challenging to solve. However, wonderments emerged not just during formal problem posing; they also occurred when students were solving one another's challenges and exploring open tasks. Wonderments are spontaneous instances of problem posing, which may or may not be pursued to fruition. When they were pursued and resulted in discovered complexity, mathematical ideas emerged that addressed topics such as constant versus nonconstant rates of change in novel sweeping situations, the effects of the center of rotation on the change in area for equal changes in angle measure, and determining the areas of segments of circles formed by two non-radii chords.

Given the small numbers of each task type, we cannot make definitive claims about which types of tasks will necessarily lead to discovered complexity. That said, it was compelling that the students did not demonstrate any wonderments when solving standard or problem-solving tasks. It may be that the motivation to develop creative tasks and solutions during the playified and open tasks, combined with an emphasis on agency and exploration, afforded students opportunities to embrace risk taking, openness, and experimentation, mirroring results from studies on mathematical play (e.g., Gresalfi et al., 2018; Mason, 2019; Williams-Pierce, 2019). We also found that it was often the students' need for causality (Harel, 2013) – the need to explain or determine the cause of a phenomenon – that resulted in a wonderment becoming a discovered complexity. These findings suggest that playful math could potentially be one avenue meriting further exploration for supporting productive problem posing.

Calculus I Students' Understanding of Implicit Differentiation

Orly Buchbinder
University of New Hampshire

Meaghan Allen
University of New Hampshire

Implicit differentiation is an important topic in first-semester Calculus, yet only recently have researchers in the RUME community turned their attention to it. Our study seeks to contribute to this growing body of knowledge. We examined students' performance on an instructional activity that emphasized the graphical representation of implicit curves alongside the symbolic competence of implicit differentiation. The students worked in small groups during recitations and then completed a similar type of question on an assessment. A researcher-designed Hypothetical Learning Trajectory was used to structure the instructional task and to analyze student written data. The results suggest that students' attainment of symbolic learning goals is higher than that of graphical ones, with most difficulties experienced with coordination between symbolic and graphic modalities. Implications for further research are discussed.

Keywords: Implicit differentiation, Calculus learning, Hypothetical learning trajectory

Implicit differentiation is one of the core topics of Calculus, yet only recently researchers have turned their attention to studying it (Speer and Kung, 2016). Implicit differentiation is a technique for finding derivatives of equations where y cannot be explicitly expressed as a function of x. Many popular textbooks on single-variable Calculus in the United States (e.g., Stewart, 2016), present implicit differentiation as a computation technique for finding derivatives, with a strong emphasis on symbolic manipulation. Little attention is paid to building the conceptual basis of implicit functions, justifying the legitimacy of differentiating both sides of the implicit equation (Mirin & Zazkis, 2019), or developing the graphical meaning of implicit functions. All these contribute to students' conceptual and technical difficulties with the topic.

Within the existing research on implicit differentiation, we identified two strands: survey studies that characterize students' difficulties with implicit differentiation (e.g., Chu, 2019; Kandeel, 2021), and small-scale intervention studies that closely examine the development of students' understanding of this topic (e.g., Borji & Martinez-Planell, 2019, 2020; Jeppson, 2019).

Our study occupies a middle ground. It was conducted in the first-semester single-variable Calculus I course, in an authentic classroom setting. After attending a lecture on implicit differentiation, students worked in groups, during a recitation on an instructional centered on graphical representation and the connections between symbolic and graphical meaning of implicit differentiation. In this context, we examined students' performance on the implicit differentiation task and the follow-up performance on a similar exam question. Due to space constraints, here we focus on the class work only.

Literature review

Calculus topics such as derivatives, the chain rule, and related rates have been previously researched (e.g., Cottrill, 1999; Infante, 2007; Martin, 2000, Zandieh, 2000). However, implicit differentiation came to the researchers' attention only recently. Several studies focused on students' difficulties with this topic. Chu (2019) surveyed 136 first-semester calculus students and found that only about 50% of solutions were correct; with most students' errors being related to calculus concepts and procedures, rather than prerequisite algebra skills. Kandeel (2021) classified common errors in an implicit differentiation survey completed by 117 Calculus students. Among common algebraic errors were isolating a common factor, simplifying expressions, dealing with exponents and radicals, and isolating y', of responses. Common calculus errors occurred in the application of the chain rule, product rule, and differentiating functions. These types of errors appeared in 25% - 50% of responses.

Researchers also attempted to unpack what it means to "understand" implicit differentiation. Mirin and Zazkis (2019) point to the conceptual difficulty of understanding the legitimacy of differentiating both sides of implicit equations. Borji and Martinez-Planell (2019) assert that first-year Calculus students have neither the background nor "mathematical tools to consider the statement, and even less the proof, of the Implicit Function Theorem, upon which a rigorous study of implicit differentiation would be based" (p. 15). The authors utilized the APOS (action-object-process-schema) theory (Arnon et al., 2014) to develop a genetic decomposition for implicit differentiation –a hypothetical sequence of mental constructs involved in learning this topic and five technology-assisted activities supporting the development of these mental constructs. The genetic decomposition and the activities emphasized a graphical understanding of implicit functions and symbolic-graphic connections. The intervention was carried out with 14 students who have completed a lecture-based Calculus I course. Ten out of 14 students showed an increased understanding of implicit differentiation, but others had no evidence of progress.

In another intervention study, Jeppson (2019) developed a hypothetical learning trajectory (HTL) for implicit differentiation. HLT is a sequence of learning goals, activities, and conjectured students' understanding of a particular content (Simon, 1995). Jeppson's HLT integrates the chain rule, implicit differentiation, and related rates under the overarching concept of nested multivariation - a covariation of multiple variables related to one another through function composition. Jeppson conducted single-subject teaching experiments with four Calculus students to study how they develop an understanding of implicit differentiation through meaningful context and careful sequencing of mathematical. Yet, Jeppson's HTL did not include graphical representations of implicit functions nor symbolic-graphic connections.

Theoretical Perspectives

Following Borji and Martinez-Planell (2019, 2020), we place a strong emphasis on symbolic-graphical connections in developing student understanding of implicit differentiation. However, the scale and methods of our study, detailed below, do not allow for examining mental constructs or cognitive processes underlying student understanding of implicit differentiation. Instead, we adopt Vygotsky's (1978) *sociocultural perspective* to examine what learners *say and do* while solving an implicit differentiation task in a collaborative group context, supported by more knowledgeable others – teaching and learning assistants (TAs and LAs). Within the sociocultural perspective, student activity is characterized by their discursive performances, which include vocabulary, visual mediators, actions, etc. (Lave & Wegner, 1990; Sfard, 2015)[1]. Student learning is cast in terms of increased, proficient participation in the discursive practices of a particular community and sifting from ritualistic to goal-oriented participation. In the Calculus course, students are enculturated into discursive practices of the mathematical community. We described these practices in a Hypothetical Learning Trajectory of implicit differentiation.

Hypothetical Learning Trajectory for Implicit Differentiation

An HLT is a theoretical model to design instruction supporting conceptual learning, which consists of learning goals, tasks, and hypothesized learning processes (Sion, 1995). Jeppson's

[1] See Sfard (2015) for the discussion of parallels between cognitive constructs and discursive perspective.

(2019) HTL was a main inspiration for our model. But our HTL (Table 1) had a strong focus on graphical representation and graphic-symbolic coordination (c.f., Borji & Martinez-Planell, 2019). The last column matches the HTL's goal to the item number in the activity (Figure 1).

Table 1. Hypothetical Learning Trajectory for Implicit Differentiation

Category	Description of Goal	Item #
Symbolic	**Develop symbolic meaning of implicit equations and correctly implement differentiation procedures**	
Symbolic Recognition (S_Rec)	Recognize an implicit equation cannot be written explicitly as $y = f(x)$.	1b
Symbolic implicit equation (S_Eq)	Given an equation with variables x and y, recognize y as an implicit function of x.	2
Symbolic Chain Rule (S_Ch)	Given implicit equations recognize the need for the chain rule in taking the derivative with respect to the implicit independent variable.	2
Symbolic differentiation (S_Diff)	Can correctly perform procedures for finding $\frac{dy}{dx}$ for an implicit equations.	2
Symbolic Evaluation (S_Eval)	Can correctly compute the derivative $\frac{dy}{dx}(x_0, y_0)$ at a point	3a, 3b
Symbolic Tangent Line (S_Tan)	Can correctly find the equation of a tangent line at a point.	3a
Graphic	**Interpret graphical properties of implicit functions**	
Graphic Recognition (G_Rec)	Recognize graphic representation of implicit equations as a curve in a cartesian place that does not pass the vertical line test.	1a
Graphic Tangent Slope (G_TS)	Interpret the meaning of $\frac{dy}{dx}(x_0, y_0)$ a slope of a tangent line at a point (x_0, y_0), and $\frac{dy}{dx}$ as slope of the tangent line or instantaneous rate of change at any point.	2a, 2b
Graphic Vertical Tangent (G_VT)	Recognize that tangent lines to a graph of implicit equations can be vertical, and at the points of tangency the derivative does not exist.	4
Graphic Constant Rate (G_CR)	Recognize in an explicit function, the lack of x in the derivative formula means the function has a constant rate of change, but a derivative formula of the implicit equation can contain no x, while the curve does not have a constant rate of change.	2b
Graphic Coordination (G_Cor)	Coordinates graphical and symbolic representations.	2b, 3a, 3b, 4

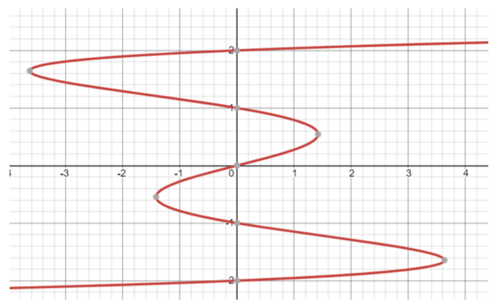
We are mindful that the construct of HTL belongs to the cognitive paradigm, hence our use of the term may not exactly align with the literature. We operationalize the HTL categories in Table 1 as *discursive competencies* that students can exhibit in their mathematical work. This allows us to characterize not just students' difficulties, but also their areas of strength. We examine the following research question: *What aspects of HTL can be observed in students' written responses to an implicit differentiation activity?*

Methods

This study is a part of the larger NSF-funded project for improving the teaching and learning of introductory STEM courses in a large public university in the northeast of the USA. Calculus I is taught in the format of large lectures (~120 students), taught by a faculty member three times a week; and recitations (~20 students), taught two times a week by graduate TAs. The reform efforts involved introducing active learning (CBMS, 2016) in recitations, the inclusion of LAs to support student work; and the use of conceptually rich activities that emphasize graphic representations of the calculus concepts. Figure 1 shows an activity on Implicit Differentiation.

Task 1: Consider the curve on the graph and the equation of the curve: $x = y^5 - 5y^3 + 4y$.

With your small group, answer the following questions using both the symbolic equation and the curve graph. Explain your reasoning.



1) Is it possible to express y as an explicit function of x?
   a) Explain your response using the graph.
   b) Explain using the symbolic equation for the curve: $x = y^5 - 5y^3 + 4y$.
2) Use implicit differentiation to find a formula for $\frac{dy}{dx}$.
   a) Explain the meaning of $\frac{dy}{dx}$. What does it represent?
   b) Sam noticed that his expression for $\frac{dy}{dx}$ does not contain x. Sam thinks that this means that the rate of change is constant for all points on the x-axes. Is Sam correct in his thinking or not? Explan.
3) a) Find the equation of the line tangent to the graph of $x = y^5 - 5y^3 + 4y$ at point (0,1). Add the tangent line to the sketch.
   b) Are there other points on the graph, where the slope of the tangent line is the same as you found in 3(a)? Respond using the graph, and then verify algebraically.
4) Determine all the points at which the graph of $x = y^5 - 5y^3 + 4y$ has a vertical tangent line. Explain how you know that. How many such points are there? Locate them on the graph.

Figure 1: Task 1 from the Implicit Differentiation Activity. Based on Boelkins et al., 2018 (p. 147).

Data Collection

Data collection occurred in Spring 2022. After a lecture on implicit differentiation, students worked on the Implicit Differentiation activity (ID-activity, hereafter) in the recitations. Students worked in groups of 3-4, but each person submitted their own worksheet, graded for completion. There was a standard textbook homework assignment, unrelated to graphical representation. The mid-term exam, about three weeks later, included an implicit differentiation close in style and content to the ID-activity. The data sources were 119 consenting students' written work on the ID-activity and the exam question. Here we only report on their ID-activity performance.

Data Analysis

The data were coded using the HLT (Table 1). Each response was coded as either exhibiting evidence of the student attaining a certain learning goal, not attaining it, or not enough evidence (Yes/No/NEE). For example, consider item 2a: "Explain the meaning of dy/dx. What does it represent?" A student's response "This represents the derivative, which is the slope of the tangent line. Rate of change" was coded as "Yes" for the evidence of attaining the goal *Graphic Tangent Slope* (G_TS). Only wrong or completely irrelevant answers were coded as "No" evidence of attaining an HLT goal. All other cases, including no response, were coded as NEE – not enough evidence. An example of NEE-coded response for question 2a is: "$\frac{dy}{dx} = y'$. Find derivative with respect to y." This response explains the notation rather than the meaning of dy/dx. Yet, it is not enough evidence to conclude the lack of attainment of the G_TS goal.

This method allowed us to identify the elements of HLT where students showed competence or lack thereof on a fine-grain scale. Figure 2 shows one student's work in response to question (2) "Use implicit differentiation to find the formula for dy/dx."

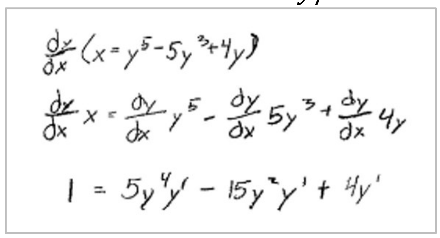


Figure 2: Coding Example

This work would score "Yes" for evidence of correctly using the chain rule to take the derivative with respect to the implicit independent variable (S_Ch) but would get NEE for symbolic differentiation (S_Diff), due to incomplete calculation of y'.

In our HLT (Table 1) the two codes S_Eval and G_TS were matched with two items, and the code G_Cor with four items. To get a single score per code we considered where most evidence is leaning, e.g., two or more "Yes" with all other NEE was coded as "Yes" (evidence of G_Cor attainment). One "Yes" with all other NEE was coded as NEE. Two or more "No" with all other NEE was coded as "No". Getting NEE in all four G_Cor items was coded as "No," since the student used none of the four opportunities to exhibit any evidence of coordinating graphic-symbolic representations. There were no "Yes/No" combinations in our data. The rest of the data was analyzed similarly, resulting in a total of 1190 codes (119 students x 10 codes/ HLT goals[2]).

Results

Table 2 shows the distribution of Yes/No/Nee codes in each of the HLT categories.

Table 2: Distribution of Yes/No/NEE codes by category, N=119

	Symbolic HLT goals					Graphical HLT goals				
	S_Rec	S_Ch	S_Diff	S_Eval	S_Tan	G_Rec	G_TS	G_VT	G_CR	G_Cor
Yes	67	100	109	107	95	109	92	35	102	20
No	0	0	0	1	0	0	2	0	1	66
NEE	52	19	10	11	24	10	25	84	16	33

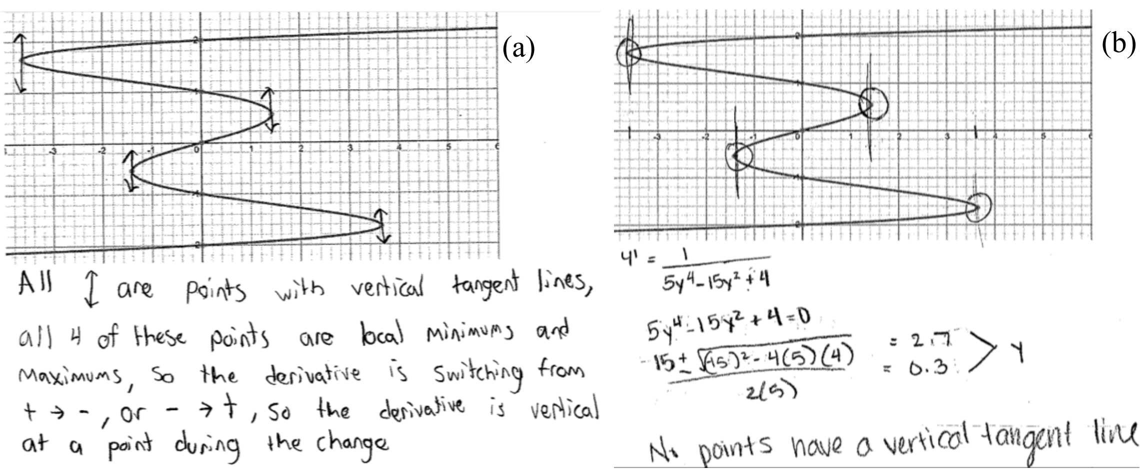
The modal categories with at least 90% show that students had the most success in calculating the derivative of the implicit function (S_Diff), evaluating the derivative at a given point (S_Eval), and recognizing that a graph of an implicit equation does not pass the vertical line test (G_Rec), hence cannot be considered as $y = f(x)$. We were encouraged by such a high percentage of "Yes" scores for the correct calculation of the implicit derivative (S_Diff), which requires correctly applying the chain rule (S_Ch) *and* correctly isolating y'. 100 students (84%) correctly applied the chain rule when taking the derivative with respect to an implicit variable.

The two goals posing the most difficulties to students were related to graphical representation: G_VT (vertical tangent) and G_Cor (coordination of symbolic and graphic modalities). The item related to G_VT was question 4 which called for finding all points where

[2] The codes S_Eq and S_Ch were merged since the worksheet explicitly asked for using implicit differentiation.

$x = y^5 - 5y^3 + 4y$ has vertical tangent line. Most students could correctly identify the four points on the graph, and state at these points y' is undefined. But only 35 students (29%) completed the calculation, and even fewer correctly interpreted the result.

We observed two types of difficulties in this item. One type is shown in Figure 3a. The student identified the points where the tangent line is vertical and marked them on the graph. But then proceeded to explain that "these points are local minima and maxima, so the derivative switches sign" from positive to negative and vice versa, hence the "derivative is vertical at a point during the change." The use of "vertical derivative" instead of "vertical tangent line" can be a mere carelessness, but it seems alarming that the student refers to these points as "local minimum and maximum." Moreover, although the derivative does change the sign at these points, it is unclear whether the student simply states known facts about local minima /maxima, or whether the student has some warrant for their claim, from the graph or from the derivative formula. This cannot be determined from a written text. Nevertheless, since this kind of response appeared repeatedly in our data, we assume that there is some underlying tendency at play, where students project their knowledge of critical points of explicit functions to implicit equations, but without recognizing how to adjust their prior knowledge to the new situation.



Figures 3 a & b: Sample student responses to item 4

Figure 3b shows another interesting response type. Here, the student marked the vertical tangent lines on the graph and correctly calculated the y-coordinate of the points where the derivative is undefined. But then the student made a seemingly contradicting conclusion, that there are "no points" with vertical tangent lines. Another student with a similar solution wrote that the answers "don't work." We conjecture the following explanation. The student solves the equation for y, obtaining the y-coordinates of the marked points on the graph. But then attempted to match these numerical values to the x-coordinates of these points. The x-coordinates being ± 3.63 and ± 1.91, they indeed do not match the calculations of 2.7 and 0.3, leading the student to a quite paradoxical conclusion that "no points have a vertical tangent line."

Students who correctly identified the points where the tangent line is vertical and calculated the y-coordinates by finding where the derivative is undefined scored a "Yes" for attaining the G_VT goal. However, correctly interpreting the meaning of the calculations corresponds to another HLT goal: coordinating graphic and symbolic representations of implicit equations (G_Cor). Four items contributed to a single G_Cor score: item 4, discussed above, and items 2b, 3a, 3b (Table 1). So, there were four opportunities for students to show some attainment of the

G_Cor goal, yet it appeared to be the most difficult one for the students. It was the only one with 66 students (55%) scoring "No" for that goal, and another 33 students (28%) scoring NEE.

The items that contributed most to these low scores were 3a and 3b, where students were asked to sketch the tangent lines, whose equations they found algebraically, on the graph. In item 3a, 95 students (80%) correctly found the equation of the tangent line at a point (0,1), but only 49 students (41%) could correctly draw this tangent line on the graph. The rest of the students either did not attempt this item (getting the NEE score) or drew an intersecting line instead of a tangent. In item 3b, 66 students (55%) justified algebraically that the tangent parallel to $y = -\frac{1}{6}x + 1$ will pass through (0,-1), but only 17 students (14%) drew the correct tangent line.

Overall, aggregating across all items and HLT goals, we obtained that the percentage of "Yes" scores was 80% for all symbolic HLT goals and only 60% for all graphic goals.

Discussion and Scientific Significance of the Study

The goal of the study was to examine students' performance on the implicit differentiation activity as they worked in small groups during a recitation in an otherwise traditional first-semester single-variable Calculus 1 course. Our study contributes to the existing literature in two ways. First, rather than using surveys or small-scale teaching experiments, our study was conducted in an authentic classroom setting and reflects what students can do collaboratively while being supported by GTA and LA. Second, our implicit differentiation instructional activity emphasized the graphical representation of implicit equations and coordination between the symbolic and graphic meanings of implicit differentiation.

Our results show that students performed much better on the symbolic HLT goals compared to graphical ones. Moreover, the percent of correct performance on utilizing the chain rule (S_Ch) and calculating y' (S_Diff) were much higher than what has been described in the literature 84% and 92% respectively, compared to about 50% in the studies by Chu (2019) and Kandeel (2021). The outcome may be attributed to the collective nature of student work, as opposed to individual survey data reported by Chu and Kandeel. In fact, the percentage of correct performance for S_Ch and S_Diff dropped to 66% and 62% respectively on individual exams, but the full discussion of these outcomes is beyond the scope of this paper.

The graphical interpretation of implicit curves, including graphing tangent lines and, specifically, coordinating between graphic and symbolic meanings of implicit functions presented the biggest challenges for the students. This outcome concurs with Borji and Martínez-Planell (2019). Students' challenges seem to be related to applying procedures and types of reasoning borrowed from their experience with explicit functions, e.g., attempting to interpret points with vertical tangent lines as "local minima and maxima", possibly due to the visual similarity, while ignoring the graph's orientation. Similarly, being used to finding the x-coordinates of critical points first, when obtaining y-coordinates from the calculation, students got confused and couldn't match them to the point on the graph. These challenges suggest that students require more exposure to and experiences with implicit curves to develop a better understanding of implicit functions. More research is needed to understand how students coordinate graphic-symbolic representations of implicit functions to support their learning.

Even though algebraic conceptual understanding is recognized as a critical skill, existing larger-scale validated algebra assessments consist mostly of computational tasks, or only assess a very narrow range of conceptions in a smaller focused domain. Further, few instruments have been validated for use with college students. In this paper, we describe the creation and validation of an algebra concept inventory for college students. We describe how items were administered, revised, and tested for validity and reliability. Results suggest that algebraic conceptual understanding is a measurable construct, and that the instrument has reasonable validity and reliability. Revision and validation is ongoing; however, lessons learned thus far provide information about what conceptual understanding in algebra might look like and how it might be assessed.

Keywords: Algebra, conceptual understanding, concept inventory, assessment, validity

In college, needing to take algebra can be a barrier to degree completion (e.g., Adelman, 2006; Bailey et al., 2010), and extensive mathematics education research has documented K-12 students' difficulties with school algebra (e.g., Booth, 1988, 2011; Kieran, 1992). Struggles with basic algebra concepts learned in school also impact even those in higher-level college courses such as Calculus (e.g., Frank & Thompson, 2021; Stewart & Reeder, 2017). One reason students struggle with algebra is that algebra courses in college tend to focus on procedures disconnected from meaning-making (e.g., Goldrick-Rab, 2007; Hodara, 2011). While procedural fluency is important, it is critical to connect it with conceptual understanding (Kilpatrick, et al., 2001). Thus, there is a critical need to better understand and assess students' conceptions of algebra concepts. However, to date there are no widely-validated assessments that measure college students' conceptual understanding of algebra. Existing large-scale validated algebra assessments for K-12 tend towards computational skills, or focus on a narrow set of conceptions in a small subdomain. Tests of computational skills are often poor measures of understanding. Students may have robust conceptual understanding, but make smaller computational mistakes, especially if they have math or test anxiety (e.g., Ashcraft, 2002; Ashcraft & Kirk, 2001; Moran, 2016; Namkung et al., 2019). On the other hand, students may have little-or-no conceptual understanding, yet produce "correct" answers for "wrong" reasons (e.g., Aly, 2022; Erlwanger, 1973; Leatham & Winiecke, 2014).

We aim to address this gap by describing a first attempt to conceptualize, develop, and test college students' conceptual understanding in algebra using the *Algebra Concept Inventory* (*ACI*). This process continues, but we have chosen to write about results at this juncture with the hope they may be helpful for others interested in conceptualizing, measuring, and teaching conceptual understanding in algebra.

Literature Review

Several instruments have been created to test algebraic proficiency; however, none were designed to test a large body of algebraic concepts and conceptions. TIMMS and NAEP (Mullis, et al., 2020; National Center for Education Statistics, 2023) are widely validated at the international and national level, and contain some questions intended to assess conceptual understanding. There are also state-wide assessments that contain some questions intended to test conceptual understanding (e.g., Massachusetts Department of Elementary & Secondary Education, 2023; New York State Education Department, 2023). However, the main focus of all these instruments is computational skills.

There is one validated assessment that targets algebraic conceptual understanding in grades 1 to 5 (Ralston, et al., 2018), and one designed to assess a few specific algebraic concepts in middle school (Russell, 2019; Russell et al., 2009). Yet these instruments measure just a few conceptions, and were not designed for secondary or postsecondary students. As such, these often focus primarily on less complex or less abstract algebraic conceptions.

Some concept inventories have been developed that assess some student conceptions of algebraic concepts, but for students in more advanced courses only. For example, the Pre-calculus Concept Assessment (PCA) (Carlson, Oehrtman, & Engelke, 2010) and the Calculus Concept Readiness Instrument (CCRA) (Carlson, Madison, & West, 2010) explore some algebra concepts relevant to students in higher-level courses; while these have been tested through extensive cognitive interviews, larger-scale psychometric validation is still needed. Recently, researchers Hyland and O'Shea (2022) in Ireland generated a 31-item algebra concept inventory for college students, but it includes algebraic objects that would not be familiar to students in a first-year algebra course and has not yet been tested through cognitive interviews or psychometric analysis. Thus, an inventory that is valid for students starting in elementary algebra is needed, as well as more extensive large-scale psychometric testing of concept inventories more generally.

Method

A total of 402 unique items were developed and tested for the ACI. Items were administered to 18,234 students enrolled in all mathematics classes (except arithmetic) at a large urban community college campus. Data reported here were collected from spring 2019 to fall 2022, in eight separate waves. Data collection followed a common-item random groups equating design, which was selected because it allowed to investigate a large item pool while allowing a simultaneous calibration across multiple forms (de Ayala, 2009; Kolen & Brennan, 2004). For the first wave of testing, the last ten items on each form were anchor items, all taken from the National Assessment of Educational Progress (NAEP) grade 8 item bank. For subsequent waves, six anchor items were included: three of these were NAEP items and three were items that had performed well during the first wave of ACI testing. Each form had roughly 25 total items. Forms were randomly administered within in each class so there was no association between test form and class or instructor.

Just before answering inventory items, students were invited to participate in cognitive interviews, and paid for their time. In total, 135 interviews were conducted with students. Each was roughly 1-1.5 hours long and was structured as a "retrospective think-aloud" (Sudman et al., 1996). Research suggests that retrospective think-aloud protocols reveal comparable information to concurrent think-aloud protocols, and are less likely to have negative effects on task performance, particularly high-cognitive-load tasks (see e.g., van den Haak et al., 2003). Interviews were analyzed qualitatively to assess construct validity of the items, but there is insufficient space to report on that analysis here. Here we report only quantitative results.

We investigated each wave of the ACI through item-response theory analysis. First, items were dichotomized into pass-fail items using the response key. Then, two-parameter logistic models (Birnbaum, 1968) were estimated using marginal maximum likelihood (MML) on each wave, using the R package "mirt" (Chalmers, 2012). Because of planned missingness data collection design, the default number of model iterations was extended to allow for all models to converge successfully. Based on these models, we examined item parameters (difficulty and discrimination) and item information functions for item analysis, and computed person estimates using expected a posteriori (EAP) factor scores for convergent validity analysis. Reliability estimates were computed directly from IRT models. To investigate model fit, we computed item fit statistics, using the PV-Q1 statistic (and significance test) (Chalmers & Ng, 2017) for each item.

To investigate measurement invariance, we used multi-group IRT models and a model comparison approach. Because of the planned missingness design (and sometimes small observed subsample sizes), we used a piecewise DIF detection strategy (Thissen et al., 1993) that starts from a fully constrained model and drops constraints for each item separately. More specifically, with respect to each examinee characteristic considered, we first estimated a fully constrained model (where, across groups, item discriminations, difficulties, latent mean and variance are constrained to equality). Then, for each item, the same model was estimated, but with unconstrained item parameters (difficulty and discrimination), thus "temporarily" allowing differential item functioning (DIF) for the item. A likelihood ratio test was then performed to test if the model allowing DIF for the item had a better fit than the constrained model. This resulted in a series of tests of the significance of differential item functioning for all items. Because it is a multiple testing strategy, p-values were subsequently Bonferroni-corrected.

Validating the ACI

IRT Models: Item Discrimination and Difficulty

Results reported here were based on an item pool in which some items were dropped because they were deemed problematic (e.g., typographical errors; multiple correct answers); however, no items were dropped from analysis simply because of unsatisfactory IRT parameters. 2PL IRT models were run on all waves of data collection (Table 1). IRT models were run on all waves of data collection. While Rasch (or 1PL) models and 3PL models were also considered, 2PL models were chosen because unlike 1PL models, they allow discrimination to vary by item, and because they were considered more parsimonious, more useable for item selection (because item coefficients are more interpretable), and less prone to calibration errors than 3PL models due to their lower number of item parameters (San Martin et al., 2015).

Table 1. 2PL Model Coefficients Across all Eight Waves

Discrimination parameter	Proportion of Unique Items
>=0.65 "moderate"[a]	63.4%

>=1.35 "high"	31.3%
>=1.7 "very high"	18.5%
Difficulty parameter	Theta
mean	0.00
1st quartile	-0.85
median	-0.14
3rd quartile	0.63
Total number of unique items in 2PL models	399

[a] Characterizations of categories of discrimination parameters are taken from Baker (2001).

Discrimination is classified as "moderate" if it is ≥ 0.65, "high" if it is ≥ 1.35 and "very high" if it is ≥ 1.7 (Baker, 2001). Based on this, 63.4% of all items (253) have at least moderate, and roughly one-third have high or very high discrimination.

We also assessed item fit in the 2PL model for each wave using Chalmers' $PV - Q_1$ test, because it performs better than other fit statistics at controlling Type I error (Chalmers & Ng, 2017) (Table 2).

Table 2. Measures of Item Misfit in 2PL IRT Models

	Number of Items With Significant[a] Misfit[b]	Total Number of Items	Percentage of Items With Significant Misfit
Wave 1	1	33	3.0%
Wave 2	5	125	4.0%
Wave 3	4	66	6.1%
Wave 4	3	72	4.2%
Wave 5	8	100	8.0%
Wave 6	5	99	5.1%
Wave 7	2	39	5.1%
Wave 8	0	31	0.0%
Total	28	565	5.0%

[a] Significant at the $\alpha = 0.05$ level
[b] Misfit as measured by Chalmers' Chi-Square Statistic ($PV - Q_1$)

Only 5% of items were significantly misfitted by the 2PL models (for $\alpha = 0.05$), suggesting this is likely due to random variation.

Reliability

In IRT, the reliability of an item varies based on Theta, which represents the number of standard deviations above or below the mean an individual is on the measure of the latent trait. Table 3 shows various measure of reliability.

In Table 3 peak instrument values have excellent reliability ($R \geq 0.9$). There are also waves where excellent reliability ($R \geq 0.9$) can be obtained for values ranging from $\theta = [-2,7,2.2]$ (assuming a standard normal distribution of knowledge, this corresponds to satisfactory reliability for ~98% of examinees). Further, shorter tests can be constructed with only those items with the highest discrimination: for example, the 10 items with the best discrimination from Wave 1 yields a test with excellent reliability ($R \geq 0.9$) for $\theta = [-2,1]$.

Table 3. Reliability (R) for each wave of item administration of the ACI

	Theta at max info[a]	Info max[b]	R for info max[c]	theta w $R \geq$ 0.8	theta w $R \geq$ 0.9	Number of Items Tested
Wave 1	-1.4	26.4	0.96	[-2.8, 0.4]	[-2.4, -0.2]	33
Wave 2	-1.5	37.8	0.97	[-3.0, 2.1]	[-2.7, 0.9]	104
Wave 3	-0.6	24.3	0.96	[-2.3, 1.5]	[-1.8, 0.7]	57
Wave 4	-0.6	30.1	0.97	[-2.4, 2.1]	[-1.9, 1.2]	69
Wave 5	0.7	177.1	0.99	[-2.3, 2.9]	[-1.4, 1.8]	100
Wave 6	-0.6	105.3	0.99	[-1.7, 3.0]	[-1.0, 2.2]	99
Wave 7	-0.1	21.7	0.95	[-1.5, 1.8]	[-1.0, 1.1]	39
Wave 8	0.1	11.3	0.91	[-0.9, 1.2]	[-1.2, 0.3]	31

[a] info = 2PL IRT model information function
[bd] max = information function maximum for 2PL model
[e] $R = 1 - \frac{1}{Info}$
[c] expected reliability in Normal(0,1) ability distribution for 2PL models

Relationship Between ACI Score and Prior Algebra Course Completion: Convergent Validity

To explore convergent validity of the ACI, we explored the relationship between scores on the ACI (using theta scores from the 2PL model) to various measures of mathematics course level. For example, correlation of students' ACI scores with the level of algebra courses they have already successfully completed would be evidence of convergent validity. First, we consider linear regression models with level of student's course (where "level" is defined based on the algebra course pre-requisite requirements of the course) as the independent variable, and ACI score as the dependent variable (Table 4).

Table 4. Regression of course level (by algebra pre-requisite) in predicting theta scores from the 2PL model on the ACI, reference group: low

Course Level	Coefficient	SE	*p*-value (vs. low)	*p*-value (vs. high)
mid	0.347	0.014	0.000	0.000
high	0.700	0.017	0.000	

low = no algebra course prerequisite
mid = elementary algebra course prerequisite
high = intermediate algebra course prerequisite

In Table 4, differences in Theta score are significant ($p < 0.001$) for all pairwise comparisons. Students in "mid"-level courses scored on average 0.35 SD higher than those in "low"-level courses; and students in "high"-level courses scored on average 0.35 SD higher than those in "mid"-level courses (or 0.70 SD higher than in "low"-level courses). This provides strong evidence of convergent validity.

We also considered a more nuanced course sequence based on prerequisites (see Table 5).

Table 5. Sequence level of various courses in the sample, based on their prerequisites

Various elementary algebra courses	1
Various 100-level courses with an elementary algebra pre-requisite	2
Intermediate algebra courses	2
College algebra	2
Discrete math with intermediate algebra prerequisite	3
Precalculus	3
Math for elementary teachers with intermediate algebra prerequisite	3
Math for elementary teachers, second term	4
Advanced statistics with precalculus prerequisite	4
Introduction to geometry with precalculus prerequisite	4
Calculus I	4
Calculus II	5
Calculus III	6
Differential equations with Calculus II prerequisite	6
Linear algebra with Calculus II prerequisite	6
Abstract algebra	7

Rerunning linear regression models using this more refined set of levels again reveals a strong correlation between level and ACI score (Table 6).

Table 6. Regression of course position in longer mathematics curricular sequences (by classification given in Table 5) in predicting theta scores from the 2PL model on the ACI, reference group: sequence level 1

Course Position in Sequence	coeff	SE	*p*-value (vs. 1)	*p*-value (vs. 2)	*p*-value (vs. 3)	*p*-value (vs. 4)	*p*-value (vs. 5)	*p*-value (vs. 6)
2	0.504	0.017	0.000					
3	0.623	0.031	0.000	0.000				
4	0.888	0.023	0.000	0.000	0.000			
5	1.059	0.033	0.000	0.000	0.000	0.000		
6	1.232	0.041	0.000	0.000	0.000	0.000	0.000	
7	1.661	0.226	0.000	0.000	0.000	0.001	0.008	0.060

One of the largest gains (one half SD) was between sequence level 1 and 2 (see Table 6), which distinguishes between students who have or have not satisfied an elementary algebra prerequisite, providing further evidence of convergent validity, as the ACI is designed to focus on concepts relevant to elementary algebra specifically.

Differential Item Functioning: Measurement Invariance and Discriminant Validity

We also assessed potential differential item functioning (DIF) related to irrelevant examinee characteristics: race/ethnicity, gender, and English-language-learner status. This is an aspect of discriminant validity, as the ACI should measure algebraic conceptual understanding and not something else, like English literacy. Each wave was tested for DIF in three separate 2PL models: one for each characteristic. There was no consistent evidence of DIF on any of these factors. Only a negligible number of items had significant DIF for $\alpha = 0.05$ (using a Bonferroni correction for the number of tests within each model). Many items were tested in multiple waves, and none of these had significant DIF in more than one wave, suggesting that significant DIF in one wave for these items was likely due to random variation.

Limitations

The City University of New York, where this instrument was tested, is very diverse but not nationally-representative; however, this makes it useful for validation with marginalized students who have often been neglected in large-scale assessment validation. A current study is underway to validate the ACI on a larger national sample. The ACI has also only been validated with college students—further studies are necessary with younger students. The ACI has also been developed to make *diagnostic* judgements about *groups* of students—not high-stakes decisions for individuals—and thus we caution against that particular use of the ACI.

Discussion and Conclusion

Results from analysis suggest that algebraic conceptual understanding, as conceptualized by the items included on the ACI, is a measurable domain. IRT analysis indicated that a large proportion of items had good discrimination parameter estimates, suggesting that the final version of the ACI is likely to have an excellent ability to differentiate between students of various levels. Additionally, reliability was excellent for all waves, and results indicated that a shorter test could be constructed that would have excellent reliability for a large range of knowledge levels. The ACI also showed evidence of convergent validity, as students with higher algebra course prerequisites showed higher item success rates. Finally, only a negligible proportion of items showed differential item functioning with respect to race/ethnicity, gender, or English-language-learner status, indicating that the ACI had satisfactory measurement invariance with respect to these characteristics.

However, the ACI is only a first attempt at measuring algebraic conceptual understanding, and much more work needs to be done to map out in detail the various conceptions that students in different contexts hold of core algebra concepts, and determine how these can best be measured. The ACI provides only a single scale number; however, further work with cognitive diagnostic models on ACI items might provide more nuanced diagnostic information that could be particularly critical for instruction, by better modeling the complex layers of conceptions that students might have about various concepts in algebra. In reality, the kinds of knowledge that the ACI is trying to measure are quite complex, and capturing only a single score is, on its own, woefully inadequate if we hope to understand how students think algebraically and how various instruction and curriculum relate to this complex conceptual development. We see the ACI as just a first step in building out much more complex models of students' algebraic conceptions.

My Mom Supports My Teaching: One Mathematician's Journey in Learning to Teach

Kelsey Quaisley
Oregon State University

In this contributed report, I tell a story surrounding one mathematician's learning to teach mathematics content courses designed for prospective elementary teachers. Namely, I describe the mathematician's background and the series of events that pushed this newer mathematics instructor to develop productive dispositions towards their students, leverage support from their mom, a former elementary teacher, and navigate challenging student questions in the classroom. This report draws on results from my dissertation study, a narrative inquiry of one mathematics instructor, involving a semester-long collection and analysis of classroom observations, observations of instructor meetings, weekly instructor reflection journal entries, three instructor interviews, and instructor-written mathematics teaching and learning autobiographies. A key implication is that mathematics instructors may benefit from early experiences developing productive mindsets towards teachers and teaching, and need access to individuals who value teachers and teaching and who avoid deficit discourses around teachers or students.

Keywords: narrative inquiry, post-secondary mathematics instructors, mathematics content courses, prospective elementary teachers, support for teaching

Introduction

Bruce was a prospective elementary teacher (elementary PT) in a mathematics content course designed for elementary PTs in a large midwestern university. During the second class of the semester, Bruce asked their instructor, Rowan, "in what grade would number lines be attainable?" Rowan responded:

> I'm not sure. I think counting numbers are Kindergarten and 1st grade. I think it would be attainable for 2nd or 3rd graders, but it would depend on the curriculum in the district. I'm not really the best person to ask because I know more about math--being from the math department--but if I was from the teaching department I might know more.

Bruce's question posed a challenge to Rowan, in part, because Rowan was teaching elementary PTs for the first time but also because Rowan did not have K-12 teaching experience. So how did Rowan learn to navigate challenging questions from their students, especially those that went beyond mathematics content and into intersections of mathematics content and knowledge/experience of K-6 students' mathematical thinking and/or K-6 schools?

As Bruce's question shows, learning to teach mathematics content courses designed for prospective elementary teachers (PTs) can be challenging. Mathematics content instructors must be prepared to not only teach mathematics content, but engage PTs in understanding children's mathematical thinking strategies, learning trajectories, and misconceptions (Carpenter et al., 1996; Carpenter & Moser, 1982; I et al., 2020). When considering how instructors might best be prepared and supported, however, one must recognize that there is significant variation in the backgrounds and expertise of mathematics content instructors (Masingila et al., 2012; Yow et al., 2016) and little is known about the preparation, knowledge, and experiences of mathematics content instructors (Even, 2008; Goos, 2009; Masingila et al., 2012; Oesterle, 2011; Zaslavsky & Leikin, 2004). Furthermore, most instructors who are newer to teaching PTs do not feel prepared and additionally report an absence of training, resources, and support at their institutions (Goodwin et al., 2014; Masingila et al., 2012; Quaisley, 2023; Yow et al., 2016). Mathematics content instructors, especially those newer to teaching PTs, need preparation and support that account for their background and teaching context.

In this contributed report, I draw on the findings of my dissertation study, a narrative inquiry connecting the background, preparation, and support of one instructor (Rowan) to their learning to teach mathematics content for PTs (Quaisley, 2023). Specifically, I detail the series of events that pushed Rowan to develop productive dispositions towards their students, leverage support from their mom, a former elementary teacher, and navigate challenging student questions, like Bruce's, in the classroom.

Literature Review

Not much research has been done with specific attention to newer mathematics content instructors' preparation and learning to teach PTs (Quaisley, 2023). What studies do exist typically focus on a few small slices of the knowledge or skills that may be important for instructors to develop (e.g., Masingila et al., 2018; Zopf, 2010) or discuss support structures that may benefit instructors (e.g., Castro Superfine & Li, 2014; Jackson et al., 2020; Shaughnessy et al., 2016; Suppa et al., 2020) but are not necessarily *about* the instructor and how they navigate this work outside of researcher intervention. Oesterle's (2011) summary of literature on post-secondary mathematics instructors holds relevance today:

> although the research is intended *for* instructors (or for course/program designers), there is very little research *about* the instructors… in this context there is a lack of documented research about what happens in ordinary mathematics content courses for preservice teachers, ones that are not undergoing studies for particular interventions. (Oesterle, p. 39, emphasis original)

What literature *about* instructors of PTs of mathematics do exist typically involve one experienced instructor reflecting on their experiences (e.g., Chauvot, 2009; Nicol, 1997; Tzur, 2001), or involve less than a handful of newer instructors (e.g., Oesterle, 2011; Van Zoest, 2006). Additionally, of the studies about newer instructors, most focus on mathematics *methods* instructors with experience teaching high school mathematics (e.g., Chauvot; Nicol, 1997; Tzur, 2001; Van Zoest, 2006). Hence, more perspectives need to be examined to thoroughly understand the complexities of learning to teach elementary PTs, specifically perspectives from mathematics content instructors who are not only newer to teaching elementary PTs, but newer to teaching more generally.

Studies about newer instructors of PTs of mathematics are important because of the opportunities they provide for insight into instructors' dilemmas, tensions, and challenges and to hypothesize about the connections among an instructor's background, teaching context and experiences. For instance, Nicol (1997) and Van Zoest (2006) both involved mathematics methods instructors with prior experience teaching high school mathematics and both studies revealed common tensions around teaching PTs to think critically about teaching. More studies that center instructor experience may reveal further commonalities among instructors with particular backgrounds and in particular teaching contexts. Such studies may also highlight key differences among instructors with similar backgrounds and teaching contexts, as well as previously undocumented challenges for those instructors.

Purpose Statement and Research Question

My research puzzle (Clandinin, 2013) was this: how might the backgrounds and teaching contexts of newer mathematics content instructors shape their experiences around learning to teach PTs? Chauvot's (2009) study calls for this kind of exploration: "different kinds of knowledge is needed to serve different roles" (Chauvot, p. 369). Connections between instructors' contexts and their learning to teach PTs do not appear to be well understood in the research literature yet are critical to making progress in understanding newer instructors' learning and growth, the challenges and successes they experience, the expertise they need to develop, and the support structures that might benefit them. Hence, the purpose of my study was to obtain a more nuanced understanding of a newer mathematics content instructor's experiences around learning to teach elementary PTs in their respective teaching context.

The central question that guided my study was: "How might a newer mathematics content instructor's background and preparation relate to the challenges and successes they experience around teaching and learning to teach mathematics content for elementary PTs?"

Theoretical Framing: Narrative Inquiry and 3-D Framework

To address my research question, I engaged in a narrative inquiry (Clandinin & Connelly, 2000) of one beginning instructor's experiences learning to teach mathematics for elementary PTs. Narrative inquiry centers on experience, both as the phenomenon being studied and the method used to understand experience (Creswell & Poth, 2018). I drew on Clandinin and Connelly's (2000) three-dimensional (interactional, temporal, and contextual) inquiry space to understand experience. First, the *interactional* dimension refers to both personal interactions, such as "an individual's feelings, hopes, reactions, and dispositions" (Creswell & Guetterman, 2019, p. 522), as well as social interactions and perspectives of other people. Second, the *temporal* dimension refers to time—past, present, and future—and means that one does not just consider the on-going experiences of the present, but also considers past events, anticipated future events, and how those might be relevant to someone's understanding of current events. Third, the *contextual* dimension refers to "the context, time, and place within a physical setting, with boundaries and characters' intentions, purposes, and different points of view" (Creswell & Guetterman, 2019, p. 522). When considered altogether, these three dimensions allow for a continuous and storied understanding of experience—not as an isolated event, but as a thread connected to the larger storyline of who someone was, is, and wants to become.

Context of the Study

The setting for my inquiry was Cardinal University (a pseudonym), a large mid-western university. Operations & Number Systems (O&NS; a pseudonym), the mathematics content course of interest for this study, is taken during the STEM semester, an integrated effort to connect the contents and pedagogies of mathematics, science, and technology. O&NS aims to develop elementary PTs' understanding of some of the earliest grades' mathematics content, such as the base-10 number system, the operations of addition, subtraction, multiplication, and division, fractions, and the properties of arithmetic. Because O&NS is taken alongside Elementary Mathematics Methods (EMM), as well as a practicum that meets at elementary schools for a full day twice a week, the hope is that elementary PTs will be able to see the value in what they are learning and apply it to teaching elementary mathematics.

I recruited one instructor, Rowan (she/they), at Cardinal University who was teaching O&NS and who identified as both a newer instructor of PTs and a newer instructor more generally. I am especially grateful to Rowan for giving me the precious gift of their time, energy, and thoughts, so that I could share their experiences. Other participants in my study included Rowan's students (18 total), as well as the other O&NS instructors (2 total) and EMM instructors (3 total).

Data Collection and Analysis

In spring 2022, I observed all of Rowan's classes and meetings with other instructors, conducted three interviews with Rowan (on their preparation, support, and overall learning), and collected Rowan's teaching and learning autobiographies, Rowan's weekly reflection journal responses, and Rowan's teaching and DEI statement. During each of my observations of Rowan's O&NS classes and instructor meetings, I composed detailed fieldnotes on what I saw and heard, as well as my interpretations. Following nearly every observation of a class or instructor meeting, I wrote descriptive and reflexive memos to assist me in interpreting situations and writing rich descriptions of themes (Emerson et al., 2011; Spradley, 2016) with specific attention to each dimension of Clandinin and Connelly's 3-D framework.

My goal for data analysis was to utilize the various data sources I collected to support me in restorying—a process of analyzing and reorganizing—Rowan's experiences. I analyzed my fieldnotes, along with the early (on preparation), mid-semester (on support), and end of semester interview (on overall learning) transcripts, Rowan's reflection journal entries, Rowan's mathematics learning and mathematics teaching autobiographies, and Rowan's teaching and DEI statement using cycles of open-coding (Saldaña, 2016) based on broad categories related to my research questions: (a) challenges, (b) successes, and (c) prior experiences, preparation, and support. As I re-read each and every piece of data and coded ideas, excerpts, or interactions within the above categories, I organized ideas and interactions from classroom fieldnotes and memos, instructor meeting fieldnotes and memos, and reflection journal responses into tables based on these categories chronologically and contextually. I also wrote analytic memos as I collected data, which provided a crucial support to me in hypothesizing about themes or narrative threads.

Results: Rowan's Learning to Navigate Challenging Student Questions

In Quaisley (2023), I described numerous concurrent challenges Rowan experienced in learning to teach mathematics content courses for elementary PTs, such as time constraints as a graduating Ph.D. candidate, the burden of unfinished grading assignments, and an overall sense of feeling "uneasy" and "unsteady," often with respect to learning "different" and "hard" content. At the same time, Rowan experienced successes around developing positive beliefs about PTs and teaching O&NS, navigating challenging student questions, learning to seek external support for teaching (and in general), having students pass exams, and surviving the semester without any "catastrophic failures." For this report, I detail the interconnected nature of Rowan's successes in developing productive dispositions towards their students, leveraging external support for teaching, and navigating challenging student questions in the classroom.

Rowan's Background & Prior Experiences

At the time of the study, Rowan (she/they) was a mathematics graduate student instructor in their fifth and final year in a mathematics Ph.D. program at Cardinal University (a pseudonym). Throughout those five years, Rowan taught calculus recitations and lecture and Intermediate Algebra, as well as assisted teaching a mathematics content course for practicing teachers during a two-week summer session (Math for Teachers). In some semesters, Rowan also taught these courses from the position of associate course convenor—a role involving additional responsibilities such as creating common exams and observing instructors' classes. In the semester in which this study occurred, Rowan was teaching O&NS for the first time.

An influential person in Rowan's story is their mom, a former elementary teacher, who made a significant impact on both Rowan's desire to teach and their perceptions of teaching.

> My mom impacts just my teaching generally, not even in relation to this course, because my mom was a grade-school teacher and then was an administrator of preschool. And she, she loved it. My mother loved teaching. And I think that that really has impacted the entire trajectory of my life... So, definitely my mom has had a big influence on like wanting to teach, and I think a lot of that comes from her passion for it, and also all the discussions we had as I was growing up about like what teaching is. (Rowan, Final Interview)

These early experiences with their mom further supported Rowan in developing an asset-oriented mindset towards practicing teachers in the Math for Teachers course.

> The students were a treat though. Since they teach, they have an empathetic understanding of the complexities of teaching. Several of the students also reminded me of my mom—my mother was a grade-school teacher, and they had similar spirits and mentalities around teaching and learning… we ended up having a lot of really productive conversations where I would give them advice on mathematics, and they would give me advice on teaching. (Rowan, Autobiography)

Specifically, Rowan positioned practicing teachers as knowledgeable experts, who not only know how to teach elementary students but have valuable knowledge relevant to an instructor of undergraduate mathematics courses.

Developing Positive Dispositions

Rowan began the semester excited to teach and voiced optimistic opinions about their O&NS students in their early reflection journals. For instance, Rowan wrote in their week one journal: "I think the students will be fun and easy to work with. Since they want to be teachers, they'll have an appreciation and understanding for both the teaching methods I use and the teaching methods for mathematics they're learning" (Week 1 Reflection Journal). By the end of the semester, some of Rowan's early semester beliefs about prospective teachers still resonated with Rowan. Rowan explained how their thinking was influenced by their mom and their previous experiences teaching Math for Teachers:

> [Rowan] says that it's really easy for them to think about what it's like to be a PT just because their mom was a grade-school teacher, and she shared with [Rowan] what it was like learning to teach. [Rowan] says, although that was 35 years ago, and things are different now. [Rowan] says that they also taught teachers when they were assisting with [Math for Teachers] and that was the greatest experience they ever had. [Rowan] says that the teachers were really great. (Researcher Fieldnotes, Week 15 Classroom Debrief)

Navigating Challenging Student Questions

From the beginning of the semester, one of the classroom events that Rowan came to rely on as "business-as-usual" was their students regularly asking Rowan questions not just about mathematics content, but questions at the intersection of mathematics content and knowledge of K-6 students' mathematical thinking and/or K-6 schools. Early on, Rowan found these questions especially challenging. Recall from the introduction that right from the second class at the beginning of week two, Bruce asked Rowan, "in what grade number lines would be attainable?" Bruce's question challenged Rowan to reflect on their ability to support their O&NS students' inquiries about K-6 students' mathematical thinking early on:

> I wish I had a better sense of the timeline on which elementary students would learn this material. A [O&NS] student asked when a [K-6] student would learn about or be able to conceptualize the idea of decimals in base-ten notation and I wasn't able to provide

anything useful, but I think it would help the [O&NS] students to be able to consider the age of their [K-6] students while they learn the material. (Week 2 Reflection Journal)

During the preparation interview (also in the second week), Rowan additionally reflected on the extent to which they "have the authority" to anticipate K-6 student thinking and worried about missing important ideas behind student thinking. Perhaps addressing questions involving knowledge of or experience with K-6 students' mathematical thinking might not have presented itself as a challenge for Rowan if they were asked these questions infrequently. However, Rowan was asked such questions in front of the whole class almost every week starting from the second week of the semester through at least week ten of the semester.

Why Not Seek Internal Support?

So how would Rowan navigate challenging questions from their O&NS students? One way in which Rowan might have chosen to navigate these questions is by seeking support internal to their institution. Rowan valued the knowledge and expertise of those with K-12 teaching experience, and as a result, they wrote about wishing to connect with practicing elementary teachers as a desired support in their reflection journals and considered reaching out to EMM instructors (all three of whom had K-12 teaching experience) as a support they did have access to. An unfortunate experience at the third and final joint O&NS-EMM instructor meeting influenced Rowan to not exercise this possibility, however. One of the EMM instructors who was looked upon to lead the meetings joined the Zoom call for the meeting and then promptly left after a few minutes. Rowan recounted feeling that O&NS instructors were "not worth their (EMM instructors') time" during the mid-semester interview about their support, and lost faith in the STEM semester as a collaborative experience between O&NS and EMM instructors.

Seeking External Support from Mom

As Rowan did not have access to practicing K-6 teachers or believe that EMM instructors could be relied upon for support, a crucial way in which Rowan navigated challenging questions from their O&NS students throughout the semester was by regularly relying on support from their mom. Following each class, Rowan would debrief with me, then call their mom and debrief with their mom on their drive home. Conversations with their mom supported Rowan in reflecting on their own K-6 mathematics learning experiences, as well as some of their mom's experiences teaching K-6 mathematics. These conversations also built Rowan's confidence:

> But definitely was impactful was thinking about, thinking about and being able to talk through what I had done (as a K-6 student) in comparison to what I am teaching. And it also helped because then I could more confidently tell my (O&NS) students, 'Oh, like, when I learned it, and possibly when you learned it, because you're only, like, a little bit younger than I am. Like, this is. I remember this being a thing'. My mom said that this was a thing. And I think that connection is useful to me. I wish I had more of it, but it would be so hard to track down because, like, I don't fully remember my experience, right? I did have to talk it through with my mom, and my mom was very involved in my schooling, which is why she remembers. (Rowan, Final Interview)

A Conversation with Kenny

An important way in which Rowan's positive dispositions towards students and their conversations with their mom may have supported their navigation of challenging questions was that Rowan demonstrated empathy for multiple perspectives, rather than asserting a superior perspective. Consider the following conversation[1] between Rowan and one of their O&NS students, Kenny, during week ten of the semester, in which Rowan offered a possible rationale for the actions of Kenny's cooperating teacher and directed the conversation away from judging those actions as right or wrong. Instead, Rowan discussed the cooperating teacher's actions as a possible approach to supporting students' learning:

Kenny: What is the most common way we do this today? My understanding is that [City] public school is moving towards partial products method. I've noticed that some students skip carrying a step, and that you say thirteen tens rather than a hundred and thirty. Does that make sense?

Rowan: That makes sense. I know from the outset that the 2 is in the tens place and allowing that mindfulness of place from the outset... [Rowan works an example with Kenny's input.]

Kenny: I understand it, but I want to know what's right for the process for kids to understand... [Rowan does another example with 38 x 6 and writes 228.] I think I understand why my cooperating teacher emphasizes it, but I also don't quite understand...

Rowan: Yeah, I think the partial products just emphasizes more of the steps. Have you ever seen kids who want to add up all the numbers from left to right and end up with too many digits? The partial products method is trying to prevent that. [Kenny nods their head up and down as Rowan explains.]

Kenny: Yeah, I think that makes sense. Sorry for taking up the time. [Rowan reassures Kenny that its fine and then asks if there are more questions.]

Discussion and Implications

Even though Rowan did not feel they initially had the preparation or the authority to address questions around K-6 students' experiences and mathematical thinking, their offering of mathematical perspectives through an empathetic lens in their conversation with Kenny provides one reason to view Rowan's navigation of this challenge as a success. Navigating students' questions and maintaining a classroom environment of openness, curiosity, and mutual respect for mathematical perspectives, but especially teaching and teachers, is not a given. Rather, this may be a skill Rowan developed through reflective practice and their desire to build productive dispositions towards teachers and teaching.

Rowan's experiences suggest that mathematics instructors may benefit from early experiences developing productive mindsets towards teachers and teaching. For professional developers, an explicit introduction to and discussion of asset-based frameworks or mindsets early in mathematics instructors' preparation for teaching may support instructors in fostering more productive beliefs in the long-run. Furthermore, not all mathematics instructors have significant relationships with individuals who value teachers and teaching and who avoid deficit discourses around teachers or students. Thus, it is important for departments to carefully consider the resources, including people, that instructors have access to in learning to teach mathematics content courses for PTs.

College Students' Conceptualizations of Symbolic Algebraic Properties

Claire Wladis	Benjamin Sencindiver	Kathleen Offenholley
City University of New York	University of Texas, San Antonio	City University of New York

Here we explore how college students across a wide range of courses may conceptualize symbolic algebraic properties. We draw on the theory of Grundvorstellungen (GVs) to analyze how learner conceptions may or may not align with instructional goals. In analyzing interviews, several categories of conceptions (descriptive GVs) emerged that may help us to better understand how students conceptualize symbolic properties during instruction.

Keywords: Algebraic properties, Syntactic reasoning, Equivalence, Algebraic transformation.

Mathematical properties are critical to justifying symbolic transformation, especially in algebra and domains that rely on algebraic representation. However, learners often use properties in ways that are not mathematically valid (e.g., Hoch & Dreyfus, 2004; Mok, 2010) and instruction may not address the use of symbolic properties (and their role in justifying transformation) explicitly enough (e.g., Barnett & Ding, 2019). Here we focus on learners' ability to identify parallel syntactic structure between symbolic properties and symbolic algebraic representations, and we explore how this may relate to learners' conceptions.

Properties and Forms

Because here the focus is on how properties are used to transform symbolic representations, we define a *symbolic property* as any mathematical statement that can be used to transform a symbolic object into an equivalent one with a different form. Two examples are: 1) the definition of negative exponents, e.g.: $x^{-n} = \frac{1}{x^n}$ for $x \neq 0$; and 2) this statement about equivalent equations: $A \cdot B = C \leftrightarrow A = \frac{C}{B}$ (when $B \neq 0$). The key feature of this definition is that 1) could be used to replace an expression of the form x^{-n} with one of the form $\frac{1}{x^n}$ (or vice versa), and 2) could be used to replace an equation of the form $A \cdot B = C$ with one of the form $A = \frac{C}{B}$ whenever $B \neq 0$ (or vice versa). Symbolic properties are made up of two sides, each of which can be viewed as a separate object, which are often referred to colloquially during instruction as "*forms*" (e.g., the "forms" x^{-n}, $\frac{1}{x^n}$, $A \cdot B = C$, and $A = \frac{C}{B}$ above).

Relatively little is known about learners' conceptions of symbolic properties. Existing research has focused on classifying errors that learners make when using properties to compute or transform (e.g., Hoch & Dreyfus, 2004; Mok, 2010); on learners' justifications for why properties are true; or on learners' ability to derive properties from arithmetic patterns (e.g., Hunter et al., 2022). Schüler-Meyer (2017) has investigated learners' structure sense for the distributive property (e.g., Schüler-Meyer, 2017), there is a dearth of research looking at this for symbolic properties more generally. Given how critical using and understanding symbolic properties and forms is for transforming symbolic representations (Kieran, 2011), it is essential that more research investigate how students conceptualize symbolic properties more generally, to address this gap in the research literature.

Theoretical Framework

Grundvorstellungen

We use prescriptive and descriptive *Grundvorstellungen* (GVs) (or "fundamental conceptions") to frame this research. *Prescriptive* GVs describe conceptions that are the goal(s) of instruction (vom Hofe, 1995); *descriptive* GVs describe actual conceptions that learners hold, which may or may not reflect prescriptive GVs. Comparing these two types of GVs can then be used to guide curriculum or instruction (Greefrath et al., 2016). Both descriptive and prescriptive GVs are intended to evolve with research over time. Further, one concept may have multiple GVs and vice versa. First we describe two *prescriptive* GVs for symbolic properties (Figure 1). After analyzing student interviews, we will present some descriptive GVs in the Results section.

Equivalence-Preserving GV	Symbolic properties describe a method for replaceing one symbolic representation with another equivalent one, based on a context-dependent pre-existing definition of equivalence (e.g., insertion equivalence; Prediger & Zwetzschler, 2013)
Mapping GV	For equivalence to be preserved, the following criteria must be met: The form on one side of the symbolic property must be mapped bijectively to the symboic representation so that: 1) A unified subexpression is mapped to each variable in the form; 2) All other symbols are mapped to notation in the form with the same syntactic meaning (e.g., different notations for multiplication can be mapped to one another).

Figure 1: Two Related Prescriptive GVs for Symbolic Properties

Operational vs. Structural Conceptions and Extracted vs. Stipulated Definitions

In constructing models of learners' descriptive conceptions, we were also influenced by research on operational vs. structural conceptions (Sfard, 1992) and extracted vs. stipulated definitions (Edwards & Ward, 2004). A learner with an *operational* conception views properties as a process of computation, while a learner with a *structural* conception views them as abstract objects (e.g., canonical representations of particular algebraic structures). Sometimes learners treat something as an object that is not the reification of any process, and this is called a *pseudostructural* conception (Sfard, 1992, p. 75). The operational/structural distinction is related to the prescriptive Mapping GV of Symbolic Properties, which focuses on conceptualizing forms within a property structurally as objects.

Extracted definitions emerge organically from observed usage of a term (e.g., when a learner extracts meanings for a property based on how it was used during computation in instruction). In contrast, *stipulated* definitions are explicitly stated—to determine if something fits the definition, one must consult the definition directly (Edwards & Ward, 2004). The extracted/stipulated distinction is related to the Equivalence-Preserving GV of Symbolic Properties, as a core stipulated part of the properties definition is that they preserve equivalence (in addition, the type of equivalence that is preserved must be based on a stipulated definition).

Methods

This project is based on 102 cognitive interviews that were conducted with college students in the US in 18 courses ranging from elementary to linear algebra on items from the Algebra Concept Inventory (Wladis et al., 2018); courses included both STEM and non-STEM courses. Students interviewed were diverse in terms of gender, race/ethnicity, national origin, and English language learner status. Thematic analysis (Braun & Clarke, 2006) was combined with an initial theoretical stance focused on noticing both extracted vs. stipulated definitions (Edwards & Ward, 2004) and operational vs. structural (Sfard, 1992) conceptions, as well as the extent to which learners provided potential evidence of Equivalence-Preserving or Mapping GVs. This allowed for the resulting coding framework of learners' descriptive GVs of symbolic properties to contain both emergent and confirmatory aspects.

Results and Discussion

Analysis of cognitive interviews resulted in a framework of learners' *descriptive* GVs of symbolic properties (Figure 2). Here operational vs. structural conception categories relate to how closely learners' GVs align with a Mapping GV and extracted vs. stipulated definition categories relate to how closely they align with an Equivalence-Preserving GV (Figure 1).

	Extracted Definition	Stipulated Definition
Operational Conception of Properties	**Pseudo-process GV:** Learners see properties as a cue to a computational process, and their approaches are extracted from prior experience rather than based on stipulated definitions. They often draw on surface structure rather than syntactic meaning. For example, learners may conceptualize the distributive property as an instruction to "take what is on the outside of the parentheses and put it next to each thing on the inside", regardless of the specific operations involved.	**Process GV:** Learners see properties as a cue to a computational process, but attend to syntactical meanings and/or equivalence as a justification (e.g., checking for appropriate operations in the expression; checking that original and resulting expressions are insertionally equivalent). However, they may struggle to conceptualize properties as objects to which structures in the expression or equation can be mapped one-to-one, and thus may have difficulty generalizing the use of properties to more syntactically complex symbolic representations.
Structural Conception of Properties	**Pseudo-object GV:** Learners conceptualize a property as something that requires mapping to the specific forms in the property, but the mapping is still somewhat ill-defined and/or based on extracted notions, such as what "looks right".	**Object GV:** Learners conceptualize the property as an object, such as a canonical form, to which the specific mathematical object (i.e., expression, equation, etc.) must be mapped one-to-one, in such a way that preserves syntactic meaning. They recognize that it is these criteria that preserve equivalence.

Figure 2: Framework to Categorize Descriptive GVs for Symbolic Properties

We illustrate the framework by presenting some examples of student work.

Operational Conceptions

Many learners appeared to draw on operational conceptions of symbolic properties. First we consider a student, Iota, who was enrolled in an introductory statistics course (elementary algebra was a pre-requisite), who was given seven questions with the following form:

Q6: Which of the following could result from using the **distributive property** to rewrite the expression $(x + 2)(3x + 7)$?

a. $x + 2 \cdot 3x + 7$
b. $x \cdot 3x + 2 \cdot 7$
c. $x + 2 \cdot 3x + 2 \cdot 7$
d. $(x + 2) \cdot 3x + (x + 2) \cdot 7$
e. None of the above.
f. I don't know the distributive property.

Figure 3: Task discussed with Iota during the interview

Other versions of this item used the following expressions: Q1: $(2x + 1)2$; Q2: $x - (2x + 1)$; Q3: $2(2x \div 1)$; Q4: $2(x \cdot y)$; Q5: $(2x + 1)^2$; and Q7: $2(xy)$. Iota stated that the distributive property could be used to rewrite the expression for each of these. They correctly chose equivalent expressions that could be the result of the distributive property for Q1 ($2x \cdot 2 + 1 \cdot 2$), Q2 ($x - 2x - 1$), and Q6 $(x + 2)(3x + 7)$ (option D). However, they also incorrectly chose "results" of the distributive property for Q3 ($2 \cdot 2x \div 2 \cdot 1$), Q4 ($2x \cdot 2y$), Q5 ($(2x)^2 + 1^2$) and Q7 ($2x2y$) that suggest that they may conceptualize the distributive property as an instruction to do something like "take what is outside the brackets and apply it to each 'thing' inside the brackets". At the same time, Iota's is able to conceptualize $(x + 2)$ as a unified subexpression within $(x + 2)(3x + 7)$ that could be "distributed" to each term in $3x + 7$, which suggests that Iota is able to think structurally in key ways. Iota explains:

> Because obviously two can distribute [makes motion with fingers as though moving two from left to right twice] with the one in parentheses. So two in the front can distribute to $2x$ multiply by $2y$. So it's gonna be $2x$ multiply by $2y$ [repeats distributive motion with fingers]—that's the result.

Here Iota focuses solely on describing a computational process based on surface similarities, without considering the mathematical validity of that computation, consistent with a pseudo-process GV. We see further evidence of this later in the interview:

Interviewer: What is the distributive property?

Iota: Distribute property is like that you can use the main number or main groups to distribute to each of another number or another groups.

Interviewer: So is that like here [highlighting $(x + 2)$ in Q6], is $x + 2$ the main number?

Iota: It's a main group. Yes.

Interviewer: And then you apply that to each of the ones [motions to $3x$ and 7 in Q6]?

Iota: Yes.

Interviewer: Okay. So, I noticed that this one [highlights + in expression $(3x + 7)$ in Q6] has a plus sign in between them. Is the distributive property only for the plus sign or could it also be subtraction? Could it be multiplication or division?

Iota: So, yeah, it could be subtraction, multiplication ... Could be any sign, but when you calculate, when you are doing it, you have to do with that own sign.

Here Iota provides further evidence that they are viewing the distributive property as an extracted process here, where whatever is outside the brackets is multiplied by each "group" inside the brackets, preserving the original operation between the multiple "groups" inside the brackets. However, when Iota was interviewed about Q7 ($2(xy)$), they appear to shift to a process view, checking for mathematical validity of the transformation results by checking insertion equivalence through arithmetic computation:

Iota: Sometimes when I see these kind of questions, at first I may think its right answer is A ($2x2y$), but what I normally do is I double check the answer. So, I create some equations and I double check it, it's incorrect. So, for this case, I create like x is *3.* Okay, let me type it now, y is *2*.

x=3, y=2

2(3*2) = 2*6 =12

2*3*2*2 = 24

I think it's wrong. So, I say no... I don't know why, but this is very tricky question for me ... So, *x* and *y* multiply each other should be done before multiply[ing] the one outside.…I don't know, it's not look like a distributive property for me. It looks like the way to calculate is you do the xy first because in parentheses, and after you get the result of xy you do with the number *2.* So, I don't think this one is like a distributive property ...to be honest, I don't know why. I don't think it's A, but I just feel it's not.

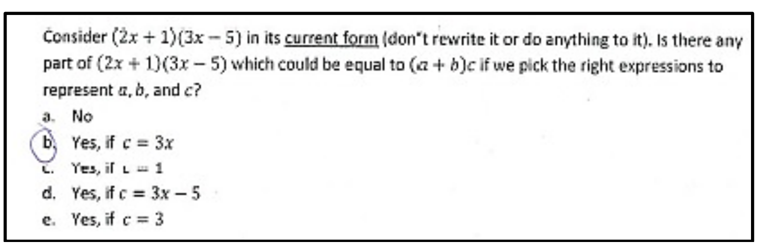
Interviewer: This strategy that you were doing, replacing x and y with numbers and seeing if they were the same: if you did that for number 6, for example, would get the same answers?

Iota: Oh, that's a good question. I don't ... Yeah. Right. I don't know ... I didn't ... I didn't try. But ... I mean, I'm just, I'm looking at it right now. Yeah, it should be the same. Because it should be only one value. Mm-hmm.

In this excerpt there is evidence of both process and pseudo-process GVs. Iota now shows evidence of the prescriptive Equivalence-Preserving GV, because they substitute numbers to check whether the result of their distributive property computation in Q7 is insertionally equivalent to the original expression, at least for one value. When it is not, they then question their use of the distributive property to replace $2(xy)$ with $2x2y$, providing evidence of a process GV. However, their explanation still draws on extracted meanings and some pseudo-process GVs: they several times mention “feeling” that the distributive property is not correct or whether an expression “looks like” the distributive property should be used. In the other six similar distributive property items, they do not use a process GV; however, when the interviewer asks them directly whether this checking process should work for those also, Iota then draws on their knowledge of the distributive property as an equivalence-preserving transformation to recognize that this is also relevant for the other expressions. Whether the pseudo-process or process GV was cued for Iota appears to be linked to the way that different expressions “look”, which may be important to keep in mind when designing curriculum and instruction. It may be that instruction and tasks that focus more on checking and justifying calculation as well as linking the equivalence-preserving GV to calculation procedures, especially for a diverse problem space with many different forms, may be critical for learners like Iota.

Pseudo-object GV

The next interview was conducted with an elementary algebra student, whom we call Eta. They were asked to interpret whether $(2x + 1)(3x - 5)$ could be viewed as equal to the form $(a + b)c$.



Consider $(2x+1)(3x-5)$ in its current form (don't rewrite it or do anything to it). Is there any part of $(2x+1)(3x-5)$ which could be equal to $(a+b)c$ if we pick the right expressions to represent a, b, and c?

a. No
b. Yes, if $c = 3x$
c. Yes, if $c = 1$
d. Yes, if $c = 3x - 5$
e. Yes, if $c = 3$

Figure 4: Eta considering whether $(2x + 1)(3x - 5)$ can be seen as having the form $(a + b)c$

Eta: $2x$ could be a then the one would be b, then the c would be $3x$… if c is equal to $3x$ then it would make sense…. I'm just doing it by order by the first number, second number, third number. Maybe that's not the best way, but that's what I was doing.

Interviewer: What’s being multiplied in each case [pointing to the expression]?

Eta: Two is being multiplied by three. Two is also being multiplied by the negative five. The same thing for the one, the one is being multiplied by three and then the one is also being multiplied by the negative five.

Here Eta focuses on mapping subexpressions to variables in the form “in order”, which reflects a pseudo-object GV: they map the “first subexpression” to the first variable, etc., without attending to grammatical meaning of the syntax. When considering $(2x + 5)(3x - 5)$ and mapping subexpressions to the form $(a + b)c$, Eta appears not to “see” the second set of brackets around $3x - 5$ initially (or not recognize them as a grouping symbol); but when further questioned by the interviewer, Eta explains that each term in $(3x - 5)$ will eventually be multiplied by each term in $(2x + 1)$. This provides evidence that Eta’s pseudo-object GV of symbolic properties is likely not caused by a failure to recognize the syntactic role of the second set of brackets. Rather, Eta appears not to focus on the existing syntactic meaning of expressions when mapping that expression to a form. Eta appears to conflate the existing syntactic meaning of $(2x + 1)(3x - 5)$ with the result of expansion, perhaps literally conceptualizing $(2x + 1)(3x - 5)$ as having the syntactic meaning $2 \cdot 3 \cdot x^2 + 2 \cdot -5 + 1 \cdot 3 \cdot x + 1 \cdot 5$. However, while these two expressions are equivalent, they do not have the same syntactic meaning, and conflating the syntactic meaning of the first expression with the second one appears to obscure the structure needed to map this expression to the form $(a + b)c$.Thus, Eta’s computational view of syntactic structure may be impacting their GV of symbolic properties. Instruction that more explicitly highlights the differences in syntactic structure of different expressions and links this explicitly to form mapping, may better prepare Eta (and learners like them) to draw on their existing knowledge of syntax, symbolic structures, and forms as objects. Future research is needed to explore this possibility.

Object GV

We now consider an interview with an elementary algebra student whom we call Theta, who was asked to interpret whether $\frac{2x^2(y-1)}{2}$ could be viewed as equal to the form $\frac{(ab)}{c}$ (where $c \neq 0$).

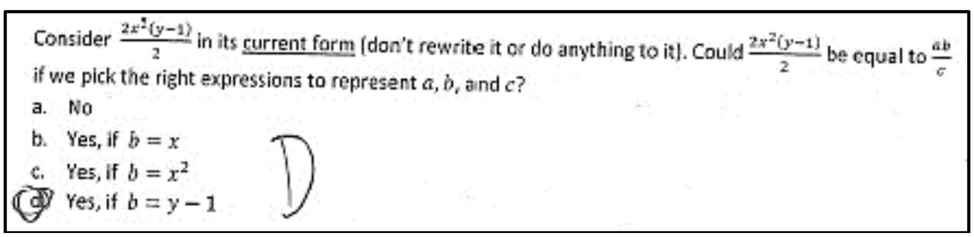


Figure 5: Theta mapping a multi-term expression to a variable in a form

Theta: I felt like D was the best option because looking at a and b over c the first equation fit that like a could be $2x^2$ squared and b could be $y - 1$ and c could be 2.

Interviewer: Did the parentheses impact your decision?

Theta: Yes.

Interviewer: How?

Theta: Because I saw that the $y - 1$, I saw it as separate from $2x^2$. And I know that looking at the second one that a and b in order for them to be multiplied they would most likely have to have parentheses around them. And I saw $y - 1$ in parentheses so I just ... looking at them all as substitutes, as soon as I saw a and b over c like I was just putting in my head okay, $2x^2$ squared is a, $y - 1$ is b, and the two is equal to c.

In this excerpt Theta provides evidence of an object GV. They identify mathematically valid subexpressions in $\frac{2x^2(y-1)}{2}$ and identify which of these should map to which variable in the form to preserve the structure. Later the interviewer asked Theta to identify different syntactic structures in the expression, and Theta was immediately able to do so correctly. Here Theta also appears to conceptualize brackets from an object view (as a grouping mechanism rather than a cue to a procedure [see Wladis et al, 2022a]) because they "separate" the $2x^2$ and $y-1$. Because Theta's object view of syntactic structure is critical to their identifying the subexpression structures that will create a syntactic-structure-preserving one-to-one mapping from $\frac{(2x^2)(y-1)}{2}$ to the form $\frac{ab}{c}$ illustrates how this object view of syntactic structure may be a critical precursor to having an object view of symbolic properties. Theta also specifically mentions substitution when describing how subexpressions relate to the properties form: thus, Theta's notions of substitution and substitution equivalence may be related to their symbolic properties conceptions (see Wladis et al., 2022b). Theta's explanations here are substantially more structural than most other students in the sample (including those in a wide variety of course levels). While this evidence is not causal, Theta's responses indicate that some elementary algebra students are capable of reasoning structurally about symbolic properties. Theta was part of an intervention that was designed to teach students the prescriptive GVs presented here (as well as others related to syntactic structure and equivalence). This may have influenced their GV formation; ongoing research is underway to explore this possibility. But regardless of whether this particular intervention played a role, Theta's responses show how elementary algebra students are capable of thinking structurally.

Conclusion

These different vignettes illustrate how conceptualizing student thinking around symbolic properties using the framework in Figure 2 may be productive for understanding the reasons that students work with symbolic properties in particular productive or non-productive ways. One interesting pattern across all three vignettes is that each of the learners shows evidence of potentially productive prior knowledge, however, the extent to which they were able to use this prior knowledge productively in the context of symbolic properties varied quite a bit. We also saw here how student conceptions of symbolic properties are also intricately related to their conceptions of symbolic structure and equivalence, and thus some conceptions of these related concepts may be essential precursors to student conceptions of symbolic properties (Wladis et al., 2023). More research is needed to explore the relationship among these various conceptions, as well as what factors enable or disable students from productively drawing on prior knowledge when working with symbolic properties. We continue to investigate these relationships in ongoing research, and hope that others will as well.

From an Inclination to Subtract to a Need to Divide: Exploring Student Understanding and Use of Division in Combinatorics

Zackery Reed
Embry Riddle University

Elise Lockwood
Oregon State University

John S. Caughman, IV
Portland State University

In this report, we provide an initial exploration into a key but under-studied phenomenon in enumerative combinatorics – the use of division in solving counting problems. We present a case of one undergraduate student solving a combinatorics problem; this case is representative of a broader phenomenon in which students may intuitively desire to account for an overcount using subtraction, when division is a productive and useful approach. We highlight the conceptions a student demonstrated as she progressed from using subtraction to using division successfully. We frame our analysis in terms of a set-oriented perspective (Lockwood, 2014).

Keywords: Arithmetic operations, Combinatorics, Discrete mathematics, Sets, Division

When solving counting problems, we may find ourselves needing to remove some undesirable outcomes from a larger set, in order to find the cardinality of the set of outcomes in question. For example, in the problem "How many sequences of 5 digits contain at least one 9?", an efficient strategy is to count all possible 5-digit sequences and then to subtract those that do not contain a 9. This strategy is common, and can be viewed as a special case of the well-known Principle of Inclusion/Exclusion (e.g., Tucker, 2002); subtraction is a powerful tool for counting.

In some cases, however, the operation of division, and not subtraction, is most useful. In fact, division represents an important, often necessary, way to account for overcounting. Consider the Table Problem, which is the focus of our case study in this paper: "How many ways are there to arrange 10 people around a circular table?" A common efficient solution involves division – we first count the ways to arrange 10 people in a line (10!), and then we note that each of the desired circular arrangements is actually overcounted by a factor of 10 (since each linear arrangement can be rotated 10 times to yield equivalent circular arrangements). Thus, we can strategically divide the number of linear arrangements by 10 to arrive at the correct answer of 9!. In such problems, we have observed that students' initial approach tends to focus on subtraction as a way to account for overcounting. Our main goal in this paper is to consider and discuss ways in which students may progress from an initial intuitive desire to subtract to a combinatorial understanding of how and when to divide in appropriate circumstances.

There are many reasons why we might want students to develop robust, productive ways of thinking about division in combinatorics. Indeed, it occurs frequently in problems, and it is a fundamental aspect of why certain formulas (such as the binomial coefficients) work as they do. As important as division is, it has not commonly been addressed in the teaching and learning of combinatorics. We argue that better understanding division as it relates to counting could be beneficial for students. Our motivation and goal here is to provide evidence for – and to lay groundwork for – future studies to examine division in combinatorics.

In this report we focus on a case study of one undergraduate student, who solved the Table Problem and, in so doing, transitioned from an approach focused on subtraction to one that successfully leveraged division. We particularly want to highlight what conceptions about division emerged for the student that allowed her to successfully solve the counting problem (particularly when she was not able to use subtraction successfully). We attempt to answer the following research questions by examining this case: *What conceptions and ways of reasoning* *emerged for an undergraduate student as she progressed from using subtraction to using division to solve a counting problem that was designed to elicit division?*

Literature Review and Guiding Perspectives that Situate Our Work

A Set-Oriented Perspective

Lockwood (2014) introduced a set-oriented perspective as a way of thinking about counting "that involves attending to sets of outcomes as an intrinsic component of solving counting problems" (p. 31). Lockwood and others have since argued for the importance of having students connect counting to sets of outcomes in a variety of ways, connecting such a perspective to listing (Lockwood & Gibson, 2016), highlighting its importance in helping students understand and interpret counting formulas (e.g., Lockwood et al., 2015; Wasserman & Galarza, 2017; Wasserman, 2019), and emphasizing its centrality to being able to engage productively with combinatorial proof (e.g., Lockwood et al., 2020; Erickson & Lockwood, 2021a). Relatedly, Lockwood (2013) presented a model of students' combinatorial thinking that included three components: counting processes, formulas and expressions, and sets of outcomes. In this model, Lockwood emphasized the importance of sets of outcomes, suggesting affordances of having students think about ways in which their counting processes generate and organize sets of outcomes. Our findings in this paper help flesh out the relatively broad view of this set-oriented perspective initially presented by Lockwood (2014). We explore how certain ways of structuring sets of outcomes may serve to support students' reasoning about division in solving counting problems. The set-oriented perspective serves as a guiding theoretical principle, and a focus on sets of outcomes is central to how we conceive of counting.

Arithmetic Operations in Combinatorics

With the exception of multiplication, arithmetic operations have generally not been studied extensively in combinatorics education. Multiplication occurs so frequently in combinatorics that the community has developed a Multiplication Principle (MP) that describes conditions under which it is appropriate to multiply when solving a counting problem. Researchers have explored a number of ways in which the MP is presented in the teaching and learning of combinatorics, including its presentation in textbooks (e.g., Lockwood et al., 2017), students' reasoning about the MP (e.g., Lockwood & Purdy, 2020a, 2020b), and problems involving Cartesian products (e.g., Tillema, 2013). To this point, however, adequate attention has not been paid to other arithmetic operations in counting, especially subtraction and division. Lockwood and Reed (2020) describe an equivalence way of thinking in combinatorics, highlighting how equivalence relates to division in counting.

> Broadly, an equivalence way of thinking in combinatorics entails recognizing equivalence between particular outcomes, and then subsequently accounting for this equivalence. So, when employing an equivalence way of thinking, two things happen: a) one recognizes that in a given set of outcomes, there are certain outcomes that should be considered equivalent (or "the same," "duplicate," or "identical") for specified constraints in a situation or problem, and b) one understands that they can use the operation of division in order to account for the occurrence of such equivalent outcomes (Lockwood & Reed, 2020, p. 4).

Lockwood and Reed noted several places in which such equivalence and division naturally arise among topics in combinatorics. Our point here is that division in combinatorics relates to important underlying concepts, and it is worthwhile to pursue as a line of inquiry. Our data sheds light on students' conceptions of division (particularly as it relates to subtraction) that illuminate the kinds of productive meanings and ways of reasoning that have thus far been absent from the literature, and suggest a need for further exploration. We are thus motivated to think more broadly about ways in which other operations can support and augment students' combinatorial understanding beyond just multiplication.

Methods

We present an episode taken from a series of task-based clinical interviews (Hunting, 1997) exploring, among other things, students' engagement with division in counting. Nine students were recruited from a large university in the United States. The participants were a mix of six undergraduates, one early-stage graduate, and two late-stage graduate students who were enrolled in a math class and had taken (or were taking) a course that featured counting. There were no selection criteria aside from their coursework and willingness to participate. We present the work of Jillian (pseudonym), an undergraduate mathematics major, in her first interview.

Interview sessions were 90 minutes long. Because of student availability, some students participated in few sessions (1-3) while others participated in many sessions (6-9). Consistent with task-based clinical interviews (Hunting, 1997), the participants were asked to describe their work as they solved multiple counting problems, and were frequently asked hypothesis-confirming questions by the interviewer about their understandings of formulas, concepts, and strategies both during and after they solved the problems. Participants worked on an iPad to solve the problems, and their written work and gestures and utterances were recorded.

The interview protocol consisted of a diverse collection of counting problems, with many problems chosen as likely to elicit use of division as part of the problem-solving process. For instance, one might solve the *Table Problem* in at least three ways, though we hypothesized that many students would be successful by leveraging division as described in the Introduction. An alternative solution involves making an initial arbitrary choice that a single person sits first at the table. Following this, there are 9! arrangements of the remaining 9 persons around her.

Notably, one might also solve the *Table Problem* with subtraction. Beginning with the 10! linear arrangements of people, and recognizing the overcount, one might attempt to remove 9 extra outcomes for each 1 desired outcome. This leads to the insight that, if for each desired outcome there are 9 to be removed, then you solve the problem by the difference $10! - 9x$, where x is the desired number of outcomes. Since x is also the solution, you establish the equation $10! - 9x = x$ to yield the solution $\frac{10!}{10} = 9!$. As many counting problems involving division can be solved in multiple ways, we attempted to choose problems for which division would be a likely solution method. We also included other problems for which division was not a targeted solution method (e.g., problems involving sums of binomials) so students would not anticipate that division was the targeted operation of the study. Following our focus on a set-oriented perspective, other interventions were enacted to support student consideration of outcome sets during their problem solving.

The video records (iPad work and gestures and utterances) were spliced together so that we could view both the student and their work at the same time. Transcripts were made and enhanced with images, references, and comments. The research team analyzed the data for this report by searching the records for episodes where students utilized division in their solution, attending particularly to problems where subtraction was involved in an earlier solution attempt. We then reviewed the records of the episodes via conceptual analyses (Thompson, 2008) to build second-order models of the students' thinking, seeking viable explanations of the students' actions and utterances in the form of theoretical models (Steffe & Thompson, 2000; Thompson, 2008). The results that we present follow from our second-order models of Jillian's cognition.

Results

In this section, we briefly describe four episodes in Jillian's work on this problem, as we document her progress from her initial inclination to use subtraction to her use and justification of division. In each episode, we comment on her reasoning and connect it to what we think are broader important points related to student thinking on division in counting.

Episode 1: Starting from 10! with an Inclination to Subtract

Jillian had correctly solved a previous problem that asked for the number of ways to arrange 10 people in a line (the answer is 10!), and when answering the Table problem, Jillian began with that previous solution. She understood that 10! would give her too many outcomes, and she immediately demonstrated engagement with the sets of outcomes by identifying specific outcomes as "the same".

Jillian: There's going to be similar iterations, because if you have *a* through *j* [i.e. the sequence *(a,b,c,d,e,f,g,h,i,j)*], that's the same as *b* through *a* just around the circle goes *j* and then come back around [to] *a* [i.e. *(b,c,d,e,f,g,h,i,j,a)*],. So we're going to have another probably, I think, subtracting problem. So I think it would start similar to the line of 10 factorial [i.e. arranging 10 people into a line]. It'll give you all the possible ways to arrange them. Not accounting for possibilities being the same iteration around the table.

Jillian thus wanted to try to solve the problem by reducing that 10! in some way to account for duplicate rotations around the table. She went on to articulate correctly that there would be nine duplicates for every desirable arrangement, as seen in the following excerpt.

Jillian: So, for each order of 10 that you complete. There's going to be nine duplicates because each order of 10 can be shifted around the table, like there's 10 ways to express the same thing. And so, each of these 10 iterations is going to have nine duplicates.

Jillian's intuition was correct – in fact, she could even articulate what precisely would get overcounted and what she wanted to remove. However, she did not see how to use the subtraction to arrive at a solution and could not figure out what to subtract. The excerpt below shows her reasoning that because each desirable outcome had 9 duplicates, she wanted to subtract nine times the desirable (possible) outcomes (she wrote this in Figure 1).

Jillian: So there's 10 iterations. […] So each order [i.e. one desired outcome] has nine duplicates, but there's a lot of possible orders. [...] So number of possibilities [writing Figure 1a]. And then I want to take away or divide or somehow remove the nine duplicates of each of those possibilities. I think. And I believe this is a number of possibilities [circling 10!]. So how would you find the nine duplicates worth of each of those possible? […] minus 9 times "possibilities".

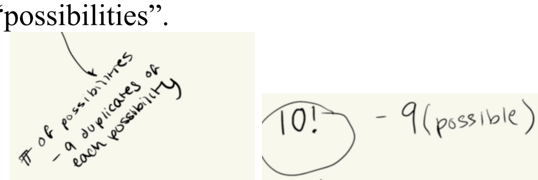

Figure 1a and 1b: Jillian's initial solution to the Table Problem, involving subtraction

She then clarified that she was using "possibilities" to mean two different things, and re-stated Figure 1a. as "# of possibilities and duplicates – 9 duplicates of each possibility". Jillian realized that the possible outcomes she sought was what she was trying to solve, which felt circular to her (note, she did not attempt to build on this towards the subtraction-based solution mentioned in the Methods Section). At this point, enough time passed to suggest an impasse, and the interviewer encouraged her to consider a smaller case, which we describe in Episode 2.

Episode 2: Investigating a Smaller Case, Still Focusing on Subtraction

Jillian wrote out a smaller case involving three people sitting around a table, and she wrote the outcomes in lexicographic order (Figure 2a). She noted, "So each of these [referring to *abc* and *acb*] had two duplicates, which makes sense because there's two iterations around the table."

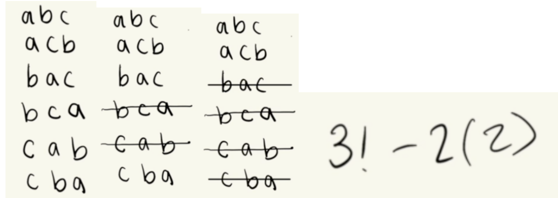

Figure 2a - 2d: Jillian's set of outcomes for the 3-person case

Jillian then proceeded to cross off some outcomes from her list. She noted that *bca* and *cab* were duplicates of *abc*, and so she crossed those off first in Figure 2b. Then, she noted that *cba* and *bac* were duplicates of *acb*, so she crossed them off next in Figure 2c. As she did this, she wrote the expression "3! – 2(2)" in Figure 2d, and she related that expression to her previous expression "10! – 9(possible)" in the larger case. Her language in the excerpt below shows her relating the expression "3! – 2(2)" to her process of crossing out the outcomes from her list; the bolded language summarizes her understanding of that equation. In this way, the smaller case and the set of outcomes helped her confirm that her expression was correct. We want to highlight that the expression here and the process by which she crossed out outcomes is reflected both in how the outcomes are listed, which aligns with Lockwood's (2013) model.

Jillian: Six original options minus […] and then instead of multiplying by nine [in the larger case] I will by two of each of those original options. By the previous logic, there would be three factorial, or six, so I'm happy with that of without not accounting for order, we're going to have the same number of options. And then instead of minus 9 times the actual amount of possibilities [i.e. desired possibilities and duplicates], I'd say minus 2 times the actual amount of possibilities, because **there's two duplicate iterations when you have three people and there's two legitimate possibilities that aren't duplicates. And so, the [expression] makes sense.**

Notably, Jillian realized that in this case she knew there were 2 possibilities (because she had actually written them out and counted them), but she wasn't sure how to get the answer in the bigger larger 10-person case. We infer that at this point the smaller case served to support her in confirming the formula could make sense if she knew what the number of possibilities were, but it did not help her actually solve the problem for the larger case. The interviewer let her wait and think, and we interpret that she had come to an impasse and was not sure how to proceed.

Episode 3: A Different Structure on the Set of Outcomes in the Smaller Case

We had hypothesized that an alternative way of organizing outcomes could help to motivate the use of division. So, once Jillian seemed unsure of how to proceed, the interviewer intervened by writing the outcomes in a different way (Figure 3a). He wrote the outcomes in two columns, with each equivalent rotation of an outcome in its same column.

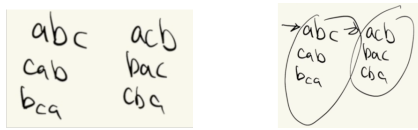

Figure 3a and 3b: The interviewer's, and Jillian's circling of two groups of 3

Jillian noted that she had two groups of three, and she realized (because she knew that the correct answer was 2) that to get the answer of 2 she would need to divide the 3! by 3. She circled the two groups and said, "Yeah, three factorial, you just needed to split it into groups. But it wouldn't be divided by two, by three." However, she continued to reason about the formula and the outcomes and to move back and forth between the smaller 3-person case and the original 10-person case. After some time, the interviewer re-stated her current strategy, as a means of confirming her current reasoning about the problem.

Interviewer: So, you're thinking we can make our two [solution to the 3-case] in this case out of three factorial divided by three. But you're noticing that your instinct is to - instead of divide - subtract by two, because there are two duplicates.

Jillian: Yes, yeah. Because you should be able to split it […] divide by. Oh. I guess in this case, it would be divided by ten [$\frac{10!}{10}$] and the other one too, divided by three [$\frac{3!}{3}$]. Because I'm dividing it into groups of three, the original and its two duplicates to see how many groups there are because that basically doesn't count the duplicates. It just counts how many original generators do we have, like for these different groups

We interpret that Jillian realized that although the desirable outcomes each had *two* duplicates, she could divide by *three* because the groups of three include the desirable outcome and its two duplicates. She also referred to generators, which the interviewer asked about and we discuss in the next episode. She then related this insight about two duplicates and a group of size three to the original 10-person case, and she said, "So wouldn't that work if we divided this [10!] by 10 because it would split it into […] 10, because we know each of these possibilities has 9 duplicates. So, if we split it into groups of 10, we should account for […] the 9 in addition to all of the original one."

Again, Jillian articulated that the division by 10 made sense because each possibility has 9 duplicates, making a group of size 10. The interviewer wanted to ensure he correctly interpreted her reasoning, and so he asked for additional justification, which we discuss in Episode 4.

Episode 4: Ultimately Justifying the Division

In this final episode, we document Jillian's understanding of why division made sense. The exchange below highlights how she came to talk about the groups of 3 (in the smaller case) or 10 (in the larger case) as including the desirable outcome and its duplicates.

Jillian: Yeah. So over here [smaller case] […] I'm counting *abc* and *acb* [draws arrows in Figure 3b] as our like "generators" [air quotes], any one of these [group members] could be a generator […]

Interviewer: And so, by generator there, you mean […] *abc* you said could be swapped out for any of the others. So, what makes that, like, a generator? Or what does generator mean.

Jillian: Yeah. I guess it's almost like if there was an operation that rotated them or something like it's operating on itself over and over again […]

Interviewer: [After confirming that Jillian was not formally referring to algebraic groups] So for you, maybe in layman's terms we would say you've got *abc* but you could generate any of the other duplicates from *abc*.

Jillian: Yes, yes, yes, yes, yes. It's like, it's kids or something. You have *abc* and then you have all of the family of *abc*. And I know that there's going to be in this [larger] case, there's going to be nine children of every parent. If we were to split it into groups of ten, even if the kids got all jumbled up and they weren't the right groups of ten, we still should account for the fact that each one is multiplied by ten different iterations.

Interviewer: So, we take the one generator, as you've been calling it, and you multiply by ten. That gives you like the entire collection of iterations.

Jillian: Yes. And so, if we divide by ten, we should get the number of generators.

Jillian could reason about the whole set of outcomes being split up into groups, and in this way she understood that the division was giving her the number of generators. We infer that she understood that each group would have one generator, and so the division would yield the number of desirable groups and, ultimately, of desirable outcomes.

Discussion and Conclusion

We highlight a couple of points of discussion here and articulate potential implications. In accounting for Jillian's transition from subtraction to division, we think that a key understanding was focusing not just on the number of duplicates (2 duplicates or 9 duplicates in the respective cases), but thinking of the entire sets of equivalent outcomes, including the desirable outcomes and the duplicates (a total of 3 or 10 in the respective cases); we call these the equivalence classes. Transitioning from a focus on a 1:2 or a 1:9 ratio and instead thinking of 3 or 10 seemed important in understanding the appropriate use of division. An implication then is that while subtraction of duplicates is useful, it is valuable to think of those duplicates not in a ratio to the desirable outcome but as part of a set (or equivalence class) with the desirable outcome itself. Jillian's notion of a generator was one useful way to think about this.

Another observation is that reasoning about sets of outcomes and a set-oriented perspective was useful, but certain ways of structuring the sets of outcomes might be associated with different solution strategies. The common lexicographic ordering of outcomes first accompanied Jillian's duplicate-removal strategy, whereas grouping the outcomes into equivalence classes provided a way for Jillian to focus on the 3 and the 10 (the sizes of the groups, rather than the sizes of the groups of duplicates). This re-orientation towards division gives insight into more nuances about *sets of outcomes* and how they might relate to *processes* and *formulas* that may be particularly suggestive of operations. Indeed, we feel that the listing and expression in Figures 2a-2d highlight Jillian's movement between components of Lockwood's (2013) model, and reinforce the currently underexplored idea that different lists of outcomes may be suggestive of different *processes* and *expressions*.

A final point and potential implication is that there are natural connections between counting problems and equivalence, and problems that focus on division in counting may offer rich opportunities and contexts in which to explore such connections. We believe that there is much more work to be done to investigate students' reasoning about division in combinatorics, and we hope that researchers will undertake systematic explorations into how students use and come to understand division in combinatorics.

Levers for Change: A Longitudinal Case Study of Two Departments

Talia LaTona-Tequida
San Diego State University

Antonio Martinez
California State University, Long Beach

Chris Rasmussen
San Diego State University

University mathematics departments are making efforts to improve student success in STEM by implementing active learning in their introductory mathematics courses. These efforts are context-dependent, driving a need to understand the varying paths departments take in making these changes. In this paper we explore the change efforts of two mathematics departments that achieved varying levels of success. We take a longitudinal perspective to capture their efforts. We identify what levers these departments used, including how robustly the levers were implemented. We conclude with a discussion on how the levers identified contributed to each department's progress.

Keywords: Department change, calculus, student success

Research on departmental change, while prevalent for some time in higher education, has only recently been a focus of undergraduate mathematics education (e.g., Smith et al., 2021). In a recent research commentary, Reinholz et al. (2020) argue for an expanded research base that attends to the process of change in mathematics departments. Such research has the potential to provide both needed insights for others wanting to embark on a change initiative and to contribute to theories of change. Previous studies have focused on various aspects of departmental change including research on communities of practice, course coordination, and the intentionality needed to initiate desired change (Smith et al., 2021a), as well as research focusing on change efforts over a two-to-three-year period (Apkarian, 2018; Smith et al., 2021b). In this report we aim to contribute to this emerging research area by examining two different departmental change efforts over the span of a five-year period.

A primary reason mathematics departments in the United States (US) and elsewhere undertake transformational change efforts is poor student experience and success in the introductory mathematics courses required of most science, technology, engineering, and mathematics (STEM) majors (e.g., PCAST, 2012). In addition to traditional markers of success, such as grades, students completing calculus courses also report decreased confidence, enjoyment, and readiness (Bressoud, 2015). While the effects of these introductory courses apply to students in general, they disproportionately affect women and students of color (Bressoud, 2015; PCAST, 2012; Rocard et al., 2007, Seymour & Hewitt, 1997, Seymour et al., 2019).

High attrition and disproportionate outcomes have led to a myriad of calls to improve student experiences in introductory mathematics courses through the incorporation of active learning (CBMS, 2016; Abell et al., 2018). Analyses of efforts to improve student outcomes through active learning strategies have shown that students improve along traditional measures of success as well as affective gains, with a significant narrowing of achievement gaps for students from underrepresented groups (Freeman et al., 2014; Kogan & Laursen, 2014; Theobald et al., 2020).

Several ongoing efforts in undergraduate mathematics education are investigating departmental change efforts to better understand how mathematics departments are making these changes and what strategies might be successful (Laursen et al., 2019; Smith et al., 2021).

However, change is difficult, highly localized, and requires systemic strategies (Sabelli & Dede, 2001; Smith et al., 2021b). What works for one institution may not work for another. The two case studies reported here provide insights into various levers of change that are useful in different contexts over an extended period answering the research question: *How do two mathematics departments implement various levers of change in an effort to implement active learning in their Precalculus to Calculus 2 courses?*

Theoretical framework

We utilize Laursen et al.'s (2019) 13 levers of change to document the progress mathematics departments made with respect to changing instructional practices. Laursen et al.'s levers of change, which act on both individuals and academic units, describe a broader change theory. The levers themselves can also serve as a descriptive set of options that characterize change efforts. We selected this framework because of its flexibility in describing the factors of change at different institutions in which the levers are dependent on local context. One contribution of our work is the expansion of this framework to account for cultural and contextual factors that determine the generation and impact of site-specific levers. The theoretical framework includes three themes describing the change process.

The three themes are: (1) levers to motivate or provide rationale, (2) levers to prepare and enable, and (3) levers to stimulate and support action. Laursen et al. (2019) describe levers to motivate or provide rationale as, "Identifying the need, suggesting solutions, and prompting individual instructors or their departments and institutions to adopt [research-based instructional strategies]" (p.159). Levers to prepare and enable, as Laursen et al. (2019) state, "can best be described as offering mechanisms for change" (p. 166). That is, what structures are in place to support instructors to make changes? The third theme, levers to stimulate and support action, includes federal and private investment to support and sustain instructional change efforts - the only lever in the framework that impacts individuals and academic units together. Specifically, Laursen et al, (2019) state that, "Funding does not work directly on instructors, nor on academic units, but rather exerts secondary force on the other levers" (p. 175). We identified one additional lever, Administrative funding, that would fit under this broader definition of stimulating and supporting action. The 13 levers identified by Laursen et al. (2019) are provided in Table 1 as well as the additional change lever identified in this study shown in italics.

Table 1. Levers for change.

Lever Themes	Operating on Individuals	Operating on Academic Units
Levers to Motivate or Provide Rationale (LMPR)	1. Accreditation of certification by disciplines of states 2. Guiding documents from professional societies/leadership bodies 3. Demands from employers for specific competencies 4. Results from research	5. Models and exemplars from other institutions 6. Local data and evidence about student outcomes

Levers to Prepare and Enable (LPE)	7. Professional development 8. Resource collections or digital libraries 9. Educational technologies 10. Communities of practice	11. Collaboration with other disciplines or departments 12. Local leaders and internal change agents with a vision
Levers to Stimulate and Support Action (LSSA)	13. Federal and private funders' investments (operating on all levels and on the system as a whole) 14. *Administrative funding* (operating on all levels and on the system as a whole)	

Setting and Methods

This work is part of a larger project that studied change strategies at multiple institutions in the US to implement and sustain active learning in their Precalculus to Calculus 2 (P2C2) sequence. The research project was carried out in stages, each with its own goals and objectives. Phase 1 was a case study of six institutions that had successfully implemented active learning in their P2C2 sequence; Phase 2 was a longitudinal case study of nine departments that received nominal funding and participated in a networked improvement community (Smith et al., 2021b). Phase 3, which is the focus of this report, investigated the change strategies of departments who applied to be part of Phase 2 but were not selected. We investigate what levers influenced the progress these departments made in implementing their change initiatives. There were 38 departments that were not selected to join Phase 2, with 11 identified as having carried out at least part of their original proposal.

Of the 11 departments, six were deemed to have moderate to substantial change efforts and five were deemed to have made minimal progress towards their change efforts (LaTona-Tequida et al., 2022). Two departments from these 11 were selected for this report: One department, Mid State University (MSU), represents a modest to substantial successful change effort and one department, Large State University (LSU), represents a less successful change effort. MSU is a primarily Asian institution with very high research activity and an undergraduate student body of roughly 14,000 students. LSU has approximately 22,000 undergraduates, is a primarily white, and is a high research activity institution.

Data sources included proposals submitted by each department, audio-recorded and transcribed semi-structured interviews with key personnel in the mathematics departments, and final reports written by each department communicating their long-term progress toward their proposal goals. Our data sources span a period of five years allowing a longitudinal perspective, enabling us to evaluate change implementation over time, uncovering sustained changes and successes. Based on our knowledge of the literature, we took Laursen et al.'s (2019) 13 levers as an *a priori* coding scheme to analyze each data source but remained open to identifying additional levels (Miles & Huberman, 1994). Each department's data sources were coded individually by 2-3 of the authors who then met to discuss coding until a consensus was reached. We further organized the levers identified for each department and each data source into a table to capture changes in the use of levers over time.

Results

In Table 2 we present an overview of the levers utilized by the mathematics departments at each institution at three time points, Fall 2017, Fall 2020, and Fall 2022. Due to space constraints, we provide detail on the 2020 data and briefly discuss the 2017 and 2022 data. Levers in bold are those we found to be the most robustly implemented and likely the most effective catalysts for change.

Table 2. Levers utilized over five years (LMPR = Levers to Motivate or Provide Rationale; LPE = Levers to Prepare and Enable; LSSA = Levers to Stimulate and Support Action).

	Fall 2017	Fall 2020	Fall 2022
MSU	LMPR4, LMPR5, **LMPR6, LPE7**, LPE8, LPE11, LSSA.13	**LPE7**, LPE10, LPE11, **LPE12**, **LSSA13**	**LPE7**, LPE10, LPE11, LPE12, **LSSA13**, **LSSA14**
LSU	**LMPR6**, LPE7, **LPE8**, LPE10, **LPE11, LPE12**, LSSA13	LMPR6, **LPE7**, **LPE8**, **LPE12**	LMPR6, LPE7, **LPE8**, LPE12

Mid State University

MSU made significant progress toward their goals, which included: 1) implementing active learning in Calculus 1 with the support of learning assistants, 2) implementing course coordination in Precalculus and Calculus 1, and 3) increasing the enrolment and retention of Indigenous students in STEM by focusing on Calculus 1.

Fall 2017. At the time of their proposal, MSU used levers from each of the three themes, with plans to expand the use of active learning, strengthening existing levers, or including new ones. In their proposal they described two levers that provided motivation and rationale, and three levers that prepared and enabled, with both themes acting on individuals and academic units. The use of local data (LMPR6) and course coordination (as a form of professional development (LPE7)) were two areas where MSU focused their change efforts in Fall 2017.

Fall 2020. By the fall of 2020 MSU expanded the use of coordination and Learning Assistants (LAs), peer-to-peer instructional aids, making use of various levers, primarily focused on levers that prepare and enable. There was no progress in data use, and MSU was limited to temporary solutions for funding.

Levers to prepare and enable. Coordination expanded in both Precalculus and Calculus 1. A permanent position was created and filled for a Precalculus coordinator and co-coordinators were incentivized through course buyouts for Calculus 1. In line with the MSU vision for coordination, Precalculus coordination evolved to include common materials and instructional support (LPE7). Instructional support was facilitated through weekly meetings where LAs and coordinators discussed areas students were struggling and strategies for attending to students' understanding. Calculus 1 coordination grew to include common midterm exams in addition to a common final exam and common materials. Notably, MSU was able to resolve resistance to coordination in Calculus 1 through teaching assignments. Permanent faculty who were at odds with course coordination were shifted away from teaching coordinated courses to teaching upper division courses.

By the fall of 2020, the LA program expanded to Calculus 1 and Calculus 2 and was the cornerstone of active learning implementation at MSU. Components of the LA program included coordination, professional development, and strong leadership. LA coordinators were responsible for creating worksheets and meeting with LAs weekly in preparation for recitation and were also incentivized through course reduction. With respect to professional development, the new LA program director taught a semester-long pedagogy course for new LAs and provided optional workshops for instructors looking to make the best use of LAs in their classrooms. The program director also acted as a local change agent and helped promote the LA program's success to administrators.

Although coordination and the LA program previously made use of professional development, resource collections, and collaboration with other departments, these levers shifted and grew more robust as change efforts progressed. Course coordination now included communities of practice and professional development via weekly meetings with coordinators and LAs. The LA program continued to leverage collaboration with other departments but shifted from working with the Physics Department to the College of Education. Also, the creation of the LA program director position supported local leadership (LPE12) that could facilitate communication about the program's benefits to administration. In addition to these levers that prepare and enable, MSU was able to secure funding to support their active learning efforts.

Levers that stimulate and support action. The expansion of the LA program started with a round of one-time funding from the Vice Chancellor's office which supported a semester-long consultation with an LA program director from another university. An additional lever that stimulates and supports action, is *administrative funding* (LSSA14). At MSU, the Dean of the college was instrumental in securing the initial round of funding, supporting the genesis of the LA program. During this initial semester, the consultant ran an LA pedagogy course, while also training a MSU faculty member from the College of Education to run the course and fill the LA program director role locally. Additionally, the mathematics department provided funding that supported the Precalculus coordinator and Calculus 1 co-coordinator positions. Despite the positive growth in their efforts, MSU also reported in 2020 that funding for the LA program was an ongoing struggle, stating they often do not know where funding will come from until right before the semester begins.

Fall 2022. At the time of their final report, MSU described no changes to their previous coordination growth, showing a degree of sustainability and also described a robust and stable LA program. Despite previous issues securing funding, the program became a priority of the administration and funding was no longer an issue. MSU did not return to expanding their use of local data citing a need for access to "guiding principles for successful data collection, analysis, and presentation" and did not report any progress in addressing the needs of their Indigenous students, which was a need in 2017.

Overall, the change efforts at MSU included a range of levers. Analysis of local data functioned as an initial motivating lever, followed by levers included in course coordination and the LA program that prepared and enabled the department to reach their active learning goals. A significant turning point was their one-time funding through the Vice Chancellor's office, supported by the Dean of the college, which allowed them to implement the LA program, subsequently highlighting its success to administrators, and securing funding that facilitated the program's sustainability.

MSU relied on a variety of levers to different degrees to sustain their efforts until permanent funding was in place. They incentivized permanent positions for coordination and created a permanent position for the LA director. They also collaborated outside of the department. First with the Physics Department and then with the College of Education. Meanwhile all of these levers were maintained and supported by motivated local change agents. MSU's integrated approach, which adapted based on need, appears to have contributed to their success in sustaining their efforts to implement active learning.

Large State University

LSU is an example of a department that made minimal progress toward their proposal goals which included: 1) rewriting the Precalculus curriculum, 2) solidifying the use of active learning in Calculus 1, 3) creating a mentorship program for instructors new to active learning, and 4) expanding the use of local data to refine and redesign efforts.

Fall 2017. At the time of their proposal, LSU utilized levers from all three themes. Their proposal described one lever to motivate and provide rationale and three levers to prepare and enable. LSU's levers to motivate and provide rationale acted primarily on individuals, although their levers to prepare and enable acted on both individuals and academic units. During this time, LSU's change efforts were focused on the use of local data (LMPR6) and the dissemination of active learning materials (LPE8).

Fall 2020. In the fall of 2020, LSU reported mixed progress toward their active learning objectives. Areas of improvement included more consistency in the coordinated Precalculus course and more buy-in from instructors teaching these courses. However, despite relying on similar levers, active learning efforts in Calculus 1 were stalling. Relevant to these differences is the segregated nature of the Precalculus course. At LSU, the Precalculus course is run through the Mathematics Learning Centre (MLC), and the rest of the courses in the P2C2 sequence are housed in the mathematics department. This separation likely led to differences in the strength of similar levers used.

Levers to prepare and enable. The increased use of active learning in Precalculus relied on the use of three levers: material resources, professional development, and leadership of a local change agent. Revising active learning materials for Precalculus was a major component of the LSU proposal. Despite not making progress in this revision, materials remained a central lever in their active learning efforts (LPE8). Those teaching Precalculus, housed in the MLC, were strongly encouraged to use these materials. Their use was essentially compulsory as the MLC Director, the person leading active learning efforts in Precalculus, was also responsible for hiring instructors for the Precalculus course.

In addition to materials, the MLC hosted a formal professional development meeting at the beginning of each semester (LPE7), led by the MLC Director and attended by everyone teaching Precalculus. These meetings aimed to encourage active learning and included outlines for the implementation of active learning in the classroom. A major goal of these meetings, reported by the MLC Director, was to generate buy-in for the use of active learning, particularly among newer instructors. Professional development for Precalculus continued informally throughout the semester via course coordinators who advised instructors in implementing group work. Central to the use of materials and professional development was strong leadership by the MLC Director (LPE12).

Calculus 1, run through the Mathematics Department, also relied on the dissemination of materials. However, a change in leadership led to changes in the levers reported at the time of the proposal in the Fall of 2017. The previous course coordinator for Calculus 1 collaborated with the MLC Director (LPE11), using the structure of the Precalculus program. In addition to encouraging the use of active learning materials, the Calculus 1 coordinator also utilized the communities of practice lever, meeting regularly with Calculus 1 instructors to discuss and share materials. This progress was brief, the Calculus 1 coordinator working with the MLC Director left the position, becoming Associate Dean, and no longer had a role in change efforts. After his departure, LSU reported struggles maintaining the active learning curriculum, especially with respect to buy-in from those teaching the course.

Fall 2022. The final report from LSU reflected four levers in their change efforts: local data, professional development, resources collections or digital libraries, and local leaders or change agents. These levers were essentially unchanged from the time of their proposal, except for funding which they were not able to secure since their proposal submission. However, this consistency does not reflect the differences in progress between Precalculus and Calculus 1.

Overall, LSU used local data as an initial motivation for their change efforts. They had a brief period in which leaders in both the MLC and the Mathematics Department collaborated to promote active learning in Precalculus and Calculus 1. However, after a shift in leadership, the gains made in Calculus 1 were stifled. Precalculus continued to consistently use active learning, leveraging materials and professional development, both supported by their most critical lever, leadership.

Conclusion

As shown in Table 2, both MSU and LSU made use of multiple levers across all three points in time. Both institutions used local data to motivate and provide rationale (LMPR6). In Fall 2020 we saw that both institutions made robust use of professional development (LPE7) and that LSU also relied heavily on resources (LPE8) and local leaders (LPE12). The reliance on local leaders at LSU was problematic when the leader in the department, an ally of the leader in the Math Learning Center, left the department for the dean's office. This left both a gap in leadership in the department and left the leader of the Math Learning Center somewhat disconnected from the department. In contrast, MSU relied less on individuals and put structures in place that were sustainable. Additionally, they were actively seeking continued financial support in Fall 2020, ultimately leading to permanent funding in Fall 2022. In comparison, LSU was not able to secure continued funding beyond 2017.

At MSU there was a clear thread from 2017 through 2022 of local leadership (LPE12) and growing opportunities for professional development (LPE7), both through course coordination. MSU was also able to demonstrate how their change initiative aligned with the interests of upper administration (LSSA14). The identification of this lever for change makes a modest contribution to the change literature and levers for change detailed by Laursen et al. (2019). Another important difference that likely contributed to the differential success of the two change initiatives was structural in nature. At LSU, precalculus was run out of the Math Learning Centre, which potentially did not position the director to be a central figure in the mathematics department. In contrast, at MSU members of the mathematics departments were central and consistent change agents.

In addition to contributing to the change literature, we hope that these two stories of change provide guidance for others wishing to embark on their own departmental transformation efforts. Key takeaways from these data include caution on relying too heavily on individuals, garnering the support of upper administration (which can lead to resources for sustainability), and putting structures in place (e.g., professional development for LAs) that allow for continuity and sustainability.

Student Thinking with a Non-Traditional Linear Coordinate System

Inyoung Lee
Arizona State University

This study explores different ways that linear algebra students reason with a non-traditional linear system, referred to as the Gulliver system, in a task-based clinical interview. Using the constructs of Naming and Locating developed in the conceptual framework, an a priori analysis outlines how students may engage in Locating and Naming tasks. The a priori analysis was used for data analysis as a basic framing. Students' engagement with the non-traditional linear system and the refined and extended a priori analysis will be presented. Students' adoption of their previous experience with the Cartesian coordinate system will be also discussed.

Keywords: Linear Algebra, Coordinate Systems, Conceptual Framework, RME, A priori analysis

Coordinate systems are widely used in secondary and collegiate mathematics. Students learn the Cartesian coordinate system in their early mathematics, where they associate an ordered pair (a, b) with a point and use it to graph equations in the plane. Later in Pre-Calculus and Calculus, many students progress to explore a new coordinate system, the Polar coordinate system. In Linear algebra, students encounter non-traditional linear coordinate systems that are similar to the Cartesian coordinate system but scaled and/or rotated. There are a decent number of studies which focus on student reasoning with the Polar coordinate system and how their understanding of the Cartesian coordinate system impacts their reasoning with the Polar system. (Montiel et al., 2008; Montiel et al., 2009; Montiel et al., 2012; Moore, Paoletti, & Musgrave, 2014; Sayre &Wittmann 2008) Despite the growing importance of linear algebra in STEM education (Tucker, 1993), there is a noticeable gap in study concerning student thinking of a non-traditional linear system and how students employ their understanding of the Cartesian coordinate system when engaging with a non-traditional linear system. This report foregrounds a non-traditional linear system that shares similarities with, yet is distinct from, the Cartesian coordinate system.

Literature

Some studies found that students' understanding of the Polar coordinate system is closely related to their understanding of the Cartesian coordinate system and sometimes students' familiarity with the Cartesian coordinate system delays the shift to other coordinate systems (Arcavi, 2003; Hillel & Sierpinska, 1993; Montiel et al., 2008; Montiel et al., 2009; Montiel et al., 2012; Sayre &Wittmann 2008). For example, Montiel and his colleagues found that students applied the *vertical line test* to a graph defined in the Polar coordinate system to check if it is a function over the Polar coordinate system even though the vertical line test is no longer useful. Similarly, Moore et al. (2014) found that the convention from the Cartesian coordinate system of using the ordered pair (input, output) may be problematic when constructing the Polar coordinate system which uses the reversed ordered pair (output, input).

In linear algebra, Wawro et al. (2013) created a lesson which includes a task that uses $y = x$ and $y = -3x$, as the new axes, to rename a location in a non-traditional linear system. Zandieh et al. (2017) found that students in the class using the task sequence symbolized locations in three different ways. (1) Some students renamed locations using geometry by identifying which new axis to treat as the x and y and the size and direction of a unit vector. (2) Other students used a matrix equation: setting up a matrix equation $A\boldsymbol{x}_{[a\ system]} = \boldsymbol{x}_{[another\ system]}$, solving for components in the two-by-two matrix A, and using A to convert names from a system to the other. (3) Another way that students renamed involves the idea of linear combination. Students found two vectors $\begin{bmatrix}1\\1\end{bmatrix}$ and $\begin{bmatrix}-1\\3\end{bmatrix}$ to match the two new axis directions of $y = x$ and $y = -3x$. Then, they determined c_1 and c_2, how much in each direction should travel along them in reaching a location in the plane. The sum of the scalar multiplications, $c_1\begin{bmatrix}1\\1\end{bmatrix} + c_2\begin{bmatrix}-1\\3\end{bmatrix}$, provided a coordinate pair with respect to the Cartesian system.

Other studies have discussed basis or other aspects of linear combinations but did not refer to these as coordinate systems. (Bernier & Zandieh, 2022; Bettersworth et al., 2022; Dogan, 2019; Dreyfus et al., 1999; Turgut et al., 2022; Wawro et al., 2012) Given that studies of non-standard linear coordinate systems are rare in the literature, this study intends to begin filling this absence.

Conceptual Framing

The conceptual framework was developed from the author's calculus and linear algebra textbook analysis (Author, year). It can serve as a useful framework when designing tasks that involve coordinate systems and analyzing students' mathematical activity. (Lee, year) The coordinate system framework includes two fundamental processes with representations: Naming and Locating. In Naming, a location in space is being measured following the convention imposed by a coordinate system and creates the measurement, a name. For example, a location in the 2D plane gets its name as (1,1) with the Cartesian coordinate system. On the other hand, in Locating, an existing name creates its location in space following the convention imposed by a coordinate system. An example of Locating is that the ordered pair (1,1) puts on a specific point in the Cartesian coordinate plane. Figure 1(left) illustrates that Naming and Locating are the reverse processes to each other. The two processes can be extended to represent an object with multiple coordinate systems: Re-Naming and Re-Locating. In Re-Naming, a location that has been measured by a coordinate system gets its new name measured in a new coordinate system that is laid atop the location. That is, the location previously paired with (1,1) is being renamed with $(\sqrt{2}, \frac{\pi}{4}) \approx (1.414, 0.785)$ in the same space using the Polar coordinate system (Figure 1, middle). On the other hand, in Re-Locating, an existing name creates two different locations in space depending on coordinate systems being used. The new location may appear different from the first, but they share the same name. For example, (1,1) corresponds to two locations: one defined by a horizontal and vertical distance of 1 each, and the other determined by a distance of 1 from the origin and an angle measure of 1 radian from the horizontal axis. (Figure1, right)

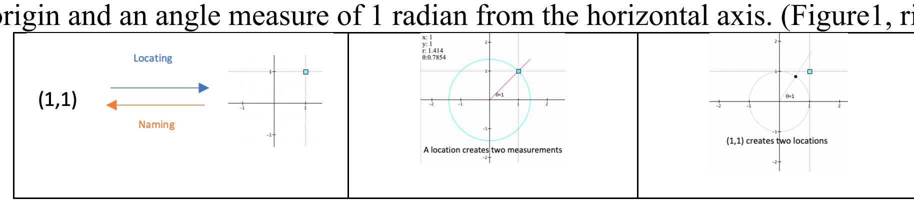

Figure 1. Naming and Locating (left), Re-Naming (middle), Re-Locating (right)

A priori analysis

Prior to conducting interviews with students, the author described an a priori analysis of how students might engage in Locating and Naming. Students' possible steps in Locating include (1) pairing known each component in an ordered pair with a proper axis, (2) identifying the location of each component by comparing it to the unit length imposed on each coordinate axis, (3) finding the intersection that comes from two locations on the axes. Reversely, in Naming, students would do (1) splitting the known location into two locations, one on the x-axis and one on the y-axis (if it is the Cartesian system), (2) measuring the length of each location by comparing it to the unit length imposed by the coordinate system, (3) expressing the measurements on the two axes symbolically. Figure 2 outlines the a priori analysis.

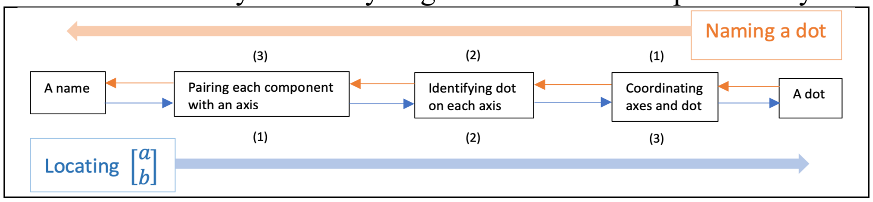

Figure 2. An a priori analysis for Locating and Naming

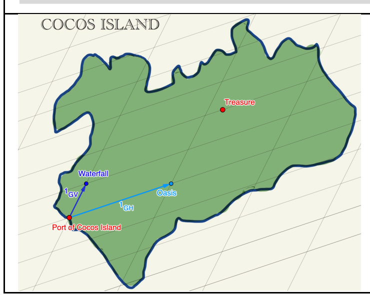
This study reports student reasoning with a non-traditional linear coordinate system in a task-based clinical interviews, designed to answer the research questions: (1) What are the different ways that linear algebra student reasons in a new linear coordinate system? (2) How do they employ their familiarity with the Cartesian coordinate system in working with the new system?

Methods

This proposal includes the first two tasks of a clinical interview, part of a longer dissertation study that consists of clinical interviews and teaching experiments. The clinical interview tasks were designed based on the central idea of Realistic Mathematics Education (RME), which emphasizes tasks to be experientially real starting point to students informed by Freudenthal (1991). A motive from the famous book "Gulliver's Travels" (Jonathan Swift, 1726) is combined with a treasure hunt. (Figure 3) Task 1 is a *Locating* task to place a dot with the number pair provided. Task 2 is a *Naming* task to name the treasure location. Both the tasks are built in the Gulliver system that is a new linear coordinate system different from the Cartesian system.

Gulliver discovered an ancient treasure map of Cocos Island in his hometown.
A grid and two arrows pointing to the location of an Oasis and a Waterfall were drawn on the map. Gulliver named the arrows $1_{GH} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$ and $1_{GV} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$.



Task 1:
Place a dot on the map indicating where $A=\begin{bmatrix} 1.3 \\ 0.5 \end{bmatrix}$ is located.

Task 2:
Describe the location of the Treasure.

Figure 3. Problem setting with Task 1(Locating) & Task 2(Naming)

Data Source and Analytic Method

The author conducted face-to-face clinical interviews with five students who have taken linear algebra at a large public university of the Southwestern United States. The students were STEM majors who had taken Calculus 1 or 2 as a prerequisite. Both their written work and interview conversations were recorded. The interview data were transcribed into spreadsheet and coded line by line, based on the author's a priori analysis. Whenever students engaged with the steps outlined in the a priori analysis, their quotes were noted and examined to characterize their reasoning. Additionally, the steps were refined and extended, resulting in the separation of one step into two distinct steps. All the names used in Results are pseudonyms reflecting their ethnicity.

Result

As shown in Figure 3, each task has its own goal aimed at examining student reasoning that corresponds to Locating and Naming. In this section, the different ways that linear algebra student reasons with the Gulliver coordinate system within steps outlined in the a priori analysis will be explored.

Locating: Determining a location in space

The students have demonstrated their ways of determining location in space. They coordinated the components in $\begin{bmatrix}1.3\\0.5\end{bmatrix}$ with the appropriate axes and identified the intersecting point corresponding to 1.3 and 0.5 on the axes.

Pairing each component with an axis

Given the components of A as 1.3 and 0.5, the participants positioned them on either the axes of the Cocos Island map or the axes separately created in a blank space. Positioning the number values requires the students' two-step commitments. First, they figure out which component of the first (1.3) or second (0.5) is paired with each direction of the horizontal or vertical axis. Second, they compare each number value to the unit length of 1. The following excerpts illustrate how they engaged with coordinating and locating on the axes.

Hann determined that the first coordinate should be in the direction of the Oasis and then it is positioned to the right of it. "*1.3, that's going to be in the Oasis direction, so that would be somewhere here* [points to the right of the 1]*"*. Wilson also attempted to mark the number values, 1.3 and 0.5, on each direction of axis, however his pairing of the first and second component with the horizontal and vertical axis went opposite. *"to go and establish where that 1.3 , 0.5 is, 1.3 roughly there* [marks on the vertical axis, above the 1] *and 0.5 there* [marks on the horizontal axis, to the left of 1]".

Jeraldo, Wanita, and Neeman marked on axes indicating where the size of the number values is located by comparing them to the size of units. Wanita said, "*I'm in going a little bit further* [than 1 for 1.3], *and then 0.5 is a little bit less from the 1*". Neeman also mentioned "*the y* [0.5] *is the midpoint here* [points on the vertical axis]…*and then so this is 1*[points to the Oasis location, the unit], *then 1.3*[marks on the horizontal axis the right of 1]."

Coordinating axes and dot; Intersecting two locations from axes. Once the students determined the location of each coordinate on the respective axis, some of them drew auxiliary lines. For instance, Jeraldo indicated a dotted line starting at 0.5 on the vertical axis and is parallel to the horizontal axis, then made some extended portion at 1.3 vertically. He finally placed a dot A by intersecting the auxiliary segments (Figure 4. Jeraldo). Neeman also indicated some auxiliary lines in yellow that pass the two locations representing 1.3 and 0.5 on the axes he marked earlier (Figure 4. Neeman). He constructed a dot for A where the two lines intersect. The written work of Jeraldo and Neeman shows that they think of the location of [1.3 0.5] as the intersection of the extended two locations from axes. Even though the other students did not draw auxiliary lines, they seemed to engage with the intersecting process in that the final dot was marked once they determine each coordinate on its corresponding axis.

I note that the auxiliary lines are not always parallel to the Gulliver coordinate system's grids; rather the vertical part of the auxiliary lines appears somewhat perpendicular to the horizontal axis. This demonstrates that the students tend to think of perpendicular grids even when it does not precisely match the appropriate projections of measurements from the axes. The students' final answers to this task are shown in Figure 4.

				Hann	Wilson	Jeraldo	Wanita	Neeman

Figure 4. Location of $\begin{bmatrix}1.3\\0.5\end{bmatrix}$

Naming: Obtaining coordinates-pair

Similar to Task 1, the students utilized their understanding of the rectangular coordinate system to determine the coordinates of the Treasure location in Task 2 (Figure 3). One of the participants, Hann, seemed to first look for measurement on each axis and then coordinate them with their corresponding axis. "*The location of the treasure looks to be probably about* <u>*1.3 in that* [Oasis] *direction and then exactly 2 in the waterfall or y direction*</u>".

Some of the participants described how to obtain the coordinates-pair from the Treasure location given on the map. I present two distinct ways that students have engaged in obtaining the coordinates: Projecting the location onto axes and Over-and-up reaching the location.

Coordinating axes and dot; Projecting a given location onto axes. Jeraldo and Neeman indicated that they need some kind of projection to obtain measurements of the Treasure location. Jeraldo noted, *"If* <u>*we follow, like, the parallel line*</u>*, it's almost at the same exact place* [refers to the Task 1's horizontal component, 1.3]. *So, I'd probably say it's around the same as the previous at 1.3".* From his description, he seemed to be looking at the slanted projection from the Treasure location onto the Gulliver horizontal axis, recognizing that the slanty line passes through location A that he had placed earlier with 1.3 in Task 1. Similarly, Neeman's written work depicted reasoning with a slanted projection indicated from the auxiliary lines in black (Figure 5. left). He drew the lines to pass through the Treasure location and to be parallel to the Gulliver coordinate grids. The measurements that he obtained result from the slanted projection of the Treasure location onto the two axes. "*This* [where the slanted projection meets on the horizontal axis] *is a little bit before the 1.3, that is like 1.2. And it's* [where the slanted projection meets on the vertical axis] *on this one* [points the Waterfall]*, which is 2. So, let's say it's a 1.2 over 2".*

Figure 5. Written work of Neeman (left) and Wanita (right) in Naming

Coordinating axes and dot; Over-and-up reaching a location. Another student, Wanita, also demonstrated her reasoning with the rectangular coordinate system to obtain the coordinates of the Treasure. She illustrated the process of moving along the Gulliver horizontal axis and then turning up towards the Treasure location (Figure 5. right).

Wanita: It would be like 1.5 and then 2. I'm supposing the port is at the zero. It would be like 1.5, 1.6 or so. <u>It's going up [indicates the horizontally positive direction] and then 2.</u>

Interviewer: Why do you say 1.5 or 1.6?

Wanita: …2 is over here [points to (2, 0) location] 1.5 should be like, right in the middle, and then you just go up [draws an arrow from the middle to the Treasure] and that's where the treasure would be…T is equal to the 1.6 and then 2.

I note that the two distinct ways of finding the coordinates-pair, slanted projection onto axes and over-and-up process, are not exclusive to each other. For example, Jeraldo, one of the students who engaged in the slanted projection, initially answered that the horizontal coordinate has to be 1.5 by over-and-up process, similar to Wanita. He was looking at the locations of one unit, two units, and midpoint on the Gulliver horizontal axis, estimating the right location to be 1.5 in order to reach the Treasure. Soon after, he realized that the slanted projection is not precisely matching the upward movement from 1.5 and switched over to the projection onto axes way from the over-and-up process.

Types of names in Naming

Once the participants determine the measurements for the Treasure location, some students attempted to represent the coordinates-pair in different ways, whether in response to my request or without any prompting. There were three different ways of representing the same coordinate found in students written expression: Vector form $\begin{bmatrix} a \\ b \end{bmatrix}$, Linear combination with opaque symbolics of 1_{GH} and 1_{GV} provided in the problem, and Linear combination with actual vectors $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$ and $\begin{bmatrix} 0 \\ 1 \end{bmatrix}$.

Hann's written answer includes all three representations. He first wrote $\begin{bmatrix} 1.3 \\ 2 \end{bmatrix}$ in a vector form and represented it using the linear combination format employing the provided opaque symbolics, 1_{GH} and 1_{GV}. (Figure 6) He commented that the symbolics could be substituted with the actual vectors consisting of 1's and 0's.

	1. Vector 2. Linear combination with opaques 3. Linear combination with actual vectors

Figure 6. Hann's symbolic representations for the same coordinates-pair

Wilson chose to represent the determined coordinates using the linear combination format as well in addition to the vector form. (Figure 7) The distinction between Wilson and Hann's representation is that Wilson made a slightly different modification to the opaque symbolics. That is, GH and GV have been used instead of 1GH and 1GV. This is an indication that Wilson conceives of the number '1' in the opaque symbolics of 1GH and 1GV as an actual measurement rather than as a symbol emphasizing a unit.

	1. Vector 2. Linear combination with opaques 3. Linear combination with actual vectors

Figure 7. Wilson's symbolic representations for the same coordinates

The other three participants, Jeraldo, Wanita, and Neeman represented the Treasure location as a vector form only using the measurements obtained from either slanted projection or over-and-up. I note that Neeman read the vector form of $\begin{bmatrix} 1.1 \\ 2 \end{bmatrix}$ "*1.1 over 2*". His treating the vector like a fraction sometimes comes a long later in the interview when he writes $\begin{bmatrix} \frac{14}{6} \end{bmatrix}$ to mean $\begin{bmatrix} 14 \\ 6 \end{bmatrix}$.

Discussion

The students have adopted their previous experience with the rectangular coordinate system to answer the first task, even though the Gulliver coordinate system is a non-Cartesian rectangular system. This aspect is well represented by one of the interview participants, Hann's comment "*Even though it's not rectangular, there's no reason not to act like it is*". The following lists different pieces of the rectangular coordinate system understanding that the participants brought to bear: identifying units as two directional line segments, labeling with 'x' and 'y', employing perpendicular axes, and pivoting a reference point. While some of them assisted the students in addressing the tasks, others were applied even though they were no longer useful.

Jeraldo called the 1_{GH} and 1_{GV} as matrices and noted that they represent one unit in each direction of x and y. The letters x and y, widely used in the mathematical community for coordinates in the rectangular coordinate system, have been used to denote the first coordinate as x and the second coordinate as y. *"I remember in back in the class that the matrices they obviously defined <u>that the first one represents the x coordinates, the second one equals the y.</u> So, x y x y* [writes x's and y's next to 1 0 and 0 1]". (Figure 8. Left) Wanita drew perpendicular axes on a blank space, and then placed two dots one on the horizontal axis and one on the vertical axis to coordinate them with $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$. She indicated that these dots are pointing to the Oasis and Waterfall locations. (Figure 8. Middle) Neeman indicated the Port of Cocos Island on the map where the two axes intersect as the coordinate pair [0, 0]. That is, the reference point was identified as two components of null. He brought the letters x and y to indicate the first coordinate and the second coordinate, respectively and noted x to be corresponding to the horizontal axis and y to be the vertical axis. Additionally, he drew the perpendicular axes labeled with x and y. (Figure 8, right)

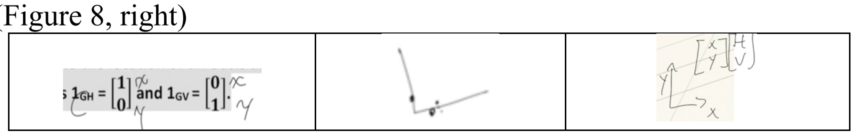


Figure 8. Employing rectangular coordinate system: Jeraldo(left), Wanita(middle), Neeman(right)

The Locating and Naming activities are reverse processes to each other. The processes were outlined in an a priori analysis in Figure 2, and it has been further refined in two ways: variations within a step and separation of one step into two distinct steps. Students have been engaged differently with the remaining steps when they progress to the subsequent set of tasks following Task 1 and 2.

Exploring How Use of a Shared Google Doc for Collective Proof Construction Supports Students' Mathematical Progress

Diana Salter
Portland State University

Tenchita Alzaga Elizondo
University of Texas Rio Grande Valley

While the pandemic brought much hardship for mathematics education, it also brought opportunity for ingenuity and transformation. This study builds on results from prior work that found Google Docs to be rich tools that supported students in effectively engaging in collaborative proof activity in a remote introduction-to-proofs course. To study if Google Docs would have similar benefits for students' collective proof activity in a face-to-face setting, we investigate how two students in a face-to-face course leveraged a shared Google Doc to support their collaborative work on a proof construction task. We found that the students used the shared Google Doc to support their collective proof construction in similar ways as students in the remote class. In addition, we observed that the Google Doc was an inherent component of students engaging in an active proof writing process.

Keywords: Proof Construction, Technology, Google Docs, Collaborative Activity

For mathematics education the COVID-19 pandemic brought drastic changes in how courses were structured and how interactions between students and teachers took place (Tate & Warschauer, 2022). While these changes brought many challenges both educationally and emotionally (Engelbrecht et al., 2023), they also brought the opportunity for ingenuity and for reimagining what mathematics classrooms could look like. Specifically, in many ways the pandemic forced educators to find new means by which to use technology to engage students with mathematics and with each other, potentially, enriching students' learning experiences. Literature on educational technology has highlighted how we can create rich learning environments with the aid of technological tools (e.g., Clark et al., 2007; Öner, 2008; Stahl, 2006). As we transition (or have transitioned) back to face-to-face (F2F) courses, it becomes imperative to reflect back on what we have learned as educators from our experience teaching remotely. Specifically, we should consider what aspects of our remote mathematics courses can be (and perhaps should be) transferred to F2F. Studying remote instruction in an introduction to proof course, Alzaga Elizondo (2022) found valuable implications of using Google Docs for students' collective work in small groups. Most notably, she found that by coordinating the use of Google Docs with Zoom, students were able to actively engage with one another's thinking and produce truly collaborative work. Subsequently, we wondered if and how shared Google Docs would provide similar support to students in a F2F version of this course. In this paper, we present a case study of two students working on a task to develop a proof in a F2F class with access to a shared Google Doc. We explore the connection between the students' use of the Google Doc to support their collective proof activity and their proof construction progress.

Theoretical Grounding

To study the role that the Google Docs played in students' collective proof construction, this study builds on the work done by Alzaga Elizondo (2022). Alzaga Elizondo studied students' small group activity in a synchronous online Introduction to Proofs course where she investigated how students operationalized technological tools (e.g., Zoom, Google Docs) in the remote environment to engage in various collective proving activities (i.e., proof construction, defining, conjecturing). To analyze the students' tool use, Alzaga Elizondo leveraged the theory of Instrumental Genesis (Rabardel, 2002) which describes a reciprocal relationship between artifacts (or tools) and their users and the impact of that relationship on cognition. Any given tool can be transformed into an instrument by assigning it a *utilization scheme* (designated methods for using the tool) for a specific *goal directed activity* (Béguin & Rabardel, 2000; Carvalho et al., 2019). In her study, Alzaga Elizondo identified several collective instruments that students developed by coordinating the different technological tools available to them. These were collective in the sense that students coordinated their utilization schemes across different tools to develop collective schemes that were closely tied to their mathematical activity. For instance, students developed an instrument to *illustrate a new idea by writing a mathematical statement* where they would coordinate the use of Zoom and Google Docs to verbally communicate and simultaneously visually illustrate a new idea. Simpler instruments were created to support the development of more complex ones, these are identified in Table 1 with the supportive instruments italicized. We conjecture that students may develop similar instruments in a F2F class where, in this setting, students coordinate their use of the Google Doc with their verbal face-to-face interactions rather than through Zoom.

Table 1. Collective Instruments

Instrument	Observed Student Action
Engage in collective argumentation by coordinating visual mediators and verbal communication	Discuss and debate ideas by using visuals on the Google Doc to illustrate verbally spoken idea.
Illustrate new idea by writing a mathematical statement	Write mathematical statement on Google Doc to illustrate an idea to group before group has agreed on new idea.
Analyze shared idea by referencing written text	Reference written text by highlighting (or placing cursor next to) text on the Google Doc and/or by using indexical terms like “this” or “that”.
Develop shared understanding by introducing diagrams and examples	Adding examples or diagrams to Google Doc for the goal of developing shared understanding among group.
Co-construct a group solution by refining shared text	Create final solution by refining written text on the Google Doc.
Execute solution by repurposing illustrated idea	Using existing text in the Google Doc for the final solution that was not originally written for that purpose.
Execute solution by validating illustrated idea	Keeping text in the Google Doc that was added to final solution for the purpose of illustrating a new idea.

Further, Alzaga Elizondo conjectured that use of these instruments supported students in engaging in a *process approach* to writing, which describes an iterative collective writing process in which students plan, draft, and revise repeatedly by incorporating feedback from peers and the instructor (Graham & Perin, 2007; Sun & Feng, 2009). These kinds of activities can reflect more meaningful engagement with proof-based tasks, as they promote exploration and testing which have been noted to reflect more authentic mathematical practices (Larsen & Zandieh, 2008; Melhuish et al., 2022; Öner, 2008). As such, students, regardless of course modality (i.e., face-to-face or remote) should be encouraged to engage in a similar writing process. The work presented here builds on Alzaga Elizondo's (2022) work by investigating how and/or if the collective instruments she identified appeared in one group's collective proof construction when using Google Docs in a F2F course. Further, and most notably, it investigates how the students' Google Doc use supported them in engaging in a process approach to collective proof construction.

Methods

Data Collection and Episode Selection

The data for this study is from a university introduction-to-proof course that was part of a larger NSF-funded project (DUE #1916490) that developed introduction-to-proof curricula and accompanying instructor support materials. The inquiry-oriented curriculum included tasks designed for small group collaborative work. In this 10-week F2F course each student had access to an iPad which enabled each group of students to share a Google Doc to work together on tasks during small group work. A stationary camera and iPad screen recordings captured one focal group's interactions each day (26 days total).

This study focuses on two students' collective work on one task during one day of this course. Jake and Roger (pseudonyms), worked together on proving the sequence $a_n = \lfloor 10/n \rfloor$ is eventually constant. The class had previously established a definition for an eventually constant sequence: *a sequence a_n is eventually constant if there exists a natural number n such that for every natural number $k \geq n$, $a_n = a_k$*. In other words, a sequence is eventually constant if at some point it becomes and stays constant. The Google Doc that the students used included the task and this definition at the top of the page. This episode was selected because the students worked together in their small group to complete the task and there was substantial discourse, both written using the Google Doc and verbal, between the students.

Data Analysis

To begin our analysis, we created a multimodal transcript (Hoffman, 2018) that captured both the students' written work on their Google Doc and their spoken interactions. Since the students' iPads recorded both their written and spoken work, time stamps added to our transcript provided an accurate record of the temporal relationship between spoken and written statements. Then, using the observed student actions in Table 1 as operationalizations of the collective instruments, the first author identified for each of the spoken and written communications in the multimodal transcript if and when a collective instrument from Table 1 was used and described any mathematical progress reflected in the communication. The second author reviewed the first author's identifications and descriptions and any disagreements were resolved through discussion. Through the analysis the authors found that students developed a sequence of proof drafts. Together, the authors then identified six points in the students' work on the Google Doc that represented completion of interim drafts of their final solution (see Figure 1). We identified a point in their Google Doc as a draft if it represented a significant mathematical change from the previous draft and seemed to be the culmination of the students' argumentation at the time. We then were able to describe how the students' instrumentation process impacted their progress through development of the draft. We present the findings from this analysis in the following section.

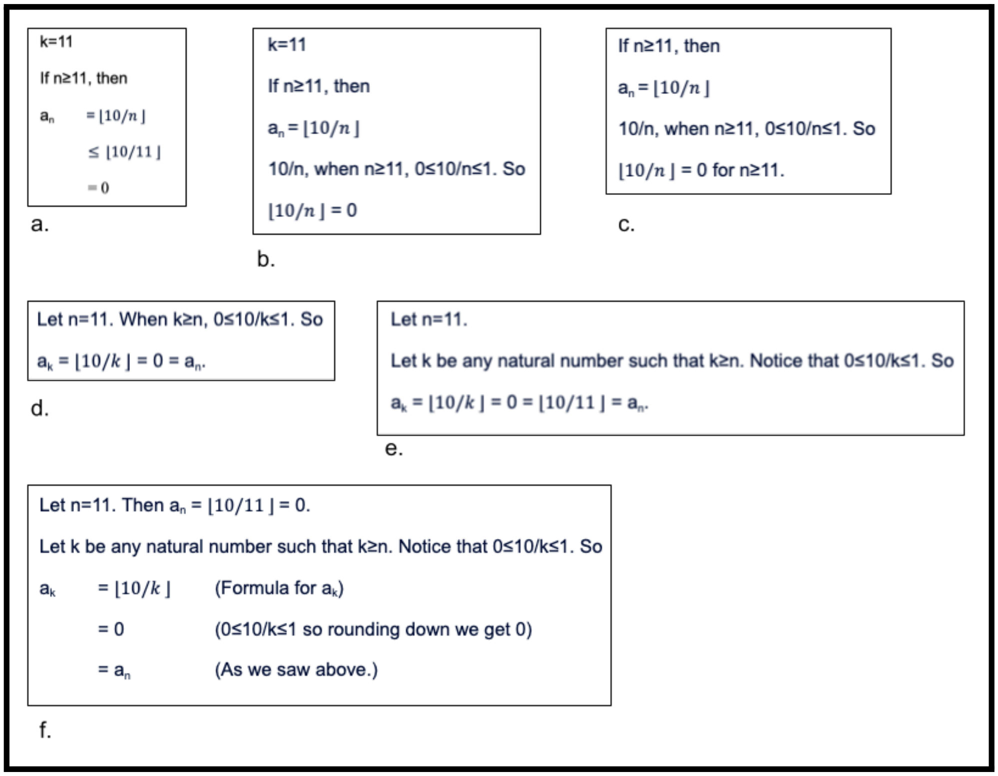

Figure 1. Students' drafts of their proof that the sequence $a_n = \lfloor 10/n \rfloor$ is Eventually Constant

Results

In the episode analyzed below we observed students using the Google Doc as a tool to engage in collaborative proof activity. Here we report the students' progress through the development of each draft, highlighting their use of collective instruments to achieve each draft.

Development of Draft 1

To start off their work, Jake suggested that they write a "few terms of the sequence and just see what it converges to". Without verbal confirmation, Roger responds by writing the first few values of the sequence in the Google Doc, writing "$a_n = 10$, 10/2=5, 3, 2, 2, 1, 1, 1, 1, 1, 0, 0, 0,...". Simultaneously, Roger verbalized his reasoning: "10 over 8, 1, 10 over 9, 1, 10 over 10, 1, and then 10 over 11, 0. I think at that point." Here Roger used the Google Doc to *develop a shared understanding by introducing examples* (i.e., the first terms of the sequence). As Roger typed, we saw evidence of Jake following along, verbally stating "and after *that* it becomes zero" at the same moment Roger says "I think at that point". In doing this, Jake is using the Google Doc to *analyze the shared idea* (the sequence terms) *by referencing text* when saying "and after *that*" where "that" referred to the 11th term in the sequence. At this point, Jake suggested that they construct a direct proof that follows the structure of the definition. Roger proceeds to *illustrate an idea by writing mathematical statements* on the Google Doc, writing

"$k = 11$, If $n \geq 11$, then $a_n = \lfloor 10/n \rfloor = \lfloor 10/n \rfloor$". As Roger is writing, Jake follows along and suggests they use inequalities instead which prompts refinement from Roger. Together, they produce the first draft of their proof (see Figure 1a).

Development of Draft 2

After a brief pause, Roger suggests "Maybe we should say something different. So like 10 over *n* when *n* is greater than 11." Simultaneously he adds to the Google Doc "10/*n*, when $n \geq 11$, 10/*n*" before the line "$\leq \lfloor 10/11 \rfloor$". This suggests Roger recognizes the inequality in Draft 1 is not correct and chooses to *illustrate a new idea by writing a mathematical statement* in the Google Doc to fix this error. After Roger writes this line in the Google Doc Jake responds by saying "is less than 1" (in other words, proposing "< 1" should follow the "$10/n$" Roger has just written). Here, Jake is not only suggesting the completion of this line, he is also communicating to Roger that he concurs with what Roger has written so far. As such, Jake is using the Google Doc to *execute a solution by validating an illustrated idea* (the line Roger has just added). In other words, Jake agrees with Roger's new addition and thinks it should be kept as part of their proof. Robert acknowledges Jake's idea and proposes a variation, saying "well yeah right sort of bound it like this. It's between zero and one." As he says this, Roger replaces "$10/n$" with "$0 \leq 10/n \leq 1$," a compound inequality. Again, using the Google Doc to *illustrate a new idea by writing a mathematical statement* that he only partially communicates verbally. Jake then again *executes a solution by validating an illustrated idea*, concurring with Roger's compound inequality by saying "Oh true. Yeah, it's not just less than one, it's [...] positive." With this validation, Roger then changes "$\lfloor 10/11 \rfloor = 0$" to "$\lfloor 10/n \rfloor = 0$." This change moves the last two lines of the proof closer to showing how the sequence formula generates 0 when $n \geq 11$ and results in Draft 2 (see Figure 1b).

Development of Draft 3:

Roger's addition to the last line in Draft 2, "$\lfloor 10/n \rfloor = 0$," prompts Jake to respond verbally "So in that case a sub n equals zero for *n* greater than or equal to 11." Jake is observing that the sequence formula does equal zero, as Roger has written in the Google Doc, but only when $n \geq 11$. Roger then *illustrates this new idea by writing the mathematical statement* "for $n \geq 11$" directly following "$\lfloor 10/n \rfloor = 0$." Roger *validates this illustrated idea* verbally when he follows up by saying "Yeah". This addition directly connects $\lfloor 10/n \rfloor = 0$ to the index value where the sequence becomes constant. This new addition prompts Roger to say "I guess we don't need *k*" and delete "$k = 11$" from the first line. Presumably, Roger suggests deleting *k* because it is now an unused variable in their proof (see Figure 1c).

Development of Draft 4

Prompted by Roger removing the variable *k* from the proof, Jake makes the case that this proof does require two variables. He says, "Yeah. I guess maybe just to make it match the definition as much as possible, what if you said at the beginning let *n* be 11. And then we used *k* after that [...] like let *n* be 11 and *k* is greater than *n*." Roger takes Jake's suggestion and adds "$Let\ n = 11.\ When\ k > n$" to the beginning of the proof, *illustrating a new idea* (Jake's) *by writing the mathematical statement* at the beginning of their proof draft. Further, Roger *executes the solution by* (implicitly) *validating the illustrated idea* when he keeps the new text and *illustrates his own new idea* by refining the rest of the proof to be consistent with this change saying, "I think I can actually cut some of this out. Let's see." He proceeds by deleting the first few lines of their proof and, changing "$0 \leq 10/n \leq 1$" to "$0 \leq 10/k \leq 1$," and changes "$\lfloor 10/n \rfloor = 0$" to "$a_k = \lfloor 10/k \rfloor = 0$" to align with the new use of "*k*" leading to Draft 4 (see Figure 1d.). Jake follows Roger's written work and eventually *validates the illustrated idea* by verbally rephrasing the argument being presented in their current draft. With the addition of these two variables in Draft 4 the students refined their proof to better match the structure of the definition of an eventually constant sequence.

Development of Draft 5

A few minutes later, with a hint from their instructor, the students have added "Let *k* be any natural number" to the beginning line of their proof. The addition of this line in the Google Doc prompts Jake to say "might need to combine *these* two statements here. I'm going to take out the "when" and say "and" or "such that". At this point, Jake is *analyzing a shared idea by referencing* lines in the proof when he says "*these* two statements here." He follows up by *illustrating his idea,* replacing "When" with "such that" so the text that defines the variable *k* now reads "Let *k* be any natural number such that $k \geq n$." This prompts Roger to follow a similar pattern when he says "I think *this* should be a new sentence. Notice that." Like Jake, Roger begins by *analyzing their shared text by referencing* a line in their proof when he says "*this* should be" and then *illustrates his new idea* when he then adds "Notice that" before "$0 \leq 10/k \leq 1$" which separates this statement from the definition of the variable and results in Draft 5 (see Figure 1e.). While minimal, the refinement in this draft supported the readability and logic flow of the proof.

Development of Draft 6

The students make two changes between Draft 5 and their final proof, Draft 6. Roger says, "[The instructor] might want *these* on new lines. He kind of likes writing justifications." Here Roger *analyzes their shared text by referencing* "these" lines in their draft. He then breaks the last line of Draft 5, "$a_k = \lfloor 10/k \rfloor = 0 = \lfloor 10/11 \rfloor = a_n$," into individual lines so that he can *illustrate his new idea by* adding justifications for each of those steps (see Figure 1f.). The second change they make is led by Jake when he says, "Maybe we should put in a part where it says then a sub n equals [mumbles to self]." As he's talking, he *illustrates his new idea by* adding "Then $a_n = \lfloor 10/11 \rfloor = 0$" following "Let $n = 11$" in the first line of the proof. This addition prompts Roger to delete "$= \lfloor 10/11 \rfloor$" from the second last line in the proof. This suggests Roger *validates* Jake's *illustrated idea* as Roger recognizes they do not need this at the end of the proof if they have already established it at the beginning. This change brings them to Draft 6, their final proof.

Discussion

These results show how a group of students used a Google Doc as a collective instrument in a F2F course to support their process of collectively developing a proof. By coordinating use of the Google Doc with their verbal F2F interactions, we saw similar collective instruments developed as Alzaga Elizondo (2022) found in a remote class, including *illustrating a new idea by writing a mathematical statement* in the Google Doc, *analyzing a shared idea by referencing written tex*t in the Google Doc, and *executing a solution by validating an idea illustrated* in the Google Doc. This suggests the productive use of Google Docs for collective activity extends beyond the online setting.

Further, throughout the students' work, we found that as a result of sharing and debating different ideas the students iteratively refined their proof, developing several drafts of this proof throughout their collective work. In other words, we found students engaging in a *process approach* to proof writing. Most notably, we found that the students' use of the Google Doc not only supported this refining activity, it was inherently tied to it. The results presented above, highlight *how* students used the Google Docs to engage in this process approach. In particular, there were multiple instances of a mathematical statement written in the Google Doc that served as a springboard for subsequent mathematical ideas. Frequently, when a student *illustrated a new idea by writing a mathematical statement*, it was immediately followed by a student *analyzing this shared idea by referencing this text in the Google Doc* with a verbal remark that reflected building on the referenced text. Often this cycle continued with the analysis comment leading to *executing a solution by validating an illustrated idea.* The validation was sometimes in the form of verbal agreement, but frequently the validation was implicit in that one student would just add to another's idea suggesting they accepted it. As an example, while developing Draft 4, Roger removing k from the Google Doc was the springboard that prompted Jake to suggest changing the variable definitions. Roger then executed and validated Jake's idea when he added k back into the Google Doc. This, in turn, served as a springboard when it prompted Roger to delete lines that were no longer needed.

We conjecture there may be several reasons the students' use of the Google Doc instruments supported their progress through this proof construction task. The Google Doc provides a written format and, unlike spoken ideas, mathematical statements placed in a Google Doc do not disappear into thin air. Relative to spoken ideas, Google Doc ideas give students something visual to consider, acting as a visual mediator (Sfard, 2008) for the students' communication. In addition, ideas in the Google Doc provide the writer with a way to express a thought they may not be able to adequately verbalize. As a written format, the Google Doc plays two roles. It is both the place where students record their interim written ideas as they work and the place where their final solution lives. As a result, when a student is considering an idea presented in a Google Doc, the format of the presentation bears some resemblance to a solution. The format itself suggests progress toward a solution. At the same time, an idea in the Google Doc is easily editable by all group members. This combination of a format that moves toward a solution and is easy to edit may well invite student participation and inspire ideas.

This case study explored how a shared Google Doc supported a small group of students working on developing a proof in a F2F class. Future research could explore the role Google Docs might play when students were faced with other types of mathematics tasks besides developing a proof. Also, while we highlight certain advantages of the Google Doc, we wonder how students' activity might compare if they were to use other non-technological tools like a whiteboard for instance which is also easily editable and shared by all members of the group. Overall, this study presents a case for using Google Docs in a face-to-face proof course as it can promote a more active writing process that naturally ties the students' collective discourse and sharing of ideas with a truly collaborative final solution.

Uncovering Mathematics Capital: Using Structural Equation Modeling to Investigate Interrelations with Traditional Measures of Mathematics Assets

Students enter undergraduate mathematics classrooms with a variety of mathematical backgrounds. We view these past mathematical experiences as assets that support students in their future mathematical learning. In this paper, we seek to characterize these assets by introducing a new concept in mathematics education: mathematics capital. This concept emerges from a framework connecting Archer et al.'s (2015) conceptualization of science capital and Bourdieu's seminal work on the forms of capital (1986). Survey data were gathered in Spring 2023 from a total of 219 students in undergraduate mathematics courses at an urban midwestern university. Path analyses in structural equation modeling showed a strong association between the variables of mathematics capital and self-efficacy. Other associations are also discussed. Our results indicate that mathematics capital is a measurable, quantifiable variable, independent from others. Future research is ongoing to better understand the nature of mathematics capital and how it is related to other variables.

Keywords: Mathematics capital, Self-efficacy, Mathematics mindset, Structural equation modeling, Path analysis

The current state of undergraduate mathematics education involves a multitude of variables related to student demographics and success. An important variable to student success is equity, which addresses purposeful accommodations and adaptations regarding student socioeconomic status, gender, and cultural differences (National Council of Teachers of Mathematics [NCTM], 2014). Students bring their individual characteristics and identities into the classroom, which ultimately impacts their learning experiences and success in mathematics (Gutiérrez, 2009, NCTM, 2014). In this study, we seek to identify student backgrounds, history, and characteristics that potentially impact their success in mathematics education. We view these student characteristics through a Bourdieusian style lens, parallel to the previously researched theory of science capital espoused by Archer and colleagues (2015). Herein, we describe our approach of using structural equation modeling to investigate a novel theoretical construct, which we define as *mathematics capital.* We posit that mathematics capital is a variable that can be measured and is related to other important variables in mathematics education.

Conceptual Framing

Bourdieu (1986) rationalized that each field has inherent capital veiled in three ways: economic, cultural, and social. He fashioned the idea that patterns are not coincidental but rather are researchable and employable trends in the social world. Previous research from Archer et al. (2015) widened the Bourdieusian lens from art-based concepts to include the theory of science capital in society. Through their work, Archer et al. developed a three-part model in order to quantify students' science capital. Our research extends this work to the field of mathematics.

Using the three-part model from Archer et al. (2015), we introduce the concept of mathematics capital. We build on the following three categories for our variables, analogous to Archer et al. (2015), that we posit are related to mathematics capital. The three variables, which we define below, are mathematics teaching and learning experiences, mathematics self-efficacy, and cultural capital. Additionally, we include a fourth variable: mathematics mindset. We include mathematics mindset to incorporate research from Boaler (2015) and Dweck (2006) that highlights the importance of how students' view themselves as mathematical learners and developing a growth mindset towards learning mathematics.

Mathematics teaching and learning experiences are defined as exposures to mathematics as process of doing (Cuoco et al., 1996), such that a student develops flexibility and fluidity within multiple mathematical representations (NCTM, 2014), and a student's responses to these experiences. Mathematics self-efficacy is rooted by Bandura's (1997) seminal work on self-efficacy where self-efficacy is defined as a person's perception of their ability to complete tasks. Specific to mathematics self-efficacy, developing agency and identity in mathematics is integral to the development of mathematics self-efficacy and outcomes in mathematics (Boaler & Greeno, 2000). Finally, cultural capital described by Bourdieu refers to a person's family background, educational attainment, and perhaps social refinement (1977, 1986). Although this is not inclusive, these short phrases can act as descriptors to understand Bourdieu's vision of cultural capital.

Mathematics capital is theorized using Bordieu's (1986) definition of social capital where social capital is a not only a person's social relations, but also the power that grows as a result of those social relationships. In other words, social capital is not just having relationships with people, but having these relationships and using them to harness forward movement in a social network. A nonexample of social capital is having positive social relationships, but not accessing these relationships for any form of person gain. In this study, we used structural equation modeling to investigate the relationship between mathematics capital, cultural capital, and the collection of one's mathematics mindset, self-efficacy and mathematics teaching and learning experiences. Most importantly, our model exhibits the independent variable that we are interested in characterizing: mathematics capital, where mathematics capital is defined as mathematical assets that actively influence a student's capability or power in the field of mathematics education and how the student utilizes these assets to exert power in the field of mathematics education. Identification of mathematics capital, and how it has historically been acquired and used by successful mathematics students, extends current mathematics education research as it relates to equity. Defining mathematics capital will help researchers and educators better understand how to take proactive steps to support students in more equitable ways. Thus, the purpose of our study is to characterize mathematics capital and understand its relationship with other variables related to student success in mathematics. To this end, we investigate the following research questions:

1. *Is mathematics capital measurable?*
2. *What relationships exist among mathematics capital, cultural capital, mathematics mindset, mathematics self-efficacy, and mathematics teaching and learning experiences?*
3. *Is mathematics capital distinctly different than the other variables in the study?*

Methods

Participants

The participants in this study were students enrolled in undergraduate mathematics courses at an urban midwestern university. Survey data were collected through Qualtrics from 219 participants where 104 participants were enrolled in foundational mathematics courses (e.g., Pre-calculus, Trigonometry, Quantitative Literacy), 79 participants were enrolled in either Calculus I, II or III, 8 participants were enrolled in Mathematics for Elementary Teachers I or II, and 28 participants did not respond to this question. No other descriptive data were collected in this study including gender, socio-economic status, age, or ethnicity. Participants were recruited through their mathematics instructor's request and were not offered any compensation. Participation was voluntary and collected anonymously.

Variables

Data were collected for the following variables: mathematics mindset (MIND), mathematics self-efficacy (SE), mathematics teaching and learning experiences (TEAC), cultural capital (CC), and mathematics capital (MC). Participants were asked to respond to survey questions using a 5-point Likert scale where options varied from strongly agree to strongly disagree. We used existing scales for both MIND and SE (Cribbs et al., 2021) where reliability had already been established. Our Chronbach's alpha values for the existing scales used for MIND and SE were .914 and .960, respectively. Thus, we proceeded with the validated scales as anticipated. For both TEAC and CC we used existing scales as templates to build items that mirrored those that had been previously validated but better fit our research. The TEAC items were based on research from Ottmar et al. (2014), while the items for CC were developed from existing research from Dumais and Ward (2010), Noble and Davies (2009), and Zabihi and Prodel (2011). Finally, to address our research question, we developed 15 new survey items that were used for MC (see Table 1).

Table 1. Survey items for TEAC, CC, and MC.

TEAC

While growing up:

1. I discussed solutions to math problems with my peers.
2. I worked and discussed math problems that reflect real life situations.
3. I solved math problems in small groups or with a partner.
4. I wrote a few sentences about how to solve a math problem.
5. I used visual representations (e.g. diagrams, tables, models).
6. I learned how to communicate ideas in mathematics effectively.
7. I worked with manipulatives (e.g. geometric shapes).

CC

While growing up:

1. I read.
2. I was read to.
3. I attended museums.
4. I was taught that education was important.
5. I was encouraged to go to college.

6. I participated in my education.
7. I participated in extracurricular activities.
8. I was taught about historic events.
9. I felt supported.
10. I did not have a lot of screen time.
11. I read music.

MC

While growing up:

1) I earned good grades in math.
2) Math was generally easy for me.
3) I used my math skills outside school.
4) I noticed patterns in math.
5) Experiences in my life helped me make sense of math problems.
6) I advanced in STEM because of my math skills.
7) I received opportunities, awards, or recognition because I was good at math.
8) Math made sense to me.
9) I worked through math problems even if they took longer than expected.
10) I worked through math tests quickly.
11) I usually knew when I had solved a math problem correctly.
12) I knew where math formulas came from.
13) I knew how to use math formulas.
14) I knew why math formulas worked.
15) I enjoyed math.

To attempt to measure TEAC and CC, we utilized 7 and 11 items, respectively, derived from existing scales. Our initial recorded alpha values were .805 for TEAC and 0.738 for CC. Through the process of investigation, we attempted to eliminate items but could not come up with a higher Chronbach's alpha value for either variable. Thus, we retained all 7 items for TEAC and all 11 items for CC as they developed the most parsimonious scale with acceptable reliability.

To attempt to measure MC, we utilized the 15 items listed above in Table 1. Our initial recorded alpha value was 0.943. Then, through the process of investigation, we reduced down to 6 items (retaining items (1), (2), (6), (7), (8), and (15) from above) which developed the most parsimonious scale with acceptable reliability. The recorded alpha value for this variable reduced to 6 items was 0.946.

Analysis

Data were collected using Qualtrics then exported from Qualtrics to SPSS (Ver. 29). In SPSS, initial analyses were performed to preliminarily assess the reliability of the survey measures. To assess the shared associations between the variables of interest, we used path analyses in structural equation modeling (M-Plus Ver. 7, Muthén & Muthén, 2012). The scale means for each construct were modeled simultaneously and the interrelations were explored.

Results

The constructed scores of mathematics capital spanned the entire range of the scale. However, most of the responses (57.20%) were between "Somewhat agree" and "Somewhat disagree" with the remaining 14.4% below towards "Strongly disagree" and 28.40% above towards "Strongly agree". Overall, the distribution of scores was less normal and more platykurtic than ideal. However, there was nothing else to suggest that the measure was not a valid reflection of the overall distribution of mathematics capital.

Path analyses in structural equation modeling (M-Plus Ver. 7, Muthén & Muthén, 2012) were used to examine the associations in the variables of interest. Figure 1 shows the correlations between each pair of variables that were interrelated. Self-efficacy was positively related to mathematics mindset ($r = .36$, $p < .05$) and teaching and learning experiences ($r = .27$, $p < .05$). Higher reported self-efficacy was linked with a more positive mathematics mindset in addition to more positive teaching and learning experiences, with 12.96% and 7.29% shared variance, respectively.

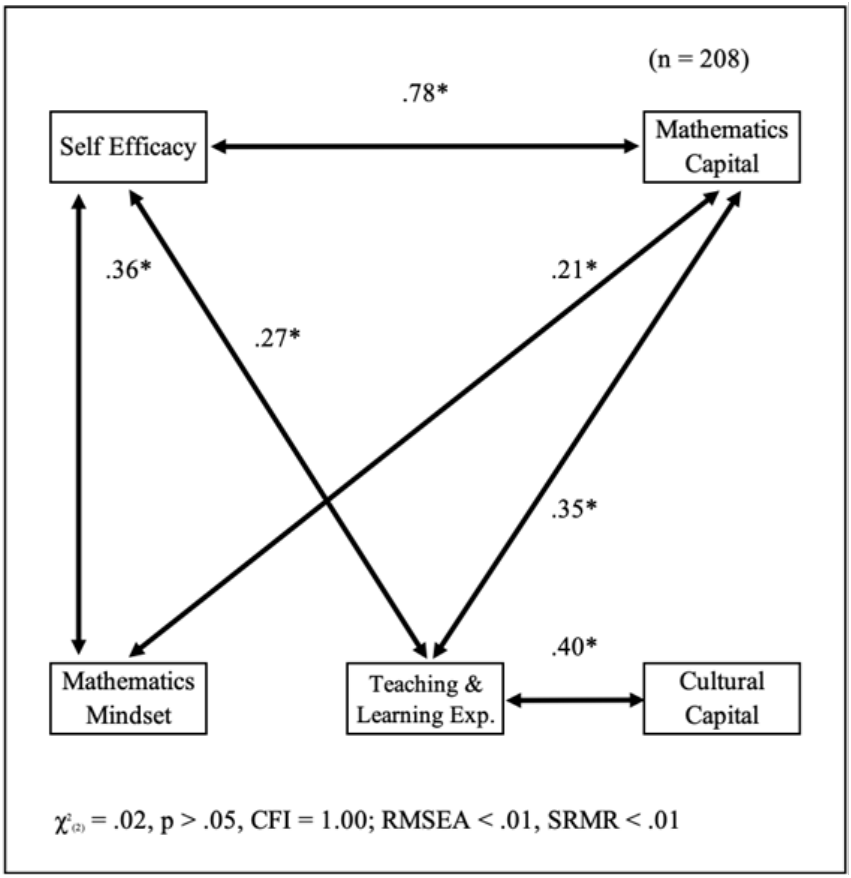

Figure 1. The shared association between the variables of interest.

Meanwhile, cultural capital was only significantly related to teaching and learning experiences ($r = .40$, $p < .05$). In other words, more cultural capital was related to more positive teaching and learning experiences with 16.00% of the variance shared between the two. Notably, however, cultural capital was not meaningfully associated with any of the other variables.

Finally, the measure of mathematics capital was positively related not only to mathematics mindset ($r = .21$, $p < .05$) but also to teaching and learning experiences as well ($r = .35$, $p < .05$). Here too, higher reported mathematics capital was linked with a more positive mathematics mindset in addition to more positive teaching and learning experiences, with 4.41% and 12.25%

shared variance, respectively. Perhaps most interestingly, mathematics capital's strongest association was with self-efficacy ($r = .78$, $p < .05$). In other words, the participants who reported more mathematics capital were also more likely to have high self-efficacy with 60.84% shared overlap in the variance. Lastly, mathematics capital and cultural capital were not related to each other in the current study. The resulting model ($n = 208$) was a good fit to the data ($\chi^2_{(2)} = .02$, $p > .05$, CFI = 1.00; RMSEA < .01, SRMR < .01).

Discussion

Our most important finding was that mathematics capital was directly and significantly related to almost all other variables in the model: mathematics teaching and learning experiences, mathematics self-efficacy, and mathematics mindset. This result suggests that increased mathematics capital is correlated to higher levels of mathematics self-efficacy, more positive mathematics teaching and learning experiences, and a growth-oriented mathematics mindset. This result also indicates that mathematics capital might be a candidate for exploring the potential mediating role in explaining the other associations we observed (e.g. the relationship between self-efficacy and teaching and learning experiences). While we did not measure the directionality between relationships in this analysis, work is ongoing to continue to understand and define the relationship between mathematics capital and these variables.

The strongest association in our model was between mathematics capital and self-efficacy. While there is research highlighting mathematics self-efficacy as a predictor of students' mathematics outcomes (e.g., Ayotola & Adedeji, 2009; Bonne & Johnston, 2015; Fast et al., 2010), our results contribute to the literature by highlighting the importance of the relationship between mathematics self-efficacy and mathematics capital. However, the nature of the relationship between these two variables must be further teased apart. Specifically, future research should investigate the items used to measure mathematics capital and mathematics self-efficacy to ensure that these two variables are psychometrically distinct. Given the strong correlation between mathematics capital and self-efficacy, we found that there was a 60.84% shared overlap in the variance, which was not high enough to claim these variables were the same. As variable validation continues for mathematics capital, we expect future research to help delineate between mathematics capital and mathematics self-efficacy.

We were surprised to find that our model showed no significant relationship between mathematics capital and cultural capital. As we continue to confirm the existence of mathematics capital, it is important to differentiate mathematics capital from other forms of capital. This distinction reiterates that mathematics capital is its own entity and does not overlap with cultural capital. This result also suggests that mathematics capital cannot be defined within cultural capital, and instead, requires its own definition. Said differently, mathematics capital is not the intersection of cultural capital and other mathematics variables such as self-efficacy, mathematics mindset, or mathematics teaching and learning experiences: mathematics capital is its own measurable, quantifiable variable.

While our analysis showed that mathematics capital and cultural capital are distinct forms of capital, it brings up the question of whether capital is transmutable. We expected to find some relationship between the two forms of capital due to the inherent transmutability of capital (Bourdieu, 1986). Thus, the lack of relationship between mathematics capital and cultural capital, raises the question: why is there no statistically significant direct relationship between these two forms of capital? Notably, mathematics capital and cultural capital are both statistically related to mathematics teaching and learning experiences. Therefore, any association between mathematics capital and cultural capital only exists inasmuch as they are both related to mathematics teaching and learning experiences. In addition, there may be other variables that were not included in our model, such as financial capital, that are associated to both mathematics capital and cultural capital. Thus, more research is needed to determine the relationships between these variables and different forms of capital.

Conclusion

A primary limitation of our study was the sample size. With 219 responses, we were able to investigate interrelations between the variables we were measuring. However, collecting a minimum of 300 responses would allow us to do latent variable modeling of the associations between the variables as latent constructs (i.e., to measure the error free associations between them). Data collection is currently ongoing to reach this sample size so that our analysis can be extended. We also plan to extend our analysis to investigate potential differences in student subgroups. Of particular interest are the differences between students who are enrolled in a calculus sequence course pursuing STEM majors and students who are non-STEM intending.

In addition to our quantitative analyses, our current survey allows students to respond to two free-response questions to gather qualitative data. In this portion of survey, we are looking to compare and contrast the measured variables, as quantitatively reported by the participants to the descriptions in their free-response questions. We are curious how students report their self-efficacy, mathematics teaching and learning experiences, and their mathematics mindset on a scale and how these compare to their experiential descriptions of these variables.

Our ultimate goal is to understand mathematics capital so that we can learn how it is acquired and better support students in attaining this capital. We view mathematics education as a holistic and comprehensive undertaking, as Bourdieu saw many capital-related concepts (1986). Developing students' mathematics capital requires understanding and describing how mathematics capital intersects with students' teaching and learning experiences in mathematics, their mathematics self-efficacy, their mathematics mindset, and their cultural capital. Having this holistic approach to mathematics education will help us as we continue to uncover more relationships between these variables and discover new ones.

This paper explores the intersection of two critical areas in undergraduate mathematics education: the pursuit of diversity, equity, inclusion, and accessibility (DEIA) in mathematics classrooms and the understanding of equity by mathematics graduate teaching assistants (MGTAs). MGTAs play a pivotal role in teaching undergraduate mathematics courses, yet their grasp of equitable teaching practices remains underexplored. In this study, we investigate 21 MGTAs' conceptions of equitable teaching. The results indicate the importance of considering the critical axis of Gutiérrez's (2009) equity framework. Ultimately, the findings offer insights into MGTAs' conceptions of equitable teaching, providing a foundation for developing effective professional development programs and advancing DEIA efforts in mathematics.

Keywords: Equity, Mathematics Graduate Teaching Assistants, Student Thinking

Background

Researchers have emphasized the need for teaching practices that support Diversity, provide Equitable and Inclusive learning spaces for students, and improve Access to mathematical content, ideas, and learning resources, referred to as DEIA (AMS, 2019; MAA, 2019; Voigt et al., 2023). Mathematics classrooms that support DEIA are often those that are active, engaging learners in meaningful mathematical activity, such as inquiry-based learning (IBL) and inquiry-oriented instruction (IOI) (Hassi et al., 2011; Kuster et al., 2017; Laursen et al., 2014). However, Brown (2018) noted that not all active-learning classrooms are equitable and provided a vision for equity-oriented IBL (E-IBL). In a recent review and synthesis of the literature on these types of classroom practices, Laursen and Rasmussen (2019) posited that mathematics classrooms should incorporate the activities outlined by four pillars: "students engage deeply with coherent and meaningful tasks, students collaboratively process mathematical ideas, instructors inquire into student thinking, instructors foster equity in their design and facilitation choices" (p. 138). For our paper, we focus our attention on the last pillar - equity. More specifically, we focus on mathematics graduate teaching assistants' (MGTA) conceptions of equity.

Mathematics departments often rely heavily on MGTAs for teaching or supporting 100- and 200-level courses. MGTAs often lead multiple recitation or lab sections for large lecture courses or teach courses as the lead instructor. At some doctorate-granting institutions, MGTAs teach up to 68% of Calculus I courses (Selinski & Milbourne, 2015). This means that during their graduate programs, MGTAs likely contribute to the learning experiences of hundreds and possibly thousands of undergraduate students. Despite their contact with and impact on undergraduate students, few studies have investigated MGTAs' understanding of teaching practices (Miller et al., 2018; Speer et al., 2010) and whether/how they comprehend instructional practices that support DEIA. We found one recent study (White et al., 2023) in which mathematics faculty members were asked how they would define equitable and inclusive teaching practices after an equity-focused professional development program. Among the 13 participants, White and colleagues (2023) found three major themes: “awareness and consideration of students, student engagement, and reflective practice” (p. 451).

Due to their impact on undergraduate learners, we investigate MGTAs’ understanding of DEIA because their understanding will influence their instructional decision-making and abilities (Schoenfeld, 2011, 2014; Speer, 2008; Speer & Hald, 2008). Additionally, studies that reveal what MGTAs associate with equitable teaching can inform the field on what is needed for an effective professional development program. Thus, to add to this literature and focus on MGTAs, we aim to explore the research question: What are MGTAs’ conceptions of equitable teaching?

Theoretical Framework

Gutiérrez (2002, 2009, 2011) defines equity as “the inability to predict mathematics achievement and participation based solely on student characteristics such as race, class, ethnicity, sex, beliefs, and proficiency in the dominant language” (Gutiérrez, 2002, p. 153). Within these definitions, Gutiérrez (2011) describes dominant and critical axes (Figure 1), each of which has two dimensions. Along the dominant axis are *access* (“the tangible resources students have available to them to participate in mathematics,” p. 19) and *achievement* (“measured by tangible results,” includes “participation in class as the mathematics pipelines,” p. 19). On the critical axis are *power* (“voice in the classroom, opportunity to use mathematics as a tool to critique society, rethinking mathematics as a humanistic enterprise,” p. 20) and *identity* (“a balance between self and others”; “opportunities to see themselves in the curriculum as well as have a view on the broader world,” p. 19-20).

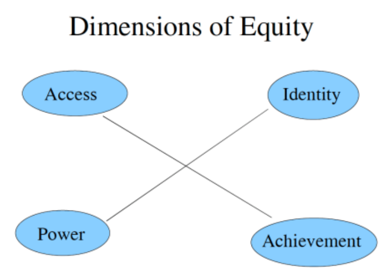

Figure 1. Gutierréz’s (2009) dimensions of equity.

While Gutiérrez (2009) noted that all dimensions are necessary for true equity, she problematizes the dominant axis through the lens of “playing the game” (p. 5) as participating in the status quo. In particular, she notes that access is “necessary but not sufficient” (Gutiérrez, 2009, p. 5) and that “equal access assumes sameness” (Gutiérrez, 2011, p. 19). In addition, she argues that focusing on providing all students with access or closing achievement gaps does not rectify past injustices that students may have experienced. In contrast, the dimensions of the critical axis help teachers and students to “change the game” (Gutiérrez, 2009, p. 5) by leveraging students’ cultural and linguistic backgrounds. Moreover, the power dimension provides students with opportunities to “rethink the field of mathematics” and to consider mathematics as a “more humanistic enterprise” (Gutiérrez, 2009, p. 6).

Researchers have used Gutiérrez’s (2002, 2009, 2011) framing of equity to redefine the actions of teachers and students in classrooms as well as describe people’s conceptions of equity. For example, Tang and colleagues (2017) used Gutiérrez’s framing to describe how inquiry can support equity. Similarly, by studying mathematics classrooms through the lens of Gutiérrez’s work, Brown (2018) revised the notion of Inquiry-Based Learning to include an equity-oriented (E-IBL) component. White et al. (2023) applied Gutiérrez’s framing to participants’ answers to interview questions to understand how people talk about equity more deeply. We continue this trend of leveraging Gutiérrez's framework to forward mathematics education.

Methodology

For this study, we conducted clinical interviews (Clement, 2000) with 21 MGTAs across three universities in the United States. MGTAs were recruited at the beginning of their graduate program (either Masters or PhD). These interviews were semi-structured (Zazkis & Hazzan, 1998) in that they were planned in advance, but the interviewer asked different follow-up questions based on the interviewee's responses. The interview took place at the start of the school year and consisted of 16 questions focused on investigating the MGTAs' conceptions of teaching. A substantial portion of these questions involved ideas of equitable teaching, such as; "How would you define equity and inclusivity?", "How would you describe equitable teaching?", "How would you describe a classroom that is not equitable?", and "Do you foresee equity and/or inclusivity impacting your plans for group or student interactions?"

Data Analysis

The analysis involved Open and Axial Coding (Strauss & Corbin, 1990) for moment-by-moment coding of students' responses and interpretations. This analysis was inductive in that the analysis was driven by what was in the data and that no pre-existing theoretical frameworks were used when creating the codes. However, as researchers aware of the literature, our knowledge of existing frameworks likely influenced what we noticed and how we decided on codes. Each interview was individually coded by at least 2 of the authors and then subsequently reconciled. During the reconciliation of codes, the authors created and refined the codes to capture patterns across students' responses. The authors repeated this process until no new codes were created, and there was agreement on using the codes in each interview transcript. This process was done to improve intercoder reliability to ensure that each code was used in the same way. We present a portion of our findings highlighting the major themes of these 21 MGTAs associated with equity.

Table 1. Summary of Code Counts Organized by Level of Association.

Code	Major	Minor	Other	Total
Access	2	3	8	13
Active Learning		3	12	15
Addressing Biases	1	1	5	7
Awareness of Diversity	3	6	9	18
Barriers		5	9	14
Content is Relevant		1	2	3
Equity and Inclusivity are Similar		1	8	9
Equity as Equality	1	1	6	8
Everyone Participating	1	3	9	13
Gauging Students		5	8	13
Individualized Approach	4	6	9	19
Lecturing is not Equitable		1	3	4
Making Things Equal	4	7	7	18
Multiple Teaching Methods		1	7	8
Not Leaving Students Behind	6	3	4	13
Students are Comfortable		2	11	13

Students are Heard		3	8	11
Valuing Different Types of Thinking	1		4	5
Valuing Students			5	5

Table 1 summarizes the most prominent themes among the graduate students, where each individual's codes were organized into *Major*, *Minor*, and *Other Association* levels of equity. The counts in each column indicate how many times a particular code was classified in each respective association level. *Major Associations* were determined by the code that emerged most frequently for each graduate student. *Minor Association*s were determined by the codes that came up less frequently than those counted in the *Major Association* category but still more than once or twice for the graduate student. All other codes were determined as *Other Association*, representing themes that did come up for the graduate students but not as much as the major or minor ones. Two graduate students had two codes come up significantly more frequently than the rest of the codes and, therefore, had two codes counted in the *Major Association* category, while the rest had only one. Most MGTAs had several minor codes, and several were counted in the *Other* association. Table 1 highlights each column's most commonly referred to codes.

Results

In this section, we highlight the three most prominent codes amongst the 21 graduate students. To do so, we explicate the meaning of these codes with excerpts that align with that code. It should be noted that each excerpt can be composed of multiple codes and does not necessarily fall under only that one code.

Individualized Approach

Excerpt 1

"I would try and focus on making what I'm teaching ***specific to each student****. I know it is hard to do that, but getting almost like* ***a personal lesson plan****, or like* ***a personal path that each student can take****."*

Excerpt 2

"So, in equity I assert that ***some people need more than others****. For example, if I have office hours, everybody is welcome to. But* ***if one student has more gaps or problems understanding something they might need more time with me.****"*

Excerpt 3

"There might be small things like, ***'Hey this student is sick, can they do makeup?'*** *or like "Can we change this policy* ***so if they miss an exam they can have their final exam score replace it?****' like little things like that"*

Figure 2: Sample Excerpts Coded with "Individualized Approach"

The most prominent theme in 19 of the 21 MGTAs was their idea that equitable teaching entailed an *Individualized Approach*. We used this code whenever an MGTA mentioned wanting to provide differentiated ways of instruction for their students, which was typically grounded in their desire to support students based on their individual needs [Excerpts 1 and 2]. Additionally, we used this code when they verbalized their desire to make accommodations for students depending on their respective situations [Excerpt 3]. In terms of individualizing education, the majority of these MGTAs discussed this in terms of a student's content understanding. In particular with Excerpt 2, this MGTA wanted to differentiate their time with students based on whether they had "more gaps or problems understanding" the material. This was a common sentiment among the 19 students where they wanted to help those who were behind by spending more time with them or by providing alternative explanations [Excerpt 1]. Overall, what is mutual amongst all the excerpts coded with *Individualized Approach* was that the MGTA expressed a desire not to treat everyone with the same standard. Instead, each MGTA explicated that depending on the individual's way of learning [Excerpt 1], understanding of mathematical content [Excerpt 2], personal situation [Excerpt 3], or other aspects, the MGTA wanted to address these and consider what would be best for each individual.

As a significant observation, only a few passages that we coded with *Individualized Approach* included a discussion on students' identities (e.g., race, gender, sexuality, ability/disability, etc.). The only exception was the few passages that considered a student's social class and the MGTA providing accommodations for them (such as flexible deadlines for students with jobs or materials for those without the necessary income). We note this because the literature clearly shows that people do not experience mathematics equally, and negative experiences are disproportionately felt by marginalized populations (Tatum, 1992; Yosso et al., 2009). For example, many women still face sexist narratives from their male peers (Yang & Carroll, 2018; Ernest et al., 2019), and therefore, one way to combat this is to take deliberate steps to ensure women have safe spaces in mathematics. In this case, educators can take an individualized approach in recognizing how to support marginalized populations, yet none of the MGTAs explicitly mentioned such actions. To be clear, we do not claim that the MGTAs are unaware of racism, sexism, etc. Instead, we assert that there is no direct evidence that they think of them as being concerned with "equity" or fully realize how a student's identity significantly impacts their experiences in the mathematics classroom.

Making Things Equal

Excerpt 4

"Like some students come without a pencil. Some students just had problems at home and that made me realize that sometimes students deserve extra attention ***in order to put them on a fair footing****."*

Excerpt 5

"I would say equitable teaching would be, not necessarily that every student gets the same. I would say it's more about ***making sure that everyone is at the same level of help or has the same opportunities as everybody else****."*

Excerpt 6

"I want to say like teaching so that it's fair. Like ***making sure that you're taking steps*** *to be fair and not giving preferential treatment.* ***Making sure that anybody should have the same ability to understand…****like everyone should be able to continue."*

Figure 3: Sample Excerpts Coded with "Making Things Equal"

Another popular theme was that equitable teaching involved *Making Things Equal* for all students. This code was used whenever an MGTA indicated the intent to ensure that all students had the same opportunities or ability to succeed. It is important to note that this code does not capture the idea of treating all students the same way. Instead, excerpts tagged with this code involved descriptions of something the teacher or university needed to do to provide equal opportunities for students. For example, in Excerpt 4, the MGTA described their awareness of students' access to resources and their background as impacting their ability to succeed. Thus, in order to provide an equal learning opportunity, a teacher should provide "extra attention in order to put them on a fair footing." Excerpt 5 also hints at this diversity of backgrounds by mentioning that not every student needs to get the same and that equitable teaching involves "making sure" everyone has the same opportunities. While Excerpt 6 may initially read as "treating everyone the same," the MGTA's emphasis on "making sure" of fairness indicates their assumption that, by default, things are likely not fair in the classroom and that the teacher needs to "make sure that anybody should have the same ability to understand."

18 of the 21 interviewed MGTAs shared this sentiment that equitable teaching involved deliberate actions from the teacher or university to ensure that students have an equal opportunity in the classroom. Underlying this idea was the awareness that students may come into the classroom with different backgrounds, associations with mathematics, and the possibility of being treated differently than other students. This code was often coded alongside "Awareness of Diversity," which makes sense since if an MGTA assumes everyone is equal, they would not articulate the need to ensure that things are equal. Instead, these MGTAs noticed the diverse populations in their classroom and the impact of those differences in mathematics education.

Awareness of Diversity

Excerpt 7

"A lesson that is not equitable? Maybe a lesson in which the assumption is that everybody knows all of the terms, or ***assuming that students have the same background, that there is no non-traditional students or foreign students.****"*

Excerpt 8

"I think that ***people come from different backgrounds have different ways they communicate and that could be a result of their environment and culture****. Those sum up who we are and how we think and to include all these different ways of thinking is to, I guess give everybody a voice that's equally relevant.*

Excerpt 9

"For equitable teaching, you get people who work like 40 hours a week and they're taking a summer class and all the material is really crammed together. So equitable teaching, I would describe it as not necessarily giving people a free pass but definitely trying to accommodate situations."

Figure 4: Sample Excerpts Coded with "Awareness of Diversity"

18 MGTAs mentioned an "Awareness of Diversity" as being associated with equitable teaching. We used this code whenever an MGTA made specific reference to people of different backgrounds when answering equity and equitable teaching questions. In all three of these excerpts, each student responded to a question by explicating an awareness of how their students come from various backgrounds. These kinds of differences that the MGTAs mentioned included the types of students [Excerpt 7], ways a student in a classroom interacts [Excerpt 8], things a student might deal with outside of the classroom [Excerpt 9], mathematical background, different learning styles, and levels of mathematical understandings. Of importance to note is that none of the students specifically mentioned that "you need to be aware of diverse backgrounds to teach equitably." Instead, we infer from their aggregate responses that their realization of students with different backgrounds was the impetus for how they envisioned teaching equitably. For example, in Excerpt 8, the MGTA described that students have different ways of communicating, and because of that, equitable teaching entails giving "everybody a voice that's equally relevant." Similarly, in Excerpt 9, the MGTA initially addresses a student's situation as the primary reason for equitable teaching involving providing situational accommodations for students.

Discussion

Overall, between the 21 MGTAs, the common theme of equitable teaching entailed supporting student success by individualizing education, making things equal, and being aware of the diversity of student backgrounds. One hypothesis for why these three codes appeared frequently is that the most prominent image associated with equity is the baseball field analogy

(Figure 5). In this widely used metaphor, equity is enacted by distributing the boxes according to each individual's needs. It is not too far of a reach to claim that the three most salient aspects of this metaphor involve "people have different needs" (*Awareness of Diversity*), "give according to those needs" (*Individualized Approach*), and that the overarching goal is to "*make things equal.*" In fact, one MGTA directly mentioned this metaphor when explaining equity: "It's the classic photo of equity versus equality. You don't give everyone a crate, you give crates according to

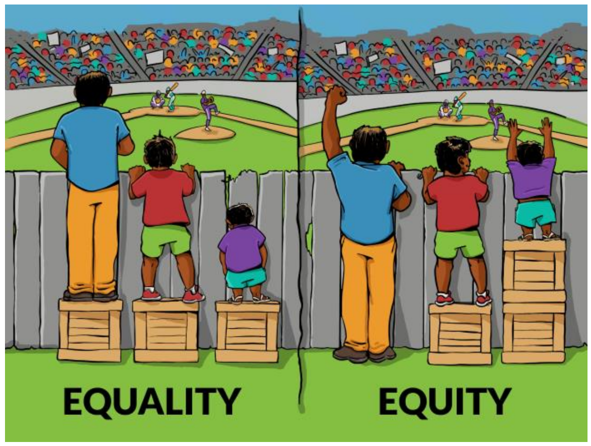

Figure 5: A Widely Used Metaphor for Equality Versus Equity

who needs to be able to see (over) the fence."

In considering Gutiérrez's framework for equity (2009), we note that the MGTAs mostly attended to the dominant axis by considering ideas of access and achievement. Most of the MGTAs focused on supporting academic success and closing achievement gaps. However, as Gutiérrez explains, attention to the critical axis is crucial for students to have true equity in the classroom. We note that we do not want to ironically gap-gaze at what the MGTAs lack. Instead, we make this comparison to highlight what professional development focused on equity for MGTAs might include. In particular, the results indicate that many MGTAs have admirable intentions and want to support students from various backgrounds. What they would likely need then, is a deeper understanding of how issues of racism, sexism, ableism, and other forms of oppression play a significant role in mathematics education. Therefore, it stands to reason that a productive professional development program for MGTAs would include aspects that address issues of inequity, specifically targeting the critical axis of Gutiérrez's framework.

We titled our paper with a quotation from one of the MGTAs who explained equitable teaching as "acknowledging my students as humans first and students second" to highlight that the MGTAs mostly have the intent of treating mathematics education as what Gutiérrez calls a "more humanistic enterprise." We believe the findings of this study indicate a better future for mathematics education and that providing training to graduate students on teaching and equity can be a worthwhile endeavor toward improving student experiences in mathematics classrooms.

The Cognitive Obstacles Associated with Structuring for Mathematization Undergraduates Encountered During Dynamic Modeling Tasks

Elizabeth Roan
Texas State University

Jennifer A. Czocher
Texas State University

Studies have described a number of blockages to mathematizing, the process of transforming a real-world situation into a mathematical model. Recently, researchers have documented four cognitive obstacles associated with those blockages in physics-based modeling tasks. We attempted to extend these findings to biological-based modeling tasks. However, we found it difficult to use the theoretical lens as described in the previous literature. This difficulty arose because the previous theoretical lens required the delineation of real-world objects and mathematical objects, a pursuit recently shown to be unattainable in some contexts. By examining students mathematization under a quantitative reasoning and symbolic forms lens, we were able to find two cognitive obstacles analogous to the ones found in previous research, confirming their existence with a different demographic of students and different task scenarios.

Keywords: modeling, quantitative reasoning, differential equations

The idea of using mathematical modeling to enrich STEM education is well established. It is an idea upheld by the Common Core State Standards (CCSSI, 2010), and researchers alike (Blum & Niss, 1991). One line of inquiry into how students learn to model focuses on identifying and improving the competencies students need to make progress in a modeling problem (Schukajlow et al., 2018). The competency which has received most attention is *mathematizing* – constructing a mathematical representation of the mental model of the scenario. It is particularly difficult for students (Brahmia, 2014; Galbraith & Stillman, 2006; Stillman & Brown, 2014). Because each phase of modeling builds on decisions the modeler made earlier, some of the difficulties students encounter carrying out mathematizing come from how they structured the real-world scenario. In order to understand why some students experience blockages when they work on modeling problems, researchers have begun to catalog the cognitive obstacles associated with structuring for mathematizing that arise when students work on modeling problems.

Literature Review

Mathematical models are mathematical systems that represent real-world systems. They are conceptual systems "consisting of elements, relations, operations, and rules governing interactions) that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)…[A model] focuses on structural characteristics of the relevant system" (Lesh & Doer 2003 p. 10). Historically, scholars have conceptualized the process of generating the representational system as an idiosyncratic cycle that can be disrupted by inadequately performing key activities to transition from one competency to another. Studies have described a number of blockages to mathematizing such as representing elements mathematically so known formulae can be applied (Galbraith & Stillman, 2006) and failing to define variables or failing to realize interdependences among variables (Klock & Siller, 2020). These blockages should be understood as arising from structural choices about which elements, relations, and operations are relevant. Recent studies affirm that lack of content knowledge was not the root of students' difficulties during modeling, but rather a two-part set of skills: structuring the scenario and then translating the structure into a mathematical representation (Jankvist & Niss, 2020; Niss, 2017). Niss (2017) observed four primary obstacles to mathematizing that could be attributed to cognitive processes. He framed mathematizing as making simplifying assumptions about objects in the real world that are specified by the modeler and generating relationships between those objects that are relevant to solving the real-world problem. From this perspective, student blockages could be categorized as (a) not identifying a mathematical object to impose on the scenario (b) not identifying a key real-world object to impose onto the scenario (c) imposing unhelpful mathematical objects, and (d) making structural choices that led to a mathematical representation that students were unable to work on (e.g., choices that would require too-advanced mathematics). In concluding remarks, Niss called for other researchers to corroborate and expand upon this list of cognitive obstacles in other content areas. A call we set out to respond by extending Niss's framework to undergraduate STEM majors' work on canonical modeling problems from biology, including disease transmission and predator-prey dynamics. We found that Niss's framework depends on being able to reliably identify and distinguish between a mathematical object and a real-world object, which was challenging to do empirically in the biological contexts since it was not obvious what the relevant mathematical or real-world objects would be. We were unable to understand what the cognitive obstacles associated with structuring for mathematizing from this perspective. Recently, Zimmerman et al., (2023) argued that there is no clear distinction between mathematical objects and real-world objects, shedding light onto limitations of Niss's framework for settings outside of physics problems. Thus, a promising approach to understanding the difficulties students face while mathematizing would need to absolve the researcher from assuming a distinction between real-world object and mathematical object.

To address this theoretical and methodological need, we adopt constructs from quantitative reasoning (QR) and symbolic forms. Quantitative reasoning is the conceptualization of a situation into a network of quantities and quantitative relationships (Thompson, 1993). A quantity is a triple of an object, attribute, and quantification (Thompson, 2011). Quantification means to conceptualize an object with a measurable attribute so that the measure is proportional to its unit (Thompson, 2011). A quantity is made from an individual's conceptions of objects meaning a quantity is idiosyncratic to the individual (Ellis, 2007). An example of a quantity in a disease transmission context could be the number of sick people at time t. The object is the sick population, the attribute is amount, and evidence of quantification could be a student explaining they could feasibly measure the number of people on one day by counting them. A quantitative operation is a conceptual operation where an individual creates a new quantity in relation to already created quantities (Ellis, 2007; Thompson, 2011). Symbolic forms are a type of cognitive resource comprising of two components: a symbol template and a conceptual schema (Sherin, 2001). For example, a common conceptual schema for the symbol template $[\,] \times [\,]$ is iterating one quantity by the magnitude of another (i.e., repeated addition). In this way, a mathematical model is a conceptual system encompassing a modeler's ideas they find relevant about a real-world system (e.g., a fish tank, or an island habitat). The elements of the model are quantities the modeler imposes onto the scenario. The relationships between elements, operations, and rules governing interactions are determined by the modeler's QR. A modeler externalizes quantitative operations by selecting the symbol template whose conceptual schema comports with the quantitative operation. For example, a modeler could multiplicatively combine number of sick people at time t and number of healthy people at time t to create the quantity number of interactions between sick and healthy people at time t. The modeler might externalize that quantitative operation via the symbol template [ ] × [ ], because repeated addition comports with how they multiplicatively combined the two quantities. In Niss' (2017) framing, cognitive obstacles arose from incongruencies in identifying real-world objects, and assigning the appropriate mathematical objects to those real-world objects. In our framing, cognitive obstacles arose from imposing quantities onto the scenario, creating new quantities by combining other quantities, and expressing that combination externally. From this perspective, we pose the question: What cognitive obstacles to mathematizing, arising from structuring, do students encounter when working on dynamics modeling problems?

Methods

This qualitative study draws data from a larger design study of facilitator scaffolding moves that foster undergraduates' modelling competencies. In this paper, we report on 12 participants' work on three canonical modelling tasks: a predator-prey dynamics scenario, a contaminated tank scenario, and a disease transmission scenario. Participants were volunteers from STEM courses who stated they had some familiarity with mathematical concepts like instantaneous rate of change and reported getting at least C's in their mathematics course work. The task design and task-based interview protocols attended to participants' QR and intentionally focused on similarities of conceptual schema across task contexts. In all three tasks, participants aimed to write a (system of) differential equation(s) modeling the dynamics of the scenario. In the predator-prey task, students were asked to create two differential equations that modeled the rate of change of cats and birds accounting for their interactions. In the contaminated tank task, a buffering agent is mixed with water to create a buffering solution. Students were asked to model how quickly buffering agent in the tank changed given the buffering solution entered the tank at 5 liters per minute at a concentration of $1 - e^{-\frac{t}{20}}$ grams per liter. In the disease transmission task, participants were asked to model how quickly a disease was spreading through a community of susceptible, infected, and removed populations.

Analysis of recordings of and written work from the interviews proceeded in four stages. First, we generated a list of quantities each participant imposed onto the task scenario by describing the object, attribute, and how the participant exhibited quantification for that attribute according to the quantification criteria developed by Czocher and Hardison (2021). Second, we created a chronological narrative documenting how participants combined quantities and externalized that combination using symbolic forms. Third, we identified instances where a participant's progress in the task halted. Some key indicators were: the participant said they were stuck, the participant wrote down two mathematical expressions for the same quantity (or quantitative relationship) and said one of the expressions should be correct, or the interviewer noticed that what the participant wrote down did not mathematically mean what the participant was explaining. In each instance, we inferred the cognitive obstacle that impeded the participant's progress based on the quantities and quantitative operations previously documented. Finally, we looked across instances for commonalities which we report as types of cognitive obstacles below.

Results

Across the three canonical modeling problems and participants, we observed many blockages to mathematization that could be attributed to cognitive processes and report on two with origins in structuring: an unhelpful quantitative relationship took precedent, and a key quantity was not salient for the participant. A third type of cognitive obstacle (a participant's specific quantification of a quantity did not permit them to sensibly combine it with other already-present quantities using well-known formulas) was previously reported in Roan and Czocher (under review). We illustrate each kind of cognitive obstacle to evidence its existence and its role in connecting structuring to mathematizing. To evidence the two types of cognitive obstacles existence, we selected instances that best exemplified a specific type of cognitive obstacle. To do that will show work from two students, Ivory (Physics) and Niali (Electrical Engineering).

An unhelpful quantitative relationship took precedent.

This cognitive obstacle occurred when a participant focused on externalizing a quantitative relationship that was not helpful (from the interviewer/researcher perspective) in creating a differential equation that modeled the scenario. To evidence this type of cognitive obstacle, we show work from Ivory (Physics) on the disease transmission task. To start, we show the quantities, quantitative relationships and the corresponding symbols and expressions she had created up to the point of interest in Table 1.

Table 1. Ivory's quantities, quantitative relationships, and the corresponding symbols and expressions.

Quantity or Quantitative relationship	Symbol or Expression
Amount of susceptible people at time t	$S(t)$
Amount of infected people at time t	$I(t)$
Amount of removed people at time t	$R(t)$
Mortality rate	d
Accumulated amount of dead people at time t	$m(t)$
Amount of recovered people at time t	$r(t)$
Amount of dead people at time t and amount of recovered people are two disjoint subsets of amount of removed people at time t	$r(t) = 1 - m(t)$

Ivory was working on creating an expression for *amount of dead people at time t*. She noted some pertinent information she needed to consider, namely, that "there's a two-week delay" between symptom onset and death "…because if you haven't died within two weeks, you've recovered, is what we're assuming here." Ivory assumed that (A) the *amount of dead people at time t* depended upon *amount of infected people at time t, 14 days ago*. We identified that Ivory had stopped progressing towards creating a differential equation for the scenario because she wrote down multiple mathematical expressions for the same quantitative relationship, as if searching for the correct mathematical expression. Table 2 shows the different expressions Ivory tried and then rejected to depict quantitative relationship (A).

Table 2. Ivory's quantities, quantitative relationships, and the corresponding symbols and expressions.

Quantity or Quantitative relationship	Symbol or Expression
amount of dead people at time t depended upon amount of infected people at time t, 14 days ago.	$m(t) = I(t+14) \times d$
	$m(t) = \frac{dS}{d(t+14)}$
amount of removed people at time t depended upon amount of infected people at time t, 14 days ago.	$\frac{dR}{dt} = \frac{dI}{d(t-14)}$
	$\frac{dR}{dt} = \frac{dS}{d(t-14)}$
	$\frac{dR}{dt} = I(t-14)$

Ivory experienced a cognitive obstacle related to her attempts to depict a quantitative relationship she did not know how to represent adequately. In Ivory's work, the quantitative relationship (A) took precedence over more helpful relationship like (B) positive flux in the removed population is proportional per unit time to the current infected population. She could not adapt her models for relationship (B) because they did not account for relationship (A) in an explicit way. Neither did she think her models accounting for (A) were adequate. She reflected she was "still caught up on the 14-day lag thing." We assert that this was a cognitive obstacle for Ivory because she was not able to meet her goal (to create a system of differential equations that modeled the disease spread) until this quantitative relationship lost precedence.

A key quantity was not quantified by the modeler.

This type of cognitive obstacle occurred when a key quantity was missing from the participant's structure so other key quantities could not be constructed. Across our participants and tasks, this cognitive obstacle seemed to occur when participants thought they could not use a quantity in an expression because they thought they needed to find an equation to determine it (a way to measure its value) first. To evidence this type of cognitive obstacle, we show work from Niali (Electrical Engineer) on the contaminated tank task. To start, we show the quantities, quantitative relationships and the corresponding symbols and expressions he had created up to the point of interest in Table 3. Niali stated that he needed to find a mathematical expression for the quantity concentration of buffering exiting, as evidenced in the exchange below:

Niali: OK, we have a-- let's see. Have a fluid in the tank. We have a tank. We have a pump which adds water with concentration. The water starts full. Uh, buffer enters through here, and out comes the water. The water exits at a rate of 5 liters per minute. It enters 5 liters per minute at a rate of-- that-- oh, what is this, grams of buffer per liter. So what does it exit at?

Interviewer: And by exit at, you're talking-- you're thinking specifically about the concentration, the true concentration of the liquid exiting, right?

Niali: Yes. So how many grams per liter of the chemical is exiting?

Table 3. Nilai's quantities, quantitative relationships, and the corresponding symbols and expressions.

Quantity or Quantitative relationship	Symbol or Expression
Rate of buffering solution entering in liters per minute	$water\ in = 5$
Concentration of buffering solution entering in grams per liter	$1 - e^{-\frac{t}{20}}$
Rate of buffering agent entering in grams per min	$5 \times (1 - e^{-\frac{t}{20}})$
Rate of buffering solution exiting is the same as the rate of buffering solution entering	$water\ out = 5$
Maximum volume of the tank in liters	300

We identified that Niali had stopped making progress towards creating a differential equation for the scenario because he wrote down multiple mathematical expressions for the same quantity, evidencing an ongoing search for an adequate one. In Table 4, we showcase all the different expressions Niali tried and rejected to depict the quantity *concentration of buffering exiting.*

Table 4. Nilai's quantities, quantitative relationships, and the corresponding symbols and expressions.

Quantity or Quantitative relationship	Symbol or Expression
Concentration of buffering solution entering is the same as concentration of buffering solution exiting	$\%\ concentration\ in = 1 - e^{-\frac{t}{20}} = \%\ concentration\ out$
Concentration of buffering solution exiting	$\frac{5 \times (1 - e^{-\frac{t}{20}})}{300}$
	$\left(\frac{5 \times \left(1 - e^{-\frac{t_{Final}}{20}}\right)}{300} - \frac{5 \times \left(1 - e^{-\frac{t_{iniital}}{20}}\right)}{300}\right) \times \frac{1}{2}$

Niali experienced a cognitive obstacle related to his attempts to create a quantity when he did not have the quantities available to him to do so. In Nilai's work, the quantity *concentration of buffering exiting* could not be constructed until the quantity *amount of buffering agent in the tank* was quantified. We assert that this was a cognitive obstacle for Niali because he was not able to meet his goal (to create a differential equation that modeled how quickly the buffering agent in the tank was changing) until the quantity *amount of buffering agent in the tank* was quantified. Further, other students in the study who did explicitly quantify *the amount of buffering agent in the tank* did not encounter this obstacle.

Discussion

In this paper, we found two cognitive obstacles associated with structuring for mathematizing students encountered in three canonical modelling tasks: a predator-prey scenario, and a contaminated tank scenario. These were (1) an unhelpful quantitative relationship took precedent, and (2) a key quantity was not quantified by the modeler. While not all participants experienced each type of cognitive obstacle, no one obstacle was specific to one task. This implies that the cognitive obstacles we showcase here are not a consequence of the task scenario but are rooted in how students' reason quantitatively while mathematizing. We set out in this work to confirm the cognitive obstacles found by Niss (2017) existed in these different task scenarios with a different demographic of student. However, due to the nature of the tasks we selected, we found it difficult to delineate real-world objects and mathematical objects. This difficulty has been empirically shown to occur in physics as well (Zimmerman et al., 2023). To continue our investigation, we elected to investigate these cognitive obstacles through a quantitative reasoning and symbolic form lens. We were successful in finding analogous cognitive obstacles found by Niss (2017). The cognitive obstacle an unhelpful quantitative relationship took precedent is analogous to Niss (2017) cognitive obstacle "making structural choices that lead to a mathematical representation that students were unable to work on". However, here Ivory made structural choices that she could not translate into a mathematical representation. Further, the cognitive obstacle a key quantity was quantified by the modeler is analogous to Niss (2017) cognitive obstacle "not identifying a key real-world object to impose onto the scenario". Our theoretical perspective offers more nuance. It is not that Niali just "didn't think" to impose the quantify *amount of buffering agent in the tank,* onto the scenario. It is that Niali thought that he couldn't. Later in the interview, when the interviewer suggested that Niali use the symbol $B(t)$ to represent *amount of buffering agent in the tank* he said "We're going to solve for $B(t)$ or something, or is that something we can do?" We infer from this question that Niali anticipated solving for $B(t)$ and so he did not think he could use $B(t)$ in his equation. This comports with the findings that it is specifically skills for structuring and mathematizing that produce cognitive obstacles not mathematical nor real-world knowledge (Niss, 2017; Jankvist & Niss, 2020). However, we did not find cognitive obstacles analogous to the other two cognitive obstacles by Niss (i.e., not identifying a mathematical object and imposing unhelpful mathematical objects). Our framing fails to pick up on those kinds of cognitive obstacles because our framing has no analogue for mathematical object. Further research is needed to determine if this is a shortcoming in the quantitative reasoning-symbolic form framing, if this kind of cognitive obstacle can be detected when looking at cognitive obstacles associated with other parts of mathematizing, specifically when externalizing the structure of the scenario via symbolic forms, or even whether they could be replicated in this student population.

Acknowledgments

Research reported in this paper is supported by National Science Foundation Grant No. 1750813 with Dr. Jennifer Czocher as principal investigator, and by Doctoral Research Support Fellowship given by Texas State University.

National Picture of Providers of Collegiate Professional Development for Teaching Mathematics: Formats, Topics, And Activities

Sean P. Yee
University of South Carolina

Huijuan Wang
University of South Carolina

Shandy Hauk
San Francisco State University

Tuto Lopez Gonzalez
San Francisco State University

Teaching professional development (TPD) in collegiate mathematics has expanded over the last few decades. Providers of TPD, people who organize and facilitate professional learning about teaching, are at the center of this growth. Yet, little is known about who Providers are and what they do. To better understand the national landscape of Providers of TPD within university mathematics departments, this report shares data from a national survey where respondents were Providers. The focus here is on findings from survey questions asking about characteristics of Providers and the "providees" with whom they work, along with formats, topics, and activities used in TPD. Results suggest that Providers value active, learner-centered instructional methods promoted by research and policy. However, in the TPD itself, formats, topics, and activities commonly used by Providers may preach but not regularly practice activity-based methods.

Keywords: Professional Development Provider, Graduate Student Instructor, Teaching Assistant

Decades of research on undergraduate mathematics teaching, learning, and curriculum development have created an evidence-based foundation of resources for equitable teaching and effective learning. These resources include instructional materials, assessment tools, and practice guides for instructors (e.g., MAA, 2018; Carver et al., 2016; Garfunkel & Montgomery, 2019). However, getting implications from research into college mathematics classrooms remains a challenge (Archie et al., 2022; Pengelley & Sinha, 2019). Entry-level college mathematics classes are often taught by graduate students (about 35% [Blair et al., 2018, p.17]). In fact, 94% of graduate students will teach at some point. Graduate students can have a variety of instructional roles, from teaching assistant responsible for a lab or recitation session associated with a primary course where the instructor-of-record is a faculty member (LabTA) to a graduate student who is an instructor-of-record (GSI). Research indicates that college mathematics instructors (CMIs) in effective undergraduate programs, particularly novices, benefit from well-structured teaching-focused professional development (TPD) (Connolly et al., 2016; Friedlaender et al., 2014; Gehrtz et al., 2022). Those responsible for offering TPD to novice CMIs, including those who lead workshops, courses, and seminars as well as those who facilitate TPD as course coordinators, have come to be known as Providers of TPD (Braley & Bookman, 2022; Braley et al., 2023). Providers have a critical role within departments. However, little is known about who Providers are, what they provide, and how they provide it.

Context of the Study

In the U.S. there are 418 institutions granting a doctorate or master's as the highest mathematics degree and more than half have at least one Provider (some have three or more; American Mathematical Society, 2023; Braley & Bookman, 2022). This survey study was part of a larger project creating support for mathematics departments for designing teaching preparation programs for graduate students. One step in the project was gathering baseline data for understanding the current status of post-secondary mathematics TPD. Among the 200 people who responded to the survey, 95 completed all aspects of it. This report uses analysis of those 95 full responses from 56 institutions. The focus is addressing two questions:

RQ1: (Who) Who are the Providers and who does their TPD target?

RQ2: (What) What formats, topics, and activities do Providers use in their TPD?

Related Literature

Understanding what Providers provide is critical at this time in undergraduate mathematics education because the field has reached a critical mass of policy and resources for TPD. In 2018, the Mathematical Association of America (MAA) released the *Instructional Practices Guide* (IPG)*,* a report on recommended teaching practices in undergraduate mathematics. The guide summarizes the evidence-base on effective methods of instruction and promotes student-centered classroom-active methods as an expectation of and for the field. Moreover, multiple calls to include inquiry-based mathematics education (Laursen & Rasmussen, 2019) and active learning methods (Braun, et al., 2017) have been on the forefront of suggestions for TPD. Concurrently, a central resource for Providers has been developed by the College Mathematics Instructor Development Source (CoMInDS) project with hundreds of documents from and for Providers in an online repository and well-established networks of people to share resources (MAA, 2020). Also, recent projects such as *Student Engagement in Mathematics through an Institutional Network for Active Learning* (SEMINAL; Gobstein, 2016) have expanded use of collaborative learning methods through active-learning for Providers.

A study by the CoMInDS project found there is a great desire, but a struggle by department leaders to make sense of resources for their institutions (Bookman & Murphy, 2019). There is a clear need for guidelines for preparing LabTAs and GSIs. However, there is a reasonable concern: institutions vary in structure and resources in ways that are consequential for graduate student TPD. Thus, localized support–as through the work of Providers–is needed to demonstrate the impact and viability of such evidence-based research.

Prior research has identified the value of TPD for graduate students and its impact on teaching and learning, from course pass rates to level and frequency of complaints by undergraduates, to improvements in responsiveness and inclusivity (Hauk & Speer, 2023, Yee et al., 2023; Yee & Rogers 2022 and references therein). There is a gap in the research about both what and how TPD is provided (Hauk, et al., 2017). To address the gap, this survey study leveraged and revised some approaches used to examine secondary teacher preparation (Yee, Otten, & Taylor, 2018) to gather baseline data on current collegiate mathematics TPD.

Methods

Quantitative methods were used to analyze the survey data to determine who Providers are, what they provide, and how they provide it. Using multiple national listservs to contact Providers (e.g., CoMInDS, SEMINAL, RUME), a Qualtrics survey (vetted by an Advisory Board and Expert Providers) was sent out to more than 500 potential Providers across the United States. Among the 95 who responded to all the items (participants), 80% were from mathematics doctoral-granting institutions and 20% from masters-granting institutions. To answer the research questions, responses to five survey items were analyzed: (1) Who was the Provider, (2) Who was the main group the Provider worked with, (3) Which formats were used for TPD, (4) Which topics were discussed in the TPD, and (5) Which activities were used in the TPD. The

"Who" survey questions required a single selection. The "Formats," "Topics," and "Activities" questions were checkboxes, where more than one could be selected. Options offered on the survey were based on prior research on formats, topics, and activities prevalent across the United States (Bookman & Braley, 2014; Braley et al., 2023; MAA 2018, 2020) and interviews with Expert Providers conducted as part of the larger project. In what follows, descriptive statistics are used to describe the Providers and providees, while matrix-like "Upset" plots are used for combinations of checkboxes.

Findings

As indicated in Table 1 and Yee and colleagues (2023), 80% reported being either non-tenure-line Teaching Faculty (42%) or tenure-track faculty (38%). Thus, non-tenure-line teaching faculty have about as much responsibility for supporting graduate student's learning about teaching as do tenure-line faculty. The majority of Providers being teaching faculty suggests care is needed in future work examining questions around a Provider's role in the department. Also, more than 80% reported a focus on graduate students – including graduate students who are teaching assistants (42%), instructor-of-record (34%), or both (9%).

Table 1. Who: Providers and providees

The **faculty position** you hold		The **main group** served by professional development about teaching in your department	
Teaching Faculty (not tenure-line)	42%	LabTA	42%
Tenure-line Research Faculty	35%	GSI	34%
Tenure-line Teaching Faculty	3%	Novice Faculty	8%
Part-time or Adjunct Faculty	3%	Undergrad. Learning Assistant	1%
Other: chair (7%), time-limited full-time/post-doc position (10%)	17%	*Other*: both LabTA & GSI (10%), post-doc (3%), faculty (2%)	15%

Format

Providers indicated their use of seven different formats (six were described, the seventh was "other" and had room for the respondent to describe it). As indicated in Figure 1 (next page), a majority of participants selected some combination of three of the six formats:

(1) pre-semester orientation (bottom horizontal bar, 79 responses),
(2) meeting with a course coordinator (67 responses), and
(3) offering a single course about teaching (45 responses).

The right side of the "Upset diagram" in Figure 1 illustrates the connections among format co-selections. Most respondents selected two or more of the three most frequently selected formats. Among the 15 respondents choosing "other" as a format, mentoring and coaching (3) and weekly meetings (2) were the most common responses.

It is worthwhile to note that very few Providers selected only "one seminar or workshop" with most selecting other formats as well. Moreover, only one respondent had only pre-semester orientation and only one respondent had only meetings with coordinators. This echoes results from the CoMInDS surveys that the field as a whole is using multiple formats for TPD over longer periods of time with an increasing frequency of course-like structures (Bookman & Braley, 2014; Braley & Bookman, 2022; Braley et al., 2023). Indeed, any combination selected by five or more respondents included meetings with coordinators, a course, multiple seminars, or multiple courses to complement a pre-semester orientation.

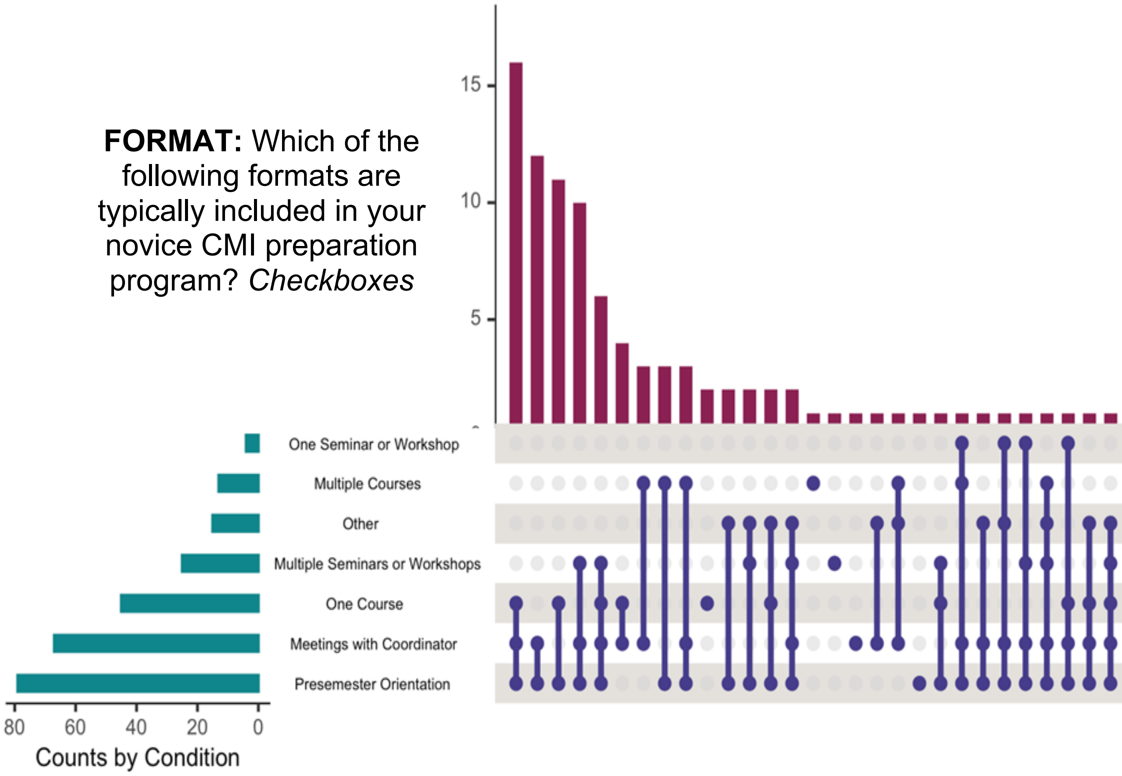

Figure 1. Formats of TPD reported by Providers.

Topics

Providers indicated their use of eight different topics (seven were described, the eighth was "other" and had room for the respondent to describe it). As illustrated in Figure 2 (next page), in order of frequency these were:

(1) university and departmental policies (90) chosen by nearly all participants,
(2) active learning (78),
(3) learning management systems such as Canvas (63),
(4) grading strategies (58),
(5) formative assessment (53).

Twenty respondents described other topics, including particular teaching techniques, (e.g., lecturing was written in by (4), student-centered teaching (3), and equitable practices (2)).

A majority selected topics aligned with the topics suggested in the IPG (MAA, 2018). Combinations of topics among more than three respondents had many of the five most popular topics (policies, active learning, learning management systems, grading strategies, and formative assessment). Notable is the pattern of exclusion for two topics: generally, those who did not select active learning also did not select formative assessment. A majority selected five of the seven possible choices, with IBL the least commonly selected.

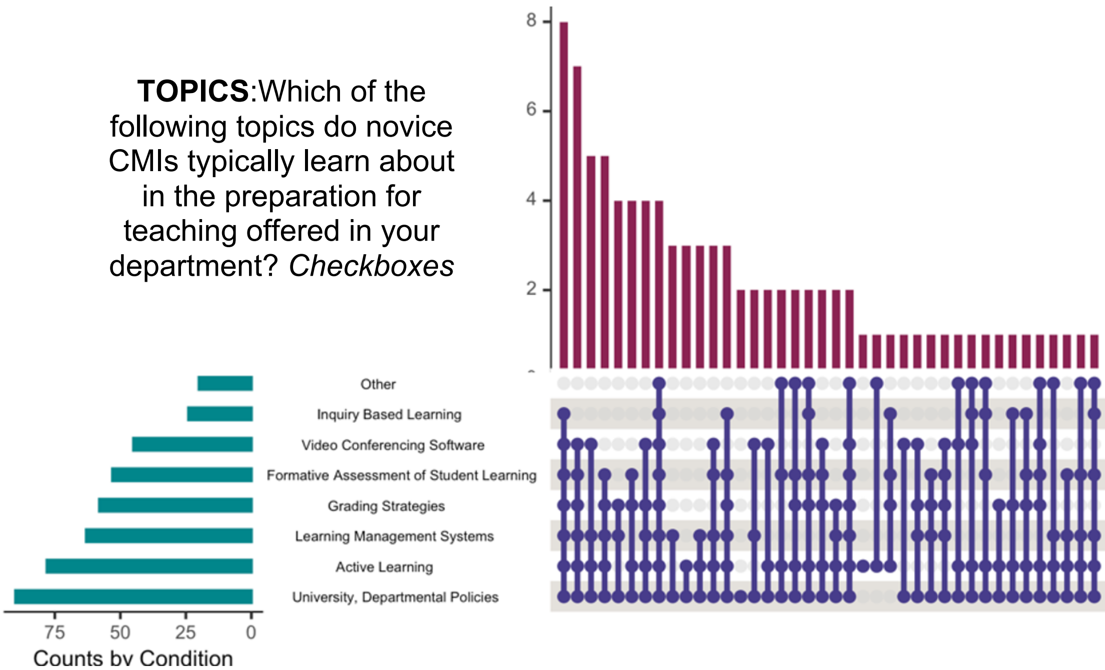

Figure 2. Topics in TPD reported by Providers.

Activities

As seen in Figure 3, (next page) the most frequently selected activities were:

(1) listen to presenters (74),
(2) discuss example cases of teaching and learning (69),
(3) read provided articles or other information (64),
(4) present a practice lecture (59), and
(5) practice assessing a student assignment (52).

Despite the knowledge in the field of the value of student-centered instruction, "listen to presenter" was chosen alongside "discussion of example cases" by more than half of respondents (52). The 30 responses about "other activities" included peer and instructor observations (6), collaborative learning (e.g., about facilitating discussions and writing lesson plans; 6), practice with teaching (e.g. "mini-lecture," "co-teaching"; 5). Six respondents only included "other" activities and did not select any of the seven given types of activity suggested as effective by the literature. Finally, it is worth noting that the most common combinations *excluded* developing a course website or delivering a non-lecture-based practice lesson.

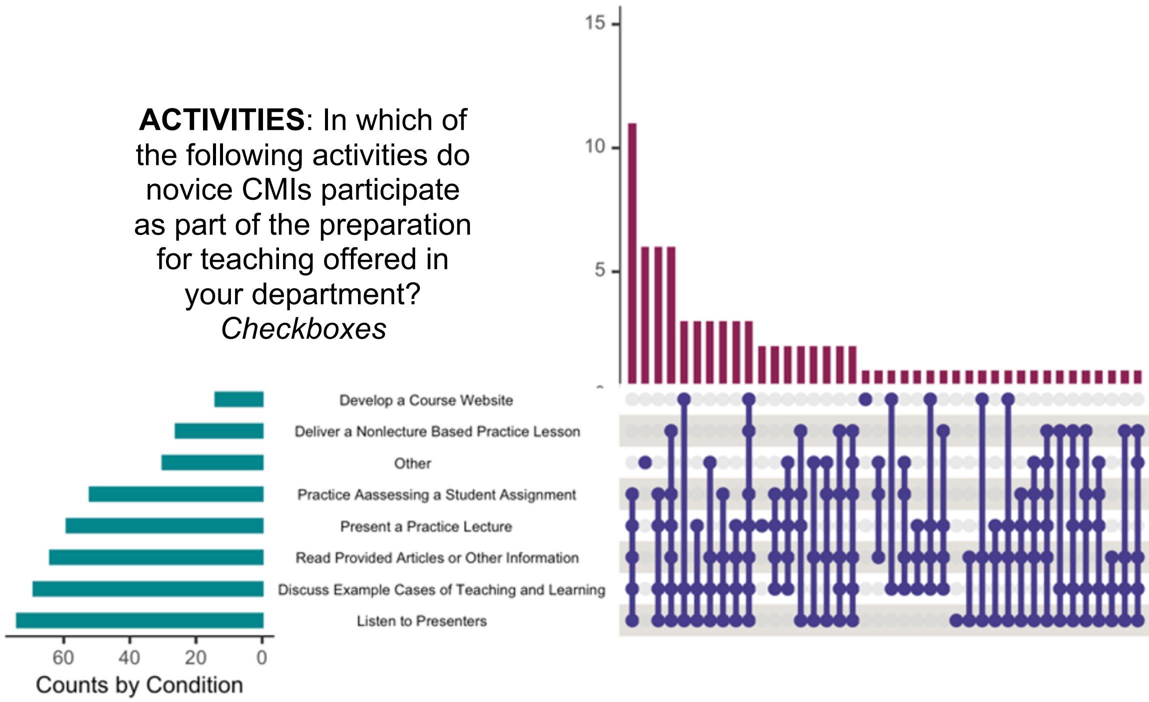

Figure 3. Activities in TPD reported by Providers

Comparative Analysis with Providers and Providees

Given that Providers were teaching faculty (42%) or research faculty (35%) and providees were split between GSIs and LabTAs, analysis included examination of variation in Formats, Topics, and Activities depending on faculty role and whether providees were GSIs or LabTAs. Analysis of Variance indicated there were no significant or practical differences in formats among Provider type (teaching versus research faculty). Additionally, there were no differences larger than 5% among activities, and only one difference among topics around video conferencing software. The existing slight differences follow from preferences of meeting the needs of particular providees. For example, pre-semester orientation was 10 percentage points higher as a format for Providers focusing on LabTAs instead of GSIs (37% vs. 27%). This coincided with one course being more commonly used when providees were GSIs (23% versus 15%). GSI-focused Providers chose coordinator meetings more than LabTA-focused (29% vs. 22%).

Conclusion and Discussion

The purpose of this study was to learn more about (1) Who Providers and their target TPD audiences are (2) What formats, topics, and activities Providers use in their TPD. Information on the first question suggests most Providers were as likely to self-identify as teaching faculty as they are as research faculty (~45% and 35% respectively) with the balance of Providers reporting roles as adjunct or time-limited faculty (e.g., postdoc). The target audiences (the "providees") for most respondents (~86%) were LabTAs and/or GSIs, with novice faculty indicated by fewer than 10% of respondents and undergraduate learning assistants by only 1%. The results from this study suggest that graduate students are the primary focus for most Providers of TPD in doctoral- and masters-granting departments.

What Providers provide in TPD was explored in terms of the formats, topics, and activities reported. Three *formats* of TPD were the most popular with the combination of these three also being the most commonly indicated by respondents: pre-semester orientation, course coordination, and a single course about teaching college mathematics. This supports Hauk and Speer's (2023) work that most doctoral and master's programs have multiple structures available to help novice instructors. The most frequently selected *topics* for TPD were university and departmental policies, active learning, learning management systems, and grading policies. A majority of respondents asserted these four topics were part of their department's TPD offerings. Inquiry-based learning was the least frequently chosen. The *activities* Providers reported using in TPD were most frequently listening to presenters and discussions of teaching examples, followed by reading/discussing articles. The Upset graph in Figure 3 showed how a majority of respondents had a combination of at least two of these three activities.

Implications and Impact

The finding that active learning was reported as a dominant topic, but not a part of TPD activity itself is worth exploring in further research. Do Providers practice what they preach? For example, activity-based learning about teaching such as "practice assessing a student assignment" or "practice a lecture" or "practice a non-lecture activity" might be expected to be more frequently reported than they were if active learning *in TPD* was highly valued. The field of college mathematics TPD is still striving to implement evidence-based teaching practices in a way that is meaningful for instructors and meaningful for TPD itself. Just as student-centered classrooms focus on student involvement and engagement, TPD can productively focus on novice instructor/LabTA/GSI involvement and engagement (in addition to listening and reading). More broadly, this indicates a need for assessment of the effectiveness of TPD. Such assessment would provide indicators and standards for the ways in which TPD is accomplishing intended goals for instructional development (Hauk & Speer, 2023; MAA 2020).

Limitations and Future Studies

Limitations of this study include the fact that this study's sample provides a national picture rather than a more granular understanding of the program. For example, this study collected survey data where respondents chose what they did according to our pre-defined categories. Although this gave us a broad national picture, it limits the understanding of how specific activities are enacted for each topic. For example, for the selection "reading articles" within the survey did not gather information on what occurred after the reading of the articles. Current projects are underway to better understand exemplar programs (Yee et al., 2022), and future studies could use the results of this study to further detail how U.S. mathematics departments implement activities within topics and within formats of TPD.

Acknowledgements

We would like to thank the Expert Providers and Advisory Board Members who helped us create the survey and those who completed some or all of the survey. This material is based upon work supported by the National Science Foundation under Grant No. DUE-2021139 and 2020952.

Experiencing Tensions of Nepantla While Working Toward Critical Transformations From Within

The ACT UP Math project is studying the role and impact of research-practice partnerships between mathematics education experts and mathematics department faculty to critically and systematically initiate transformative efforts to improve the experiences of students with marginalized identities in introductory mathematics programs. This paper explores the shared experiences we encountered while working toward critical transformations of three departments from within those departments, focusing on three tensions that surfaced and framing these tensions as expected and necessary components of the process of critical change. These three tensions explore the role of identity as neutral or central, the enactment of power as power over or power with, and the role of students as experts or novices. These expected and necessary tensions are evidence of the transformations from dominance toward criticality happening within the departments.

Keywords: critical transformation, equity, department change, research practice partnership

Motivation and Overview

Barriers to equitable learning outcomes and inclusive learning experiences in mathematics education have been widely researched and include issues of implicit bias (Greenwald & Banaji, 1995), microaggressions (Leyva et al., 2021), instructors' minimization of existence and impact of microaggressions (McNeill et al., 2022), negative instructor relationships (Battey et al., 2018; Hill et al., 2010), stereotype threat (Steele et al., 2002), and sense of isolation (Good et al., 2012). Math stakeholders are aware of the need to attend to equity within their math programs, but they are often not familiar with how to accomplish this, and they feel disengaged from these conversations due to a lack of training (Apkarian, et al., 2021). Stakeholders need support to develop critical understandings of the factors contributing to differences in outcomes and experiences for marginalized students and to translate their understanding into action. To accomplish this, the ACT UP Math project is studying the role and impact of research-practice partnerships between critical mathematics education researchers and mathematics department faculty to critically and systematically initiate transformative efforts to improve the experiences of students who are members of marginalized identity groups in introductory mathematics programs.

In Fall 2022, the leaders from the three mathematics departments in collaboration with critical mathematics education researchers began the formation of a Networked Improvement Community (NIC) to initiate improvement cycles to critically transform their introductory mathematics programs. Each of the mathematics departments formed local NICs composed of various stakeholders (instructors, administrators, and students). The local NICs collected quantitative and qualitative data to observe the equity issues needing to be addressed; then they met to reflect and discuss what they saw in the data and developed a plan for programmatic changes to implement in Fall 2023-Spring 2024. Throughout this process, the mathematics education researchers worked with the local NICs to support their understanding of critical transformations and develop action plans and collected data to better understand the experiences of the NICs. This paper explores the shared experiences we encountered while fostering critical transformations, focusing on the tensions that have surfaced and framing these tensions as expected and necessary components of the process of critical change.

We are guided by the following research question: *What tensions are experienced by research-practice partnerships, as mathematics department stakeholders work together to critically transform their introductory mathematics programs?*

Framing Critical Transformations and Tensions

Critical transformations require that we critique and challenge the existing structures that shape students' mathematical experiences, and we seek to make improvements that extend beyond the confines of these systems. These systems include the mathematical content we teach, the way we teach it, the support programs for students, the departments that house these programs, the advising processes placing students into these courses, and much more. As we work in partnership to change introductory mathematics programs from within these programs, we draw on Gutiérrez's (2002) distinction between the dominant and critical axes of equity within mathematics education. The dominant axis attends to achievement and access, and is the primary - and sometimes only - component of equity that gets attention when undergraduate mathematics stakeholders discuss the importance of diversity, equity, and inclusion (DEI) (Tremaine et al., 2022). Focusing equity efforts on the dominant axis positions these changes within the existing system. While programs seeking to improve access and achievement can be important in supporting students from marginalized identities to succeed (Palid et al., 2023), such programs do nothing to change the system that these students are entering and can actually function to maintain systems of oppression rather than reform them (Martin, 2019). To discuss equity fully, we must also attend to the critical axis, which encompasses issues related to identity and power. Attention to the critical axis emphasizes not only valuing the representation and success of a diverse population within a current system, but also valuing the changes that population may require or make to the system. Therefore, attending to the critical axis necessitates working toward changes to the existing system.

Gutiérrez draws on the indigenous Nahuatl word *nepantla* to emphasize the tensions that exist within the intersection of the dominant and critical axes. Nepantla describes the in-between, liminal space between worlds. Anzaldúa (2002) emphasizes that "transformations occur in this in-between space, an unstable, unpredictable, precarious, always-in-transition space lacking clear boundaries," and that nepantla is associated with "being in a constant state of displacement - an uncomfortable, even alarming feeling" (Anzaldúa, 2002, p. 243). Gutiérrez (2015) emphasizes the power of these tensions; within this transformative and liminal space of nepantla we will experience tensions, but these tensions are necessary to transform mathematics education.

In this study, we explore the tensions observed as the NIC members work within the systems of introductory college mathematics programs to change these very programs. We specifically view the NIC members as walking with one foot in each of the worlds of the dominant and critical discourses in undergraduate mathematics. By operating from within the existing systems, one must have experienced some degree of success within that system: all of the NIC members are working to complete a mathematics degree or already hold graduate degrees in mathematics or mathematics education and are employed within or work frequently with mathematics departments. Recognizing the success the NIC members have experienced in these systems does not ignore the systemic barriers and struggles the NIC members themselves experience, but it does place them in a precarious position to see these systems and critique them. This analysis identifies shared tensions expressed among the three NICs and tensions that the research team observed and expressed. Drawing on the framing of nepantla, we emphasize that these expressions of tensions are evidence of the transformations occurring within these departments as they move within one world (dominant discourses) to create another (critical discourses), and we hold these expressions of tensions up as positive enactments of working to change the systems from within. We deeply respect and value the NIC members for engaging in this work and expressing their tensions and vulnerability.

Methods

Networked Improvement Communities

A consensus is emerging that "the department" is a prime locus for change (e.g., Austin, 2011; Larnell, 2023; Lee et al., 2007; Reinholz & Apkarian, 2018; Smith et al., 2021; Voigt et al., 2023). ACT UP Math seeks to support critical changes through Networked Improvement Communities (NICs; Penuel, 2020). In a NIC, a group of stakeholders convenes around a common aim, conducts a problem analysis, engages in continuous improvement cycles, and shares information across the network to contribute to collective progress. Each of the three local ACT UP Math NICs are positioned as *change agents* working to instigate critical transformations within their departments. The broader ACT UP Math NIC is made up of the members of the local NICs and the research team.

Alpha University is a public master's degree-granting university with moderate research activity. Alpha University is both a Hispanic-Serving Institution and an Asian American Native American Pacific Islander Serving Institution. Introductory math courses are taught primarily by faculty members in small classes using active learning strategies. The NIC is composed of two faculty leaders, two faculty members, one lecturer, one graduate student instructor, and two undergraduate transfer students. The NIC met every two weeks for two hours during Spring 2023. After a first iteration of their data exploration, the NIC developed plans to disrupt the placement system for lower division mathematics courses through self-placement and is driven by a goal to create positive relationships between students and mathematics.

Kappa University is a private, not-for-profit, highly selective doctoral degree-granting university that is research-intensive. Introductory math courses at Kappa had previously been taught primarily by graduate students in small, coordinated courses with a group-work focused recitation once a week, but very recently have shifted to having all calculus I and II courses taught by a teaching faculty member in large classes with weekly recitations taught by graduate students. The Kappa NIC includes eight members, six of whom regularly attended meetings. Of these, four are administrators outside of the mathematics department and four are mathematics instructors and/or coordinators, including the two co-leaders. The Kappa NIC meets monthly via Zoom. Many NIC members had personal relationships with the co-leaders and joined because of those relationships and their trust in the co-leaders. Although it was not an explicit intention of the NIC leaders to only recruit women, all regularly attending NIC members identify as women.

Tau University is a public, doctoral degree-granting, comprehensive university with a *high research activity* Carnegie classification and two campus locations. Most math courses are taught by faculty in small classes with some instructors using active learning strategies. The Tau NIC includes 11 members and is led by three faculty members. Nine members are instructors in the mathematics department and two members are administrators at the college level. The NIC meets monthly via Zoom, partly due to their institution being spread across two campuses, and the leaders meet monthly to plan each NIC meeting. One of the leaders recruited the other two co-leaders, and together they encouraged other faculty members to join with a mass email describing the project. After a first iteration of their data exploration, the NIC has decided to focus on improving individual instructor pedagogy given the varied nature of the data they observed and cultural values about instructional autonomy.

The **Research Team** is composed of eleven people from five different, research-intensive universities. Our varied identities and experiences shape how we enter this work, the power dynamics at play within our team and how we relate to the local NIC members, our individual motivations for engaging in this research, and how we interpret our work. We practice reflexive journaling as researchers and often engage in discussions about how our own identities may be leading to biases and blindspots in our approach to this work. The **ACT UP Math NIC** is made up of the research team and the members of the local NICs, and we meet once a month. As a research practice partnership, the research team is considered part of the broader NIC, and as such we view the tensions the research team experiences as part of the data for this study.

Data and Analysis: Critical Ethnography

Our analysis draws on approaches from critical ethnography, an ethnographic research method that seeks to explicitly critique and transform systems of oppression and inequitable power relations (Palmer & Caldas, 2015). This study takes a participatory research approach using research-practice partnerships such that the researchers and the local NIC participants are in ongoing dialogue and engagement, operating together as a research-practice NIC to make changes to departments and cultures (Bryk et al., 2015; Coburn et al., 2021; Martin et al., 2020).

The data from this analysis comes from structured field notes of NIC meetings, semi-structured interviews, and reflexive journals completed by NIC members during Spring 2023. The structured field notes were completed by a researcher who attended each of the NIC meetings and documented our observations, reflections, successes, challenges, noteworthy language, and observed power dynamics. The semi-structured interviews asked NIC members about their experiences over the last semester, how they became a part of the NIC, how data were explored, and the role of equitable decision making. The interviews were conducted via Zoom and were audio recorded and transcribed. NIC members engaged in reflexive journaling throughout the semester, completing 2-5 journal entries, which allow emancipatory dialogue with the data and can help mitigate power relations between participants (Malacrida, 2007).

The research team conducted an analysis of each NIC's experiences over the past year, seeking to identify stories that were emerging from the data. This included reading all reflexive journal entries, field notes from the NIC meetings, and interview transcripts and notes from the end of the semester. We then identified storylines focused on tensions that were either directly expressed by the NIC members or leaders (including the local NICs and the broader ACT UP Math NIC) or observed by the research team. In the results, we identify these tensions as specific instantiations of moving between the two worlds of dominant and critical discourses within undergraduate mathematics.

Results

Through our experiences, observations, and analyses, we recognized ways these tensions were experienced by all local NICs and the broader NIC. In telling the story of these tensions, we chose to center the ways each tension was experienced by one of the three local NICs.

Role of Identity: Neutral and Central

The NICs are positioned in nepantla between two worlds: the critical world of centering students with marginalized identities in their change efforts and the dominant world of not naming the specific populations and instead seeking improvement changes for all students. As we set out to support mathematics departments to critically transform their introductory mathematics programs from within, we purposefully chose to not specify any populations of students that we wanted the NICs to center in their action plans. Specifically, we did not encourage the NICs to explicitly attend to race, gender, sexuality, or other social identities. We recognize that this choice may perpetuate color evasiveness and other identity neutral stances which can serve to reinforce power structures (Goldin & Khasnabis, 2022).

Our choice to not prescribe a student population for each site came from wanting to support the equity needs specific to each institution through exploring disaggregated data from their institution in comparison to a national data set. We created data dashboards (Bolick & Voigt, 2023) drawing from extant data from 21 institutions (including each of the local NIC institutions) about students' experiences in introductory college mathematics. These dashboards, and the data exploration reflection activities created for them, encouraged the NIC members to explore the data by filtering various identity markers, including race and ethnicity, gender, first generation status, sexuality, and institutional comparisons. Some of the research team assumed the NICs would use these data explorations to identify populations of students who expressed exclusionary experiences and to use this to inform their action plans in their unique context, while others did not expect the NICs to center an identity group. The research team reflected on how we did not communicate these assumptions or expectations to the local NICs, because some of the research team believed their engagement with data dashboards would naturally lead to identifying populations of students at their institution who were especially in need of critical transformations to their introductory mathematics program.

Though the NICs did attend to student identity in their data explorations, they did not attend to a specific identity in their action plans. The Tau NIC's goal was to motivate all students to engage/succeed in mathematics, with little attention brought to any specific population. The Alpha NIC have been exclusively attending to lower division courses and the students who take those courses. The Kappa NIC members expressed interest in focusing on students who persist in the calculus sequence and those who do not and are interested in students who did not have access to calculus. Both of these populations can be proxies for other populations, given that research shows women are more likely to not persist in the calculus sequence (Ellis et al., 2016) and that low-income students have less access to advanced mathematics courses (Battey, 2011; Solorzano & Ornelas, 2002), but the Kappa NIC did not explicitly name any student population.

Role of Power: Power Over and Power With

The NICs are positioned in nepantla between two worlds: the critical world of collectively leading from within their departments to make changes to them, and the dominant world of hierarchies and privileged groups exerting power over others. While striving to increase equity within mathematics departments, we see a tension between discomfort with an image of power that we are most experienced with—*power over*—while working collectively toward changing systems built on this version of power. To work within this space of tension, we turn toward a different understanding of power. Allen (1998) defines *power with* as "the ability of a collectivity to act together for the attainment of a common or shared end or series of ends" (p. 35), contrasted with *power over*, defined as "the ability of an actor or set of actors to constrain the choices available to another actor or set of actors in a non-trivial way" (p. 33). The tension we see related to power describes the difference between enacting leadership through power over others via hierarchies and top-down decision making versus enacting leadership through power with others, which emphasizes democratic decision making and a rejection of hierarchies.

Tensions related to power dynamics were present among all three local NICs and among the researchers and the broader NIC. The Kappa leaders expressed not wanting to center their own "random ideas" about how to improve the department, discounting their own informed perspectives. The Alpha NIC leaders similarly expressed hesitancy toward enacting power over their NIC members and were "reluctant leaders," as noted in a researcher's summary of their NIC dynamics. Power dynamics were especially apparent within the Tau NIC. The researchers who observed the monthly Tau NIC meeting documented in the fieldnotes a sense of "power avoidance" or hesitancy to make decisions among the three co-leaders of the Tau NIC (Olivia, Natalie, and Garrett) throughout the spring semester. These co-leaders also reflected on the power dynamics at play in their leadership, noting individual experiences of these tensions. Olivia is a math education researcher and administrator at the college level at Tau with primary responsibilities to lead instructor professional development; this formal leadership role may have led to implicit assumptions she would lead the Tau NIC. She opted for distributed leadership by selecting Garrett and Natalie as co-leaders of the NIC, purposefully choosing instructors within the introductory mathematics courses to support more buy-in to any initiatives proposed by the NIC. Olivia reflected on the challenge of simultaneously valuing their voices and recognizing that they have not "gone through some sort of training ahead of time," so she supports them and tries "to push them out of those areas where they're comfortable to get them to do things that they might not otherwise do if they weren't pushed." After co-leading the Tau NIC for the semester, Natalie and Garrett expressed confusion and feelings of imposter syndrome in leading a group to enact changes while learning more about equity in higher education themselves. By putting the onus to enact equity-centered changes on mathematics department members, rather than equity experts from outside the mathematics department, such discomforts and feelings of inadequacy are to be expected and supported.

Role of Students: As Novices and as Experts

The NICs are positioned in nepantla between two worlds: the critical world of viewing students as experts of their own experiences and the dominant world of believing students are novices. In their work toward adopting more critical views of teaching mathematics, all three NICs recognized the importance of students' voices in telling their own stories but met tension when implementing policies that reflect this belief due to dominant structures. This tension arose for the Alpha NIC while navigating the inclusion of students within their NIC, for the Kappa NIC while coming to the realization that they wish to not only gather student feedback as data but also to incorporate students into the structure of their NIC, and the Tau NIC while transitioning from thinking of student voices as aggregated and biased opinions on course evaluations to meaningful perspectives that can be actively sought as qualitative data.

Here we highlight how the inclusion of students in the Alpha NIC surfaced tensions. NIC members were cognizant of the power imbalances arising within the NIC, and the research team noted this dynamic at the onset of the NIC formation. One faculty NIC member, Caroline, called out the power dynamics within the NIC, acknowledging in an interview that there is a "power dynamic between faculty (of different ranks/positions) and students in the NIC." The NIC faculty attributed these power imbalances due to "natural" hierarchies (student/instructor), logistical aspects (who leads the meeting), or the result of student characteristics (shyness).

NIC leaders attempted to mitigate this power differential by creating inclusive spaces for students to hold equal weight in the conversations through intentional pairings of instructors and students, small group discussions and share-outs, and a democratic voting system to decide next steps. While the democratic process of voting within the NIC introduced a measure of equality in decision-making, it did not counter the authority of faculty perspectives in decisions since faculty members outnumbered the students in the NIC. Students did not explicitly name a power dynamic occurring across students and faculty, but shared experiencing discomfort while in NIC meetings. One student NIC member shared that although they are not shy, settings "like [the NIC] make me a little bit nervous," and "it is a bit intimidating having professors in the group, especially since three are current professors of mine." Students identifying their own discomfort without recognizing the power imbalance placed the blame on themselves. The Alpha NIC was simultaneously grappling with the role of student perspectives to inform action plans. The Alpha NIC created two action plans focused on suggestions disclosed during a student focus group: restructuring the placement system for first year mathematics courses for students to self-place and engaging in interdisciplinary mathematics seminars. By valuing the voices of students in the focus group, the NIC saw students as experts on their own experience. Juxtaposing the students in the focus group with the status of student NIC members illustrates the tension well. The students outside of the NIC are positioned as experts, yet the students within the NIC are positioned as novices.

Conclusion, Implications, and Next Steps

Our research team felt empowered in naming the tensions around the roles of identity, power, and students and sharing them with our local NIC partners. By framing these tensions through the lens of nepantla, we feel more validated in our experiences and empowered to live with them instead of trying to rush away from them. When we shared these tensions with our local NIC partners, they expressed also valuing the tensions being named and shared, that these tensions "resonate," and that they "appreciate the space to think about the tensions." When responding to each specific tension anonymously on a Jamboard, most participants reflected on how they experienced these tensions, however one commenter shared that they did not resonate with the power tensions: "Perhaps I'm oblivious, but I haven't noticed power-over tensions, despite the fact that we have college-level and department leadership working alongside junior faculty."

These tensions also bring to the forefront the benefits and challenges of working within a research-practice partnership (such as through NICs) and how to do so equitably (Denner et al., 2019). Ryoo et al.'s (2015) definition of equitable research-practice partnerships includes "challeng[ing] power dynamics and hierarchies; regularly clarify[ing] and surfac[ing] needs, wants, and expectations relating to the partnership and partners' professional contexts; and attend[ing] to the changing needs of the collaboration" (p. 1). We position tensions as part of our work of being an equitable partnership, and by framing these tensions as existing within nepantla we view them as evidence of the progress the local NICs and the broader NIC are making to shift from a dominant to a critical framing. Our next steps within this work include asking the local NICs and the researchers to regularly reflectively journal about these tensions as they engage in action planning and implementation and use these insights to guide our attention during our observations of the NIC meetings.

Investigating How Students Try to Solve Real Analysis Problems

Brandon Watson
Texas State University

This study observed real analysis students attempting the homework assigned by their instructor to identify how they used resources, specifically example proofs, to complete their homework. The data consisted of seven students in total over three instructors. Overall, the study found that students tended to adopt a recurrent style of how they used their notes, or did not use their notes, to advance their solutions. However, there were some instances where the students would deviate from their style which could be linked to the type of problem as well as how the instructor taught that topic. This study contributes insight into how real analysis students may use their resources for the tasks assigned by the instructor.

Keywords: Problem situation image, Tentative solution start, Resource framework

Introduction

In Real Analysis, instructors introduce definitions and theorems which are part of the material that the student needs to know. Theorems and other statements come tied to proofs that are both material the students need to know as well as something the students must learn to write. The proofs that the instructor demonstrates in-class, thus, serve a dual purpose. One role of the proof is to prove the theorem/statement the instructor has introduced. The second role of the proof is to serve as a demonstration of the process of proving to the students. Research has already suggested that lecturers tend to recommend their notes as the primary resource for students (Ni She, Bhaird, Fhloinn, & O'Shea, 2017). It stands to reason that a skill the students should develop is to be able to reference the proofs they do in class as examples to inform themselves on how to write the proofs that they are asked to do for homework.

Studies have shown that students do tend to use curriculum materials and class notes as a primary resource when working on class material (Anastasakis, Robinson, & Lerman, 2017; Ni She, Bhaird, Fhloinn, & O'Shea, 2017; Pepin & Kock, 2021). Albeit, the students may leverage certain resources more heavily when with certain goals such as high grades or simply passing in mind (Anastasakis, Robinson, & Lerman, 2017). This study wanted to dive deeper into *how* students used their resources. As such, this study documented students working on homework tasks and found that students tended to have a style on how to use their class notes to complete homework tasks. Interestingly, certain homework tasks tended to deviate students away from their usual style. This seemed to occur due to certain features of the task and how the instructor presented related proofs. Building on an existing framework, this study extends the literature on how students use resources and worked examples in the context of proof-based mathematics courses.

Research Questions

1) When and how do real analysis students leverage the examples presented in-class to complete their homework tasks?
2) What factors influence the reason that real analysis students use their notes to complete their homework tasks?

Resource use has been investigated by a number of researchers (Galbraith et al., 2000; Guedet & Pepin, 2018; Muir, 2014; Radovic & Passey, 2016). However, research on resource use remains limited for a proof-based mathematics context. This study focuses on that context in an effort to broaden our understanding of how students use their instructor-provided resources for the problems they are assigned for homework.

Firstly, it is important to describe how a student comes about making a solution attempt for a homework problem. While working on homework, students may have different problem situation images associated with the topics in the question as well as the task assigned to them (Selden et al., 1999). Students typically make an initial judgement of the difficulty of the task and assesses whether they need to reference their notes or if they think they know how to do it. This initial assessment leads the student to their initial tentative solution start (Selden et al., 1999). For this study, it was important to note the instances of when students did not feel the need to reference their notes or note what they referenced when they did reference their notes. This helped define *when* students would use their notes by looking both at the task itself as well as how a student initially responded to the task.

As for *how* students used their resources, I adapted the technology framework developed by Galbraith, Goos, Renshaw, & Geigher (2000) into a Resource Use Framework. I conjectured the use between resources and technology can be similarly classified since in both cases the object being used by the student is still a tool for completing a task. As such, there are four categories that students could be classified for how they used their resource:

Table 1: Resource Framework

Resource as Master	A student copies a proof or makes every decision based on their notes without a way to check the adequacy of their decisions
Resource as Partner	A student has a tentative strategy but searches their notes to either find a new strategy or justify their own, or the student finds a relevant example but needs assistance to adapt it into a solution
Resource as Servant	A student either has a strategy and uses their notes to complete their strategy, or a student finds a relevant example and is able to fully adapt it into a solution without assistance
Resource as Extension of Self	A student knows exactly what they need from their notes so the notes act more as an extension of memory rather than a tool

Data Collection

Data was collected from three Real Analysis classes over two semesters each of which had different instructors from a large, public university in the United States. I observed the instruction and took field notes. The field notes consisted of what was written on the board, the comments the instructor added, and questions or remarks the students made. The field notes provided a detailed reference for the information the students received during class and what their resource of written notes could possibly resemble when they are doing their homework.

I recruited students from the aforementioned classes. In total, seven students participated. The student interviews consisted of asking students to attempt problems from their assigned homework. Priority was given to problems that I could connect to parts of the instruction that occurred in class. This provided an opportunity to observe whether the student needed the resource from class or could identify the same resources I had if they did look into their notes. Students were videoed as they attempted to solve each problem. The video provided both verbal and visual evidence of what the student was doing at the time. The overall structure of the interview had three parts per question. Firstly, I let the student attempt the problem independently, noting whether or not they used any resources. If they formed a solution independently, I moved on to the next task. If not, I would ask them if they knew of anything from class that could help. Sometimes the student would find something and other times they would not find anything. If the student did not find anything or they did not yet look at what I thought was most relevant, then I would suggest for them to consider what I thought was relevant. Sometimes the student could use what I suggested and other times they could not. If the student was struggling with using the resource I referenced, I would continue to work through why the example could be useful to see if they could ever connect why I would use that part of their notes. Overall, this provided insight into the problems that a student may not need notes for and what problems a student may want notes for. If the student wanted notes, there was an opportunity to observe what the student deemed possibly relevant to the problem. If they found something they thought was relevant, then there was a chance to see if they could evaluate whether or not it was relevant. Lastly, if provided something relevant according to the interviewer, then it could be observed whether the student could make connections from what was provided to the problem.

Data Analysis

For each student, I made an initial profile based on the experience of the interviews. These profiles were made by considering each problem the student did and how they used resources during each one. Each interview consisted of about 5 problems and most students had 5 interviews providing me with approximately 25 questions to use as my unit of analysis per student. This provided a frequency on the ways they used their resources which provided insight into the tendencies of each student.

Students' resource use was broken down per task and I coded each student attempt at a task using the following categories: (a) Did not use any resources, (b) referenced class notes, (c) made their own example, (d) looked for an example or tried to make their own but failed, and (e) could or could not use an example provided by the interviewer. Of these actions, they also have varying degrees of success as well as different ways of being performed. However, these cover the actions around resources that students could perform. A frequency table was generated showing how frequently each student performed any of those actions. With the frequencies, I sought to identify whether each student had a recurrent style of resource use, addressing Research Question 1. As a note, the students were not asked directly to describe their own resource use style.

After this, I examined students' resource use by tasks. Though not all students were assigned the same problems, the topics were largely consistent among all the students. The topics mostly spanned set theory, like supremum and infimum, and sequences. Thus, the data gathered covers similar problems for each student. This uncovered that some problems tended to have the students perform similar actions to one another even for students that did not typically behave in that way. This suggests that the task itself has influence on how the student will decide to tackle the problem regardless of their usual tendency. The characteristics of the task itself as well as how similar tasks may have been presented in class both serve as factors towards addressing Research Question 2.

Results

The following are a few exemplary student cases that show how students can adopt different styles on their usual resource use when attempting homework tasks.

Jordan

Jordan frequently looked through their notes for help on their homework tasks. On several occasions, Jordan was able to adapt proofs efficiently and effectively from class into solutions for their homework tasks. Here is an example: Given a set $E \subset \mathbb{R}$ and $r > 0$, define the set $rE = \{rx: x \in E\}$. In Jordan's notes, they found where the instructor proved that: $\sup(E + r) = \sup E + r$ for the set $E + r = \{x + r: x \in E\}$. The following table provides the proof that the instructor gave during class and how Jordan adapted it to solve the problem.

Table 2: Instructor vs Student Proof for a Similar Task

Instructor's Work	Jordan's Work
Assume that $a \in E + r$ Then, $a = x + r$ for some $x \in E$. Since $\sup E$ is an upper bound of E, $x \leq \sup E$ so $a = x + r \leq \sup E + r$. Thus, $\sup E + r$ is an upper bound of $E + r$. Now assume N is an upper bound of $E + r$. Let $x \in E$. So $x + r \in E + r$ so $x + r \leq N$. Then $x \leq N - r$. Since $N - r$ is an upper bound of E, $\sup E \leq N - r \Rightarrow \sup E + r \leq N$ Then $\sup E + r$ is the supremum of $E + r$.	Assume $a \in rE$. Then, $a = rx$ for some $x \in E$. Since $\sup E$ is an upper bound of E, $x \leq \sup E$ so $rx \leq rsupE$. Thus, $rsupE$ is an upper bound of rE. Now assume N is an upper bound of rE. Let $x \in E$. So $rx \in rE$ so $rx \leq N$. Then $x \leq \frac{N}{r}$. Since $\frac{N}{r}$ is an upper bound of E, $\sup E \leq \frac{N}{r} \Rightarrow rsupE \leq N$. Then $rsupE$ is the supremum of rE.

When working on this problem, Jordan read their notes and interchanged the parts as they read. Jordan was able to write the proof without assistance from the interviewer. This illustrates how Jordan was able to both recognize a relevant example to adapt as well as an ability to recognize what parts of that proof were interchangeable with different characteristics. I coded this as Resource as Servant. Jordan both identified the relevant proof as well as efficiently identified all the relevant parts that should be changed based on the context. The notes served as an outline, but Jordan had the knowledge on how to fill in the blanks or change the instructor's work.

Peyton

Peyton did not frequently use their notes. However, they did reference them a few times. More frequently, Peyton thought up their own *conceptual examples* or recall *conceptual examples* from class. Conceptual examples refer to specific cases from which Peyton would try to generalize from. Such as using the interval [2,3] to reason why a closed, bounded interval must contain its supremum. They would try to use those to reason through what they needed to do with their homework tasks. Occasionally, this strategy showed a lot of power for certain tasks. However, at other times this technique was not effective enough for Peyton to produce a proof.

One instance of Peyton using their notes was when asked to prove that $x_n = 2n + 6$ is a strictly increasing sequence. Peyton initially looked up where the instructor talked about monotonicity, but they did not find an example they judged to be similar. During the second phase of this task, I suggested to look at a proposition where the instructor proved that $\{x_n\}$ is non-decreasing if $x_n \leq x_m$ for all $n \leq m$. Peyton noted that the instructor used induction, so they tried to implement induction for this problem. With this approach, Peyton noticed that: $x_n = 2n + 6 \leq 2(n+1) + 6 = x_{n+1}$.

Peyton finished up their argument by establishing that $P(1) < P(2)$ and, by the logic before, $P(n+1) < P(n+2)$. After completing this, Peyton decided that a direct proof just stating that $x_n = 2n + 6 < 2n + 2 + 6 = 2(n+1) + 6 = x_{n+1}$ was a sufficient proof.

I coded this proof construction as Resource as Partner. Peyton initially could not find any examples they thought would help to solve this problem. With my suggestion, Peyton was able to find an instance where they did something sort of similar to this problem. Peyton noted that the instructor used induction and decides to take that as a suggestion to do that themself. With this suggestion, they were able to make a satisfactory solution. However, afterwards, they noted that they do not think induction is necessary. This suggestion at the end is what distinguishes this resource use as Resource as Partner rather than Resource as Master. Peyton took the suggestion from their notes, but they keep a critical eye on what we're doing.

Charlie

Charlie frequently did not use their notes nor construct their own examples. The frequency analysis of their task solutions revealed that they rarely used their notes and often attempted to reason using the definitions and theorems presented in class. Occasionally, Charlie would construct their own examples, but this usually did not yield a valid solution to the task. When they ran into obstacles, I would provide Charlie with examples from the class or create a unique example to reason with, but they frequently did not use these to produce a valid task solution. Charlie usually mentioned that they wanted to go talk to the instructor during office hours to get help when they got stuck. This overall disinterest in using their notes or reasoning with examples contrasts with all the other students. However, in many cases, Charlie was successful at making strong reasoning connections between the definitions and theorems from class and the problem. With these connections, Charlie demonstrated throughout the interviews that they could construct proofs in real analysis without using their resources for many problems. However, there were several times that Charlie got stuck, but rather than using their available resources at the time instead opted to visit the instructor. For the purposes of this investigation of example use, I found that this student showed individual preference against using examples. However, there were a few occasions where they did opt to use examples, which I will discuss next.

There were only two instances where Charlie directly used notes. One of these instances was for the first tasks asking to prove a limit of a sequence by definition. The other time was to answer the following question: Suppose $S \subset \mathbb{R}$ is nonempty and bounded below and let $v = inf\ (S)$. Prove the following statement: For every $y > v$, there exists $s \in S$ such that $s < y$.

Charlie noted that the instructor proved something similar for the supremum. They changed necessary components to achieve a correct argument. This time the instructor's proof was the analogous supremum problem. As such, the student had to change very little, but Charlie did both identify the relevant proof and adapted it effectively for this context. Similar to the first example, I coded this as Resource as Servant.

Summary of Student Cases

For the students in this study, there were no particular moments where the students seemed to demonstrate Resource as Extension of Self. As such, there is no example given here. Resource as Extension of Self would look like a student bringing up a specific instance where a process was showcased by the instructor, but the student did not necessarily need it to complete the problem. Rather, the student would like to have the resource available in case they need just a reminder. In some sense, the resource would act as an extension of memory rather than a tool needed to help actively.

Additionally, it is important to end off by noting that all the students could change their position to their resources from problem to problem. For instance, every student faced with their first sequential limit problem to solve using the definition of convergence used their Resources as Master. Every student flipped to an instance where the instructor proved the limit of a sequence by definition and used that as a line-to-line inspiration of their approach. I conjecture that this is due to how the instructors emphasized the routine of this type of proof. When doing these proofs in class, the instructors tackled the problems using the same routine and would always mention that this is how the definitions proof work. While this can sound similar to the Resource as Servant examples from above, these students approached the problem differently in these cases. They acknowledged that they were relying on the instructor's notes to complete the problem. Before, they knew those problems held everything necessary to prove the problem, so they strategically used that structure to make sure their proof was complete. Here, they did not know how to write the proof, so they needed to rely on everything from the notes to complete their proof. This shows that students can renegotiate their position with their resources as they realize different limitations in their preparedness for certain tasks as well.

Discussion

For this study, the class notes were the standard that the student resource use was considered against. The class notes could be divided into providing Conceptual Examples and Proof Examples. Conceptual being the specific examples such as $(1,3)$ as an open interval, and Proof Examples being any instance of a complete proof provided in class. When considering these types of resources, the uses of them can be restrictive. From the observations made, the four categories that the framework considers are sufficient to categorize the resource uses. Largely, Proof Examples are the main resource used by students for their homework. As such, for proof-based mathematics, the resource use framework here could be a useful tool to describe how students are interacting with their available resource in a certain context since it was adapted to fit this situation.

The analysis brings forth a few details about how students use their resources while working on homework tasks. Namely, real analysis students adopt typical styles on how frequently they use their direct class note resource. Some students use their notes at a much higher frequency than others. This frequency might be tied to how confident a student is in their capability to adapt what they read in their notes. This can be partially substantiated by the fact that when I would bring up aspects from class, students that would frequently not reference their notes tended to have a harder time adapting the resources brought forth to them. For instance, Charlie would not commonly use the resource I mentioned to them. Instead, Charlie would frequently continue thinking about the problem using just the definitions and theorems they were already considering. On the other hand, Jordan frequently used their notes to complete their homework and could commonly take at least one useful part from any resource that I offered to them.

A second result of this data is that some types of questions tend to influence students to seek out help from their resources regardless of their previously established style. For instance, when students were asked to prove a limit of a sequence using the ϵ-k definition, every single student looked up an example from class and attempted to copy that structure for the homework task's sequence. I conjecture that this results from how the instructor routinized the problem during the instruction, or the very specific technique the instructor required the problem to be completed using. With this, the students might have decided that their best strategy would be to attempt an adaptation of what the instructor was doing in-class. In turn, this leads them to return to their resources and attempt to use them as closely as possible. This could influence them approaching the Resource as Master.

Conclusion

In conclusion, students can use their resources in various ways. The way that students use their resources can even vary from problem to problem and context to context. This suggests that students may develop an overall style to how they approach their work, but the way that questions are worded or what content they are covering may change how the student decides to approach the problem than they usually would. One of the strong ways that an instructor may be able to influence resource use of the students is by emphasizing a routinization of certain problems like sequential limits. This can be beneficial when the instructor wants students to solve problems in certain ways. By both verbally reinforcing the routine being used as well as repeated demonstration of the routine in use can help bolster a connection for the students between the routine and the types of problems it is relevant for in a student's problem situation image. For students, knowing how to adapt a proof is a key competence for being successful in a class like real analysis. This is not something emphasized in the literature, but it may be an important part of learning at this stage in a student's apprenticeship in proving.

Future research into the link between routinization and resource use by students could provide interesting results into how instruction could be meaningfully designed. Also, this could provide more insight into how problems that share structure may not be seen as routinized by the students.

It is essential to provide opportunities for prospective secondary mathematics teachers to connect advanced mathematics content to secondary mathematics teaching practice, if advanced mathematics courses are to be useful to these teachers. We argue that for teachers to frame teaching and learning in equitable ways, connections to teaching must represent learning in anti-deficit ways. We review a selection of curricular materials satisfying two criteria: first, they are written for use in advanced mathematics courses that prospective teachers may take; and second, they feature explicit connections to secondary teaching practice. We find that representations of learning in curricular materials tend to take binary views of mathematical legitimacy, and frame students as either being correct or incorrect. We conclude with implications for mathematics teacher educators in RUME.

Keywords: content knowledge for teaching, secondary mathematics teacher education, advanced mathematics courses

Many prospective secondary mathematics teachers (PSMTs) complete multiple courses in advanced mathematics (e.g., Ferrini-Mundy & Findell, 2004; Tatto & Bankov, 2018). As recent empirical work demonstrates, it is essential to provide opportunities for PSMTs to connect the content of these courses to the *practice of teaching*, if these courses are to be useful to prospective teachers (Álvarez et al., 2020a; Lai et al., 2023; Wasserman & McGuffey, 2021). Multiple scholars have followed this approach in creating curricular materials for secondary mathematics teacher education (e.g., Hauk et al., 2018; Heid et al., 2015; Lischka et al., 2020; Mathematical Education of Teachers as an Application of Undergraduate Mathematics [META Math], 2020; Wasserman et al., 2022). In this approach, scholars represent teaching through descriptions of student thinking and teaching scenarios. This approach to secondary mathematics teacher education raises the question of how secondary students' learning is represented in curricular materials. This is a critical issue, as instruction in teacher education, including in mathematics classes, is part of the socialization that shapes teachers' images of teaching practice (e.g., Lai et al., 2023).

Our purpose is to review how secondary students' learning is portrayed in curricular materials for advanced mathematics courses that enroll PSMTs. To do so, we reviewed a selection of curricular materials satisfying the following criteria: they were intended for use in advanced mathematics courses that PSMTs may take; and they featured explicit connections to secondary teaching practice. Our review was guided by the research questions: *(1) What approaches have been taken by curriculum writers to connect advanced mathematics* *coursework to secondary teaching practice? (2) How do these connections portray students' learning of mathematics?* We suggest that approaches taken are consistent with Grossman et al.'s (2009) pedagogies of practice. We then analyzed portrayal of students' learning of mathematics in line with Louie's (2017) exclusive and inclusive frames of mathematics and mathematical ability.

Background

Advanced mathematics knowledge can potentially strengthen secondary mathematics knowledge (Conference Board of the Mathematical Sciences [CBMS], 2012; Murray et al., 2017). A typical approach has been to follow Felix Klein's (1924/1932) prescription of considering "elementary mathematics from an advanced standpoint" (p. 1). The hope here is that with a more sophisticated understanding of secondary concepts, teachers will take more productive actions when teaching.

Yet secondary teachers lament their mathematical preparation was irrelevant to secondary teaching (e.g., Goulding et al., 2003; Wasserman & Galarza, 2018; Zazkis & Leikin, 2010). Even when prospective teachers develop a richer understanding of the secondary mathematical concepts that they will teach, they may still exit advanced mathematics believing that they may have become better mathematicians, but not better mathematics teachers (Wasserman & Ham, 2013).

Mathematics teacher educators have historically connected advanced mathematics to secondary teaching along two dimensions: *mathematics content at the secondary level* and *mathematical practice*. The concept of a capstone course for teachers, which is offered by many institutions in the U.S. (Cox et al., 2013), exemplifies the first dimension. In their review of then-present-day capstone coursework for secondary teachers, Murray and Star (2013) found that connections took the form of generalizations or abstractions of secondary mathematical ideas (e.g., geometric transformations and group theory, factoring polynomials and Galois theory), or specific uses of advanced mathematics to define concepts that secondary students may encounter (e.g., limits and irrational numbers). As for mathematical practice, scholars such as Cuoco et al. (1996) called attention to the importance of mathematical habits of mind in teaching and learning mathematics. CBMS (2001) theorized that mathematics teachers must experience mathematical practices in their own learning, so that they can cultivate experiences of mathematical practices when teaching secondary mathematics. This argument is compatible with research on the perspective of teachers. Some scholars have found that when teachers found coursework relevant, it was due to understanding the nature of mathematics practice, and how learning can feel (Baldinger, 2018; Even, 2011; Hoffman & Even, 2019).

The potential of these approaches is unmet. Begle (1979) found that secondary students' performance was associated with neither the number of tertiary mathematics courses taken by teachers nor the average grade received by teachers in these courses. Goulding et al.'s (2003) and Zazkis and Leikin's (2010) surveys found that many teachers report their mathematical preparation is disconnected from teaching. In a study of an abstract algebra course, Ticknor (2012) found that even when secondary teachers wanted to do well in the course, and the instructor saw connections between abstract algebra and secondary mathematics, the teachers still perceived the course as irrelevant to teaching. Wasserman et al. (2018) articulated concrete reasons, given by prospective and in-service teachers, for why their knowledge of real analysis did not inform their teaching, even when they understood the material.

There is a promise of advanced mathematics to shape teachers' practice and an observed inefficacy of advanced mathematics courses to do so. In response, secondary mathematics teacher educators have pushed for explicit connections from advanced mathematics to secondary teaching practice and enacted such connections in written curriculum materials (Álvarez et al., 2020a; Hauk et al., 2018; Heid et al., 2015; Lai, 2019; Lischka et al., 2020; Wasserman et al., 2022). Many of these authors are in the RUME community; indeed members of the above cited teams behind curricula and research have all presented at RUME in the past 5 years.

Another factor in the ecology of secondary mathematics teacher education, particularly when it comes to courses taught by mathematics faculty for PSMTs, is a shift in the teacher education community's focus. For a long time, the sentiment that 'you can't teach math and have students learn without knowing the math yourself' drove funding, research, and course design; now, there is the urgent problem of increasing equitable access to mathematics. A corollary of this observation is that when assessing connections of advanced mathematics to secondary teaching practice, one must not only assess the mathematics, but also the images of equity and inclusiveness in teaching in connections.

To our knowledge, there has been no systematic review of materials taking the approach of connecting advanced mathematics to teaching, including the ways that these curricular materials represent student learning and teaching. In view of the posited connection to teaching practice, and the abundance of materials aligned with this approach, now is the right moment to analyze how exactly teaching and learning are portrayed. The results of this analysis, particularly in terms of equitable and inclusive educational principles, is essential to future work by the RUME community in improving teacher education.

Conceptual Perspective

Mathematics *teaching practice* at any level entails relational work with students, routines for disciplinary discourse, and norms for establishing the legitimacy of solutions. In this sense, the term *practice* is about what practitioners do rather than think or know (Lampert, 2010). Moving up a level from teaching to the teaching of teaching, Grossman et al. (2009) proposed the concept of *pedagogies of (teaching) practice*. By this term, Grossman and colleagues refer to the intentional design of experiences for future teachers that develop their future teaching practice.

Representations and approximations of practice

To articulate potential pedagogies of practice, Grossman et al. (2009) analyzed the education of future teachers, pastors, and therapists. These professions were chosen as comparisons due to their commonality of requiring relational work in combination with the expectation of particular routines and harnessing technical knowledge. Through this work, Grossman and colleagues identified pedagogies of practice that spanned the fields of teacher education, liturgical education, and clinical education. These pedagogies of practice included representations and approximations of practice. In the descriptions below, we follow Grossman et al. (2009).

Representations of practice allow novices to observe aspects of practice. When teachers engage with representations, they can develop ways of noticing and understanding teaching practice. Representations can vary in comprehensiveness and authenticity, and can take a variety of forms, including short narratives of teaching scenarios, videos, animations, and case studies. We consider curriculum materials (for advanced mathematics courses for PSMTs) to feature a representation of practice if they feature a description of a teaching scenario that for instance engages PSMTs in evaluating, describing, or reflecting upon features of the presented scenario.

Approximations of practice allow novices to simulate practice so they can attend to particular aspects of practice, rather than all aspects of the complex, relational practice that is teaching. Approximations may vary in authenticity and complexity. We consider curriculum materials to feature an approximation of practice if teachers are asked to simulate responding to students' mathematical work, evaluate students' work, explain content, or teach a full lesson. Note that approximations of practice may embed representations of practice, as the prompt for an approximation of practice may describe a teaching scenario.

Exclusionary and inclusive frames for the nature of mathematics and mathematical ability

We posit that inherent in any representation of practice of mathematics teaching is an at least implicit frame for mathematics and mathematical ability. Louie (2017) conceptualized exclusionary and inclusive frames for the nature of mathematical activity and the nature of mathematical ability. Within the exclusionary frame are the "rote practice frame", where "mathematics is a fixed body of knowledge" involving closed questions and a focus on answers; and the "hierarchical ability frame", where speed and correctness are valorized, and some students are positioned as helpers and others as in need of help. Within the inclusive frame are the "sense-making frame", where "mathematics is about making sense of ideas and understanding connections" and "the multidimensional math frame"; and the "multidimensional ability frame", where a variety of students are named as resources for peers' learning and skills outside of speed and correctness are valorized (p. 496).

Data & Method

We sought to review curricular materials satisfying two criteria: (1) they were intended for use in advanced mathematics courses that secondary teachers may take, and (2) they sought to make explicit connections to secondary mathematics teaching practice. We also restricted this review to materials developed in the US. In searching for curricular materials, we looked for both the materials themselves as well as reports of their enactment. We considered textbooks commonly used in capstone courses (as reviewed by Cox et al., 2013), those published by professional organizations of mathematicians, and the literature reporting the use of these materials and textbooks in advanced mathematics courses. As well, we conducted a Fastlane search for materials created with the support of the U.S. National Science Foundation.

The authors of this manuscript are developers of curricular materials, namely the MODULE(S^2) materials (Lai, Strayer, Casey, Lischka) and ULTRA materials (Wasserman, Weber, Fukawa-Connelly). We contacted all curriculum writers and investigators that came up in our search (other than ourselves) for copies of materials. Not all authors and investigators responded to requests. Table 1 (on the next page) displays materials and reports we obtained. Note that in this table, "algebra" refers to the study of number systems, functions, or relations, whereas "abstract algebra" refers to the study of mathematical groups, rings, fields, or related constructs.

We analyzed descriptions of enactments and the text of curricular materials in three stages. First, we identified instances of presenting secondary teaching context to PSMTs. By context we mean the contextual elements of teaching practice such as hypothetical or actual secondary student talk or pieces of hypothetical or actual secondary curriculum materials (Lai & Jacobson, 2018). Second, we coded these instances for whether they satisfied conceptualizations of representation of practice and approximation of practice (consistent with the descriptions given in the section on Conceptual Perspective) and then inductively coded categories of representations of practice and approximations of practice. Third, we analyzed these instances holistically for how their prompts and descriptions of students and teachers in the teaching context aligned or not with various aspects of Louie's (2017) framework. For instance, if student work was described as "correct" or "incorrect", this is indicative of an exclusionary frame for mathematical activity. Or, if teachers were asked to name strengths of student work beyond correctness, this would align with an inclusive frame for mathematical ability.

Results

In all 10 projects, we found evidence of representations of practice and approximations of practice. Within representations of practice, we found 5 aspects of teaching context constituting the representation: student contributions (that is, depictions of student talk, work, or thinking, where teachers are not explicitly described); teacher-student interactions; written curriculum and assessments (such as actual or hypothetical textbook or lesson plans); personal experience with secondary-level tasks (where teachers are asked to notice features of their own experiences solving a secondary-level task); and an educator's modeling of a teaching practice (where the experience of the task becomes an object to notice). Within approximations of practice, we found 4 teaching practices that PSMTs were asked to simulate: responding to students' mathematical contributions; evaluating students' work; explaining content; and teaching a full lesson (where PSMTs were either teaching a full lesson of the advanced mathematics course in which teachers were enrolled [Artzt et al., 2011; Winsor, 2009], or teaching a lesson to secondary students [Buchbinder & McCrone, 2020]).

We now turn to frames within representations and approximations of practice. Evaluating student contributions was by far the most prevalent structure for engaging with representations of practice, and evaluating teacher contributions (such as appraising a described secondary teacher's teaching moves) was the second most common. A standard format for evaluating student contributions was showing teachers a sample of student work or dialogue, and then asking teachers to identify strengths and weaknesses of the mathematics shown (e.g., Bremigan et al., 2011; Casey et al., 2021a; Hauk et al., 2017, 2018; META Math 2020a; Sultan & Artzt, 2011; Wasserman et al., 2022). See Figure 1 for an example. Across the multiple secondary education projects reviewed, the majority of approximations featured the practices of responding to students' mathematical contributions, evaluating students' work, and explaining content (e.g., Álvarez et al., 2020b; Alibegović & Lischka, 2021b; Aubrey et al., 2021; Bremigan et al., 2011; Buchbinder & McCrone, 2020; Hauk et al., 2017; MAA META Math, 2020b; Sultan and Artzt, 2011; Wasserman et al., 2022). For instance, the Capstone Math materials provided teachers with a set of student work samples and asked teachers to work in groups to "sort the work into categories that represent different ways of thinking and/or difficulties" (Hauk et al., 2017, p. 9).

Two parts of [a student's] work on a task are shown.
(i) Name things [that this student] has done well when analyzing the data.
(ii) Name things [that this student] needs to work towards understanding about analyzing univariate quantitative data.

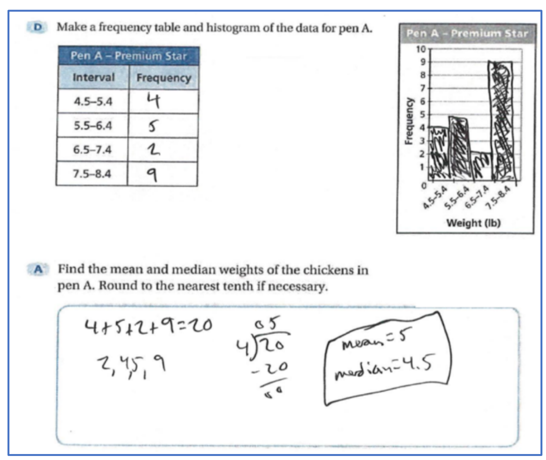

Figure 1. Example approximation of practice with embedded teaching context (Casey et al., 2021a, p. 175).

Across the reviewed materials, we saw a dominance of the inclusive sense-making frame, where mathematics is about making connections across ideas. However, within representations and approximations of practice, the secondary-level tasks tended to be closed rather than open. While this may a practical consideration for the curriculum developers, it also means that when PSMTs are asked to simulate teaching practice, they engage with an exclusionary frame. In multiple approximations of practice, an incorrect response was juxtaposed with a correct response. This juxtaposition may feed into an exclusionary hierarchical ability frame where some students are positioned as helpers and others as in need of help.

For brevity, we discuss only one example here in depth, that shown in Figure 1. The approximation of practice shown potentially supports an inclusive multidimensional frame of mathematical ability mathematics. In this example, PSMTs are asked to name strengths of student work. However, PSMTs may also gravitate toward correctness or incorrectness of the student work, which aligns with the exclusionary frame of mathematics as a fixed body of knowledge. On the other hand, within the materials reviewed, we saw multiple instances of representations and approximations which explicitly asked PSMTs to evaluate student work in terms of selecting which was the best work, or being presented with work that was incorrect and being asked to articulate what is incorrect (without asking PSMTs to articulate what may be worth building on). One set of materials contained prompts that asked PSMTs to rate solutions as "high, medium, or low". While assessing mathematical work for mathematical correctness and incorrectness is a skill that teachers need to have, only turning to this skill in engaging with student work leads to an exclusionary frame of mathematics and mathematical ability.

Conclusion

How secondary teaching is represented impacts the opportunities that PSMTs have to engage with inclusive frames of mathematics and mathematical ability. Representations and approximations may also reinforce exclusionary frames of mathematics and mathematics ability within PSMTs. In our review, we found examples of representations and approximations of practice that may foster an inclusive frame of mathematics. At the same time, these representations and approximations of practice did not explicitly support reframing away from exclusionary frames. Supporting PSMTs in inclusive framing of mathematics and mathematical ability is ongoing work that will require potential revision of existing materials (including our own) and broadening constructions of what counts as representations and approximations of secondary teaching practice in advanced mathematics courses that PSMTs experience.

Acknowledgments

We acknowledge here the imagination and dedication of the developers who created materials reviewed in this chapter (especially those who do not include ourselves!). The work of these developers provides a starting point for future research and practice. This work was partially supported by NSF DUE-1726707, 1726098, 1726252, 1726723, 1726744, and 1726804, and DUE-1524739, 1524681, and 1524619. To Do Calculus, We Need to Specify R: Lecture Meta-stories & their Underlying Assumptions.

Anna Zarkh
University of California, Berkeley

This papers examines the stories two instructors tell about why formally defining real numbers in the context of a Real Analysis course is a desirable objective. While the two stories exhibit some variations, the analysis shows that both narratives relied on the following constitutive elements: (1) calculus is a desirable activity, (2) students' current understanding of R is lacking, and (3) to use R for calculus, there is a need to specify it precisely. I discuss how these assumptions can be misrepresenting of practice and experienced as problematic impositions on students.

Keywords: real analysis, real numbers, meta-mathematics, narratives, values.

The stories we tell about the nature and purpose of mathematical practice matter. They frame mathematical activity in and out of the classroom, render it sensible (or not), and help delineate what actions are deemed appropriate, valuable or even feasible in a given context (Schoenfeld, 1989). Stories about math can be problematic. Many mainstream stories, such as "there is only one math" (Hersh, 1991) or "math is a young man's game" (Barany, 2021), both misrepresent disciplinary practice and alienate students by constructing a world that few can see themselves in. One context for meta-mathematical story-telling is introductory proof-based university courses, such as Real Analysis (RA). In such courses, instructors may feel the need to explicitly explain and justify the course and its new way of doing math.

RA is a challenging course in the undergraduate curriculum, largely due to the novelty of its proof-oriented epistemic game. Dawkins and Weber (2017) suggested that the norms and practices of this epistemic game are difficult to learn in part because the underlying values and purposes these norms uphold are not made explicit in instruction. However, we have little empirical evidence about whether and to what extent instructors address such meta-issues in lectures. This paper addresses this issue, by examining how instructors describe and justify real analysis in the first lectures of their RA courses. In particular, I address the following research question: What meta-stories about the nature and purpose of RA do instructors tell in lectures?

This study is informed by sociocultural theories (Wertsch, 2012). Mathematics is conceptualized as a discourse that involves telling stories (Sfard, 2008). Here, I focus on meta-stories, which I define as stories *about* mathematical practice. I refer to these as stories, rather than instructors' beliefs, to highlight their contingent and situated nature.

Methods

This study is part of a larger video-based micro-ethnography (Derry et al., 2010; Erickson, 1992) of undergraduate RA lectures taught in Fall 2020 at a large public research university in the US. All lectures were delivered online, over Zoom, due to covid-19. Primary data for the larger study include video recordings of all lectures, and auxiliary documents such as lecture notes. Four instructors (Alex, Cai, David and Emmett) participated in the study. All four worked as research mathematicians at the time of data collection. Alex, Cai and David were early career scholars and Emmett was a senior faculty member in the department. For this study on meta-stories, I consider only the first lecture of each instructor (Alex, David & Emmett, 50 min; Cai, 90 min).

Data Analysis

Data analysis proceeded in two steps. First, I generated secondary data through transcription, segmentation and descriptive coding of episodes. Then, I coded episodes for meta-talk, consolidated into story themes, and iteratively constructed summary descriptions for each theme.

Transcription, segmentation & descriptive coding. Each of the introductory lecture videos was transcribed for talk and salient gestures. Transcripts were segmented into short episodes, of 1 min length or less. Segmentation was based on "natural" transitions. These included linguistic markers (e.g. "So" and "Okay"), and shifts in topic or inscriptional focus. Each 1 min episode was given a title that served as its descriptive summary, using a mixture of content and in-vivo coding (Saldaña, 2021). I then grouped the short 1 min episodes into larger coherent wholes, according to the overall type of classroom activity (e.g. if episodes 3-8 were all part of a single proof, they were grouped together under the heading "proof of …"). This multi-step process resulted in a hierarchically structured outline of each lecture's transcript (Erickson, 1992). The structured transcripts were the data sources used for subsequent analysis.

Coding meta-talk & meta-story summaries. Meta talk appeared in lectures in two ways. There were entire episodes devoted to meta talk, and there were shorter instances of meta-talk (e.g. a single sentence) that occurred in the midst of an episode with a different focus. The coding process was inductive and proceeded as follows. First, I flagged episodes of meta-talk that addressed either what the course or the sub-field of RA are, or why they are worth studying or doing. To determine whether an episode or utterance counted as meta-talk, I relied on explicit linguistic indicators such as "our goal in this course" and "Real Analysis is." I then went through each episode that was flagged for meta talk, and created sub-codes to capture different story types. Shifts to different stories were often marked by the instructors themselves (e.g. "another goal of this course is…"). Through an iterative process of refinement, I delineated distinct categories of meta-stories about RA that together account for all meta-talk episodes and instances. With these meta-story categories, I went through the structured transcripts again, looking for confirming and disconfirming evidence and more instances of meta-talk. This process led to further refinement of the codes and consolidation in the form of story summaries.

Findings

All four instructors devoted class time to meta-talk about the nature and purpose of RA during their first lecture. Across the data set, I identified the following five meta-stories about RA:

1. To do calculus, we need to specify R (Real numbers). Our current understanding of R is vague. In RA, we define R precisely and build calculus from it.
2. RA is calculus with proof. Since calculus is known, RA is good for learning to prove.
3. Calculus is a tool that sometimes breaks. RA is a theory of how the tool work. It is good to learn the theory for future tool use and new tool development.
4. Mathematicians made mistakes in calculus and found solution in rigor. We follow them.
5. RA is a theory of connections between calculus and more fundamental topics. It is good because it makes calculus simpler and more elegant.

The table below (figure 1) shows the presence or absence of the five narratives in each of the instructor's lectures. In this paper, due to space limitations, I elaborate only on the first story: "to do calculus, we need to specify R." In the remainder of the findings section, I will describe how Emmett and David each constructed a version of this story in their first lecture, and then compare their version across key underlying assumptions: (1) calculus is a desirable activity, (2) students' current understanding of R is lacking, and (3) to do calculus, there is a need to specify R.

	Alex	Cai	David	Emmett
S1: precise R			precise R	precise R
S2: learn to prove	learn to prove	learn to prove	learn to prove	
S3: fix calculus	fix calculus	fix calculus		
S4: follow community		follw community		
S5: connections	connections			

Figure 1: Appearance of meta-stories in each instructor's first lecture.

Meta-story 1: To Do Calculus, We Need Precise R.

Emmett's meta-story. Emmett discussed the two constitutive terms of the course title, 'real' and 'analysis,' separately. Starting with 'analysis,' he offered the following definition:

> … an informal and incomplete definition of analysis is that analysis is that part of mathematics in which limits are used to solve problems. So, the key concept in analysis is that of a limit. I would say maybe the second concept is that of an inequality. But maybe the most fundamental concept is the limit. And that's really what this course is about. Limits and closely related concepts. (episode 10)

In the above quote, Emmett defined analysis as a subfield of math, characterized by its focal concepts (limits, inequality) that are framed as tools for solving problems.

Next, he shifted attention to the other part of the title, namely, the adjective 'real.' He posed the question "so, what about real numbers?" and shared a slide with the following famous quote from the German mathematician Leopold Kronecker: "God made the whole numbers; humans made the rest." Emmett interpreted the distinction Kronecker's quote makes between god-made and man-made numbers as implying that the real numbers are "not as fundamental as the whole numbers," and declared that the course will take that "point of view."

On the next slide, he elaborated on what makes real numbers less fundamental. He asked "what is a real number?" rhetorically and provided three "informal descriptions" as answers: real numbers are (1) points on the number line ("when you teach a calculus class, you draw a line on the board and you say here are the real numbers"), (2) expressible using decimals ("Any number you can write like that, positive or negative, is a real number"), or (3) possible values of a variable x in a calculus course. Emmett then explicitly framed these descriptions as inadequate:

> So that's obviously not a very rigorous notion, but that captures what we're talking about. I hope that you'll all agree with me that none of these answers are anywhere near as clear and unambiguous as the positive whole numbers. We all are confident that we can start with one, add one to it, add one to it, add one to it, and keep going. And we more or less understand what sort of objects we're getting that way. The real numbers are a bit more mysterious. (episode 12)

In the perspective offered above, familiar descriptions of real numbers (standard in calculus courses) are declared problematic because they are "informal" and not "very rigorous." The ambiguity and mystery of real numbers is justified through a comparison to the presumed clarity with which whole numbers are comprehended. According to Emmett, whole numbers as mathematical objects are clear and unambiguous; by imagining repeated addition, "we can more or less understand what sort of objects we're getting." Emmett uses this appeal to a presumably shared experience of different degrees of ontological clarity to justify assigning real and whole numbers a different epistemic status: “And in this course, we will not take basic properties of the real numbers for granted. Unlike these more basic kinds of numbers.”

In Emmett’s story, filling this ontological and epistemological void is a key problem the course aims to solve. Accordingly, constructing the real numbers in a clear an unambiguous way played a central role in “the program” Emmett laid out next:

> Instead, we're going to spend some time and we're going to use the rationals, which we've agreed, we do understand that we can assume things about. We're going to use the rationals to construct some objects. And this collection of objects will have all the properties that the real numbers ought to have. And then we'll just call these objects the real numbers. And as the course goes on, we'll use them. We'll use them, we will develop the concept of a limit. And we'll use them with, together with limits to develop the theorems that underpin calculus and to solve various other kinds subproblems. Ok, so that's the program. (episode 13)

The “program” Emmett articulated describes RA as sequential coverage of mathematical content (R, limits, calculus), where each step is ‘built’ on top of the previous one: rational numbers are used to construct real numbers, real numbers are used to develop limits, limit are used to develop calculus theorems. Analysis is situated later than real numbers in the sequential development of content. But, how are these two connected? Why are real numbers needed for doing analysis, assuming the latter is an agreed upon goal? Later in the lecture, Emmett made additional meta-comments, that can be seen as filling this gap in the story:

> … the rationals are not complete. And that, in a nutshell, is why this course is real analysis instead of rational analysis, the rationals are defective from our point of view. We want to be able to take limits, completeness, the rationals are not complete and there will be instances when we can't take limits when we want to. So the rationals don't work for us and we need the reals. (episode 34)

Here, the course’s focus on real numbers is justified by their necessity for doing limits. In this argument, we don’t care about real numbers *just* because they are unclear and complex. We care about them because we want “to take limits,” and rational numbers do not always allow it. The problem is that rational numbers, unlike real numbers, “are not complete” which makes them “defective from our point of view.”

In a later meta-comments, Emmett repeated the course’s program description, adding detail:

> … we're going to construct a set of objects that has all the properties that the real numbers ought to have. We'll just call that set the real numbers, and then we'll use it together with limits to solve problems and to justify the foundations of calculus. OK. And the objects that we construct are called cuts, or they are called Dedekind cuts after, after a mathematician named Dedekind. (episode 43)

In this last comment, Emmett provided additional information. Namely, that the to-be constructed real numbers are “objects” called Dedekind cuts. He immediately followed this programmatic outline with a comment about the resulting ontological status of real numbers:

> So notice that this approach sidesteps the basic question of what the real numbers actually are. And, you know, that's some sort of metaphysical question that doesn't really have a mathematical meaning. So, we're simply not going to go there. We're simply going to construct something and we'll call it the real numbers. Because of the theorem I told you at the end of the last set of slides, that's a reasonable approach. Any fully mathematical question you can ask will have the same answer for our real numbers, as for anybody else's real numbers. (episode 43)

In this last quote, Emmett clarified that the course's "program" will not provide an answer to the ontological question of "what the real numbers actually are." Despite the fact that he used the (presumed) ontological ambiguity of real numbers to motivate the program at the beginning of the lecture, in this later comment, he framed the ontological question as "metaphysical" and devoid of "mathematical meaning." To justify this dismissal of the original question, he referenced the theorem that any two complete, Archimedean, ordered fields are isomorphic.

Based on this meta-talk, I summarized Emmett's narrative as follows: *We are interested in doing analysis, which is using limits to solve problems. To do limits, we need real numbers. But, we don't know what real numbers are in a clear and unambiguous way. We do, however, clearly understand natural, whole and rational numbers. So, the course starts with constructing [something we call] real numbers from rational numbers, and develops calculus from that.*

David's meta-story. David began his meta-story by rhetorically posing the question: "what's the goal of this course?", and immediately providing the following answer:

> This is introduction to analysis or real analysis. So what we're <u>really</u> trying to do is come up with a set of tools to rigorously study what happens on… what the real numbers are and how the real numbers behave. (episode 9)

The above description features some of the themes we saw in Emmett's presentation. David claimed that the course's objective ("what we're really trying to do") is to develop "tools." The tool metaphor is similar to Emmett's framing of limits as something that can be used to solve problems. However, unlike in Emmett's story where the nature of the problems remains underdetermined, in David's description the objective is characterized as the exploration of a mathematical reality in which real numbers are the landscape and focal characters: "what happens on [the number line]" "what real numbers are," "how they behave." At this point in David's story, understanding phenomena pertaining to real numbers is the goal, whereas in Emmett's story, it was a necessary step in a 'program' whose ultimate objective was calculus, i.e. 'using limits to solve problems'. But, this was just the start of David's story. He continued:

> … the core ideas in this course, and the core themes we are going to explore are. Well, I guess one core theme is essentially approximation. And the real question we have, right? You know you have a vague notion, probably sort of what a real number is, but if you <u>actually</u> want to specify what a real number is, it can be a little tricky. (episode 9)

David mentioned approximation as a theme but did not connect it to the declared focus on real numbers. It seemed as though he was about to list several core ideas, not just approximation, but he quickly shifted to what he called "the real question," which is that of specifying real numbers. Similarly to Emmett, David problematized real numbers by invoking a binary opposition between two epistemic stances: having a "vague notion" versus "actually" specifying. This binary allows seeing the specification of "what a real number is" as a problem to be solved.

David proceeded to justify why specifying real numbers is useful. Recall that in Emmett's story the only justification is the purported experience of ambiguity (for David, "vagueness") with familiar descriptions of real numbers. David's narrative features more rationales. Specifically, he claimed that specifying real numbers is necessary for more advanced calculus:

> … if we want to start doing complicated things like calculus or analysis of things in higher dimensions or working on- or doing calculus on a surface that isn't actually the real line. If you want to do calculus on the surface of a sphere, for example, it gets a little bit tricky and it becomes important to know precisely what sort of thing you're talking about. And so the goal of this class is to sort of lay that groundwork that dealing with the real numbers are, so that we can then in the future expand it to talk about more interesting, more interesting topics. (episode 10)

Similarly to Emmett, David invoked a building-foundation metaphor ("lay the groundwork") to interpret the significance of 'specifying real numbers' as a base step in the development of a hierarchically organized system of mathematical knowledge. However, unlike in Emmett's story where the end point was 'regular calculus,' here the motivating horizon is more advanced versions of calculus – calculus in higher dimensions or on surfaces such as a sphere – that are "interesting," yet "tricky" and "complicated." Thus far in David's story it is the complexity of these more advanced topics, rather than any difficulty with regular calculus, that necessitates an ontological specification of R ("it *becomes* important to know precisely what sort of thing you're talking about"). He developed this idea further in relation to infinite dimensional calculus:

> You might be curious. Can you do something that looks like calculus in infinitely many dimension? I mean, you've probably taken- I'm sure one of the courses you've taken as a prerequisite to this is a multivariable calculus class that probably did two or three, maybe n-dimensional calculus. But can you have meaningful kinds of calculus in infinitely many dimensions? And the answer is yes. But developing that, there are many, many subtleties to get through to develop that. So we're going to start somewhere to have something to build on. And so we really want to make these ideas of <u>what</u> makes the real numbers, what they are, precise. (episode 10)

We see here a repetition of the same theme. Doing more advanced calculus (in this case, infinite dimensional) is subtle and complex. Mathematical knowledge is a hierarchical structure. To be able to (in the future) cope with this complexity of more advanced levels, it is necessary to do preparatory work at the base ("start somewhere to have something to build on"). In particular, the prep work involves specifying real numbers. Unlike Emmett, David did not provide an explanation for why real numbers, specifically, is the "somewhere" where one "starts."

I summarized David's narrative as follows: *We are interested in doing advanced calculus, such as calculus on surfaces, and calculus in multiple and infinite dimensions . To do advanced calculus, we need precise real numbers. Our current understanding of real numbers is vague. So, the course focuses on specifying real numbers, to have something to build on.*

Summary. I compare Emmett and David's meta-stories across constitutive assumptions.

The first assumption is (1) students are interested in doing calculus. Emmett treated interest in calculus as a taken-for-granted goal, both in defining analysis and in positioning calculus theorems and limits as the end goals of content development. In David's meta-story, the objective is not regular calculus, but rather more advanced versions, such as calculus on surfaces and in infinite dimensions. But, like for Emmett, the interest in such topics is assumed and positioned as an ultimate goal. A RA instructor may reasonably assume that a motivation for calculus – What kinds of problems do limits help solve? Why should we care? – was addressed in previous courses. However, David's framing of interest in infinite dimensional calculus as something one is naturally curious about after doing finite dimensional calculus can be problematic. It is historically inaccurate and potentially alienating, as few students are likely to see themselves reflected in this positionality of wondering about artificial extensions of theory.

The second assumption is that (2) students' current understandings of real numbers are lacking. Emmett conveyed this by listing descriptions of real numbers students are familiar with and framing them as "not very rigorous," unclear, and ambiguous. David, similarly, claimed that students only "have a vague notion … of what a real number is." In both stories, the negative epistemic stance is not fully justified. Emmett's use of phrases such as "obviously" and "I hope that you'll all agree," actually highlights the absence of an explanation. Indeed, a negative epistemic and ontological stance toward real numbers is not self-evident. Students (and various professionals, including mathematicians) have been successfully using 'informal descriptions' of real numbers for a long time (e.g. in calculus) without feeling the need to specify them in the way Emmett and David suggested. To date, in many (if not most) contexts of doing calculus, people unproblematically rely on representations of real numbers which Emmett and David labeled as ambiguous and vague. Thus, the offered stance can be experienced as an imposition.

The final assumption is that (3) to do calculus, R needs to be specified. Emmett did not provide explicit justification for this claim, but the programmatic description he offered relies heavily on building-foundation metaphors for mathematical knowledge, and within such a metaphorical conceptualization of math it may seem as self-evidently true that concepts need to be 'built on solid ground' to be viable. David's story incorporated building-foundation metaphors too (e.g. "lay the ground work"). However, David offered an additional rationale by positioning the specification of R, not as something done for its own sake, or as something needed for doing regular calculus (that may directly contradict students' experiences of doing calculus without specifying R), but rather as something necessary for doing more advanced calculus, one that students have not yet seen. This story defers a compelling motivation for specifying R to a future context (e.g. infinite dimensional calculus). The fact that students are tasked with 'taking David's word for it' further highlights the absence of an accessible rationale.

Discussion

Mainstream stories about math are rife with idealizations of the discipline that both alienate many learners and do not tell the full story of what the practice is like and what, and for whom, it is good for (Hersh, 1991; Wagner, 2022). This paper aims to contribute to our understanding of how such idealizations are constructed in the gatekeeping educational context of RA lectures. Critically examining the assumptions instructors' meta-stories rely on and how these assumptions relate to past and current professional practice and students' past curricular experiences, can help us craft meta-stories that are both realistic and more compelling. The analysis also illustrates that instructors *do* address axiological issues in lectures (Dawkins & Weber, 2017), though the effect of their stories on students requires further examination.

Lesson Planning Practices of Undergraduate Mathematics Instructors: What Do We Know?

George Kuster	Sarah Hartman	Cassie Dick	Nicholas Fortune
Christopher Newport U.	Western Kentucky U.	Western Kentucky U.	Western Kentucky U.

We surveyed university mathematics instructors across the United States about their planning practices. We sought to better understand the complexities involved in the work that goes into preparing for instruction at the university level. Research indicates that the quality of instructors' lesson plans can be linked to the quality of their instruction (Akyuz et al., 2012). Instructors self-reported as either using inquiry-based practices, lecture-based practices, or an even mix of both. Instructors that indicated using both inquiry-based and lecture-based practices spend more time lesson planning, but often feel less supported by the lesson plans they create. These instructors attempt to do practices that both the inquiry-based instructors do (i.e., spend time preparing for and accounting for student thinking) and lecture-based instructors do (i.e., ensuring a clear understanding of the mathematics for themselves). We discuss implications for instructors and the undergraduate mathematics education community.

Keywords: lesson planning, university mathematics instructors, teaching practices

For decades researchers have investigated the teaching and learning of mathematics. Much of the focus has been on understanding how students think and learn particular topics or ideas, and what in-the-moment instructional practices support student learning. This work is crucial, and more recently some have pointed to the importance of carefully considering this type of information during the instructional planning process (e.g., Akyuz et al., 2012; Stephan et. al., 2017). Much of this work lives in the context of K-12 education, and though it is largely relevant to university education, there are some added complexities. More specifically, pedagogical freedom at the university level means not all instructors teach the same topics or even teach them the same way. This freedom also means individual instructoprs can significantly change pedagogies from semester to semester. Little is known, however, about how instructors build their lesson plans, what they consider when doing so, and how their pedagogical decisions impact their planning practices. This research paper describes an investigative journey into the planning practices of undergraduate mathematics instructors, aiming to better understand the complexities involved in the work that goes into preparing for instruction at the university level. We also explore some similarities and differences in these practices across broadly defined instructional categories: Inquiry-Based, Lecture-Based, and an Even Mix of Both.

Literature Review

While there is some literature about planning practices for K-12 teachers as either pre-service or in-service teachers, there is a lack of literature regarding the lesson planning practices of university mathematics instructors. For example, O'Donnell and Taylor (2007) investigated the relationship between preservice mathematics teachers' focus on student thinking in lesson analysis and lesson planning tasks. Their results highlighted a pedagogical lesson planning format consistent with Shulman's (1987) model of pedagogical reasoning and action which includes comprehension, transformation, instruction, evaluation, reflection, and new comprehensions. This model is used to theorize the knowledge required to develop the knowledge of teaching. Additionally, Amador (2016) investigated the role of teacher noticing during lesson design. Amador's findings emphasize the importance of supporting teachers through professional development opportunities, specifically focusing on student outcomes, student mathematical understanding, and teacher noticing. Further, Amador (2016) raises questions about how to better support these teachers but also how to further support teachers more broadly as they work in the space between lesson planning and enactment. Additionally, this thinking can also be applied to middle grades educators. For instance, Akyuz et al. (2012) aimed to extract the planning practices middle school mathematics teachers used to create adequate assessments, introduce important ideas, and choose tasks that are appropriate given the objectives of lesson materials. The results mention five core practices that are the foundation of the development of effective planning: preparation, reflection, anticipation, assessment, and revision. These practices align with Shulman's (1987) dimensions. These five practices also align with Stephan et. al.'s discussion of Lesson Imaging (2017) - where they build on Schoenfeld's (1998) work on how teachers expect their plans to be enacted in the classroom. Stephan et. al. outline a visualization process through which K-12 STEM teachers can develop effective lessons by unpacking the goals, imaging the launch of the lesson, anticipating student thinking and reasoning, and then imagining how they will use that thinking and reasoning to support meaningful discussions. Though the previously mentioned literature focuses primarily on K-12 planning, we argue that the same notions may apply to researching the lesson planning practices of university instructors. However, literature about university instructor's lesson planning practices is limited, as the field continues to grow.

Undergraduate instructors' pedagogical decisions in the classroom are represented in literature. Uniquely, undergraduate mathematics educators have the choice to teach in certain ways, often in a lecture format (Fukawa-Connelly et al., 2016). This freedom to choose could impact lesson planning practices. Johnson et al. (2018) stated that the "distinction between lecture and non-lecture pedagogy is not clear cut, especially when looking at how instructors self-identify" (p. 256). In an attempt to investigate why instructors choose to lecture, Johnson (2018) detailed a survey of national abstract algebra instructors at masters and doctorate-granting institutions. Ultimately, Johnson provided insight into factors that influence pedagogical decisions in American abstract algebra classes as well as avenues for approaching and providing better support for those interested in implementing non-lecture teaching approaches (Johnson, 2018). Johnson et al. (2013) indicated an opportunity for the research field of undergraduate mathematics education to "gain insight into the factors and considerations that matter to mathematicians," (p. 2) specifically in teacher identity and stance towards instructional materials. Lastly, research indicates that the quality of instructors' lesson plans can be linked to the quality of their instruction (Akyuz et al., 2012). Thus, understanding undergraduate instructors' lesson planning practices can also shed some light on their instructional practices.

Methods

Our study investigated the lesson planning practices of university instructors through a survey with both quantitative and open-ended items.

Data Collection

Survey creation. We designed a survey using Akyuz et al. (2012)'s lesson planning practices as the overall dimensions that characterize lesson planning activity: preparation, reflection, anticipation, assessment, and revision. In addition to these dimensions we asked questions about different classroom environments, teaching styles, and university characteristics. In light of the discussion by Johnson and colleagues (2017) concerning reasons for making certain pedagogical choices, we were particularly interested in how instructors defined success in terms of their lesson planning. In this work, we will focus primarily on the preparation and reflection dimensions. Preparation outlines any work prior to the start of instruction. Generally, it includes activities such as creating a learning trajectory, designing an instructional sequence, studying relevant literature, and considering the big ideas of the unit (Akyuz et al., 2012). Reflection involves taking a look into past teaching experiences and classroom interactions to assess quality instruction as well as evaluation of unexpected situations, misconceptions of students, and improvement of instruction (Akyuz et al., 2012).

Survey description and questions. The survey included 11 demographic questions such as instructor gender identity, university type, average class size, and how long they had been teaching. We also asked quantitative and qualitative questions about teaching styles. For example, we asked, "Which of the following best typifies your teaching style?" (with choices of inquiry-based, lectured-based, or a mix) and "Briefly describe why you teach this way. Please be detailed." Then each of the five main dimensions had both quantitative and qualitative items. For preparation, we asked questions such as "On a scale of often, sometimes, rarely, never, please indicate how frequently the following activities are part of how you prepare for a lesson. - Reading relevant education research on the topic (e.g., student learning of the topic)." The anticipation stem contained questions such as "Consider preparing for lessons. On a scale of strongly agree to strongly disagree, please select if you agree with the following statements. - I consider what might happen during a lesson." Questions such as "When teaching, approximately how often do the following occur on a scale of often, sometimes, rarely, never? - I stopped to consider how the students were thinking about the content" was used to assess the reflection stem. The assessment stem asked questions such as "Consider times when you used informal assessment. On a scale of strongly agree to strongly disagree or not applicable (N/A), please select if you agree with the following statements. - I change future lesson plans if grades are poor." Finally, questions including "Consider preparing for lessons. On a scale of strongly agree to strongly disagree, please select if you agree with the following statements. - I often change the order of the content from the textbook as a means to support student learning" were used to assess the revision stem. For quantitative questions, a scale was used for all 5 stems in order to get a clear response, while still offering a range of answer options.

Qualitative questions on the survey included inquiries such as "How does the teaching style you use impact your lesson planning practices?" These questions were designed to differentiate the planning practices of university instructors with different teaching styles and provide us with more data to compare to our quantitative results.

Survey population. The sample for our survey utilized several email listservs as well as directly emailing mathematics department chairs. Listservs included Research in Undergraduate Mathematics Education (RUME), Associate of Mathematics Teacher Educators' (AMTE) Service, Teaching, and Research (STaR), and the American Mathematical Society (AMS) directory of institutions. Potential participants were told that they had to be full-time instructors and that they had to teach mathematics content classes (i.e., general education, mathematics content classes for future teachers, or mathematics majors classes). We received 65 complete survey responses.

Data Analysis

We broke the respondents into three groups based on their responses to a question asking which teaching style they best fit into. We then conducted a series of Analyses of Variance

(ANOVA) to examine the relationships between their chosen instructional style and the responses to the various survey items. Norman (2010) and Carifio and Perla (2008) note that when examining multiple likert-scale items, using a method that compares means and standard deviations (such as ANOVA) is appropriate and yields valid results. We found many statistically significant differences in the way the respondents in the three groups tended to answer the survey questions. All open ended survey items were coded by three of the researchers using thematic analysis (Braun & Clarke, 2006). All three researchers did a first pass of coding then met to discuss codes and repeat the process until a codebook was developed. Then we all coded the data to be able to describe themes from the open-ended items. All disagreements were discussed by all three coders. Lastly, the qualitative data gave us a deeper understanding of what we found from results from the quantitative data and it supported some quantitative findings.

Results

Demographics & Teaching Style

The average length a respondent had taught was 16 years. 80% of respondents worked at 4-year public universities. Likewise, 80% worked at universities that granted PhDs or Masters. 36% of respondents taught K-12 prior to their current teaching position. 25% had degrees in mathematics education and the rest in some field of mathematics. 32 respondents identified as female, 26 as male, 1 as nonbinary, and 6 that preferred not to answer.

Participants were asked “which of the following best typifies your teaching style?” 18 said inquiry-based (i.e., student centered), 15 said lecture-based (i.e., teacher centered), and 32 said an even mix of lecture and inquiry activities. We also asked respondents the following question: “When teaching, approximately how often do the following occur on a scale of often, sometimes, rarely, never? - I stop to consider how the students are thinking about the content.” Inquiry-based instructors stop significantly more often to think about student thinking than even-mixed ($p=0.026$) and lecture-based ($p<0.001$), and even-mixed stop significantly more often to think about student thinking than lecture-based ($p=0.048$). This, to us, aligns with a broad interpretation of these teaching styles. In the most basic sense, the role that student thinking plays in these teaching styles is crucial. Instructors that identify as lecture-based indicated they stopped significantly less frequently than even-mixed or inquiry-based instructors.

Lesson Planning

Respondents who identified as inquiry-based do not spend as much time making or reviewing their lesson plans; however, they feel more supported by them. When asked Q21_4: “On a scale of strongly agree to strongly disagree, rate the following statement: I use a textbook to determine how I teach material,” respondents who identified as an even mix of teaching styles said that they agree significantly more with this statement than either lecture-based or inquiry-based ($p=0.01$).

Similarly, when asked Q20_8: “On a scale of often, sometimes, rarely, never, please indicate how frequently the following activities are part of how you prepare for a lesson - Reviewing from course materials (e.g., textbook, notes)”, respondents who identified as an even mix of teaching styles reviewed course materials significantly more than inquiry-based respondents ($p=0.003$), but there was no significant difference between even mixed and lecture-based and inquiry-based and lecture-based.

However, on Q21_7 despite indicating that they do not create detailed lessons, inquiry-based respondents indicate that they feel supported by their lesson plans, significantly more so than respondents who identified as an even mix of teaching styles (*p=0.014*). There was no significant difference between other groups.

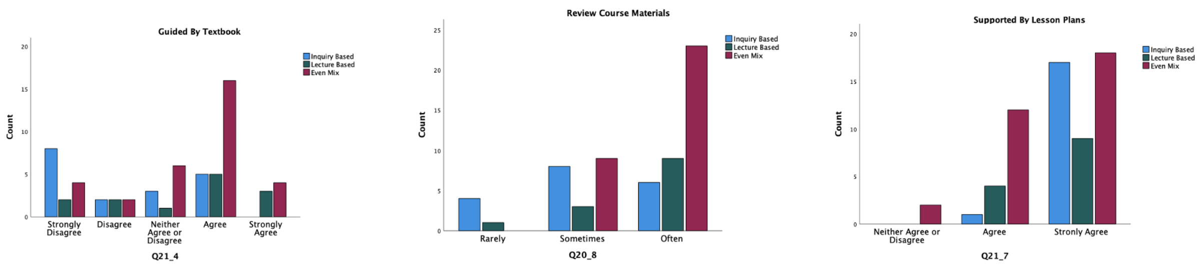

Figure 1. Bar charts showing all responses to Q21_4, Q20_8, and Q21_7.

These results also appeared in the qualitative data. Respondents were asked "How does the teaching style you use impact your lesson planning practices?" and "Please fill in the blank, and be detailed: I feel like I am prepared for a lesson when I have ____." Respondents who identified as lecture-based indicated overwhelmingly that their lesson plans are good because they know what they are going to talk about and the lesson plans are their notes (although those notes varied in format of in their head, on paper, in a PowerPoint, etc.). One participant said, "My planning process is mostly deciding which examples I want to include in class. I usually work through a few examples for each topic. The topic may be explained as I work through the first example." Inquiry-based respondents indicated on open-ended survey items that because they are sensitive to student thinking, their lesson plans are intentionally fluid to account for this. One participant said, "Because I teach in an inquiry-based style, it is important to carefully structure student interaction with each other and the course material to set the stage for their mathematical connections and discoveries." Respondents who indicated using an even mix of teaching styles said that their lesson planning notes are guided by the development of the mathematics, but they know they need to be sensitive to how students are reacting to it. One participant said,

> Rather than a lesson plan "template" that uses the same template or outline for every lesson, at the college level, once I consider the content and the students' needs for that content, then I prepare lesson materials that are most appropriate for that lesson in that moment, whether it be lecture notes, guided notes, activity/inquiry/discovery instructions for the students to engage, problems for the students to explore in problem-based learning, etc. Regardless, I typically will have in my notes (increasingly on Google Docs) a timeline with short notes about process, and more detailed notes where I see fit.

Reading research plays a role in lesson planning. Unsurprisingly, those that engage in inquiry-based teaching or an even mix of teaching styles are more interested in performing research on teaching and learning ($p<0.001$, $p<0.001$) and are more interested in reading literature on teaching and learning ($p=0.009$, $p=0.018$). However, while even mixed respondents are interested in research and anticipating student thinking, they are not doing it as often as inquiry-based respondents ($p=0.002$).

Lesson Reflection

Respondents were asked Q31_4: "On a scale of strongly agree to strongly disagree or not applicable (N/A), please select if you agree with the following statements. - I change future lesson plans if students indicate the content is not clear to them." Even-mixed instructors are more likely to change their lesson plans if students are struggling to understand than both inquiry-based and lecture-based ($p=0.015$). One even-mixed participant said they are prepared when they have:

> ...A goal in mind for that lesson. I am prepared if I have activities that will support that goal and have anticipated questions that the students may ask. I also like to have a means of measuring learning by providing closing questions or homework that I can monitor to see how the material is being understood. This measure allows me to reflect on how the next lesson will begin.

When asked Q24_4: "On a scale of often, sometimes, rarely, never, please indicate how frequently you discuss how a lesson went with colleagues" inquiry-based instructors do this significantly more than either other group ($p=0.005$, $p=0.028$).

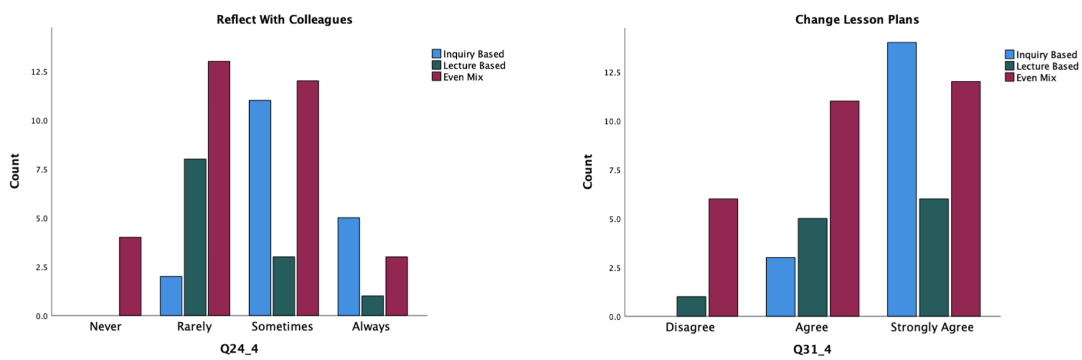

Figure 2. Bar charts showing all responses to Q24_4 and Q31_4.

Limitations

Before discussing our results, we want to acknowledge important limitations of this work. First, 65 responses, while large, is still small in terms of the power of our study. Second, as the data are self-reported, all reference to self-identifying their preferred teaching style was based on their selection of those three categories. Importantly, teaching practices are more than three categories, it is a continuum and it's not easy to distinguish between the ends of that continuum (Johnson et al., 2018). Additionally, we acknowledge that just because someone self-selected into a category, we do not have actual data from their classroom to confirm that their teaching practices in fact do align with these categories. Nevertheless, we believe our study sheds important light on the lesson planning practices of university mathematics faculty.

Discussion, Conclusion, and Next Steps

Our data indicates that different teaching styles do indeed relate to different planning practices. Respondents who identified that they use both inquiry-based and lecture-based teaching styles plan more than either inquiry-based or lecture-based instructors. However, even-mixed instructors do not feel as supported by their lesson plans compared to both inquiry-based and lecture-based instructors. This begs the question, what are the three groups including in their lesson plans to cause these differences and how do they relate to their goals?

Inquiry-based instructors do not report prioritizing doing the mathematics for themselves prior to a lesson as part of their lesson planning. Lecture-based instructors report having a strong sense of the mathematics for themselves. Whereas, even-mixed instructors seem to be pulled in both directions. They reported that they wanted to ensure they knew the mathematical progression of the content for themselves but still provided enough space to let student thinking drive the lesson. This aligns with the fact that their lesson plans and lesson planning are more involved; they appear to indicate a need to be prepared for everything (i.e., supporting the students' thinking and the mathematics).

Even-mixed instructors also indicated that they are most willing to change their lessons and lesson plans based on student reactions and their perception of how lessons are going. This further indicates the potential that even-mixed faculty are pulled in different directions. Both inquiry-based and lecture-based instructors stay their course, reporting they do not as frequently change lesson plans. Despite inquiry-based instructors reporting they reflect on their lessons more frequently than the other groups, even-mixed faculty make changes to their lessons more often. This further provides insight into why their lesson plans and lesson planning practices are more involved. Perhaps changing their lesson plans so frequently leads to less certainty in the success of lessons.

Collectively, our results indicate that the instructional goals and preferred teaching styles of instructors impacts their lesson planning practices. But more specifically, while most of our respondents indicated they used both inquiry-based and lecture-based teaching practices, that same group also indicated being the least comfortable doing so. Research on teaching practices tells us that instructors use both inquiry-based and lecture-based practices often (Johnson et al., 2018). In fact, as indicated earlier, teaching practices are on a continuum and are not dicotomous. However, regularly shifting along that continuum appears to be the most difficult in terms of preparing for those lessons.

Next Steps

In this work, we only discussed the lesson preparation and reflection (Akyuz et al., 2012) dimensions concerning how university mathematics instructors plan lessons. There is a clear indication that some faculty who try to use both inquiry-based and lecture-based teaching practices need support. Considering our results with those of Johnson et al. (2018), even-mixed instructors often feel overwhelmed by their lesson planning processes and they often change their plans as they go; more so than instructors who self-identify as lecture-based or inquiry-based. Thus, we wonder what support do these faculty need? The undergraduate mathematics education community has provided many professional supports (e.g., TIMES NSF#1431641, SEMINAL NSF#1624643), but it appears that institutional support is just as needed. The average years of teaching was 16 years (which was roughly the same for each teaching category as well) and our data did not find significant differences in terms of how supported instructors feel from their institutions. However, even-mixed instructors did indicate feeling the least supported by their institutions and departments. And these instructors are the ones doing more lesson planning.

Exploration of TAMI-OP as a Professional Development Tool for Mathematics Instructors

Sarah Wise
U. of Colorado Boulder

Kyra Gallion
U. of Colorado Boulder

Sandra Laursen
U. of Colorado Boulder

The VIP-Math project aimed to understand whether and how teaching practices of mathematics instructors are influenced by discussions of their classroom data visualized using the TAMI-OP classroom observation tool. We found that TAMI-OP data visualizations supported discussions that led the participating mathematics instructors to set both short- and long-term teaching goals, and to experiment with teaching practices related to at least one of their goals. Given the limitations of the participant pool, further research is recommended with a greater diversity of instructors and coaches.

Keywords: classroom observation tool, professional development, college instruction

Introduction

Research in STEM higher education has investigated a number of tools for measuring teaching, in order to study teaching practices in real time. Alongside surveys, interviews, and classroom artifacts, classroom observation is a valued tool in the education researcher's toolbox because it provides direct evidence of what teachers and students are doing and can be used to measure change in effective teaching over time (AAAS, 2013; Weston et al., 2021). Observations can also be used for evaluating teachers for retention or advancement, for providing feedback to teachers about their work, and for evaluating professional development offerings and their impacts.

For any of these distinct purposes, the observation protocol and sampling must be carefully chosen to align with the goals of the measurement and the purposes for which the data will be used (Esson et al., 2022; Hora & Ferrare, 2013; Weston et al., 2021). Classroom observation tools tend to be either segmented or holistic. Segmented tools typically describe teacher and student classroom activities by taking data across short time intervals. Holistic tools tend to use Likert-scaled items to arrive at ratings. Holistic tools are more inferential, requiring more expertise to use reliably (Weston et al., 2021), though both types require attention to features that affect the tool's validity and interrater reliability (Weston et al., 2023).

Many tools have been developed and tailored for specific kinds of classrooms, including for example the RTOP (holistic, applied to K-12 and college contexts; Sawada et al., 2022), the TDOP (segmented, for college instructors; Hora et al., 2013), the COPUS (segmented, designed for college STEM classrooms; Smith et al., 2013), the GSIOP (segmented, designed for use with graduate student teaching assistants; Yee et al., 2019), and the CRIOP (holistic, for middle school instructors; Powell et al., 2013).

One observation tool developed for college mathematics classrooms is the TAMI-OP, a segmented, descriptive tool (Hayward et al., 2017, 2018; Weston et al., 2021, 2023). The classroom observer records what both the instructor and the students are doing across each two-minute interval of class time and can record notes. The tool includes codes for modalities of active learning often seen in mathematics classrooms—students working in groups or individually, answering or asking questions, giving presentations—as well as listening to lectures (Laursen et al., 2014). Instructor codes include asking and answering questions, reviewing student thinking, moving and guiding student work, lecturing, and working problems. Thus TAMI-OP can capture teaching activities that involve students actively or more passively, and the mix of these. Designed to track changes in teaching behaviors such as may result from professional development, the TAMI-OP is deliberately behavior-focused and non-evaluative.

The TAMI-OP tool automatically generates two visualizations that display 1) a timeline of what students and teachers were doing across the class period, and 2) the proportion of two-minute periods of class time in which certain codes appear (Hayward et al., 2018). The visualizations highlight how class time is used, enabling instructors to quickly see class features such as how much class time is devoted to activities other than lecture, the use and timing of questions and answers, and the balance between instructor questions and student answers.

With a few exceptions (Dillon et al., 2020; Reinholz et al., 2020; Yee et al., 2022), the use of observation data has not been well explored as a formative feedback mechanism for improving college instruction (in contrast to education research). Interest in this application is growing, however, and follows a long tradition of employing observation for feedback (and evaluation) in K-12 education (Martinez et al., 2016). Recent work exploring the use of observation tools in the college arena for feedback purposes have emphasized their application to spur instructor self-reflection (Dillon et al., 2020), and to assess the impact of feedback on graduate student teaching assistants' teaching practices (Yee et al., 2022). Observed instructors have reported that observation-grounded feedback opportunities are helpful (Dillon et al., 2020). Graduate students were found to improve instruction when the feedback was well contextualized (Yee et al., 2022). It has been suggested that interactions between expert teaching faculty and research-oriented faculty (including through observation-grounded feedback) could support the adoption of student-centered instructional practices (Rozhenkova et al., 2023).

Previously, the TAMI-OP had been used for research and evaluation purposes, but its descriptive emphasis and simplicity led us to explore how the TAMI-OP tool could be used in a professional development context focused on supporting observation-grounded feedback and instructor reflection. The theory of planned behavior (Ajzen, 1991; Archie et al., 2022) shapes our understanding of how teaching arises from planning. The theory led us to design a cyclical process of gathering data, reflecting, and conversing about teaching can help teachers to assess and change their practices in self-driven ways. Thus, we did not use the theory to make predictions or model quantitative data, but it informed the design of the professional development process.

The process specifically involved two coaches facilitating a series of goal-oriented discussions with instructors about TAMI-OP visualizations. We wanted to know if instructors would use the data to experiment with their teaching or change some teaching practices in ways aligned with their goals and, ideally, also aligned with evidence-based teaching. We nicknamed this project VIP-Math (Visualization Instructional Practices). The coaches engaged each VIP-Math participant as follows: they met with instructors to learn their initial set of teaching goals and orient them to the TAMI-OP instrument. Instructors then video-recorded a session of their mathematics class. The coaches scored the teaching video using TAMI-OP and met with the participant to discuss patterns in the data and visualizations. Participants were prompted to reflect on progress around their goals and set future intentions. This cycle was repeated two more times over the academic term, roughly 4 weeks apart.

Here "VIP-Math process" refers to this process of repeated gathering, sharing and discussing the TAMI-OP data and visualizations. We asked the following research questions:

- RQ1: Which elements of the TAMI-OP data and visualizations did VIP-Math participants tend to focus on?
- RQ2: How did the VIP-Math process influence participants' teaching practices?

Using the findings, we consider the affordances and limitations of the TAMI-OP as a tool for coaching, and the implications of the results for observation-based professional development.

Methods

Development of the VIP-Math process. Two of the authors were the coaches for this project, an early-career research assistant with classroom and professional development observation experience and a mid-career researcher with teaching and research experience in K12 and higher education. The coaches co-developed the VIP-Math process in consultation with the third author and conducted all participant-facing activities. Participants were sent a digital video camera and instructions for recording, and they uploaded each recording to a secure cloud storage folder.

Participants. Three mathematics instructors participated in this study, recruited from a list of participants in teaching professional development workshops. All three were white women with over 5 years of college-level instructional experience, and each stated a commitment to creating student-centered and active learning classrooms. Each also described herself as influential to colleagues, through formal or informal means. Two were full-time tenured faculty and one was a full-time, non-tenure-track lecturer. All worked at primarily undergraduate institutions, two at community colleges and one at a small liberal arts college.

Coding and analysis. The two coaches coded several sample videos to arrive at a common understanding of TAMI-OP code application. Both coaches coded all participant videos, coming to consensus on codes prior to discussing them with participants. Coaches tracked qualitative features of the classroom using the notes feature of the TAMI-OP. During each discussion, coaches prompted instructors to reflect on their video-recorded class, patterns in the TAMI-OP visualizations, their initial teaching goals and ways they are addressing them, and to revise their goals and intentions for future sessions or classes. Coaches responded to such reflections with a mix of follow-up questions, encouraging comments, and ideas for the instructor to consider in planning. Discussions were conducted and recorded on Zoom, and coaches also documented the flow of ideas in a research journal. Both the research journals and discussions were analyzed qualitatively for evidence related to the research questions, and the TAMI-OP data provided quantitative evidence about teaching.

Results

We present brief summaries of each participant's engagement with VIP-Math, referencing each by their first initial (Table 1). These summaries focus on the goals the instructors set and related patterns in TAMI-OP data we observed across their three recorded sessions, which provide evidence of change in their teaching practices.

Table 1. Characteristics of courses, goals, and key change made by the three participants.

Participant	J	S	M
Course	Calculus 1	Precalculus	Finite Math
No. students	20	20	15
Class length	90 min.	60 min.	90 min.
Initial goals	Assess use of class time	Active learning; wait time	Student math talk; equity
Key change	Increased use of reasoning questions; Created plan to adjust materials	Introduced structured group work	Alternated questions between Zoom & room students

Participant S

Coaches noted that S's first videotaped class was highly interactive, with over 55% of time spent on activities other than lecture. She asked informational questions that students typically answered (Figure 1, Q&A). Students spent significant class time working on problems individually and used white boards to show individual work to S (Figure 1, IND).

The coaches suggested that S could expand the variety of her active learning techniques by incorporating structured group work and inviting students to present their work, and S set related goals. With the second recorded class, S incorporated structured group work for the first time. By the third class, she improved the written directions provided for group work, to increase their ability to work independently, and had one student present their group's work on the board.

S set long-term intentions to continue using structured group work and student presentations in both the Precalculus class that we observed and other classes, even though she anticipated some challenges:

> I am teaching precalc again in the fall so this is great, because I can implement it again. [I] want to start the student presentations earlier in the semester, and [I am] hoping that motivates them to be on time. My next goal: How do I add that level of structure in the group to ensure that everyone in the group participates and has a role?… I haven't tried [this] with the higher-level classes yet, but I definitely think I would try them. The actual physical classroom is logistically challenging because the class is really full and the room is really small. Could definitely do pairs though.

Participant M

In M's hybrid class for non-STEM majors, students could choose each day to attend online or in person. Her initial recording featured 90% of class time spent on activities other than lecture. In accordance with M's goal, coaches tracked the numbers of questions that M posed to students in the Zoom room and overall. The fraction of questions to Zoom students (typically about ⅓ of the class) rose from 20% to 35% across the three sessions. For M, making this change didn't feel entirely comfortable, but she had developed a system that seemed to work:

Intentionally directing Qs to Zoom vs room without knowing whether they are actually there – that feels tricky. I'm doing it alternating now, and if there is no pick-up in Zoom, I pivot to room.

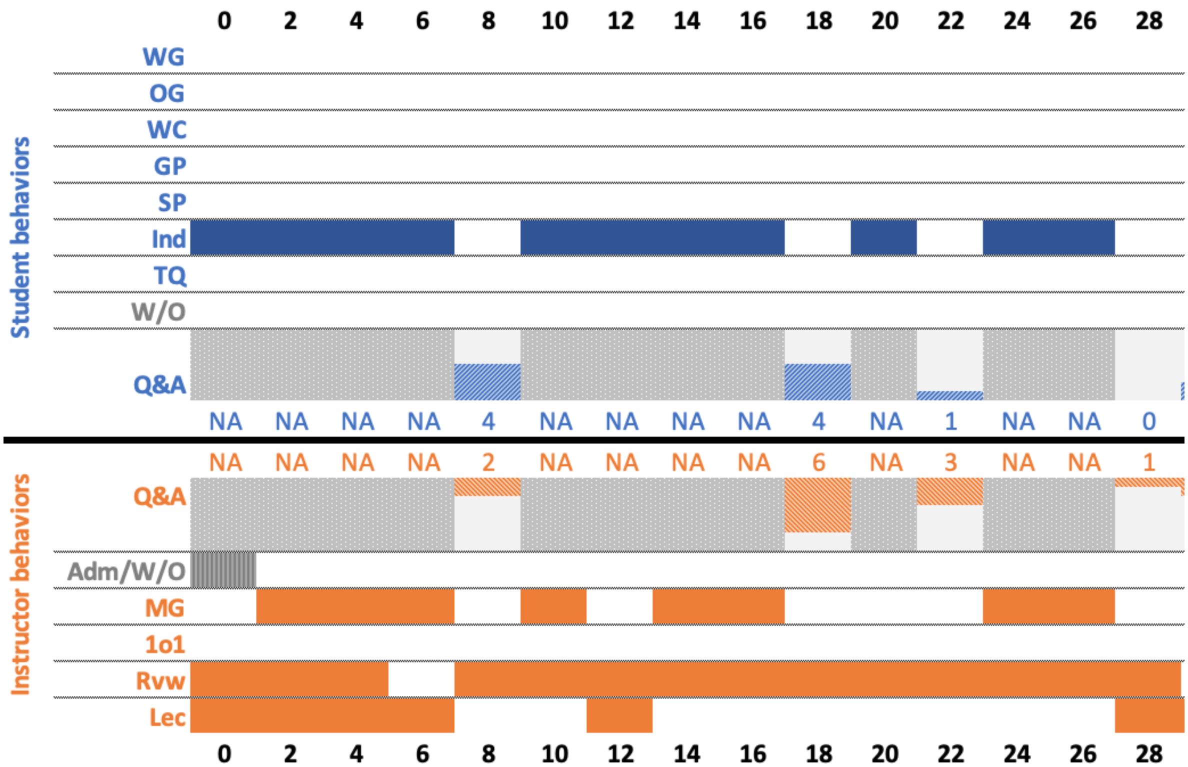

Figure 1. Excerpt of timeline visualization of S's first class, generated from TAMI-OP codes. Student codes (blue): WG, working in groups; OG; other group work; WC, whole class discussion; GP, group presentation; SP, student presentation; Ind, students working individually; TQ, taking a test or quiz; W/O, waiting/other. Instructor codes (orange): Adm/W/O, administrative/waiting/other; MG, moving and guiding; 1o1, teacher interacting with one student; Rvw, reviewing student thinking; Lec, lecturing. Horizontal axis represents elapsed time in class session, in minutes. Q&A numbers represent questions and answers from students (blue) and teacher (orange).

M devoted significant class time (25-90%) to student group work, in ways aligned with evidence-based teaching. Coaches noticed several ways in which class time was spent inefficiently, limiting opportunities for students to communicate mathematical understandings, but M did not engage with this observation.

During her final discussion, M continued to wrestle with the problem of engaging Zoom room students, in line with her initial goals. The coaches encouraged her to look at the norms she was setting around Zoom participation during her introduction to the course, and she came up with an idea to encourage Zoomers to use emojis to signal their presence and willingness to answer questions. She additionally generated an idea to create an introductory video of how Zoomers appear and sound in her hybrid-flexible classroom, to help Zoomers know how they appear to the in-person class.

Participant J

We observed three of J's Calculus I sessions. J's initial goals were to assess the balance of student group work time to other teaching activities, and to increase student voice in her classes. She wanted to devote 50% of class time to group work; in her initial class, she spent >60% of class time on activities other than lecture.

Across the three class sessions, TAMI-OP data revealed that J allocated 25-35% of class time specifically to group work. Discussion of J's second class centered around this balance:

> I have been thinking about restructuring the worksheets for this day. This is confirmation of that, that there is something missing in the balance of how it is set up.

J realized she needed to carefully choose example problems to illustrate new material, so there is "conceptual meat" yet without distracting details such as "dividing fractions." By our final discussion, J expressed a related long-term goal: "I need… to redevelop so I can get around them being bad at algebra." This was related to J's goal of increasing active learning: by restructuring class materials to maintain focus on new concepts, she could shift the balance of class time away from explanations and toward group work. Further, J described how TAMI-OP data led her to alter her expectations for use of class time:

> I have mentally adjusted by benchmark to realize that 50% group work may not be realistic… It will change how I approach others in my department. [I] don't want to set unrealistic expectations for other people.

Coaches also noticed that J asked 70-95 questions per class session, mostly informational. In discussions, J did not respond directly to the coaches' prompts around reasoning questions, but she did begin to ask more reasoning questions, increasing their share from 0% to 25% across the three class sessions.

RQ1: Which elements of the TAMI-OP data and visualizations did VIP-Math participants tend to focus on?

All three participants oriented quite quickly to the instrument. They had few questions about the meaning of different code categories and were able to interpret sample visualizations readily. Most frequently discussed were instructor codes LEC (lecture), REV (review), IQ and RQ (informational and reasoning questions), and MG (moving and guiding); and student codes SA (student answers), WG (working in groups), and SP (student presentations). Conversations focusing on TAMI-OP data tended to be brief. None of the participants tended to pore over the data, looking for patterns that were not obvious.

Participants tended to focus on TAMI-OP elements that aligned well with their initial goals. M tended to focus on the share of questions that she was asking to students in the Zoom room, while S and J tended to focus on the amount of class time devoted to student active learning. Participants also often commented on TAMI-OP data that they perceived as validating their current teaching practices.

RQ2: How did the VIP-Math process influence participants' teaching practices?

We found that the VIP-Math process influenced participants to change specific teaching practices in the short term. Each participant altered some teaching practices across their recorded classes, and mentioned altering some practices in classes that were not recorded. Some teaching practices changed as recommended by coaches, even when goals were not explicitly set around them. Changes were observed in how participants allocated class time to student group work and presentations, and how participants asked questions. At final discussions, all three participants also set long-term teaching goals, some of which could be traced to patterns in their TAMI-OP data. S set goals for increasing student presentations and structured group work, while M set goals about increasing the engagement of her online students, and J set goals for altering class materials so student group work can proceed more efficiently.

Discussion

Patterns across the three VIP-Math participants suggest some preliminary answers to our research questions. Participants readily engaged with the data visualizations generated about their class sessions and referenced them in reflecting on how their uses of class time related to their teaching goals (RQ1). Participants also made specific goal-related changes to their teaching, and they set long-term goals for future teaching changes (RQ2).

The VIP-Math project also allowed us to gather insights about the affordances and limitations of TAMI-OP as a professional development tool. As affordances, we found uploaded recordings of class sessions easy to score remotely, and we could accomplish an observation-feedback cycle with less than a week of lag between recording and discussion. Participants oriented quickly to the codes and visualizations, maintained a focus on their teaching goals, made related changes across the course of their sessions, and reacted positively to the VIP-Math process overall.

However, the VIP-Math process was time-intensive for coaches, and two coaches were needed to manage the logistics across three sessions. Coaches found some aspects of high-quality teaching challenging to address, particularly evaluative elements not captured by the protocol, and elements not well aligned to participants' teaching goals. For instance, coaches' concerns about M's efficiency in using class time were never discussed in depth, in part because these concerns did not align with M's goals.

This study is also limited by the small sample of participants with limited diversity. There were no instructors of color, novice or early-career instructors, instructors who expressed ambivalence around incorporating active learning into their teaching, or instructors who were teaching large classes. This limits our ability to generalize about the tool's benefits in professional development contexts.

Acknowledgments

We thank the three instructors who participated in VIP-Math, and Chuck Hayward, who provided early advice on the design of the VIP-Math process. The work was supported by the National Science Foundation under award DUE-2111273.

Using Balacheff's (2013) model of conceptions we analyzed textbook examples in the linear independence section of an interactive linear algebra textbook and 61 student responses to a similar reading question. Reading questions seek to entice students to read the textbook before attending the lesson when the ideas will be discussed; the responses are immediately available to instructors. We found ten additional parts of conceptions (control structures) used independently or in combination with the ones promoted in the textbook. We discuss the implications of our findings and our plans for future research.

Keywords: linear independence, conception, linear algebra, cK¢ model of conceptions

We contribute to investigations of students' understanding of fundamental notions in linear algebra by bringing a different theoretical approach to such investigation with the goal of exploring its usability in large-scale analysis. Linear algebra is a course that is nearly universally taught at four- and two-year institutions across the United States (Blair et al., 2018). Extensive research documents the difficulties students experience with the high abstract level of the notions, which also demands substantial computational dexterity. While much work has been done to address student difficulties (e.g., using curricula that emphasize building mathematical understanding through concrete experiences and visualizations that are progressively mathematized; Wawro et al., 2012), managing these difficulties in the classrooms is not straightforward. As they learn the material, independently of the curriculum that is being used, students face difficulties in transitioning from concrete to more abstract and from managing visual representations to working with spaces that can not be visualized. Our position is that independently of the textbooks or the mode of teaching, such difficulties will emerge; thus, finding ways in which these difficulties can be readily identified could promote better teaching and learning.

Literature Background

The research on the learning of linear (in)dependence has focused on identifying students' conceptual difficulties with the notion and its formal/abstract definition (Dorier, 2017; Hannah et al., 2013; Stewart & Thomas, 2007, 2009) and characterizing students' ways of thinking about linear (in)dependence. Regarding conceptual difficulties, researchers have shown that, although students make mistakes when solving routine problems, their procedural understanding is sounder and less varied than their conceptual understanding of this notion (Celik, 2015; Parker, 2010). To investigate ways of thinking, researchers have relied on a handful theorizations, and although they are named differently, the categorizations they produce are similar: abstract, algebraic, geometric (Ertekin et al., 2010; using Hillel's [2000] descriptive modes); travel, geometric, vector algebraic, matrix algebraic (Plaxco & Wawro, 2015; using Tall and Vinner's [1981] notion of concept image); embodied, symbolic, formal (Stewart & Thomas, 2007; using

Tall's [2004] three worlds of mathematics); or synthetic-geometric, analytic-arithmetic, analytic-structural (Dogan-Dunlap, 2010; Sierpinska's [2000] three worlds of mathematics). Across these studies, there is consensus that visual, embodied, or geometric forms of thinking about linear (in)dependence can help students overcome their difficulties with its algebraic and formal modes.

We focus on research addressing the problem of determining whether a set of vectors is linearly independent. Celik (2015) organized 186 student responses to this problem into 18 categories. The most common student approach was finding scalars that satisfied the definition of linear (in)dependence. Bouhjar et al. (2021) categorized the reasoning of 255 about the problem into six strategies: comparing Reduced Row Echelon Form (RREF) to the identity matrix, identifying the number of pivots, writing one vector as a linear combination of others, solving $Ax = 0$, comparing the number of rows and columns, and establishing the existence of free variables. Because linear independence was defined in terms of the solution to the homogeneous vector equation corresponding to $Ax = 0$, solving $Ax=0$ and comparing the RREF were considered the more appropriate approaches. Analyzing student responses to the same problem, Dogan (2010, 2018) showed that when not using geometric ways of thinking, most students use one of the following: (1) find a linear combination among the vectors, (2) find that the only solution to a linear combination is the trivial solution, (3) find whether scalar multiple and/or adding the vectors gives the zero vector, or (4) find RREF.

We complement this work in three significant ways. First, in addition to identifying student reasoning when learning how to solve the problem of determining whether a set of vectors is linearly independent, we study how their linear algebra textbook addresses it, which helps frame students' work. Second, while researchers have investigated students' various modes of thinking or types of reasoning, we only focus on one semiotic register: the symbolic vector-matrix. This allows us to fully investigate the difficulties of this representation, which is preferred for formalization to higher-order spaces. Third, although it is common to draw a line between procedural and conceptual understanding, we assume that these approaches are intertwined and can significantly inform one another. Therefore, we use a theoretical framework that bypasses analysis of conceptual and procedural understanding and instead focuses on the actions and the decision-making processes as students determine whether a set of vectors is linearly independent.

Theoretical Framework

Balacheff (2013; Balacheff & Gaudin, 2009) posits that meaning derives from the system that encompasses a milieu and a cognizant subject rather than being inscribed in either of them alone; meaning is created through the interactions between the milieu and the subject through the actions of the subject on the milieu and the feedback the milieu provides to the subject. His work responds to three needs related to investigating student thinking (1) explaining why particular held conceptions of a notion that appear contradictory to an observer are not to the holder of the conceptions; (2) describing the array of conceptions that can be held by learners, which are the result of historical and pedagogical process of concept development; and (3) understanding the connection between behaviors and knowing. Following this tradition, *savoir* (knowledge), the subject matter developed by a community, is differentiated from *connoisseur* (knowing, as a noun), the knowledge held by an individual, which can be incomplete or even mathematically invalid. For this reason, knowledge and knowings are tied to the problems in which they emerge. Thus, understanding the practices in which specific mathematical ideas are called for is the first step in understanding conceptions.

The cK¢ model is a heuristic of sorts for identifying conceptions. It has four components: problems, operators, semiotic and representation systems, and control structures. *Problems* correspond to the "class of the disequilibria the considered conception is able to recover from" (Balacheff & Gaudin, 2009, p. 190); they emerge from the sets of practices in which individual concepts are called for. *Operators* refer to "actions on the milieu" including those needed "to transform and manipulate linguistic, symbolic or graphical representations" (p. 190). The learner receives feedback from the milieu as a result of their actions (action-feedback loop). The *semiotic and representation systems* are defined as the "linguistic, graphical or symbolic means which support the interaction between the subject and the milieu" (p. 190). Finally, the *control structures* refer to the "components supporting the monitoring of the equilibrium of the [Subject - Milieu] system" (p . 190), or said differently, the strategies that the cognizant subject relies on to decide whether they had solved the problem and that they had done so correctly. This model has been used to identify potential conceptions that could emerge as students work with different components in textbooks, such as the problems, the examples, or the textbook presentation with different concepts (functions, Mesa, 2004; differential equations, Mesa, 2010; angles, Mesa & Goldstein, 2016). We use this theorization to identify: (1) What conceptions of linear independence are promoted by examples in an interactive undergraduate linear algebra textbook? and (2) What control structures do students use when answering reading questions about linear independence embedded in these textbooks?

Methods

The data for this study come from a larger study that investigates undergraduate mathematics students' and instructors' use of interactive textbooks in calculus, linear algebra, and abstract algebra courses (Beezer et al., 2018). The linear algebra textbook, *A First Course of Linear Algebra* (Beezer, 2021), is designed to be a bridge-to-proof linear algebra course and it follows the definition-theorem-proof presentation style (Love & Pimm, 1996). The textbook is authored in PreText (https://pretextbook.org/), which allows the inclusion of interactive features. *Reading Questions* are one such feature designed to entice students into reading material before coming to class; students are supposed to answer a few of these short answer questions in each section directly in their textbooks before coming to class. Their responses are then collected and made available for their instructor in real-time so that instructors can learn about their students' thinking before a lesson and alter their plans as needed.

To investigate how the textbook content related to the chosen reading question in this section (Figure 1), we identified one example in the Linear Independence and Spanning Sets (LISS) section directly related to it (Figure 2). The example, named Linear Independence in M_{32} (LIM32) is about the vector space of all 3x2 matrices and illustrates the work needed to decide whether two different sets of matrix vectors are linearly independent or dependent. We analyzed the example using Balachef's (2013) cK¢ model.

LISS Reading Questions

1. Is the set of matrices below linearly independent or linearly dependent in the vector space M_{22}? Why or why not?

$$\left\{\begin{bmatrix} 1 & 3 \\ -2 & 4 \end{bmatrix}, \begin{bmatrix} -2 & 3 \\ 3 & -5 \end{bmatrix}, \begin{bmatrix} 0 & 9 \\ -1 & 3 \end{bmatrix}\right\}$$

Figure 1: The first reading question in LISS

Example LIM32 Linear independence in M_{32}
Consider the two sets of vectors R and S from the vector space of all 3×2 matrices, M_{32} (Example VSM)

$$R = \left\{ \begin{bmatrix} 3 & -1 \\ 1 & 4 \\ 6 & -6 \end{bmatrix}, \begin{bmatrix} -2 & 3 \\ 1 & -3 \\ -2 & -6 \end{bmatrix}, \begin{bmatrix} 6 & -6 \\ -1 & 0 \\ 7 & -9 \end{bmatrix}, \begin{bmatrix} 7 & 9 \\ -4 & -5 \\ 2 & 5 \end{bmatrix} \right\}$$

$$S = \left\{ \begin{bmatrix} 2 & 0 \\ 1 & -1 \\ 1 & 3 \end{bmatrix}, \begin{bmatrix} -4 & 0 \\ -2 & 2 \\ -2 & -6 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ -2 & 1 \\ 2 & 4 \end{bmatrix}, \begin{bmatrix} -5 & 3 \\ -10 & 7 \\ 2 & 0 \end{bmatrix} \right\}$$

One set is linearly independent, the other is not. Which is which? Let us examine R first. Build a generic relation of linear dependence (Definition RLD),

$$\alpha_1 \begin{bmatrix} 3 & -1 \\ 1 & 4 \\ 6 & -6 \end{bmatrix} + \alpha_2 \begin{bmatrix} -2 & 3 \\ 1 & -3 \\ -2 & -6 \end{bmatrix} + \alpha_3 \begin{bmatrix} 6 & -6 \\ -1 & 0 \\ 7 & -9 \end{bmatrix} + \alpha_4 \begin{bmatrix} 7 & 9 \\ -4 & -5 \\ 2 & 5 \end{bmatrix} = \mathbf{0}$$

Massaging the left-hand side with our definitions of vector addition and scalar multiplication in M_{32} (Example VSM) we obtain,

$$\begin{bmatrix} 3\alpha_1 - 2\alpha_2 + 6\alpha_3 + 7\alpha_4 & -\alpha_1 + 3\alpha_2 - 6\alpha_3 + 9\alpha_4 \\ \alpha_1 + \alpha_2 - \alpha_3 - 4\alpha_4 & 4\alpha_1 - 3\alpha_2 + -5\alpha_4 \\ 6\alpha_1 - 2\alpha_2 + 7\alpha_3 + 2\alpha_4 & -6\alpha_1 - 6\alpha_2 - 9\alpha_3 + 5\alpha_4 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$$

Using our definition of matrix equality (Definition ME) to equate entries we get the homogeneous system of six equations in four variables,

$$\begin{aligned} 3\alpha_1 - 2\alpha_2 + 6\alpha_3 + 7\alpha_4 &= 0 \\ -\alpha_1 + 3\alpha_2 - 6\alpha_3 + 9\alpha_4 &= 0 \\ \alpha_1 + \alpha_2 - \alpha_3 - 4\alpha_4 &= 0 \\ 4\alpha_1 - 3\alpha_2 + -5\alpha_4 &= 0 \\ 6\alpha_1 - 2\alpha_2 + 7\alpha_3 + 2\alpha_4 &= 0 \\ -6\alpha_1 - 6\alpha_2 - 9\alpha_3 + 5\alpha_4 &= 0 \end{aligned}$$

Form the coefficient matrix of this homogeneous system and row-reduce to obtain

$$\begin{bmatrix} \boxed{1} & 0 & 0 & 0 \\ 0 & \boxed{1} & 0 & 0 \\ 0 & 0 & \boxed{1} & 0 \\ 0 & 0 & 0 & \boxed{1} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

Analyzing this matrix we are led to conclude that $\alpha_1 = 0$, $\alpha_2 = 0$, $\alpha_3 = 0$, $\alpha_4 = 0$. This means there is *only* a trivial relation of linear dependence on the vectors of R and so we call R a linearly independent set (Definition LI).

So it must be that S is linearly dependent. Let us see if we can find a nontrivial relation of linear dependence on S. We will begin as with R, by constructing a relation of linear dependence (Definition RLD) with unknown scalars,

$$\alpha_1 \begin{bmatrix} 2 & 0 \\ 1 & -1 \\ 1 & 3 \end{bmatrix} + \alpha_2 \begin{bmatrix} -4 & 0 \\ -2 & 2 \\ -2 & -6 \end{bmatrix} + \alpha_3 \begin{bmatrix} 1 & 1 \\ -2 & 1 \\ 2 & 4 \end{bmatrix} + \alpha_4 \begin{bmatrix} -5 & 3 \\ -10 & 7 \\ 2 & 0 \end{bmatrix} = \mathbf{0}$$

Massaging the left-hand side with our definitions of vector addition and scalar multiplication in M_{32} (Example VSM) we obtain,

$$\begin{bmatrix} 2\alpha_1 - 4\alpha_2 + \alpha_3 - 5\alpha_4 & \alpha_3 + 3\alpha_4 \\ \alpha_1 - 2\alpha_2 - 2\alpha_3 - 10\alpha_4 & -\alpha_1 + 2\alpha_2 + \alpha_3 + 7\alpha_4 \\ \alpha_1 - 2\alpha_2 + 2\alpha_3 + 2\alpha_4 & 3\alpha_1 - 6\alpha_2 + 4\alpha_3 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$$

Using our definition of matrix equality (Definition ME) to equate entries we get the homogeneous system of six equations in four variables,

$$\begin{aligned} 2\alpha_1 - 4\alpha_2 + \alpha_3 - 5\alpha_4 &= 0 \\ \alpha_3 + 3\alpha_4 &= 0 \\ \alpha_1 - 2\alpha_2 - 2\alpha_3 - 10\alpha_4 &= 0 \\ -\alpha_1 + 2\alpha_2 + \alpha_3 + 7\alpha_4 &= 0 \\ \alpha_1 - 2\alpha_2 + 2\alpha_3 + 2\alpha_4 &= 0 \\ 3\alpha_1 - 6\alpha_2 + 4\alpha_3 &= 0 \end{aligned}$$

Form the coefficient matrix of this homogeneous system and row-reduce to obtain

$$\begin{bmatrix} \boxed{1} & -2 & 0 & -4 \\ 0 & 0 & \boxed{1} & 3 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

Analyzing this we see that the system is consistent (we expected this since the system is homogeneous, Theorem HSC) and has $n - r = 4 - 2 = 2$ free variables, namely α_2 and α_4. This means there are infinitely many solutions, and in particular, we can find a nontrivial solution, so long as we do not pick all of our free variables to be zero. The mere presence of a nontrivial solution for these scalars is enough to conclude that S is a linearly dependent set (Definition LI). But let us go ahead and explicitly construct a nontrivial relation of linear dependence.

Choose $\alpha_2 = 1$ and $\alpha_4 = -1$. There is nothing special about this choice, there are infinitely many possibilities, some "easier" than this one, just avoid picking both variables to be zero. (Why not?) Then we find the dependent variables to have values $\alpha_1 = -2$ and $\alpha_3 = 3$. So the relation of linear dependence,

$$(-2) \begin{bmatrix} 2 & 0 \\ 1 & -1 \\ 1 & 3 \end{bmatrix} + (1) \begin{bmatrix} -4 & 0 \\ -2 & 2 \\ -2 & -6 \end{bmatrix} + (3) \begin{bmatrix} 1 & 1 \\ -2 & 1 \\ 2 & 4 \end{bmatrix} + (-1) \begin{bmatrix} -5 & 3 \\ -10 & 7 \\ 2 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}$$

is an iron-clad demonstration that S is linearly dependent. Can you construct another such demonstration? △

Figure 2: Example LIM32 in LISS

Next, we analyzed 61 responses to the reading question in LISS from 61 unique students from four different sections during Fall 19, Fall 20, Spring 21, and Fall 21. All four instructors used the textbook and assigned the reading questions to their students. During analysis, we noticed that the operators were implied in most of the student responses and the steps taken were not outlined. However, the justification for their conclusion was usually explicit. Therefore, we solely focused on the control structures stated in the student responses. After coding all the responses individually, we met to compare the coding and resolve disagreements. Six of the 61 students' responses to the reading question were uninterpretable or did not have a stated control structure. We also looked for patterns when students used more than one control structure.

Findings

Inferred conceptions from Example LIM32 in the textbook

Example LIM32 addressed the problem "where a given set of vectors is linearly independent" (see Figure 2). Relying on a 3x2 matrix, this example uses symbolic representations. We identified a total of five operators (OP) in the solution and two control structures (CS).

The author starts by constructing the homogeneous system by equating an arbitrary linear combination of all vector matrices with a zero matrix (OP1: *Construct homogeneous system*). He then creates an augmented matrix for the system (OP2: *Construct matrix*) and performs a row-reduced echelon transformation on the matrix (OP3: *Row reduction*). He proceeds to inspect the resulting RREF matrix. He first starts by asserting that "the system is consistent (we expected this since the system is homogeneous, Theorem HSC)", then he states the observation that the RREF "has $n - r = 4 - 2 = 2$ free variables, namely α_2 and α_4" (OP4.1: *Free variables*, feedback = "there are free variables"). This observation implies that "there are infinitely many solutions" (OP4.2: *Number of solutions*) which leads to the criterion "we can find a nontrivial solution." This enables him to use the control structure *Nontrivial* (CS1) that alludes to the existence of nontrivial solutions to the homogeneous system to justify the claim that the given set is linearly dependent. Conversely, if the homogeneous system only has a trivial solution (which is implied by having one unique solution, as it can not have no solution because the system is consistent by default), then the given set is linearly independent. Even though "the mere presence of a nontrivial solution (…) is enough to conclude that *S* is a linearly dependent set," the author also provides an optional operator, *Find nontrivial scalars* (OP5) by explicitly constructing a nontrivial relation of linear dependence. This suggests another control structure in solving this problem, namely *Scalars* (CS2) that justify the linear dependence of the set by providing a set of nonzero scalars that satisfy the homogeneous system.

Control structures in student responses to LISS reading question

Nontrivial (CS1) was observed in 14 responses (out of 55 total; e.g., "Linear independent, because it only contains the trivial solution", #50). Despite OP7: *Find nontrivial scalars* being described as optional, *Scalars* (CS2) was observed in 10 responses (e.g., "This set is linearly dependent as there is the nontrivial dependence relation \`a_1=-2, a_2=-1, a_3=1\`." #3). Here, because the student provided nontrivial scalars, we only coded the responses for *Scalars* and not *Nontrivial*.

We identified 10 additional control structures in student responses, four of which were identified in at least six responses: *FreeVar* (CS3), *NumSol* (CS4), *LinearCombo* (CS5), and *Pivots* (CS6). *FreeVar* (CS3, 10 responses) and *NumSol* (CS4, 6 responses) could derive from the solution path demonstrated in the textbook. *FreeVar* alludes to the number or existence of free variables in the justification (e.g., "Set is linearly dependent. These can be modeled by a system of 4 equations which can be represented in a matrix that, when row-reduced, yields a free variable." #17) whereas *NumSol* alludes to the number of solutions to the homogeneous system in their justification. For example,

> Following Example 2 of this section, if we form a general relation of linear dependence, find the corresponding system of homogeneous equations of each of the matrix entries, create the coefficient matrix and row reduce, we see that the resulting RREF of the coefficient matrix gives us a 4x3 matrix that has one free variable. This says that there are infinitely many solutions for the scalars in the relation of linear dependence, which further means (by Def LI) that the given set of matrices is linearly dependent. (#15)[1]

The other two control structures—*LinearCombo* (CS5, 14 responses) and *Pivots* (CS6, 8 responses)—were not directly related to the textbook examples. *LinearCombo* (CS5) alludes to the existence of linear combinations within the set or to finding the exact linear combination by expressing one vector matrix in terms of others (e.g., "The set of matrices are linearly dependent because 2[[1,3],[-2,4]]+[[-2,3],[3,-5]] = [[0,9],[-1,3]] thus making one vector a linear combination of the others." #1) whereas *Pivots* (CS6) is assigned when the students' responses suggest a comparison of the number of pivots with the number of vectors in their justification (e.g., "The set of matrices are linearly independent because there are less pivots than vectors.").

Other control structures were observed in at most three responses ("Others" in Figure 3). For example, students gave justifications: using the consistency of the homogeneous system (CS7:

[1] Note that this response also used *FreeVar* (CS3, "... has one free variable"). We could not find responses using only *NumSol* (CS4).

Consistency), using singularity of the coefficient matrix (CS8: *Singularity*), by reducing the vector matrix to identity (CS9: *VectorMatrix=I*), by reducing the coefficient matrix to identity (CS10: *CoefMatrix=I*), mentioning the shape of the coefficient matrix (e.g., number of rows or columns, number of vectors, number of equations; CS11: *MatrixShape*), and using a theorem, (Theorem Row-Equivalent Matrices represent Equivalent Systems, CS12: *REMES*).

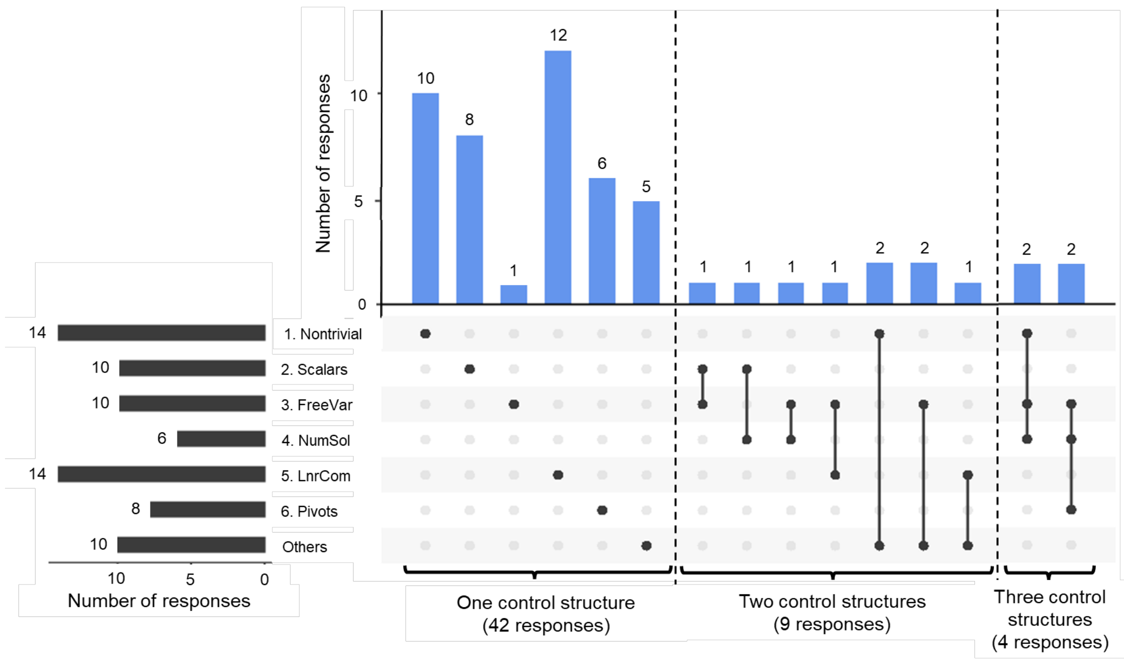

Figure 3: Distribution of control structures used in LISS-RQ1 (n = 55)

Figure 3 is an UpSet plot (Conway et al., 2017; Lex et al., 2012) that summarizes the distribution of control structures in student responses. Among the 55 interpretable responses, 42 used one control structure; nine used two control structures; and four used three control structures. *FreeVar* (CS3) and *NumSol* (CS4) was the most common combination, recorded in five of 13 responses with multiple control structures.

Discussion and Conclusion

Analyzing the control structures in student responses to reading questions allowed us to learn more about how students interpret the content in the textbook and potentially rely on other resources to tackle the problem of deciding whether a set of vectors is linearly independent. In the textbook example, the connection between the existence of free variables, the number of solutions to the homogeneous system, and the existence of nontrivial solutions are demonstrated sequentially, as if one needs to go through all these steps to answer the question. It is possible that the author wants to stay consistent with the definition of linear independence in the textbook (Figure 4) by ending the action-feedback loop with the criteria "whether there are non trivial solutions to the homogeneous system." However, given that the conditions are equivalent mathematically (e.g., free variable(s) exist ⇔ infinitely many solutions to the homogeneous system ⇔ existence of a nontrivial solutions), students may have realized that is possible to justify linear dependence after carrying out either or both operations—*Free variables* (OP4.1) and *Number of solutions* (OP4.2)—and inspecting the feedback. This suggests that students may see these three conditions as equivalent, rather than as a uni-directional line of reasoning as described by the author (free variable(s) exist ⇒ infinitely many solutions to the homogeneous system ⇒ existence of non-trivial solutions), which is an important learning objective and must be emphasized throughout the course.

> **Definition LI. Linear Independence.** Suppose that V is a vector space. The set of vectors $S = \{\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3, \ldots, \mathbf{u}_n\}$ from V is ***linearly dependent*** if there is a relation of linear dependence on S that is not trivial. In the case where the ***only*** relation of linear dependence on S is the trivial one, then S is a ***linearly independent*** set of vectors.

Figure 4: Definition of linear independence in section LISS.

LinearCombo (CS5, 14 responses) and *Pivots* (CS6, 8 responses) were not mentioned in the textbook example. Independently, CS5 was more frequently observed than *Nontrivial* (CS1, 10 responses), which was demonstrated in the example. We suspect that students may be relying on the textbook's definition of the dependence relation (Figure 5) and not necessarily on the operator paths or the control structures presented in the textbook example. Likewise using *Pivots* might be justified by students making connections across sections as the connection between pivots and number of solutions is explained in section Types of Solution Sets (TSS), 17 sections before LISS. This implies a potential avenue for future research, which entails conducting a longitudinal examination of students' responses to reading questions across different sections in order to observe how their conceptions evolve over time.

> **Definition RLD. Relation of Linear Dependence.** Suppose that V is a vector space. Given a set of vectors $S = \{\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3, \ldots, \mathbf{u}_n\}$, an equation of the form
>
> $$\alpha_1\mathbf{u}_1 + \alpha_2\mathbf{u}_2 + \alpha_3\mathbf{u}_3 + \cdots + \alpha_n\mathbf{u}_n = \mathbf{0}$$
>
> is a ***relation of linear dependence*** on S. If this equation is formed in a trivial fashion, i.e. $\alpha_i = 0$, $1 \le i \le n$, then we say it is a ***trivial relation of linear dependence*** on S.

Figure 5: Definition of linear dependence relation in section LISS.

More Relatable? Students' Positioning of Undergraduate Teaching and Learning Assistants in Mathematics Courses Taught by Graduate Students

Rachel Funk
University of Nebraska-Lincoln

Undergraduate teaching and learning assistants (UTLAs) can support learning and students' sense of belonging in undergraduate, active learning STEM classrooms. One main goal of incorporating UTLAs into a classroom is to connect students to a peer-like instructional figure whom, it is assumed, students find more relatable. However, little is known about how UTLAs change the social dynamic of undergraduate mathematics classrooms, particularly those taught by an instructor of record who is a graduate student (GSI). I used positioning theory as a lens to understand how students locate UTLAs in instruction. I analyzed 411 undergraduate precalculus student responses to the survey question: "Do you interact differently with [the GSI] than [the UTLA]? If so, please explain." From a qualitative analysis of responses, I found that students positioned UTLAs along three storylines that have different implications for the distribution of instructional duties between UTLAs and GSIs in an active learning environment.

Keywords: undergraduate teaching and learning assistants, graduate student instructors, active learning, student perceptions

For several decades, institutions have been hiring advanced undergraduates to provide academic and social support for their peers, with positive outcomes (Barrasso & Spilios, 2021; Dawson et al., 2014; Gafney & Varma-Nelson, 2008; Whitman & Fife, 1988). These efforts are grounded in the view that knowledge is socially constructed, peer-to-peer interactions are important, and that undergraduates, as "near-peers" (Whitman & Fife, 1988, p. 5) have a unique ability to support students (Gafney & Varma-Nelson, 2008; Otero et al., 2006). These near-peer teaching models can be particularly effective in acting as change levers (Laursen, 2019) to support the institutionalization of active learning in postsecondary education.

Undergraduate teaching and learning assistants (UTLA; Jardine, 2020) are undergraduates specifically hired to facilitate active learning during lectures or recitations. The learning assistant model is perhaps the most prominent peer teaching model that specifically integrates near-peers into regular class time (Barrasso & Spilios, 2021; Otero et al., 2006). Research on this model suggests that it supports increases in students' conceptual understanding, higher-order cognitive skills, satisfaction, and sense of belonging and decreases in failure rates (Alzen et al., 2018; Clements et al., 2022; Goertzen et al., 2011; Otero et al., 2010; Sellami et al, 2017; Talbot et al., 2015). But the field is still emergent. With few exceptions (e.g., Stringer, 2023; Webb et al., 2014) most research has been in physics (Barrasso & Spilios, 2021) and to date, focuses primarily on positive outcomes. This also holds true for other models that use UTLAs. There is a specific gap in research on UTLAs in classrooms led by graduate student instructors of record (GSIs). Indeed, most research focuses on classrooms taught by faculty. Given that a key assumed benefit of UTLAs is their positioning as a near-peer, and thus as a more relatable teaching figure, it is worth interrogating this assumption in a context in which the instructor is a graduate student.

The purpose of this study is to explore how students perceive UTLAs in relation to GSIs within active learning mathematics classrooms, and what influences that perception. Toward this aim, I focus on the following two research questions:

RQ1: How did students in active learning precalculus classrooms position UTLAs versus GSIs in interactions with students?

RQ2: Why might students have preferred to interact with either the UTLA or the GSI?

Theoretical Framework

Positioning theory has been used as a lens to understand the multiple ways that faculty and UTLA interact with one another. I argue that it can also illuminate the nature of student and UTLA interactions (Jardine, 2020). Positioning theory focuses on social interactions, specifically on "the ways in which people use action and speech to arrange social structures" (Wagner & Herbel-Eisenmann, 2009, p. 2). It specifically is useful in highlighting the assumed rights and duties of people in interactions. There are three mutually determining components of positioning: positions, speech acts - or communication acts as Herbel-Eisenmann et al. (2015) suggest - and storylines (Van Langenhove & Harré, 1999). Positions are a cluster of personal attributes which determine the distribution of rights (what one is owed) and duties (what one owes others) within a certain social milieu. These positions contribute to and are influenced by an unfolding storyline, which is likely also influenced by historically, personally, and culturally significant stories (Davies & Harré, 1999). Positions and storylines imbue meaning to the ways that people communicate in an interaction. Researchers interested in the positions taken up by participants may study communication acts for patterns to identify what storylines participants may be assuming, thereby illuminating how rights and duties are being distributed in an interaction.

Although positioning theory often focuses on immanent, moment-by-moment communication acts, others have used positioning theory to analyze how people position themselves and others through narratives (Bamberg, 1997; Deppermann, 2013). Kayi-Aydar (2021) presents an analytic framework to support the identification of positioning in narratives. They suggest focusing on four components: a.) attributes and biological dimensions, b.) categorical membership, c.) storyline structure, and d) emotions. Attributes and biological dimensions include character traits and dispositions (e.g., creative, helpful). Categorical memberships refer to an individual's membership in a cultural or identity group. Storyline structures can be identified through multiple means, including word choice, sentence structures, abrupt shifts in topic, and the introduction of new people. Emotion words include emotional states (proud) as well as words or sentences that express or imply emotion (e.g., "gross!", "I can do it"). In the methods section I discussed how I used this analytic framework from Kayi-Aydar (2021) to help identify the storylines students implicitly followed when positioning UTLAs and GSIs through the narratives they shared in survey data.

Methods

This study is part of a larger case study of the UTLA role[1] at a predominately white Midwestern University and focuses on data collected in fall 2021. UTLAs supported two precalculus courses: College Algebra and a combined College Algebra and Trigonometry course. All students in the sections of these courses were invited to participate in a survey for extra credit. In this survey, students were asked to directly position UTLAs in relation to GSIs by answering the question: "Do you interact differently with [the GSI] than [the UTLA]? If so,

[1] Locally, the UTLAs were called "LAs"; however, a defining feature of the LA model is that students receive pedagogical training throughout the semester (Otero et al., 2006). At Midwestern, UTLAs received pedagogical training at the beginning of the semester, but in fall 2021 a pedagogy course was not offered. Thus, Midwestern University did not implement the LA model as intended in fall 2021.

please explain." There were 411 responses to this question. I coded each of these responses as "Difference," "No Difference" or "N/A" to capture perceived differences between student-GSI and student-UTLA interactions. In total, I classified 390 responses as either "Difference" (n=194) or "No Difference" (n=196) and included these responses in subsequent analysis. I read through these 390 responses and took analytic memos to capture factors influencing differences or similarities in student-GSI and student-UTLA interactions. Several responses were general (e.g. "we generally ask him [the UTLA] more questions than [GSI]"); however, 209 responses provided sufficient detail to be included in a secondary analysis. Criteria for inclusion were broad to include all responses that could illuminate why students perceived interactions with their GSI to be the same or different from interactions with the UTLA. For example, the response "No, I respect them both equally as an instructor for this course" was included because, although not overtly specific, this response suggests that the student positions the UTLA and the GSI in similar ways (positioning both "equally" as instructors), because they respect them as teachers.

To identify how these 209 students positioned UTLAs and GSIs in their interactions with them, I developed codes informed by my memos about factors and Kayi-Aydar's (2021) recommended strategies for identifying positioning in texts. These codes were: dispositions, labels/categorical membership, emotions, and perceived teaching quality. See Table 1 for a summary of these codes. I then analyzed each of the 209 responses with these codes, before engaging in an axial coding process to identify related themes on how students interacted with their GSI and UTLA. I structured these themes around storylines to highlight how students positioned UTLAs in interactions. I also coded these responses for student preference, as in, their expressed preference to interact with the GSI or the UTLA (GSI, UTLA, or Other).

Table 1 Codebook for Identifying Storylines in SPIPS-M Data

Code	Definition	Example
Dispositions	Attributes personality traits and dispositions to a UTLA or GSI	"Yes, because [UTLA] seems more personable and available to help. I also like the way he explains things better."
Labels/ categorical membership	Mentions membership in particular cultural groups or uses specific labels to describe the UTLA or GSI. This includes designations such as student, peer, woman, etc. as well as titles (e.g., professor).	"Yes, [UTLA] is closer to our age so we talk to him more often."
Emotions	Mentions emotions arising from or during interactions with a UTLA or GSI.	"I can more easily say when I don't understand something to her and stop her while she's explaining - I feel a little rude to do that to Professor [GSI]."
Teaching Quality	Mentions a perceived teaching quality of the UTLA or the GSI.	[GSI] is better at answering questions.

Preference	Use to capture explicit preferences for the UTLA or GSI (or to indicate no explicit preference) Sub-codes: UTLA, GSI, Other	Other: “No, [UTLA] has helped me more since he's closer to our table, but we all interact the same.”

Findings

In the findings section, I use positioning theory to share how students in active learning classrooms positioned UTLAs and GSIs in interactions with students. I present three major storylines students followed to position UTLAs and GSIs, particularly related to one another. As I introduce these storylines, I share quotations from students as well as the number of responses that the storyline draws from, as a proxy for understanding how prevalent the storyline was in the data.

Storyline 1: UTLA ≅ GSI

In this section I present evidence of one of three storylines: *UTLAs and GSIs only differ superficially, and thus have the same duties in interactions with students*. Evidence for this storyline came from responses in both the “Difference” and “No Difference” categories. Seventeen of the 194 “Difference” responses indicated that the only difference between their interactions with the UTLA versus the GSI was due to incidental factors, such as proximity or the initiative of the instructional figure. One student said “usually [UTLA] helps answer our questions first.” Another student said that they did interact differently with the UTLA, “just because [UTLA] sits closer to our table. [GSI] helps people on his side.” Although this student did perceive there to be a difference in how they interacted with the GSI versus the UTLA, their reasoning for this difference was tied explicitly to their location in the classroom, rather than an explicit preference for interacting with the UTLA or the GSI. Several “No Difference” responses specifically labeled the GSI and UTLA similarly, which in effect positioned the GSI and UTLA as occupying the same position (e.g., "No, I see them as both of my teachers who teach me the course material in and out of class, "No, I treat them both as my professor..."). Teacher, instructor, and professor were the most common labels in this group, but one student also referred to their GSI and UTLA as “guides” through “the journey of math class," and another student labeled them as “mentors” to help them learn. Overall, this storyline calls attention to a group of students that did not perceive there to be any meaningful differences between the UTLA or GSI. However, these students did not provide enough information in their responses to glean the perceived, shared, duties of the UTLA and the GSI. The following storyline elaborates on these duties.

Storyline 2: UTLA ≅ GSI: Emotions, Dispositions, and Teaching Quality Matter

When students shared a preference for interacting with either the UTLA or GSI, they often explained their preference along three themes: (a) emotions felt during interactions (b) perceived teaching quality and (c) UTLA and GSI dispositions. Student responses related to these themes suggest that students judged UTLAs and GSIs based on a similar set of expectations, which effectively positioned UTLAs and GSIs similarly. Thus, the second storyline I present is an elaboration of the first: *UTLAs and GSIs hold similar positions, in which both have a duty to make interactions comfortable for students by having an inviting disposition and teaching content well*. Below I elaborate on each of the themes that contribute to this storyline.

Forty students discussed the emotions they felt in interactions with UTLAs or GSIs. Typically, students brought up emotions to explain with whom they preferred to interact. For example, one student said:

> *[GSI] makes me feel more comfortable because she is engaging and friendly. She explains the answer and why the problem works the way it does. She is encouraging and makes me feel like I can actually do the problem. [UTLA] walks around and occasionally gives the answer. However she is not very clear, and does not explain her thought process. She is reserved and does not make me feel confident in my answer.*

This student positioned their GSI as someone who makes them feel and capable of solving mathematics problems. In contrast, the student does not feel confident when working with the UTLA. Other students had similar sentiments, but about their UTLA. One student shared that they felt "more comfortable asking [UTLA] questions…because he makes sure I understand the problem." In contrast, they found interactions with the GSI "confusing" and time-consuming. Most emotions centered on the level of comfort and confidence felt by students. It was also common for students to simultaneously evaluate the teaching ability of their GSIs and UTLAs when comparing how they interact with these teaching figures[2].

In sum, 101 students described the teaching quality of their GSI or UTLA. Out of these responses, 61 responses focused on the ability of the GSI or UTLA to explain content or answer questions to support their understanding. One student shared that their GSI's approach to student questions (answering questions by asking questions) was ineffective. In contrast, they perceived their UTLA to be more adaptable to their learning needs:

> *Yes, I believe that both are good instructors however, my interactions with [UTLA] are different because he takes my learning disability into account and bases his methods of teaching or explaining off of it. No offense to [GSI], I think he is a good teacher and works very hard but I cannot learn efficiently or effectively with his style of teaching.*

Often, students positioned UTLAs as someone who provided more thorough explanations, which they valued. However, some students shared a preference for their GSI's explanations, usually for similar reasons as those cited by students who preferred interacting with their UTLA. For example, one student described a preference for interacting with their GSI because of their focus on understanding "why the answer is the answer it is," in-depth explanations, and scaffolding. Nine students also described how differences in the knowledge of the UTLA or the GSI impacted their perceptions of interactions with them. One student expressed a preference for interacting with the GSI because the "[GSI] knows what he is talking about usually and can help with homework and [UTLA] cannot." Interestingly, a different student in the same section said "[UTLA] is usually more helpful with homework or workbook questions, so I ask him rather than [GSI]." Students focused primarily on how the UTLA or GSI explained content and answered questions, but some students did discuss the opportunities given to students to figure things out on their own and receive feedback.

Fifty-two students attributed dispositions that a GSI or UTLA may have to describe their interactions with UTLAs and GSIs. Most of these students described preferring to interact with someone that had dispositions which promote interactions (e.g., nice, personable, trustworthy, relatable, talkative, friendly, approachable). For example, one student described their GSI as "more personable so it is easier to have a conversation with him." However, students also shared

[2] These evaluations reflect student perceptions of their interactions with instructors and UTLAs; however, I purposefully am not making any claims about the quality of the teaching by UTLAs or instructors involved in this study.

dispositions that inhibited their interactions with either the UTLA or the GSI. These included dispositions likely to result in less communication with students (e.g., quiet, reserved) as well as traits that were likely to result in negative interactions (e.g., rude, complainer). Often students used antithetical dispositions to highlight differences between the GSI and UTLA:

> *If I have a question about a problem that I really do not understand, I will ask [UTLA]. He takes the time to explain things and is super helpful and patient. [GSI] always seems like they are in a rush to get to the next table or does not understand/ listen to what you are trying to ask.*

Table 2 provides a complete list of the dispositions used to describe UTLAs and GSIs when students also expressed a preference for interacting with either the UTLA or the GSI. The dispositions students ascribed to UTLAs and GSIs, and the connection of these dispositions to their preference for whom they interact, suggest that students view it as the duty of the UTLA and the GSI to be inviting.

Table 2. Dispositions Students Attribute to UTLAs and GSIs

Preference	LA Disposition	GSI Disposition
LA	approachable (2); calm; communicator; easy-going; engaging; friendly (3); helpful (5)*; kind; patient; less intimidating; chill; outgoing; passionate; personable; relatable (3)	difficult to approach; quiet; rude; rushed; straightforward; kind*; helpful*; passionate*
GSI	complainer; down to business; less engaging; reserved; nice*	easy-going; encouraging (4); engaging (3); friendly; helpful (2); nice (2); not personal but knowledgeable; personable (4); talkative; relatable; trustworthy; understanding (2)

Note. Each disposition was mentioned by one student unless otherwise noted (n)
*Three students described both their UTLA and their GSI using similar dispositions (kind and helpful; passionate; and nice) while still expressing a preference for the other teacher figure. Preference was dictated by other factors (e.g., perceived teaching quality).

Storyline 3: UTLA ≇ GSIs

The prior two storylines focused on duties held in common between UTLAs and GSIs. However, several students described interactions with the UTLA and GSI that suggest they perceive their roles to be different, and at times, complementary. This is distinguished from the storyline above, in which students often expressed a preference for working with either the UTLA or the GSI based on a set of common criteria. I capture this idea as the storyline: *UTLAs and GSIs have different duties in instruction*. This storyline was the least prevalent; responses from 17 students form the basis of this storyline.

Sometimes, but not always, students felt that interactions were more comfortable, easier, or less intimidating with UTLAs than with GSIs. Further, some of these students attributed this to belonging to the same community as the UTLA. For example, one student shared:

I don't act differently between [GSI] or [UTLA] but I feel slightly more comfortable with [UTLA] just because he's closer to my age. I feel that I can crack jokes and make silly mistakes when [UTLA] helps me and I'm not afraid to not know an answer.

This student positioned the UTLA as someone that allows them to be mathematically vulnerable due to their closeness in age. Another student said it was "slightly easier" to talk to the UTLA because they were a "student," whereas they viewed the GSI as a "professor." Thus, some students preferred to interact with the UTLA because of the UTLA's status as a peer, student, or because of their age. For others, gender played a role in how they perceived interactions with their GSI versus their UTLA. As an example, one student said:

I'm a college girl and so is [UTLA], it's just easier for us to interact I think. And I can more easily say when I don't understand something to her and stop her while she's explaining - I feel a little rude to do that to Professor [GSI].

Another student said they interact "better with women than men, and with students vs. teachers" and that she felt she had "more in common" with the UTLA than the GSI. Both students preferred to interact with their UTLA because they shared assumed commonalities in gender, but also academic status as a student. Some students acknowledged similarities between themselves and the UTLA but did not connect this to a preference for interacting with the UTLA versus the GSI. As an example, one student said "I think I treat [UTLA] more as a peer because we are closer in age" but did not say that they preferred one over the other.

Some students described intentionally interacting with GSIs and UTLAs for different purposes. One student explained that the "[GSI] is my professor so I come to her with more important or difficult questions. I also act more professional with her" whereas with their UTLA they are "much more relaxed" and ask "mundane questions." Other students discussed approaching the UTLA for help on particular components of the course (e.g., homework) while approaching the GSI for different help (e.g., clarification on the notes).

Discussion

There were likely multiple storylines students drew from to make meaning of their interactions with the UTLAs and the GSI. However, these findings suggest that most students viewed, at one point or another, the UTLA as having the same position as the GSI in the classroom, and further judged the value of the UTLA according to their perceptions of what good teaching is, the dispositions of the UTLAs and GSIs, and how they felt in those interactions. Furthermore, although only a relatively small number of students did position UTLAs as providing a unique perspective or difference in instruction, for those students the impact of having someone they could relate to was impactful to their experience. Many of these students described similarities between the UTLA and themselves (i.e., categorical membership in the same communities) as supporting their desire to engage with the UTLA. Other students valued the different perspectives and expertise brought by the GSI and UTLA and used these differences to guide who they interacted with and for what purposes.

A major storyline in the literature about UTLAs is that the UTLA are near-peers, and thus more relatable. Yet, several students positioned UTLAs in ways that run counter to this storyline. Further research could investigate more deeply how the identities of UTLAs and instructors influence students' storylines about UTLAs, particularly regarding the near-peer assumption. Research could also investigate the tacit and explicit ways that mathematics instructors and departments position UTLAs in active learning classrooms and connect that to the storylines evoked by students. Such research would expand our understanding of the roles UTLAs can play in supporting active learning mathematics classrooms.

Analyzing an Instructor's Oral Follow-Up Assessment Strategies in an Introductory Proof Course

Nurul Wahyuni
Davis & Elkins College

David Miller
West Virginia University

This study investigates the characteristics of an instructor's communication in one-on-one oral assessments for an introduction-to-proof course and how they impact student learning. It examines the instructor's strategies for evaluating the depth of students' knowledge. Using thematic analysis, the study examines patterns in question types and their relation to revision quality and presentation fluency. Findings reveal that well-revised proofs prompted questions about comprehension and logical structure. For revisions needing improvement, questions guided students to establish correct proofs before addressing comprehension. The study also explores teaching elements resulting from the instructor's assessment practice using commognitive theory. These findings contribute to assessment practices, particularly in revision and oral assessment for introduction-to-proof courses. By highlighting communication's role in student learning, this research advances alternative assessment understanding in higher education mathematics.

Keywords: revision, oral assessment, objective-based grading, commognition, proof feedback

One crucial element of teaching practice revolves around the creation and execution of assessment methods. Gaining insight into how an instructor carries out his/her teaching practices can offer valuable insights into the implementation of a course. Given the significant role mathematical proofs play in the field of mathematics, evaluating proofs forms an integral aspect of teaching practice. Prior research has delved into how mathematics instructors assess students' written proof submissions using conventional point-based systems (Miller et al., 2018; Moore, 2016). This study aims to extend our understanding by exploring oral assessment methods, specifically focusing on objective-based grading (OBG) in an introduction-to-proof course.

The course that is being studied in this paper implemented oral assessments to evaluate proof revisions under the implementation of OBG. In OBG, student performance is typically assessed as pass or fail, based on near-perfect or perfect solutions, with minor errors sometimes overlooked. However, making a judgment about how serious a mistake is can be a challenging task when evaluating mathematical proofs (Miller et al., 2018; Moore, 2016). Oral assessment, however, has the advantage of clarifying whether a small mistake was indeed insignificant to the overall mastery of the material through follow-up questions.

Studies highlight the advantages of oral assessments for evaluating students' proof skills (Soto-Johnson & Fuller, 2012; Stylianides, 2019) and reveal that when students orally present their proofs, they often offer more comprehensive explanations, resulting in stronger proof outcomes (Soto-Johnson & Fuller, 2012; Stylianides, 2019). Other studies have discussed the implementation and outcomes of the use of OBG (e.g., Cooper, 2020; Iannone & Vondrová, 2023; Prasad, 2020; Zimmerman, 2020), and have discussed the benefits of oral assessment (e.g., Iannone et al., 2020; Iannone & Simpson, 2012, 2015). However, there has been limited research on oral assessment with OBG and this study will inform readers about the instructor's communicative approach to the implementation of oral assessment in an introduction-to-proof class using OBG. The main research goals of this study are: (1) What are the discursive characteristics of the instructor's oral communication during oral follow-ups when grading students' proof productions? and (2) What is the significance of the instructor's communication practices in the oral follow-up assessment?

Literature Review

Objective-based Grading

The traditional grading system still dominates higher education mathematics in the U.S., employing partial credit for each problem submitted (Nilson, 2015). There is, however, an alternative grading approach known as OBG, also referred to as mastery-based grading or standard-based grading. Under this system, the course is organized around a set of specific objectives that students must successfully achieve. Students are provided with multiple chances to demonstrate their comprehension for each objective and any initial failure to pass an objective does not impact their overall grade; only the final outcome is counted (Campbell et al., 2020).

Studies consistently demonstrate that OBG offers numerous advantages for both students and instructors (Knight & Cooper, 2019; Linhart, 2020; Zimmerman, 2020). Students benefit from reduced testing anxiety through multiple attempts, learning from mistakes, fostering autonomy, and prioritizing learning over points. This approach can significantly impact the depth of their understanding and intrinsic motivation (Linhart, 2020). Instructors, on the other hand, find satisfaction in streamlined grading processes without the need for complex rubrics, appreciate their students' increased effort and improved quality of work, gain insight into students' capabilities and understanding through objective-based assessment, and experience enhanced purposefulness in their teaching (Knight & Cooper, 2019; Prasad, 2020).

Proof Evaluation Practices

Teaching goes beyond classroom instruction; as Moore (2016) noted that when professors assess students' proof productions, they effectively engage in teaching by making corrections, providing comments, and discussing students' thought processes to enhance their proof-writing skills. Evaluating proof productions is a challenging aspect of teaching, influenced by individual judgments of the seriousness of proof errors, student comprehension, and perceived abilities, leading to considerable scoring variability among professors, especially in traditional point-based grading (Miller et al., 2018). However, OBG minimizes this variation, resulting in more consistent grading outcomes, except in cases when the seriousness of proof errors is disputed.

Mathematicians grade students' proofs based on several aspects, such as logic, clarity, fluency, understanding (Moore, 2016), and perceived ability (Miller et al., 2018). Some professors also focus on linguistic and academic rules, which students often overlook (Lew & Mejía-Ramos, 2019). Surprisingly, students and professors have contrasting views about language conventions on proofs. For instance, students, regardless of language skills, do not realize the importance of correct academic English in proofs. Mathematicians emphasize complete sentences, with most deducting points for incomplete ones, while only a few students find this unconventional. In addition, professors and students have varying opinions about overusing variables in proofs (Lew & Mejía-Ramos, 2019).

Oral assessments may have distinct evaluation criteria compared to written assessments, especially when students prepare written solutions in advance without supervision. In oral assessments, follow-up questions are crucial for evaluating a student's understanding, making the grading criteria more complex (Iannone & Simpson, 2012). This study aims to contribute to mathematics education literature by shedding light on the evaluation of students' proof productions in oral assessments, addressing a gap in the existing literature. It will provide insights for both researchers and professors in higher education mathematics on the practice of oral assessments and proof feedback in higher education mathematics.

Theoretical Framework

From a commognitive perspective, human actions fall within specific discourses, each defined by its objects, communication methods, and participant rules, thereby establishing distinct communities of communicators (Sfard, 2008). For example, discussions centered on mathematics form a mathematical discourse. Within mathematics, a discourse is built upon structured activities known as mathematical routines, which Sfard (2008) defines as "a set of metarules that describe a repetitive action" (p. 208). These routines serve the purpose of generating narratives about mathematical concepts and objects.

Kontorovich (2021) introduced the concept of the didactical discourse on proof (DDP) to encompass the discourse of the teaching and learning of mathematical proofs. DDP has two key aspects: the pedagogical aspect and the mathematical aspect (Kontorovich, 2021). For the pedagogical role, DDP guides educators on what and how to teach in a proof course. For the mathematical aspect, participants must adhere to community-accepted rules for mathematics when discussing mathematical proofs. The primary goal of this research is to uncover patterns of DDP within the context of assessing mathematical proof productions through oral assessments.

He also examined routines in feedback practices using DDP and the commognitive framework to analyze proof feedback in a graduate topology course, focusing on comments and point deductions on graded assignments. He found that fully-scored proofs received comments related to mathematical concepts (mathematizing), while reduced-score proofs often received comments addressing the student personally (subjectifying). Point deductions were always linked to issues concerning the proof's idea, but not its representation (Kontorovich, 2021).

Viirman (2014, 2015) explored routines among mathematical instructors during lectures. Viirman (2014) discovered variations in lecture routines, including construction routines (common to all instructors, involving concept definitions and diverse examples) and substantiation routines (related to theorem proving, with varying emphasis). Viirman (2015) listed three key didactical routines: explanation routines for clarifying concepts, motivation routines to engage students, and question posing routines (featuring rhetorical questions).

The didactic practices of mathematics instructors remain relatively unexamined. There is very little (or no) existing research that delves into the routines involved in the execution of oral assessments within higher education mathematics courses. This study aims to contribute to the body of literature in mathematics education by exploring the routines employed by mathematics instructors when conducting oral assessments to evaluate mathematical proofs.

Methods

Context

The research was conducted in an introduction to proof course, involving four students and an instructor with pseudonyms of Amy, Clara, Dana, Gina, and Dr. Jones. The study focused on evaluating proof productions on quizzes, following a specific process. Initially, students completed a closed-book, in-person written quiz in which each learning objective was graded as a success, growing, or not assessable. Only a grade of success counted as passing and contributed to the final grade. For students who did not obtain success on certain learning objectives on the quiz, they had the opportunity to revise their solutions and present them in a one-on-one virtual oral follow-up assessment within a week of receiving feedback. During this oral assessment, Dr. Jones could ask additional questions related to the presented proofs.

Data Corpus

The data for this study was comprised of: (a) original proof productions by students, (b) feedback from the instructor, Dr. Jones, (b) students' revised written proof productions, (d) recordings of the oral follow-up meetings, and (e) interviews with Dr. Jones. The study concentrated on proof constructions, assessed on Quizzes 2 through 5. Four participants (Amy, Clara, Gina, and Dana) presented 4, 10, 10, and 3 revised proofs, respectively, in some of the oral follow-up assessment meetings.

The interviews with Dr. Jones were conducted twice through Zoom using a semi-structured format, covering various themes. The main topics discussed during the interviews included Dr. Jones' teaching background, course structure, quiz assignment procedures, oral follow-ups, written feedback practices (both general and specific), and the implementation of mastery grading. The first interview with Dr. Jones took place at the end of the semester, and the second interview occurred approximately three months after the course had concluded, focusing more on the implementation and outcomes of mastery grading in the course.

Analysis

The types of follow-up questions were analyzed in relation to the quality of revised proof productions. The revised productions were categorized into one of the following: successful revised proof production with no improvement or correction suggested by Dr. Jones - *coded as P1*; revised proof production that is correct but could be improved by adding more information, such as additional details or explanations, or by refining some phrases - *coded as P2*; revised proof production that has one or more mathematical errors – *coded as P3*.

The oral follow-up recordings were the main data for this study. The thematical analysis coding was conducted using MAXQDA software for qualitative analysis. Because of our interest in depicting Dr. Jones' communication routines, the codes were developed to emphasize the aspects of communication in Dr. Jones' phrases. We particularly focused on capturing on the type of communication, rather than the specific content of the communication itself. For instance, when Dr. Jones inquired, "Why did you change the quantifier?" the code used is "question on changes" rather something related to quantifier. This approach allows us to center the analysis on the communication aspects rather than the mathematical aspects.

Results

The analysis revealed that Dr. Jones employed two distinct approaches when interacting with students based on the quality of the revised proof productions (P1, P2, or P3): the routines when encountered with correct narratives and reconstruction of an alternate narrative.

Routines when Encountered with Correct Narratives

There are two possible cases of Dr. Jones' actions when encountered with correct proof productions: the proof was instantly endorsed without any follow-up questions or there was an examination of the students' comprehension of the proof presented. When questions were posed, they were usually centered around logical aspects of the proof or the rationale for changes in the proof.

From a total of 27 proof presentations in the oral follow-up sessions, 11 of them were categorized as P1, which means the revised proofs had no issues. This categorization was based on the nonexistence of Dr. Jones' comments for disapproval or comments on improvement. Among these 11, there were five performances that received successes instantly. During the interview with her, Dr. Jones pointed out two important aspects describing the circumstances that do not require follow-up questions. The first aspect is the authenticity of writing. This is important because the nature of the assessment allows the students to access any resources available to them. However, they are expected to be able to write it in their own words. The second aspect is the fluency of their verbal communication in which the presentation of the proof should sound very natural. Therefore, a good quality of mathematical verbal communication is valued not only in terms of its validity, but also the fluency of the explanation part.

In most cases, error-free revised proof productions were subject to scrutiny by Dr. Jones. This was done to ascertain whether students had indeed learned and understood the material that they presented. Dr. Jones mentioned that "the oral follow-up gave me that option to figure out if they just copied it from somewhere or if they had really learned something." The routines of Dr. Jones implemented when she encountered an error-free proof productions can be distinguished into two types of inquiry: Question/prompts related to the logical structure of the proofs and questions/prompts related to the changes from the originals to the revised versions of the proofs.

Question/prompts related to the logical structure of the proofs. Dr. Jones collected information about the students' logical structures through implicit and explicit methods. In the explicit approach, Dr. Jones would request students to explain the reasoning behind their proof structures. Here's an illustration of how this explicit examination of the proof's logic works.

Gina revised her proof for the following objective: "I can construct a correct proof of a conditional statement involving sets." The statement to prove was as follow: Let A, B, V, and W be sets. Prove that if $V \subseteq A$ and $W \subseteq B$, then $V \cap W \subseteq A \cap B$. After Gina presented her revised proof for this objective, Dr. Jones asked her the following question, "So, what's the key word that tells us ultimately that definition of subset? That key word that's allowing us to conclude V intersect W is a subset of A intersect B?" Gina replied, "The key word?", to let Dr. Jones know she did not understand the question. Dr. Jones then clarified by stating, "So, somewhere in your proof you're saying by definition of subset. So, what is that definition of subset? Where's that in your proof that it's allowing you to make that conclusion?"

Dr. Jones questioned Gina's understanding of how the definition of "subset" influenced her proof's logic. Gina struggled to identify this crucial element in her proof. After some discussion, Dr. Jones clarified further, "that's the thing [circling the word *implies*] that actually allows you to make this conclusion [underlying $V \cap W \subseteq A \cap B$] at the end. Because if you had written that as an and then you will be talking about intersection […]. So, this is [pointing out the word *implies*], this word is what's telling us that you're using this definition [the definition of subset]."

In the implicit approach, Dr. Jones questioned the student about a statement's definition without directly connecting it to the proof. This allowed Dr. Jones to assess the consistency between the applied definition and the student's narrative. In the following discussion, Dana presented her revised proof for the statement: "If $A \subseteq B$, then $A - C \subseteq B - C$". After Dana presented the proof, Dr. Jones asked, "Alright. Here's two statements [wrote "$x \in A$ and $x \in B$" and "if $x \in A$, then $x \in B$"]. Are those two statements the same or are they different?" Although Dana accurately revised a proof that relies on the concept of a subset, she struggled to correctly identify the definition of a subset. Dr. Jones then provided the correct information in which she explained, "So, this one is the definition of subset [pointing to the second one]. We're talking about we've got a set A and it's inside of some larger set B. But the first one, we're talking about our two sets don't necessarily have to be nested and things are just in between them. So, this is the definition of intersection [pointing out to the first one]." This exchanged suggests that Dana might not have had a complete grasp of the logical structure underlying her written proof.

Dr. Jones did not immediately allow Dana to falter; instead, she offered her another opportunity through a series of different questions. Dr. Jones then tried to delve into Dana's logical structure more directly on another proof by asking, “How do you know to start with x is an element of A minus C?” During the second round of questioning, Dr. Jones found Dana's response satisfactory and deemed it a success and choose to provide further clarification after acknowledging the student's success, emphasizing the answers to the questions.

Questions/Prompts Related to Changes Made. On many occasions, success in the follow-up meeting requires students to not only construct a correct proof but also explain why the initial proof was rejected. This ability is crucial for meeting the learning target. Failing to articulate the errors in the original proof, even if the revised one is correct, can still result in failure.

This example illustrates how Dr. Jones probed a student’s understanding on the changes she made from the original to the revised proof. Gina presented her revised proof for the following problem: “Let A, B, and C be sets. Prove that $A \times (B \cap C) = (A \times B) \cap (A \times C)$." In Gina's initial proof, she had notational problems, like omitting parentheses when denoting an element in the Cartesian product. However, she successfully rectified this issue in her revised proof, prompting Dr. Jones to pose the question, “Also, things like parentheses around that x, y, why is that important?” A student who presented a revised proof correctly may still not achieve success if she cannot provide a clear explanation for why the alterations were required.

Reconstruction of an Alternative Narrative. When a student presents a correct proof production, Dr. Jones may make a point to highlight an alternative version. The alternative version can involve a minor modification or substantial changes to student’s version of the proof. Among the data collected, there were three instances when Dr. Jones constructed alternative proof productions. The construction process was conducted through a dialogue with the student in which Dr. Jones guided the process. For example, Dr. Jones illustrated that a proof by cases (with even and odd integers cases) could be simplified to a straight-forward direct proof.

Routines when Encountered with a Flawed Narrative

When a student presented a revised proof that had an error, Dr. Jones provided her with prompts and questions to rectify the issue. The observed flaws in students' revised proofs fell into two categories: those needing additional information or details (P2) and those that were mathematically or logically incorrect (P3).

Eliciting Missing Information. When gaps in the proof arose from missing information, Dr. Jones prompted students to fill in that missing information. In one of Clara's revised proofs, there was a lack of crucial details regarding the requirement for a valid fraction, specifically that the denominator should not be zero. The excerpt below shows how Dr. Jones guided Clara to provide more details about the object's properties used in her proof. Dr. Jones began with the question, “So, those integers a and b that you’re using to make up as a rational [number], is there any other condition that should be there?” Clara replied, “Yeah, that they are co-prime, right?” Dr. Jones then stated, “Co-prime, I’m less concerned about that” and Clara exclaimed, “Okay, well, b is not zero.” Dr. Jones replied encouraging, “Yeah, that one is kind of important.”
