The second category of constraint is known as *semantic similarity*, which focuses less on the abstract structure that may exist between two domains, and more so on the similarity of the underlying appearance or meanings associated with the two domains. In the previous example comparing the *taller than* relation to the *more massive than* relation, you might notice that the two situations are quite irrelevant to one another despite possessing a common basic structure. Thus, the two statements are low in semantic similarity. In contrast, consider the analogy that underlies the pair of statements (1) *Oliver is taller than Paul* and (2) *William is older than Tim*. In this case, not only is basic structure preserved, but there is also a high semantic similarity. Both situations define relations between people, focusing on properties that are often used to compare and describe people in every-day life. One interesting observation about semantic similarity is that, while it may serve as a constraint to assist with developing analogies in general, it is often argued that a high degree of semantic similarity is less appealing when creating "good" analogies. In fact, preference is often given to analogies that determine similarity between two highly disparate situations that share no surface level similarities (e.g., Gentner, 1983). This concept is ubiquitous to pure mathematical thinking as well, given that isomorphisms only require abstract structure to be similar without any reference to whether the objects themselves within the structures are similar or not (e.g., integers under addition are isomorphic to the free group on one element, yet there is no specific similarity to the elements contained in each group.)

The final constraint is *pragmatic centrality*. This crucial constraint dictates that even when analogies might possess high levels of structural consistency and semantic similarity, an underlying pragmatic purpose must be present for the analogy to be observed. Out of all possible analogies that might be generated, pragmatic centrality serves as the constraint that ensures that analogies are created with purpose. Indeed, pragmatic centrality extends beyond just the analogical creation itself; the constraint of pragmatic centrality is visible when students question the purpose of their choices and reflect upon their overall goal, as well as consider the consequences of their choices. For a summary of the three constraints, see Table 1.

Table 1. Types of Analogical Constraint

Structural Consistency	Adhering to the constraint of purposely generating one-to-one mappings between structures.
Semantic Similarity	Adhering to the constraint of purposely generating analogies between domains with observed similar meanings.
Pragmatic Centrality	Acknowledging underlying purpose of the analogy, either before, during, or after creation.

In this study, I aim to answer the following research question: *In what ways did four students adhere to the three constraints of structural consistency, semantic similarity, and pragmatic centrality while reasoning about ring-theoretic structures by analogy with group-theoretic structures?*

Methods

The data for this study was collected as part of a larger project investigating students' analogical reasoning in abstract algebra. In the Fall of 2019 and the Spring of 2020, rosters were acquired from the abstract algebra courses taught at a large 4-year research university in the southwestern United States. Four students, named Andrew, Brandon, Ellen and Nathan (all pseudonyms) were solicited to be interviewed and participate in a series of 5 clinical task-based interviews (Goldin, 2012). During these interviews, a single camera was positioned toward the student's written work and a lapel mic was given to the student for audio recording. The first interview served to allow students to recall various aspects of group theory and associated concepts and definitions, while the subsequent interviews focused on exploring concepts in ring theory.

The final three interviews all corresponded to the construction of a different ring-theoretic analogy to group-theoretic structures. There were two pertinent goals of these interviews. First was to generate a ring-theoretic analogue to subgroup, homomorphism, and quotient group based on what they knew from group theory by openly responding to the task: *Make a conjecture for a structure in ring theory analogous to _____ in group theory*. Second was to inquire into properties, examples and theorems associated with their newly generated ring-theoretic analogue. During the interviews, the students' understanding of structure was revealed based on what features they attended to while developing their ring-theoretic analogue and was also revealed based on what properties and theorems they decided to investigate following the completion of their analogy.

To analyze the students' interviews, transcripts of the audio were coded alongside the video with respect to the three constraint categories. In particular, the statements made by the students in addition to their written work were scrutinized for any evidence of attention to structural or semantic similarity, as well as any attention to an underlying purpose for their utterances/writing, or considerations of consequences for their construction in the moment (pragmatic centrality). Such utterances were then assigned a code based on the adherence to one or more of the constraints along with descriptions of how the constraint influenced their analogical creation. Following this process, I then identified themes delineating the extent to which each constraint was present across the students' thinking elicited in each interview.

Results

The extent to which each student adhered to the constraints provided insight into their sensitivity to recognizing underlying concepts associated with both group- and ring-theoretic structures, thus reaffirming previous findings related to their sense of analogical structure (Hicks & Flanagan, 2024). But, by attending to the presence of the three constraints in the participants' thinking, a window into their underlying rationale for developing their ring-theoretic analogues was opened, providing further insight into the students' reasons for establishing their analogies. In this section, I present three themes that were identified as possessing particular significance to these constructions: (1) adhering to basic structure, (2) adhering to conceptual structure, and (3) flouting constraints to advance exploration (see Table 2).

Table 2. Observed Themes

Adhering to Basic Structure	Exhibiting adherence to structural consistency and semantic similarity of surface level concepts, such as naming conventions, written symbols, etc.
Adhering to Conceptual Structure	Exhibiting adherence to structural consistency and semantic similarity of deeper concepts, such as mapping the concept of structure-preserving maps from the domain of group theory to the domain of ring theory.
Flouting Constraints	Ignoring one constraint in an effort to freely investigate properties or aspects of an analogous structure.

Adherence to Basic Structure

Perhaps unsurprisingly, most students adhered to a high level of semantic similarity when generating a name for their ring-theoretic analogy for most structures. For example, each student provided the names "subring" and "ring homomorphism" to describe their newly created analogy in comparison to subgroups and group homomorphisms. Across all structures, the students appeared to be strongly adhering to both constraints of structural consistency and semantic similarity, often with little reference to any sort of underlying purpose to the name. For example, when constructing the ring-theoretic analogue to quotient groups, Nathan introduced the concept of a "normal subring" without any suggestion as to what "normal" might mean in the context of ring theory. I refer to the presence of both structural consistency and semantic similarity of surface level concepts as *adherence to basic structure*.

A notable example of adhering to basic structure occurred when Ellen developed her definition for a ring-theoretic analogue to homomorphism. Despite recognizing differences in the structure of group and ring in general, Ellen made an effort to maintain structural consistency and semantic similarity when developing her analogue for homomorphism by combining the homomorphism property into one statement (see Figure 1.) This allowed Ellen to establish a one-to-one relation between the two homomorphism definitions (i.e., each required only one function and one homomorphism property), while also maintaining a similar appearance for both. However, Ellen did not immediately question the underlying meaning of her newly formed homomorphism property that combined the operations into one expression, thus suggesting that pragmatic centrality was absent from her initial creation.

1. **Make a conjecture for a structure in ring theory analogous to homomorphisms in group theory.**

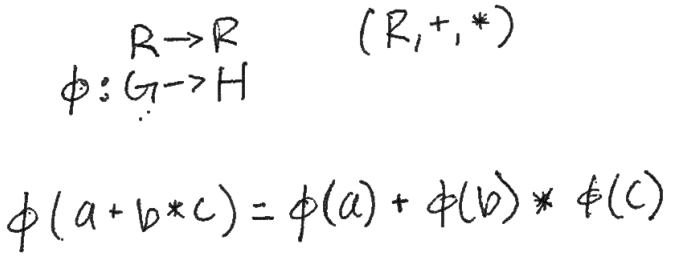

Figure 1. Ellen's initial written response when developing a "ring homomorphism".

Adherence to Conceptual Structure

The presence of pragmatic centrality at the outset of the generation of an analogical structure influenced the manner by which the structure was initiated. In this data, the presence of pragmatic centrality when initiating construction was often indicative of a strong adherence to both structural and semantic similarity, but with significantly different emphasis on *where* the attention was when developing the structure. For example, Ellen attended heavily to the group homomorphism definition when constructing her ring-theoretic analogue, and thus she relied heavily on written, symbolic similarity. In contrast, Andrew adopted a different approach at the beginning. He first established that there would be a ring R with operations + and *, and asserted that a second ring S should exist. However, he immediately began to question what the operations on S would look like:

> *Andrew*: But these (pointing to ring S) don't have to have the same operations, and I don't know what to use.
> *Interviewer*: Can you explain what you mean by that?
> *Andrew*: Well, when we have groups, we can something like this: $\phi(a \cdot b) = \phi(a) * \phi(b)$. If this homomorphism is from G to H, then the dot is the operation on G, and the star is the operation on H. So maybe I can use a dot here (*writing the multiplicative operation for S*), and I can just use a minus for… Yeah, I don't know what to use, unless you have a suggestion.

From this, we can see that Andrew's initial construction of the homomorphism property was guided in part by the constraint of pragmatic centrality; even before writing anything, he was already reflecting on the consequences of working with multiple operations in the context of ring theory.

Compared to Ellen's construction, it would appear that Andrew was perhaps less concerned with structural consistency given that Andrew's definition involved two homomorphism properties rather than one. In terms of establishing structural consistency between the two definitions, Ellen successfully mapped one homomorphism property for groups to one homomorphism property for rings. However, I claim that Andrew still maintained a high level of both structural consistency and semantic similarity, but at a different level than Ellen had previously done. This was present in the following interaction:

> *Interviewer*: Could you tell me what your overall thought process was in making this definition?

Andrew: Yeah, so I figured you need to preserve operations. That's basically how a homomorphism is defined, it's a function that preserves operations. So, if that's how it's defined I just have to preserve operations, but with two different operations now.

Thus, while Andrew's adherence to a written, symbolic structural consistency was not as strong as Ellen's, Andrew displayed an adherence to structural consistency and semantic similarity of a more conceptual structure. Andrew successfully encapsulated the concept of *preserving operations* into one object to be mapped between domains, thus achieving a greater degree of a one-to-one mapping despite having to break structural consistency at the basic level. I refer to this phenomenon as *adherence to conceptual structure.*

Flouting Constraints to Advance Exploration

Adherence to one of basic or conceptual structure was not necessarily the norm for all participants and wasn't even standard for any one particular student across all of their created structures. Indeed, a third phenomenon that occurred was that one of structural consistency or semantic similarity would be flouted in favor of the other, whether at the basic or conceptual level. This often occurred when a student began to question their creation in order to begin exploring alternatives. For example, Nathan initially began describing his concept for ring homomorphism by adhering strongly to symbolic semantic similarity. Unlike Andrew, Nathan's construction was tied to ensuring a similar basic appearance to that of group homomorphism with the added caveat that there were two operations defined on rings. As such, Nathan initially flouted structural consistency in order to accommodate the presence of two operations.

However, after developing a definition for a ring-theoretic analogue to homomorphism (see Figure 2), Nathan began to question his choice. He mused:

> Writing it like this makes sense, because that's how the group is written. But, if I wanted to write two functions, I feel like you would have to separate it, like you would be like, psi maps (R,+) to (S,+'), and then zeta or something maps (R,*) to (S,*')… Now there's two of them.

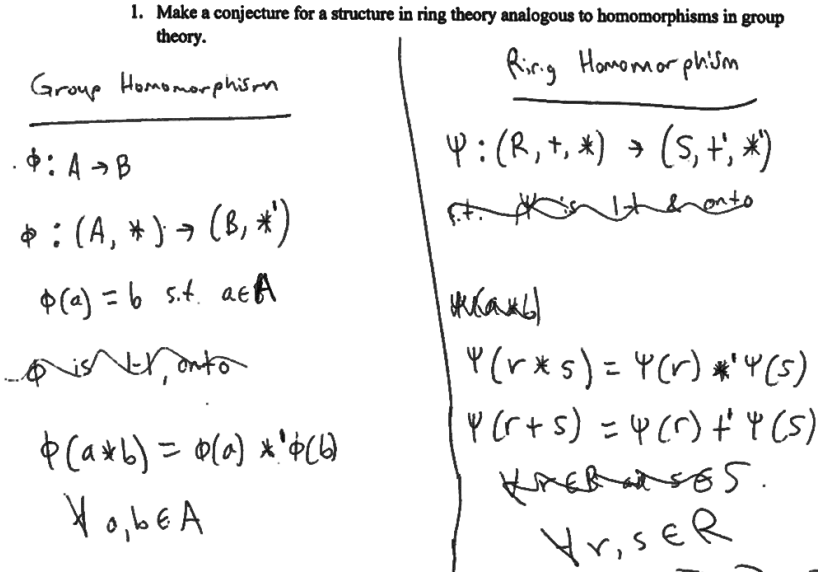

Figure 2. Nathan's written response when developing a "ring homomorphism".

Here, we see that Nathan is now wondering whether there should be two *functions* rather than two homomorphism properties defined on the same function. This investigation led Nathan to ponder whether he could describe both functions in terms of groups (see Figure 3.) In doing so, Nathan purposefully continued to flout structural consistency with the goal of accommodating the presence of two operations for rings.

Unlike Andrew, Nathan never appeared to recognize any one-to-one mapping between the underlying concepts of homomorphism properties for groups and rings during his investigation. Instead, Nathan focused primarily on adhering to a basic semantic similarity, albeit in two forms: (1) establishing similar homomorphism properties for groups and rings, and (2) establishing similar functions defined on the groups and rings where only one operation was mapped at a time.

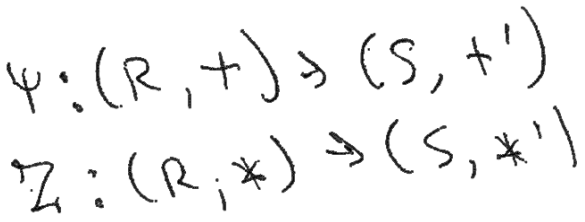

Figure 3. Nathan's proposal to define two functions rather than two homomorphism properties.

Discussion

The results of this analysis affirm a subset of previous findings related to parsing students' analogical reasoning. In particular, multi-constraint theory provided another method for observing that students can engage in a creative process of analogical reasoning in order to actively *invent* new (to them) concepts in abstract algebra (see Hicks, 2023). However, the use of multi-constraint theory to parse students' analogical reasoning revealed new perspectives on understanding *why* students may make certain decisions. Of particular significance is the observation that students may flout constraints in an effort to advance their construction or exploration of a new analogy, and that a stronger adherence to pragmatic centrality may develop over the course of an investigation. This supports the view of analogy as a problem-solving process to sometimes be purposefully implemented (e.g., Carbonell, 1983), rather than only a spontaneous process that occurs only by chance.

I end this paper by offering two suggestions stemming from this analysis that may be beneficial for successfully using analogy in mathematics classrooms. First, teachers may benefit from observing the distinction between adhering to basic and conceptual structures and understanding the value of each. Indeed, while it may appear that adhering to conceptual structure is always the ideal goal, adherence to basic structure also resulted in rich initial investigations and allowed the participants in this study a foothold for furthering their constructions. In contrast, many theories of analogical reasoning devalue those analogies that might adhere too strongly to basic structure (e.g., see Gentner's (1983) concept of *literal similarity*), and typical applications of multi-constraint theory investigated how the constraints supported individuals to avoid creating "bad" analogies.

Second, teachers should encourage their students to push on and question their analogical constructions, even when a correct analogy is given from the beginning. As was the case with Nathan's construction of ring homomorphism, the constraint of pragmatic centrality was not initially present. However, once he began to question his construction, he was able to explore alternatives and consider the deeper meaning of what a ring homomorphism is.

Nigar Altindis
The University of Alabama

Kayode Obafemi
The University of Alabama

This study examined the role of students' graphical, covariational, and proportional (GCP) reasoning skills in predicting performance in introductory STEM courses. Specifically, it investigates whether GCP proficiency predicts overall course performance. Data from 382 students revealed significant course-level differences, $F(2, 379) = 10.27$, $p < .001$. Students in Introductory Chemistry for Engineers scored highest (EMM = 59.0), significantly outperforming peers in Biology (EMM = 49.5) and Chemistry (EMM = 43.9). GCP scores were moderately correlated with course performance ($r = .56$). Mixed-effects modeling confirmed that GCP scores were a strong predictor of final performance ($\beta = 0.025$, $p < .001$), even when accounting for variation across majors. This study has implications for STEM instructors. Assessments should be designed to evaluate students' application of knowledge, problem-solving skills, and ability to formulate coherent arguments. This would give a more comprehensive picture of a student's academic potential that goes beyond memory recall.

Keywords: Graphical Interpretations, Covariational Reasoning, and Proportional Reasoning.

Introduction

Science, Technology, Engineering, and Mathematics (STEM) courses are crucial for addressing the complex problems that plague today's society. They equip students with the knowledge and skills necessary to perform multiple tasks, collect and evaluate evidence, and make informed judgments about information (English, 2016; Topsakal et al., 2022; Whitacre, 2024). Research indicates that STEM graduates make significant contributions to increased economic growth and employment (Bacovic et al., 2022), underscoring their importance. Despite the benefits, success in introductory STEM courses remains a significant challenge, with many students struggling and ultimately leaving STEM majors (Rasmussen et al., 2019; Smith & Funk, 2021). A growing body of research suggests that students' difficulties may be linked to foundational reasoning skills necessary for engaging with STEM content. In particular, graphical interpretation, covariational reasoning, and proportional reasoning are essential for making sense of quantitative relationships, modeling dynamic systems, and applying mathematical concepts in scientific contexts (Altindis et al., 2024; Bowe et al., 2025; Rodriguez & Jones, 2024; Carlson et al., 2002, 2022; Moore, 2025). This study examines whether these forms of reasoning predict success in STEM courses.

Literature Review

Graphical interpretation, covariational reasoning, and proportional reasoning are foundational quantitative practices that underpin success in STEM learning. These forms of reasoning allow students to move beyond rote memorization by supporting their ability to analyze data, model relationships, and draw meaningful conclusions from quantitative information (Altindis, 2025; Emeji et al., 2025). For instance, graphical interpretation enables students to extract and synthesize information from visual representations, a skill necessary in disciplines ranging from biology to engineering (Bowe et al., 2025; Rodriguez & Jones, 2024). Covariational reasoning enables students to track how quantities change in relation to one another (Carlson et al., 2002).

Proportional reasoning enables the recognition and application of multiplicative relationships, which is essential for problem-solving across STEM contexts (Modestou & Gagatsis, 2009). Together, these reasoning practices provide students with the cognitive tools needed to interpret evidence, evaluate claims, and engage in scientific inquiry (Altindis et al., 2024; Altindis & Fonnger, 2025; Carlson et al., 2002, 2022; Rodrigues & Jones, 2024; Moore, 2025).

Graphical interpretation can be defined as a cognitive process through which students actively extract information, recognize patterns, and construct meaning from visual representations (Altindis et al., 2024; Bowe et al., 2025; Curcio, 1987; Glazer, 2011). The process of graph interpretation occurs through three steps: (1) recognizing visual patterns; (3) translating visual patterns into quantitative relationships; and (3) associating the relationships with the referents (Carpenter & Shah, 1998; Shah et al., 1999). While linear graphs are often manageable, interpreting them becomes more challenging as the graphs become more complex. As students struggle with translating nonlinear patterns into quantitative relationships and with identifying how the rate of change varies across different points of a function domain (Altindis, 2025; Altindis & Fonger, 2025; Altindis et al., 2024; Bowe et al., 2025; Carlson et al., 2002; Jones, 2019; Moore & Thompson, 2015; Moore, 2025; Roth & Bowen, 2001).

Covariational reasoning requires a high level of reasoning, as it can enhance students' comprehension of essential mathematical ideas (Thompson & Carlson, 2017). Covariational reasoning is a cognitive process that involves coordinating the values of two changing quantities and considering how they change in respect to one another (Altindis, 2025; Altindis & Fonger, 2025; Altindis et al., 2024; Bowe et al., 2025; Büchter et al., 2024; Carlson et al., 2002). A study by Carlson et al. (2002) revealed that with CR, students were able to create images of a function's dependent variable changing simultaneously with the imagined change of the independent variable, and in certain cases, images of the rate of change for continuous intervals of a function's domain. However, the students' abilities are sometimes misinterpreted by teachers who possess low-level covariational reasoning. When Zeytun et al. (2010) conducted a study on the mathematics teachers' reasoning levels, they found that some teachers have weak covariational reasoning, which leads to poor predictions about a student's ability. The degree to which covariational reasoning is fundamental in educational systems varies among countries (Thompson et al., 2017). The curriculum and Instruction in the United States, as indicated by Thompson and Carlson (2017), are not developing the covariational reasoning abilities of the students, thus resulting in many weaknesses in core mathematical concepts. Proportional reasoning is the ability to understand and work with multiplicative relationships between quantities (Modestou & Gagatsis, 2009). It involves knowing when two situations are proportional and using multiplication to solve problems instead of simple addition. Martínez Ortiz (2015) found that integrating LEGO robotics with mathematics instruction supported students' proportional reasoning by embedding ratio and proportion tasks within engineering design challenges.

Despite their importance, graphical, covariational, and proportional reasoning have often been studied in isolation rather than jointly as an interconnected set of quantitative practices. There is limited understanding of how these reasoning skills interact to shape students' STEM performance and whether they can serve as predictors of success across courses. This study addresses that gap by examining the role of these reasoning constructs in undergraduate STEM achievement, thereby contributing to both theory and practice in STEM education.

Aim of the Study

This study examines undergraduate students' graphical, covariational, and proportional (GCP) reasoning skill,—as measured by the GCP scale—in the context of introductory STEM courses. Specifically, it examines whether students' GCP reasoning proficiency predicts overall course performance. The two research questions guide this work: (1) Do students' GCP scores differ significantly across Introductory Biology, Introductory Chemistry, and Introductory Chemistry for Engineers? (2) To what extent do students' GCP skills predict their final performance in STEM courses?

Method

This study was conducted at a research-intensive university in the northeastern United States. The university is primarily comprised of White students (82%) and has a greater proportion of female students (56%) than male students (44%). Participants (n=382) were recruited from two sections of an introductory biology course required for life science majors, two sections of an introductory chemistry course required for life science and chemistry majors, and one section of an introductory chemistry course required for engineering majors. Data collected included pre- and post-assessments. There was no intervention for these courses; this is an exploratory study.

The GCP assessment scale consisted of 17 multiple-choice items: six testing covariational reasoning skills (Carlson et al., 2015), five focusing solely on graphical reasoning, and six assessing students' proportional reasoning skills. Each item was scored as correct (1) or incorrect (0). A percentage score was calculated for each student to represent overall proficiency in GCP reasoning skills. These students participated in three courses: Introductory Biology, Introductory Chemistry, and Introductory Chemistry for Engineers - taught by five instructors. Sample sizes varied across instructor–course combinations: Introductory Chemistry for Engineers with instructor A (n = 39/132, 30%), Introductory Chemistry with instructor B (n = 168/483, 35%), Introductory Chemistry with instructor C (n = 75/183, 41%), Introductory Biology with instructor D (n = 32/183, 18%), and Introductory Biology with instructor E (n = 68/181, 38%). These differences highlight the uneven distribution of students across courses and instructors. To address these disparities and variations in grading standards, students' final course grades were normalized. Specifically, scores were ranked within each course, converted to percentiles based on their relative standing, and then standardized using a normal distribution (mean = 0, SD = 1). This process ensured fair and consistent comparisons across courses and instructors, allowing student performance to be evaluated on a common scale.

Validity and Reliability

The content validity of the assessment was established through expert review by STEM education researchers in mathematics, biology, chemistry, and physics, who are subject matter specialists who confirmed the relevance, clarity, and representativeness of the items. In addition, several items were adapted and revised from previously validated instruments, including the *Calculus Concept Readiness (CCR)* assessment (Carlson et al., 2015), which was itself developed through research and expert input and has documented evidence of reliability and validity. Construct validity was further examined through Rasch analysis, with all 17 items demonstrating acceptable fit within the threshold of 0.6–1.4, thereby supporting the internal structure of the assessment. Item difficulty values ranged from –1.866 (easiest) to 2.026 (most difficult), reflecting a broad spectrum of student ability levels. The strong negative correlation (r = –0.999) between item difficulty and the proportion of correct responses confirmed the expected

patterns. Reliability was evaluated using multiple indices of internal consistency, as shown in Table 1. All coefficients fell within the acceptable range of 0.70–0.80, indicating that the assessment demonstrates moderate and dependable reliability.

Table 1. Reliability Measures and Scores

Reliability Measures	Reliability Score
WLE (Weighted Likelihood Estimation) Reliability	0.736
EAP (Expected A Posteriori) Reliability	0.76
Cronbach Alpha	0.77

Results

Differences in GCP Scores Across Introductory STEM Courses

Table 2 below shows the differences in GCP scores across STEM courses. At the course level, students in Introductory Chemistry for Engineers achieved the highest GCP reasoning scores (Estimated Marginal means (EMM) = 59.0, SE = 3.23, 95% CI [52.6, 65.3]). Students in Introductory Biology scored moderately, with a combined mean of EMM = 49.5 across two instructors. In contrast, students in Introductory Chemistry had the lowest performance, with a combined mean of EMM = 43.9 across two instructors. These results indicate that students in Introductory Chemistry for Engineers outperformed their peers in both Introductory Biology and Introductory Chemistry on GCP measures.

Table 2. Estimated Marginal Means of GCP Scores by Course

Course	EMM	SE (range across instructors)	95% CI (range)
Introductory Chemistry for Engineers	59.0	3.23	[52.6, 65.3]
Introductory Biology	49.5	2.44–3.56	[42.9, 58.3]
Introductory Chemistry	43.9	1.56–2.31	[39.4, 47.8]

The analysis of variance (ANOVA) confirmed that the effect of course on GCP scores was statistically significant, $F(2, 379) = 10.27$, $p < .001$. ANOVA assumptions were assessed prior to analysis. Levene's test confirmed homogeneity of variance across groups, and the Q-Q plot indicated that residuals were approximately normally distributed, with only minor deviations at the tails. Thus, both assumptions of homogeneity and normality were satisfied. A Tukey post hoc test further confirmed that students in Introductory Chemistry for Engineers scored significantly higher than students in both Introductory Biology and Introductory Chemistry, whereas no significant difference was found between the latter two courses. GCP reasoning scores were moderately correlated with final course performance ($r = .56$), suggesting that stronger reasoning skills were consistently linked to higher achievement.

GCP Reasoning Skills as Predictors of Course Performance

We checked the normality assumption for the final course score and observed clustering in the data. Then, we examine a series of linear mixed-effects models. GCP pre-assessment scores were included as a fixed effect, while course, instructor, and major were initially treated as random effects. We examined the variability of random effects and conducted model comparison tests. As shown in Table 3, the standard deviations of the random effects for Instructor, Majors,

and Course were generally small, with Course exhibiting the smallest values, suggesting a limited contribution to the overall variability. Bootstrap confidence intervals supported this finding, as the standard deviation for Course was nearly zero while Majors displayed slightly more variability. Given these patterns, we further compared models using both the Likelihood Ratio Test (LRT) and the Permutation-Based Test (PBtest). Results indicated that including Majors as a random effect significantly improved model fit (LRT = 4.893, p = 0.027; PBtest = 4.893, p = 0.019). Therefore, the final model retained Majors as a random effect, while Course and Instructor were omitted to achieve a better-fitting model.

Table 3. Random Effects and Model Selection Results

Effect	Std. Dev. (95% CI) – Normal Approximation	Std. Dev. (95% CI) – Bootstrap	Decision
Instructor	0.059 – 0.305	0.069 – 0.359	Omit
Majors	0.000 – 0.223	(–0.044) – 0.108 (p=.027 *)	Retain
Course	0.000 – 0.191	0.000 – 0.000	Omit
Residual	0.681 – 0.790	0.684 – 0.793	–
Intercept	–0.975 – –0.563	(–1.027) – (–0.579)	–
GCP Score	0.021 – 0.029	0.022 – 0.029	Fixed effect retained

**Note: LRT = Likelihood Ratio Test; PBtest gave similar results (stat = 4.893, p = 0.019)*

We examine the extent to which students' GCP skills predicted final performance in STEM courses, while also accounting for variation across majors. As shown in Table 4, the GCP score was a strong and statistically significant predictor of students' normalized final scores. This indicates that for each one-unit increase in GCP scores, students' normalized final scores increased by approximately 0.025 units, holding other factors constant. Thus, GCP skills demonstrated a consistent relationship with STEM course performance.

Table 4. Final Mixed-Effects Model Estimates Predicting Normalized Final Scores

Parameter	Estimate	Std. Error	95% CI (Lower, Upper)	Variance	Std. Dev.	df	t	p
Fixed Effects								
Intercept	–0.769	0.105	[–0.98, –0.57]	–	–	161.91	–7.29	< .001
GCP Score	0.0248	0.0019	[0.021, 0.029]	–	–	367.09	12.94	< .001
Random Effects								
Majors (Intercept)	–	–	[0.07, 0.37]	0.03	0.18	–	–	–
Residual	–	–	[0.68, 0.79]	0.54	0.73	–	–	–

Discussion

This study revealed notable differences in GCP reasoning among introductory STEM courses. Students who enrolled in Introductory Chemistry for Engineers scored significantly higher than students in both Introductory Biology and Introductory Chemistry. These findings suggest that engineering-oriented chemistry courses may place greater emphasis on reasoning practices or attract students with stronger quantitative preparation. Lower performance in

Introductory Chemistry and Biology courses may point to missed opportunities to engage students with reasoning practices as central tools for inquiry. Prior research has indicated that students often struggle with graph interpretation and rate-of-change reasoning when these skills are not explicitly scaffolded (Moore & Thompson, 2015; Roth & Bowen, 2001). Thus, the results highlight the importance of intentional instructional design that develops quantitative reasoning across STEM disciplines, not only in engineering contexts.

We found that GCP skills were a strong predictor of final course performance across all introductory STEM contexts. The final mixed-effects model indicated that for each unit increase in GCP scores, students' normalized final scores increased by approximately 0.025 units, even after accounting for variation across majors. This finding highlights the crucial role of reasoning skills in fostering academic success in STEM. It aligns with earlier work demonstrating that covariational reasoning is critical for understanding functions, modeling phenomena, and solving quantitative problems (Altindis & Fonger, 2025; Altindis, 2025; Altindis et al., 2024; Bowe et al., 2025; Carlson et al., 2002). The moderate correlation between GCP and course performance ($r = .56$) further reinforces this relationship, suggesting that reasoning proficiency can serve as an early diagnostic indicator of students' potential achievement.

The model also revealed that major-level differences contributed modest variability, while course- and instructor-level effects were negligible. This suggests that students' disciplinary orientation and preparation may matter more for performance than differences in course delivery. However, further research is needed to understand why these differences emerge, how majors influence students' reasoning development, and whether specific curricular pathways or instructional approaches account for the observed variability.

Implications

The results carry several implications for STEM education. First, they emphasize the need for instructional strategies that explicitly develop graphical, covariational, and proportional reasoning across disciplines. Biology and chemistry courses, in particular, may benefit from integrating reasoning tasks into laboratory and lecture settings to promote deeper conceptual engagement. Second, the strong predictive role of GCP skills suggests that reasoning-based assessments could serve as early indicators of student achievement, providing opportunities for targeted support. Finally, embedding reasoning tasks in authentic, applied contexts that are similar to those found in engineering courses may help foster quantitative practices across STEM.

Limitations and Future Directions

While this study provides evidence for the importance of GCP reasoning, several limitations should be noted. First, the data were drawn from a single institutional context, which may limit generalizability. Second, although the study controlled for majors, other factors, such as prior mathematical preparation and demographic variables, were not included. Future research should explore these additional influences, as well as examine how instructional practices within biology and chemistry could be redesigned to support reasoning more effectively. Ultimately, longitudinal research is necessary to investigate how GCP skills evolve and whether targeted interventions can bridge performance gaps across courses.

Mathematical Mnemonics as Tools for Shaping Concept Images in University Mathematics Tutoring

Keith Gallagher
University of Nebraska at Omaha

Deborah Moore-Russo
University of Oklahoma

Nicole Infante
University of Nebraska at Omaha

In mathematics, the teaching and use of "tricks," known formally as mathematical mnemonics, is commonplace. However, little research has focused on this topic, particularly in university mathematics tutoring. In this study, we investigated when and why undergraduate mathematics tutors implemented mathematical mnemonics in their tutoring practice. Video recordings of online tutoring sessions were collected from eight tutors working at an R1 university in the United States. Of the eight, five were observed using mathematical mnemonics in their tutoring practice. Our results show that these tutors used mathematical mnemonics for three reasons: in response to a student committing an error or demonstrating a misconception, as a response that represents how the tutor reasons about the topic, and as part of a predeveloped curriculum script. We argue that each of these reasons is an implicit attempt by the tutor to reshape a student's concept image of the topic under consideration.

Keywords: Tutoring, mathematical mnemonic, concept image

The teaching and use of "tricks" in mathematics education is commonplace. These tricks are formally known as *mathematical mnemonics*. Miller and Obara (2017) defined a *mathematical mnemonic* (referred to herein simply as a *mnemonic*) as "a visual cue or verbal strategy used to aid initial memorisation and recall of a mathematical concept or procedure" (p. 13). While some mnemonics help with recalling definitions and concepts, others help with the application and interpretation of procedures.

The National Council of Teachers of Mathematics documented that, in many mathematics classrooms, "... too much focus is on learning procedures without any connection to meaning, understanding, or the applications that require these procedures" (National Council of Teachers of Mathematics, 2014, p. 3). Indeed, although many mnemonics can help students correctly answer assessment questions, they can obscure the conceptual underpinnings that make them work, reinforcing the common perspective that mathematics is simply a set of rules to be memorized rather than a set of concepts to be understood (Kalder, 2012; Miller & Obara, 2017). While the use of mnemonics can improve student understanding (Greene, 1999; Mastropieri, Scruggs, & Levin, 1987), over-emphasis on such tools can lead to decreased conceptual fluency (Karp, Bush, & Dougherty, 2014; Kilpatrick, Swafford, & Findell, 2001).

Despite this potential pitfall, mnemonics have been shown to produce positive outcomes for conceptual, as well as procedural, learning when they are accompanied or followed by conceptual instruction (NCTM, 2014). Although mnemonics often allow students to succeed in math classes despite lacking the conceptual understanding that makes them work, they can also act as scaffolds for students until they are developmentally prepared to adopt the conceptual understanding (Karp, Buch, & Dougherty, 2014; Manalo, Bunnell, & Stillman, 2000; Miller & Obara, 2017).

In this exploratory study, we observed online university mathematics tutors sharing a variety of mnemonics with the students they were tutoring. The research team's curiosity about the pedagogical value of these mnemonics led to posing the following research question: What are

university mathematics tutors' implicit goals when sharing mnemonics with students during tutoring sessions?

The Importance of Tutoring and the Influence of Tutors

Tutoring brings with it myriad benefits, including improved course grades (Bloom, 1984; Rickard & Mills, 2018), increased mathematical confidence (Lepper & Chabay, 1988), and improved sense of mathematical identity (Bjorkman & Nickerson, 2019), among others. Indeed, Merrill et al. (1995) observed that, while doing problems is the best way to learn, it is essential that this effort is guided such that learners receive positive feedback when they are moving in a productive direction and corrective feedback when making mistakes.

Citing Vygotsky (1978), Mascolo (2009) argued for the importance of the learner's interaction with a more knowledgeable other and that such interactions "pull the less expert partner's functioning to levels that are higher than that which he is capable of sustaining alone" (Mascolo, 2009, p. 5). Although experienced tutors take very deliberate actions during tutoring sessions to provide individualized instruction for their students (Gallagher et al., 2025; Lepper & Woolverton, 2002), tutors also sometimes proceed through a largely preordained set of interactions known as a *curriculum script* (Putnam, 1987). "A curriculum script is an ordered set of goals and actions for teaching a particular topic – the skills and concepts students are expected to learn and activities and strategies for teaching this material. ... [I]t is the teacher's curriculum script, rather than a model of the student based on detailed diagnosis, that determines the sequence of instruction" (Putnam, 1987, p. 39). Tutors, as well as teachers, can use curriculum scripts where they speak and act in a particular sequence that can fail to take the learner's needs into account.

Concept Image

Tall and Vinner (1981) define an individual's *concept image* for a concept as "the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and processes" (p. 152). Although one's concept image for a concept can be rather expansive, only certain parts of an individual's concept image may be evoked when solving problems. Problematically, however, an individual's concept image need not be accurate or even internally consistent, and the portion of one's concept image that is evoked while solving a particular problem may not be helpful for obtaining a solution. These challenges may lead to struggle or even failure during problem solving.

Individualized tutoring often reveals problematic inaccuracies in students' concept images. Fortunately, concept images are malleable and can be updated with further learning (Tall & Vinner, 1981; Vinner, 1983). Our data suggest that the university tutors in our sample used mnemonics to reshape their students' concept images to bring them more in line with their own, which were seemingly more productive.

Theoretical Framing

For this work, we adopted Merrill et al.'s (1995) conceptualization of *tutoring as guided learning by doing*. A significant body of research demonstrates the benefits of active learning (Abell et al., 2018; Bressoud et al., 2015; Deslauriers et al., 2019; Freeman et al., 2014; Prince, 2004; Theobald et al., 2020), in which students engage in idea generation, problem solving, and practice. While this work appropriately places the onus of knowledge creation on students, much of it neglects the importance of having a more knowledgeable other (Vygotsky, 1978) present during this process. Merrill et al. (1995) noted that, although students' active participation in

problem solving is the key to learning, leaving students to practice without the appropriate supervision and support can lead to floundering, confusion, and frustration, which hinders learning. Mascolo (2009) echoed this point, emphasizing the importance of the teacher's role in an active learning environment: "... the idea that students must actively construct their skills and understandings *for themselves* is not the same as suggesting that [they] must actively construct their skills and understandings *by themselves*" (p. 7). While Mascolo's work focused on classroom instruction, Merrill and colleagues' work is focused on tutoring. Still, both agree that the more knowledgeable other guiding the lesson is a critical component of effective instruction.

Tutoring as guided learning by doing (Merrill et al., 1995) emphasizes the importance of the individualized instruction involved in tutoring. Similar to Mascolo's (2009) views on the importance of the teacher, it has been argued that effective tutoring involves the tutor taking an active role in their student's learning. Merrill and colleagues (1995, p. 316) argued that "rather than letting students solve problems on their own, with occasional advice, tutors carefully monitor the problem solving to ensure that it stays on track and to help direct students back toward a productive solution path when needed." Merrill and colleagues referred to this as "guided learning" and pointed out that this practice allows "students to attain the benefits of learning by doing while avoiding some of the costs" (p. 316).

Methods

The current analysis is part of a larger ongoing project studying different aspects of online mathematics tutoring at the university level. The data set consisted of online tutoring sessions focused on topics ranging from College Algebra through Multivariable Calculus that were recorded at an R1 university tutoring center from January 2022 through May 2024. There were eight online tutors who worked 5-10 hours per week. As the research team members were cataloging the mathematical content of these sessions, they made notes of other interactions they found interesting. The data analysis reported here occurred over five months between the research team of co-authors on this paper.

While initially going through the videotaped tutoring interactions, the research team observed several instances where five of the eight tutors shared "tips and tricks" for being successful on a variety of problem types during their tutoring sessions. These tips and tricks met Miller and Obara's (2017) definition of *mnemonics* provided earlier. The research team decided to focus on these instances of mnemonic use for this study.

One researcher reviewed all videos during the timeframe noted above and identified when mnemonics were being used by the tutor. A second researcher then reviewed the videos that the first researcher categorized; there was 100% agreement on the identification of the mnemonics. The whole research team discussed each mnemonic, decided on categorizations, and came to agreement on the attributes of each category. The third researcher then classified each video into the mutually agreed upon three classifications discussed below in results; note that the categories as not mutually exclusive. Thus, a video could have been identified as falling into more than one classification. Finally, the research team reviewed each classification assigned and discussed until consensus was reached.

Results

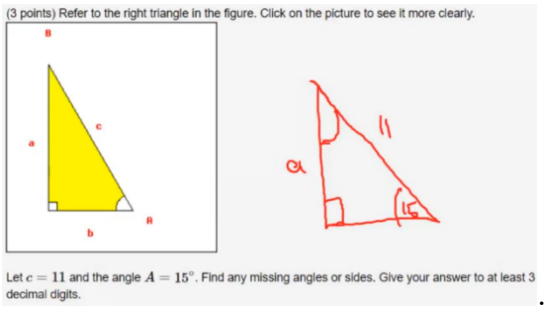
We identified reasons why tutors use mnemonics when tutoring. First, almost all mnemonics were used in response to a student error or misconception. Second, a tutor introduced a mnemonic because it seemed to be how they thought about the topic under consideration. Third,

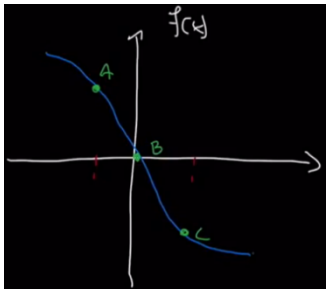
tutors used mnemonics "automatically," even after students had self-corrected and figured out a correct path forward. We now present examples of each of these situations.

Mnemonics as Response to Student Errors and Misconceptions

Mnemonics were almost always used after the tutor saw an error or a misconception. Working with a trigonometry student to find the length of side *a* of a triangle in which the opposite angle and the hypotenuse were known (Figure 1a), Aaron used the mnemonic *SOH-CAH-TOA*. Aaron drew and labeled a picture with the known information and asked the student which trigonometric function should be used to find *a*. When the student suggested cosine, Aaron responded, "I would probably use sine, because remember *SOH-CAH-TOA.* So, sine of 15 degrees would be equal to the opposite side, *a*, divided by the hypotenuse, which is 11."

Another tutor, Bernardo, used a mnemonic for thinking about increasing and decreasing to help a student sketch the graph of a derivative from the graph of a function that was decreasing over an interval from point *A* to point *C* but its concavity changed from concave down to concave up at an inflection point *B* (Figure 1b). The student explained that, starting from the left, the graph of the derivative should be negative and would decrease until point *B* was reached, conflating the notions of *increasing function* and *increasing derivative*, explaining that since the derivative is increasing from point *B* through point *C* and beyond, the graph of the derivative should be drawn in the first quadrant over this interval. The tutor used an analogy of walking on a hill, explaining that in this case, even after passing through point *B*, he would still be "walking downhill" even though "the hill was becoming less steep."





Figures 1a and 1b. Situations prompting mnemonics

Mnemonics as Tutors' Genuine Reasoning

Tutors brought up mnemonics because that is how they, themselves, think about certain problems. More than once, Selena described a mnemonic for determining concavity by drawing eyes on the graph to make happy and sad faces (Figure 2). Selena worked with two students to distinguish between intervals on which a function is increasing and intervals on which the function is concave up. Selena explained, "I'm not gonna lie, I do this really dorky thing whenever I do this – I kinda draw sad and happy faces. And if they're sad, they're concave down. If they're happy, they're concave up." Selena's students found this technique comical, but they immediately began correctly answering questions about concavity by implementing it.

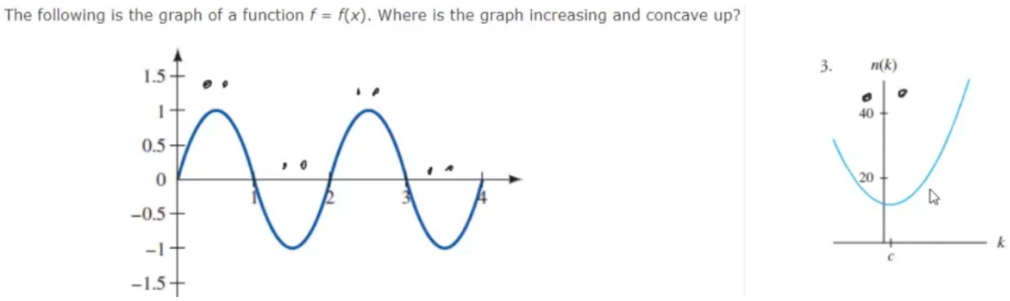


Figure 2. Selena's drawings of eyes to determine concavity of graphs.

Marian seemed to use the mnemonic *rise-over-run* as a command to apply the slope formula. On an algebra review assignment for a calculus class, the student Marian was tutoring had been asked to write equations for two lines (one passing through the origin, and the other with a nonzero *y*-intercept). The student was confused because he had applied the method of dividing a single point's *y*-coordinate by its *x*-coordinate, resulting in the correct slope for the line passing through the origin but the incorrect slope for the other. Marian explained that "You can just find the rise-over-run of that... you just take those two points, and you find their rise-over-run." As she said this, Marian wrote down the algebraic slope formula, that is $(y_2-y_1)/(x_2-x_1)$, and then applied it to the line for which the student had found the correct slope, then used this as a model to repeat the process for the other line. She continued to describe this process as "finding the rise-over-run" throughout the entire tutoring session.

Mnemonics as Curriculum Scripts

Tutors introduced mnemonics even after students detected their own errors and self-corrected, suggesting the mnemonics are part of curriculum scripts the tutors have developed for certain concepts. When asked about a question in which the student needed to determine the sine of an angle whose terminal side lay in the third quadrant, Marian drew and labeled a picture to represent the angle's terminal side and the right triangle it forms with the *x*-axis (Figure 3).

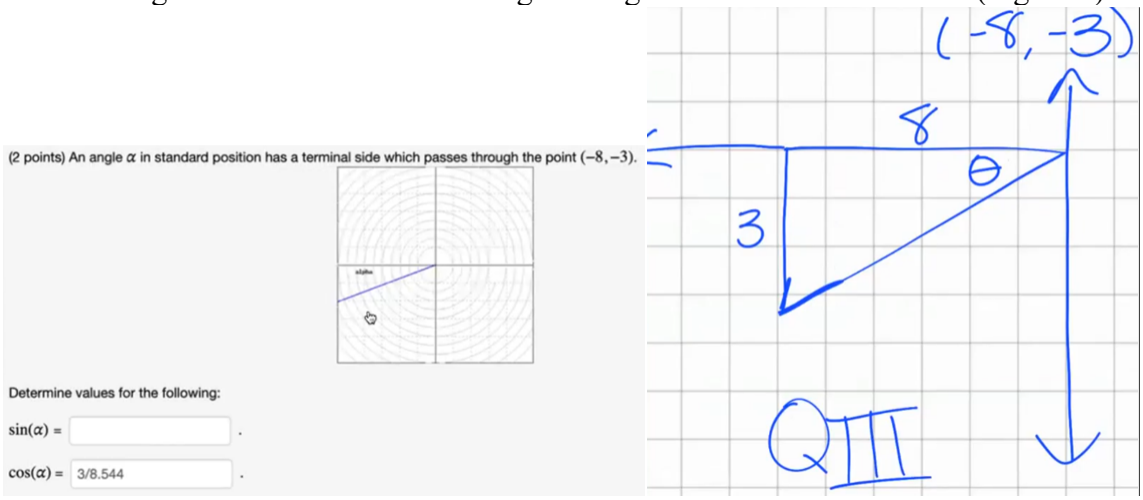

Figure 3. Marian's drawing of an angle with its terminal side in QIII.

As Marian was drawing, her student acknowledged aloud that his mistake was a sign error; he had neglected the fact that the vertical side length should be negative because the terminal side lay in the third quadrant. Marian continued to explain the problem even though the student's

question had been resolved and described the mnemonic *All Students Take Calculus* that she used to identify which trigonometric functions are positive in each quadrant (**A**ll are positive in I, **S**ine is positive in II, **T**angent is positive in III, and **C**osine is positive in IV; see Figure 4).

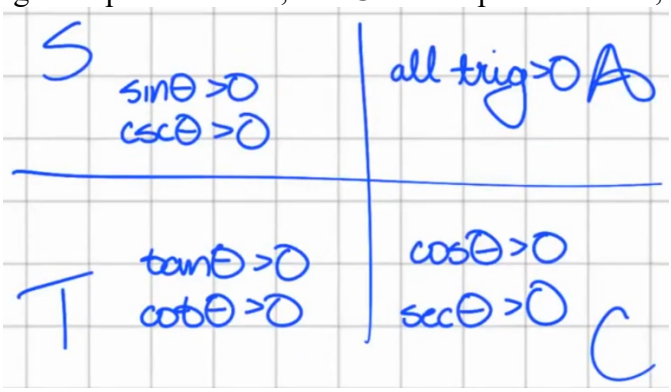

Figure 4. Marian's diagram explaining the All Students Take Calculus mnemonic.

In a session with Carey, a student mistakenly suggested that $a^2 - 4$ should be factored into $(a - 2)(a - 2)$ but quickly corrected himself to $(a - 2)(a + 2)$ after realizing that his initial factoring would yield a positive 4 in the constant term. Although the student had self-corrected, Carey was intent on ensuring the student understood factoring by explaining the "x-method" (Figure 5).

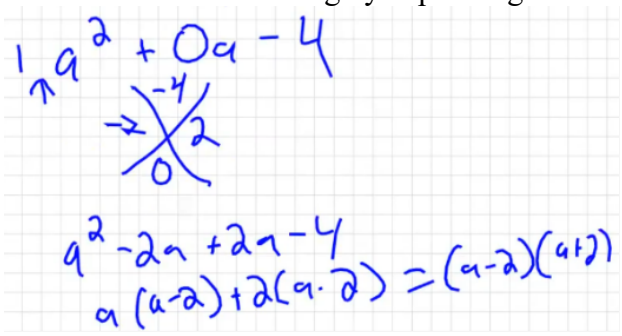

Figure 5. Carey's explanation of the "x-method" used to factor a difference of squares.

Discussion

We found that tutors in our sample used mnemonics for three reasons: in response to the detection of a student error or misconception, because it represented how they think about a concept or problem, and as part of predeveloped curriculum scripts they use for tutoring certain topics. Underlying all of these reasons is an attempt to reshape their student's concept image of the topic under consideration to bring it more in line with their own.

Merrill and colleagues (1995) argued that one of the major benefits of working with a tutor is the tutor's ability to curtail students' unproductive activities. When the students in our data demonstrated a misunderstanding, tutors' uses of mnemonics "direct[ed] students back toward a productive solution path" by providing students with a useful way of conceptualizing the topic, gently suggesting that the student should reconsider their current approach and update their way of thinking to be more in line with how the tutor thinks. Furthermore, as more knowledgeable others (Vygotsky, 1978), tutors modeled modes of thinking that they knew to be reliable and encouraged their students to adopt them, even when students identified and corrected their own mistakes.

Considering the use of a mnemonic as part of a curriculum script, we echo Mascolo's (2009) suggestion that, although students must build their own knowledge, they need not do so on their

own. Curriculum scripts provide a structured framework in which students work on specific kinds of activities designed to help them construct specific knowledge. Although it may not have been necessary for our tutors to describe mnemonics in these situations, as their students had already detected their own errors and self-corrected, they chose to share them to reduce the likelihood of such student mistakes recurring in the future by updating or reinforcing concept images already held by their students.

Implications and Directions for Future Research

This research expands the current body of research related to the use of mathematical mnemonics, specifically by addressing tutors' motivations for teaching mnemonics to the students they assist. Although the students in the sessions we observed seemed to appreciate and derive benefit from the mnemonics tutors showed them, it is essential that the research community ascertains exactly what benefits and drawbacks students might experience from learning and applying such mnemonics. It has been noted that the use of mathematical mnemonics (and, indeed, much of modern mathematics teaching) places a heavy focus on getting the right answers to problems, often at the expense of conceptual understanding (Kalder, 2012; Miller & Obara, 2017; NCTM, 2014). However, it has been suggested that mathematical mnemonics can lead to improved conceptual understanding, either by using them as a scaffold building toward conceptual understanding or by teaching mnemonics and concepts side-by-side (Karp, Buch, & Dougherty, 2014; Manalo, Bunnell, & Stillman, 2000; Miller & Obara, 2017; NCTM, 2014). In our review of the data presented here, we hypothesized that the use of certain mnemonics, such as "rise-over-run" or the use of happy and sad faces to determine concavity, might foster conceptual understanding, while other mnemonics, such as "ILATE" (an abbreviation of *inverse trigonometric*, *logarithmic*, *algebraic*, *trigonometric*, and *exponential* used by Marian but not discussed in this paper) for integration by parts, might obscure or at least not develop concepts. Future studies of mathematical mnemonics need to explore the effects of individual mnemonics on conceptual and procedural fluency among mathematics students at various levels of their mathematical education.

Analyzing a Student's Observations and Conjectures About Markov Chains: Identifying Scheme Elements and Their Instrumentation of Digital Figures

Ryan Peffer
Washington State University

Judi McDonald
Washington State University

Sepideh Stewart
University of Oklahoma

This study investigates how a first-year undergraduate mathematics student engaged with a set of digital interactive figures to explore properties of stochastic matrices and Markov chains. Using the frameworks of instrumental genesis and Vergnaud's theory of conceptual fields, we analyzed the student's interaction in terms of their observations and conjectures, two key stages in our Observation, Conjecture, Proof, Theorem (OCPT) pedagogical model. Through task-based interview data, we identified elements of the student's emerging conjecturing scheme, including rules-of-action and theorems-in-action that illustrate their process of sensemaking and experimentation. We argue that this scheme development evidences the student's instrumentation of the figures into a functional instrument for mathematical reasoning.

Keywords: Linear algebra, CAS, eigentheory, conjecture, scheme, instrumental genesis

Linear algebra is a foundational discipline within mathematics, underpinning a wide range of theoretical and applied fields. Its concepts and techniques are essential in areas such as data science, computer graphics, quantum mechanics, machine learning, and systems modeling. Both iterations of the Linear Algebra Curriculum Study Group (Carlson et al., 1993; Stewart et al., 2022), convened by prominent linear algebra educators and education researchers, have proposed agendas and goals for the effective and beneficial teaching of linear algebra. Those recommendations include, among others, a need for the study of linear algebra to be integrated with and responsive to digital technology, as well as to be attentive to the formal theoretical training that has traditionally been reserved for advanced courses in linear algebra.

In keeping with these recommendations, we are interested in developing and advancing a pedagogical model of how students, even at the introductory linear algebra level, can engage in meaningful and authentic formal mathematical practices. We have called this model the Observation Conjecture Proof Theorem (OCPT) model, in contrast to the traditional textbook Definition-Lemma-Proof-Theorem-Proof-Corollary (DLPTPC) mode of content delivery, criticized by Uhlig (2002). OCPT seeks to place the mechanisms of discovery, investigation, and reasoning before the presentation of polished textbook theorems. Lin et al. (2012) define the task of mathematics and the sciences as "first to observe phenomena, then to explain them, and finally to predict." Implicit in this definition is the formalizing process by which the observation of a phenomenon or relationship is formalized, conjectured, into a mathematically coherent, provably true or false statement. This process of conjecturing, and its interplay with observation, is nuanced; example generation and experience are powerful and necessary skill to prompt insightful conjectures, even as examples cannot be accepted as sole proof (Lesseig, 2016; Lynch, Lockwood, & Ellis, 2024), except in the case of counterexamples. The sub elements of the conjecturing activity and the role of observation therein have been described as motivating an initial conjecture, boundary testing on the conditions and assumptions, and encountering structures that may lead to a justification (Lannin et al., 2006).

We are currently primarily interested in facilitating and creating digital environments for students to engage in processes of observation and conjecture, which we call interactive figures.

Our previous collection of interactive figures focused on fundamental concepts of linear combinations, determinants, and eigentheory (Peffer, McDonald, & Stewart, 2025). Markov chains are a critically powerful field in linear algebra and have been recognized as a salient and meaningful application by which to explore concepts in linear algebra and specifically eigentheory (e.g., Harsy & Smith, 2024). However, there is little other instructional or theoretical treatment of the teaching of Markov chains in the literature. In this paper, we will discuss a task-based interview conducted using a new pair of interactive figures targeting the properties of stochastic matrices and Markov chains. We will pay attention to the actions and processes of observation and conjecturing enacted by the student, and the underlying mental schemes involved that enable the student to make use of the interactive figures to explore those properties of Markov chains.

Theoretical Perspectives

With an interest in understanding how the interactive figures facilitate students engaging in the mathematical activities of observation and conjecturing, we first turned to the framework of instrumental genesis to describe this interaction. The theory of instrumental genesis has been adopted in mathematics education literature to describe how students use tools and technology as adaptable problem-solving instruments (Artigue, 2002; Guin et al., 2005). A common, prototype application of instrumental genesis is the analysis of students adapting their algebraic and graphical abilities with a graphing calculator (Trouche, 2020), wherein the calculator (or any other tool) known as the artifact acts to reciprocally influence and be influenced by the learner.

Of particular interest to this study is the process of instrumentation, whereby engagement with the artifact in a goal-oriented, problem-solving scenario influences a student to adapt their cognitive, analytical processes to acknowledge and employ the artifact's utility, thus generating the psychological entity of an instrument. In diagnosing and analyzing the process of instrumentation, whose product is a cognitive reorganization of a student's mental models, it is standard to employ schemas to capture this structural adaptation (Turgut & Drijvers, 2021; Gueudet et al., 2022). By identifying behavioral and analytical features of a schema and distinguishing the ways in which a student has adapted or developed a schema to include and employ an artifact, researchers can investigate and qualify the adaptation of the instrument.

Relatedly, Vergnaud (2009) establishes a theory of conceptual fields, described as a class of situations and problems, together with the schemes and individual constructs and employs to address these situations, and the modes of representation that the individual operates and communicates by. While we might envision the model of OCPT as a networking of conceptual fields that coalesce to constitute a mathematician's formal activity, in this paper we will focus specifically upon Vergnaud's compartmentalization of scheme, which dissects schema into four levels of activity, which are described as (p. 88):

- The intentional aspect of schemes involves a goal or several goals that can be developed in subgoals and anticipations.
- The generative aspect of schemes involves rules to generate activity, namely the sequences of actions, information gathering, and controls.
- The epistemic aspect of schemes involves operational invariants, namely concepts-in-action and theorems-in-action. Their main function is to pick up and select the relevant information and infer from it goals and rules.
- The computational aspect involves possibilities of inference. They are essential to understand that thinking is made up of an intense activity of computation, even in

> apparently simple situations; even more in new situations. We need to generate goals, subgoals and rules, also properties and relationships that are not observable.

We wish to employ these components of scheme then to analyze student interactions and their products to describe the forming and adapting schemas at play. As mentioned, the mathematical activity that we are most interested in with these figures is that of observation and making conjectures, and thus we seek to identify the generative rules-of-action that students develop or display in interacting with the figures, and subsequently to interpret the cognitive concepts- and theorems-in-action as they are guiding the student's rules-of-action. In doing so, this scheme documentation should serve to identify the emergent instrumentation of the interactive figures by the student to participate in the described process of observation and conjecture.

As such, our research questions for this study are: How did the student in this study engage with the interactive figures to make sense of conceptual questions regarding Markov chains? What scheme aspects, in the context of observation and conjecture, were displayed?

Method

To collect evidence of scheme relating to observation and conjecture, we designed a qualitative case study consisting of four task-based interviews that were conducted at a public land-grant research university in the USA. Volunteer participants were recruited immediately following their final examination in a first course in linear algebra. These students were all concluding their first year of study, with aspiring majors in mathematics and engineering.

These interviews will constitute data in the first author's PhD thesis, and in this paper, we will discuss one such interview with Alice (pseudonym). At the time of the interview, Alice had just completed her spring semester of her first year of university, intending to study mathematics and having received an A in her first course in linear algebra. The course covered systems of equations, span and linear independence, linear transformations, matrix algebra and invertibility, subspaces of $\mathbb{R}$, determinants, eigentheory, and orthogonality. We chose to present Alice's interview analysis because Alice was entirely unfamiliar with our interactive figures, she had no experience with Markov chains in her linear algebra coursework or other classes, nor had she taken any advanced proof-based mathematics courses.

The materials for the interview included the two digital interactive figures built in Mathematica concerning properties of stochastic matrices and Markov chain iteration. The figures were accompanied by a six-question assignment task mimicking a potential homework. Two questions, Questions 3 and 6, were of particular interest to this study as they asked students to make observations of the properties of stochastic matrices and sequences of Markov chain iterates via the provided interactive figures, though in this paper we will focus exclusively on question 3:

> Question 3: The matrix you have created is called a stochastic matrix: that is, it is a matrix where each column is a probability vector whose entries must be non-negative and sum to 1.0 (probability 100%). Using the first interactive figure, what patterns do you notice about the eigenvalues and eigenvectors of stochastic matrices compared to non-stochastic matrices?

The remaining four questions included conceptual and computational questions involving constructing and analyzing a Markov chain in context of a 2-population dynamic application and

were intended to motivate or build from the student's observations. The assignment also provided relevant working definitions such as for probability vectors, stochastic matrices, and Markov chains. Furthermore, the students were provided with a copy of the course textbook and a calculator for their convenience. The student was prompted throughout the interview to proceed as if they were completing this assignment as regular homework and were thus permitted to use any other standard resource they would consult in their own time, including internet sources.

The data collected for this interview included transcribed audio and video recording of the subject, including screen recording of their work with the interactive figures. As well, the written responses of the student on the assignment document or scratch paper were preserved. At the end of the interview, the students were given a brief exit survey asking what else they might have done in the pursuit of this assignment were it a real assignment, how strongly they believed in the validity of their observations made, and for feedback and user sentiment on the interactive figures. A brief analysis of Alice's observation confidence will be included in the Results section.

In order to target a schematic notion of conjecturing, Alice's interview data was individually analyzed via thematic analysis and open coding (Strauss & Corbin, 1998), by identifying novel propositions or formulas that arose as answers to the above question 3, interpreting their testimony and recorded actions for the generative rules-of-action being followed, and subsequently for the implied cognitive concepts-in-action and theorems-in-action informing these decisions, as prescribed by Vergnaud's theory of conceptual fields. Furthermore, these scheme elements were corroboratively identified as being technology-integrated, in actively involving or relating to the use of interactive figures as a digital artifact. In this way, we may show evidence for the student's incipient instrumentation of the interactive figures involving their schemes of observation and conjecture.

Results and Discussion

Alice's Conjectures of Properties of Stochastic Matrices

We begin by looking at Alice's observations regarding the properties of stochastic matrices via Interactive Figure 1. An example of Interactive Figure 1 as it appeared in the interview (Figure 1), as well as Alice's response to question 3 regarding her observation of properties of stochastic matrices and their powers (Figure 2) are shown below. In the interactive figure, a procedurally generated (stochastic or not) matrix A is provided, as well as its power A^k. For both matrices, the figure displays whether the matrix is stochastic, its eigenvalues, and its eigenvectors. The controls of the figure allow the user to vary the size of A, the exponent k, and to select generating a new stochastic or non-stochastic matrix A.

Alice's response to question 3 contains several conjectures. First, Alice has stated that all stochastic matrices have an eigenvalue equal to 1, though makes no qualification on the other eigenvalues. Next, she has conjectured that the eigenvector associated with eigenvalue 1 has entries that sum to 1, and further remarks that this aligns with a probabilistic interpretation, given that question 3 also defines a probability vector as having non-negative entries that sum to 1. It is worth noting that the figure was specifically configured to display an entry sum of 1, since Mathematica otherwise defaults to normalize eigenvectors with respect to the Euclidean norm. However, Alice does not comment on the potential of scalar multiples of an eigenvector to allow different vector sums for otherwise equivalent eigenvectors.

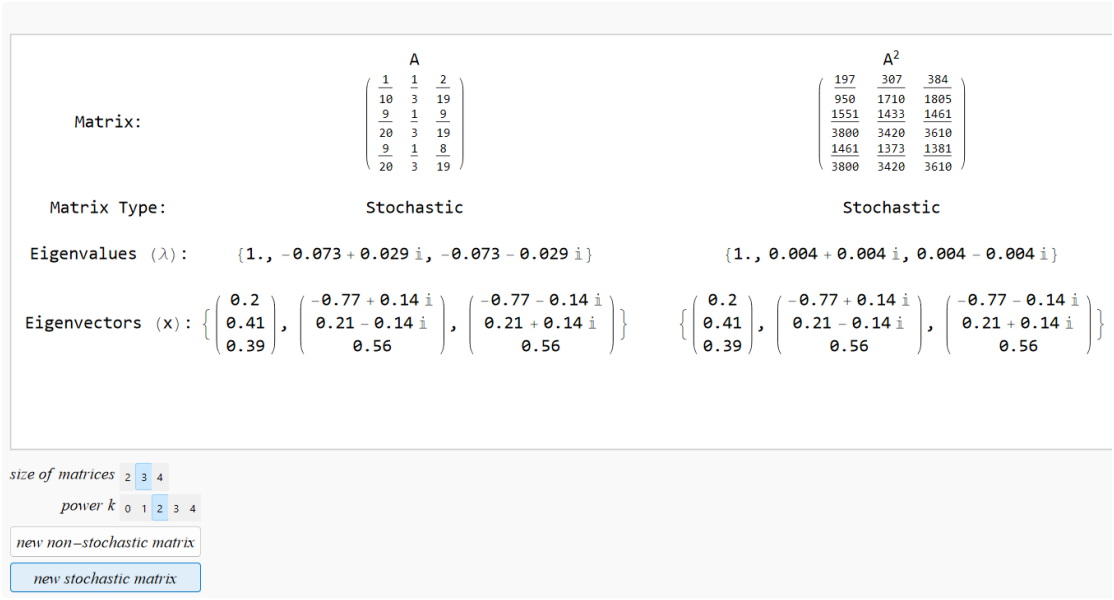

Figure 1. Interactive Figure 1: Properties of stochastic matrices and their powers.

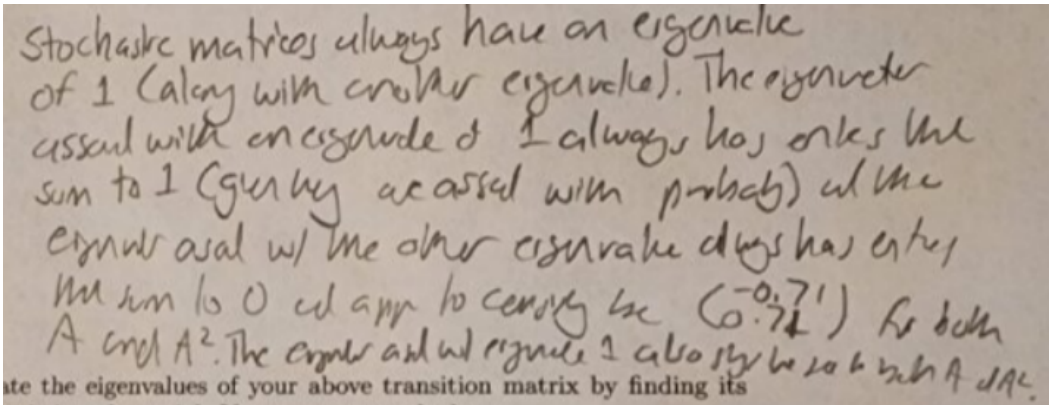

Figure 2. Alice's response to question 3.

While Alice's above response includes other meaningful conjectures, we'll now turn to the interview transcripts to analyze Alice's process of arriving at these ideas.

Alice's Scheme Elements of Observation and Conjecturing

Given free reign over the interview materials, Alice chose to inspect the interactive figures before reading the assignment and the instructions to make mathematical observations via the figures. An excerpt of the interview follows:

Alice: Interesting. These are numbers that don't look very fun to work with. It's probably my first impression. (Alice generates several new stochastic matrices). It's like they all have one. It's my first impression on that.

Interviewer: All have one…?

Alice: As an eigenvalue. (Alice alternates generating several stochastic and non-stochastic matrices). Just interesting for the stochastic matrix.

Immediately from this interaction, we identify several rules-of-action that Alice is employing to inspect the interactive figures to arrive at these mathematical ideas, such as "I look for

convenient or otherwise remarkable phenomena" and "I look at several examples of a situation to draw parallels." From these rules of action, Alice was able to draw forth observations such as the eigenvalue 1 property of stochastic matrices. However, she did not make some less convenient observations such the eigenvalue 1 is the largest eigenvalue of a stochastic matrix, which align her comment that the other eigenvalues are "numbers that don't look very fun to work with."

Thus, it is reasonable that Alice has, by way of the interactive figures, constructed mathematically coherent statements about the properties of an otherwise unfamiliar object, stochastic matrices. However, Alice goes on to display other rules-of-action that display a more complex conjecturing activity. After qualifying her statement about the eigenvalue 1 of a stochastic matrix, Alice alternates generating stochastic and non-stochastic matrices, wherein she does view examples of non-stochastic matrices with leading eigenvalues significantly larger or smaller than 1. We might interpret this activity as following several other rules-of-action such as "I look for conditions under which a conjecture does or does not hold" or "I return to the interactive figures to gather additional evidence in support of a conjecture." From these and the preceding rules-of-actions, we interpret several theorems-in-action, invariant logical propositions that Alice holds to be true and to be motivating her actions:

1. A mathematical conjecture should apply to a specific class of objects (e.g. stochastic matrices).
2. A (universally quantified) mathematical statement should be true in all cases; additional evidence may support a statement but does not prove it.
3. The interactive figures are a source of data and examples of mathematical phenomena.

The first theorem-in-action is evidenced by Alice's intentional distinction between the eigenvalues of stochastic and non-stochastic matrices; her alternating matrix generation implied an experimental phase of cross-examination wherein she became increasingly convinced that the presence of eigenvalue 1 was unique to stochastic matrices. This second theorem-in-action, given by Alice's recurrence of viewing multiple examples even after stating a conjecture, is further supported by her exit survey. Alice was asked about her confidence in her conjectures, including specifically the appearance of 1 as an eigenvalue of stochastic matrices. Alice responded:

> I would say I feel somewhat convinced, like I think experimentally, because I pushed the buttons a lot and I was kind of messing with it for a while. I would say that I think I'm like, at least anecdotally, I feel like that's true, but I would want to have like more explanation of what's happening probably before I'd be fully like, this is definitely what's going on. Like I'd want to go to class and have the teacher be like, this is the result you should be getting, or this is like the reason behind why a stochastic matrix has that result.

This excerpt highlights Alice's cognitive relationship between an observed relationship and the justification of that fact. Even though her response indicates a willing appeal to authority, referring wanting the teacher to tell her "the result [she] should be getting," we still gather that Alice recognizes the observations and examples gathered via the interactive figures as providing compelling anecdotal evidence for the truth of her conjecture. This observed cognition about the role of evidence in conjecture and proof further aligns with the literature on the aspects of conjecturing activity and the role of example generation in forming new ideas.

Finally, in the third listed theorem-in-action, we identify Alice's demonstrated relationship to the interactive figures, namely that of reliable example generation and a source of data for her mathematical experimentation. Beyond Alice not seeking additional sources of stochastic matrices with which to make observations, Alice can be seen to make targeted, intentional

actions via the interactive figures. These include successively generating examples to search for commonalities and patterns and alternating generating stochastic and non-stochastic matrices to test for differences. By these intentional, mathematically reasoned actions taken within the interactive figures, Alice shows evidence of having begun to instrumentate the interactive figures for engaging in the mathematical activity of making observations and forming conjectures.

Alice's Experimentation with the Definition of Stochastic Matrix. Alice had first looked at and begun to hypothesize about stochastic matrices before she read the definition of stochastic matrix provided in question 3. Her first action after reading the definition of stochastic matrix, as well as the sub-definition of probability vector, was to return to earlier matrix computations and visually check if they satisfied those definitions. Thereafter, seemingly primed to search for probability vectors, Alice returned to the interactive figure as instructed by the problem and was quick to make the following new observations:

> These ones are interesting (gesturing to the second eigenvector of A) because it's well these add up to 0 and these (gesturing to the first eigenvector of A and A2) both add up to 1. Yeah, so adding down this representative eigenvector associated with the eigenvalue of 1 sums to 1. And then for the other eigenvalue, the –0.139, the adding up the entry sums to 0... I'm assuming that they [the eigenvector corresponding to eigenvalue 1] because they're associated with probability like the matrix is.

Armed with a new conceptual tool (in this case, that of probability vectors), we may once again describe several rules-of-action Alice is employing, such as "I test a new definition with examples," "I interpret situations in terms of newly acquired language," and "I ascribe meaning to my observations based on definitions and terminology." These rules-of-action, centered on her activity involving a definition that she accepted, mirror earlier rules-of-action she employed when approaching a conjecture that she formed herself. These common features include testing via new examples, including examples that do not fit her conjecture or definition, and collecting her exploratory data from the interactive figures. This example of exploratory action surrounding the definition of stochastic matrices thus aligns with our previous investigation of Alice's conjecturing scheme aspects.

Concluding Remarks

We have observed, in agreement with literature in student conjecturing, several facets of Alice's conjecturing activity, framed as aspects of her observation and conjecturing scheme. These aspects included both generative rules-of-action by which Alice directed her activity, and the interpreted epistemological theorems-in-action that guided her rule system. Furthermore, we made explicit the role of the interactive figure in Alice's pre-proof activity, in part by referencing her direct actions with the figures in her rules-of-action. In doing so, we have evidenced that Alice was successful in some qualities of instrumentating the interactive figures, specifically for the purpose of engaging in mathematical observation and conjecture.

While we have referenced an Observation Conjecture Proof Theorem pedagogical model of promoting student proof activity, the complete explication of this model and the component scheme descriptions of observing, conjecturing, and proving remain a larger goal of the thesis work and beyond. As such, further analysis of this interview data, as well as the remaining interview data, is necessary and planned. Based on this initial analysis, the first and second authors are confident in the figures' ability to encourage productive activity and plan to incorporate them into their teaching.

Conceptual Blending as a Problem-Solving Tool in Topology

Caleb Judkins
University of Oklahoma

Sepideh Stewart
University of Oklahoma

The topic of topology is an important and unique course in advanced mathematics that carries two simultaneous complexities: logical proof and spatial reasoning. While proof and problem-solving are two areas that are well documented in mathematics education research, topology itself is a fairly rare topic to appear in the literature of mathematics education written in English. To address the gap in the literature, this paper analyzes a study in which two students attempt a topology question in order to understand their problem-solving techniques and how they leverage their various forms of thinking. We networked the theories of Tall's Three Worlds of Mathematical Thinking and Cognitive Blending to describe the participants' behaviors. The results showed that students leveraged a blend of their thinking to progress through the proof.

Keywords: Topology, problem-solving, proof, Tall's Three Worlds, cognitive blending

Introduction

Topology is an important topic in the world of advanced mathematics, with James (2006) claiming, "Topology, for many years, has been one of the most exciting and influential fields of research in modern mathematics. (p 1)" Often said to be "rubber-sheet geometry", undergraduate courses in topology are primarily concerned with the heavily set-theoretical definitions, theorems, and properties. It is a unique course in that context, as it is a heavily proof-focused topic that is supported by a significant amount of spatial reasoning. Even so, there is a lack of educational research on topology. While the topic was used in developmental psychology (Piaget & Inhelder, 1967) and is a field often brought into studies concerning pre-university math education, research that focuses on RUME in topology is scarce among the literature available in English (Vizcaíno et al., 2023).

Literature Review

Educational research in topology is still in its infancy. While researchers have had some interest in topology, the topic is often used as a setting rather than being central to the study. For example, Hicks et al. (2023) attempted to develop a model for "abstraction through analogical reasoning" (p. 807) and used topology as an example to demonstrate part of their model. Additionally, Clark et al.'s (2017) study focused on the incorporation of "primary source projects" into a topology course. The authors' motivation for doing so was based on the idea that original sources for mathematical concepts framed the issues the mathematicians were facing for the students so that they could better understand why the concepts were developed in the first place. Topology was chosen for this study as it was the course the researcher was teaching at the time. On the other hand, some studies have topology near the research interests. Bardelle (2011) explored students' understanding of the topological concepts of finiteness and boundedness with metric spaces, claiming, "everyday use of mathematical terms combined with a lack of coordination of different representations proves to be a hindrance in the conceptualization of basic properties of subsets of Euclidean spaces" (p. 1). Additionally, O'Brien (2023) establishes the connection between the topology of knot theory and tapestry weaving as she claims that those engaging in tapestry weaving internalize and embody diagrammatic instructions in the same way that a mathematician does with topological diagrams.

For papers that are written in English, we have identified three doctoral dissertations in recent years that are principally concerned with education in topology (e.g., Cheshire, 2017; Gallagher, 2020; Berger, 2021). Cheshire (2017) examined the development and adaptations of concepts that students previously encountered as they make sense of the new version of those ideas in the context of topology, primarily with the topic of continuity. In a similar vein, *Reopening the Case of Schema: A Topological Perspective* is a doctoral thesis that seeks to understand and describe students' adaptations to their bodies of knowledge and approaches to problems as they encounter concepts in topology (Berger, 2021). Both studies found that students may struggle with increasingly abstract topics, but they are generally able to adapt to new problems. Another thesis seeks to understand students' use of examples, gestures, and problem-solving strategies to answer questions in topology (Gallagher, 2020). This work demonstrates and describes the ways that students use verbal, gestural, and visual ideas as tools in topology as well as parts of their own thinking. Gallagher found evidence to suggest that it is useful for students to associate their mathematical concepts with diagrams in order to manipulate them and search for important components of the concepts, concluding that teachers should foster students' intuition. All three of these studies referred to the importance of the nature and mechanisms of students' internalization of topological concepts and how they learn to think about them. These three were all empirical studies that included undergraduate students solving problems in topology, and Berger also included graduate students and a research mathematician.

As is evident by the nature of the topic, proof is a fundamental part of topology. To that end, it is necessary to understand the state of the literature on proof in mathematics education research. The study of proofs, proof writing, and the learning of it is now a relatively well-researched area of mathematics education (Mulhuish et al., 2022; Stylianides et al., 2024). According to Selden and Selden (2013), students in higher level math courses have difficulty producing proofs, partly since proofs outside of an intro-to-proofs course have their own content that students must adapt to while trying to structure their proofs. Selden and Selden categorized a written proof into two parts: the formal-rhetorical part and the problem-centered part. The formal-rhetorical part is that which involves the logical structure of the proof. The problem-centered part consists of the content in the proof oriented around the mathematical constructs and concepts at hand. Thus, to understand how students approach proofs, it is necessary to understand problem-solving itself.

Theoretical Framework

The framework for this study is adapted from Schoenfeld's (1985) problem-solving, Tall's (2013) Three Worlds of Mathematical Thinking, and the theory of Cognitive Blending (Fauconnier & Turner, 2002).

Problem-solving in mathematics is a well-researched topic that has had an influence on the educational practices of teachers for many years (Schoenfeld, 1992), and there are four components of problem-solving outlined by Schoenfeld (1985). The notion of *heuristics* is used to describe the problem-solving strategies that students employ, with the idea of *control* referencing how different heuristics and content *knowledge* resources are used. The subtle concept of *belief system*s also plays a role, as Schoenfeld (1985) claimed, "...their beliefs about mathematics –consciously held or not– establish the psychological context within which they do mathematics" (p. 14). Schoenfeld's problem-solving lens provides a context to ask about students' thought processes in topology.

Tall's Three Worlds of Mathematical Thinking describes the embodied, symbolic, and formal worlds as the three forms of thinking in mathematics (Tall, 2013). The embodied world is

that which is influenced by one's perception of the physical world, involving notions such as images, haptics, and motion. The symbolic world involves symbols and operations on them, as often seen in the context of algebra. The formal/axiomatic world describes the thinking dealing with theorems, definitions, and the structured logic-focused concepts of mathematics. This theory enables researchers to describe the different behavior of students as they work through proofs. However, it is worth noting that it is not accurate to the theory to take these worlds as separate, and it is not accurate to suggest that one can move between the worlds of thinking. Instead, the worlds are all descriptions of different manifestations of a given topic as it exists cognitively, and one does not "move" amongst various qualities of a given object. Rather, students can be observed using the different worlds of thinking in conjunction with each other, which demands a theory to describe such a blending of ideas.

The theory of Cognitive (or conceptual) Blending refers to a supposed fundamental cognitive tool of reasoning that involves a person incorporating two worlds of thinking into a single realm to gain further understanding from it (Fauconnier & Turner, 2002). There are two descriptions of a blend: single-scope and double-scope (Bing & Reddish, 2007). Single-scope blending occurs when one world provides framing/information to make sense of the other without any interplay; this is the case when understanding "time flies like an arrow," as one's understanding of arrows is framing a description of time through one's imagination of an arrow in flight. Yet, the phrase does not influence the way one would think of an arrow. Double-scope blending is more advanced, as ideas from both worlds are at play and influencing cognitive creation. It can easily be observed in the context of language that the spoken and written components are distinct yet have great simultaneous influence on each other, creating a double-scope blend when they are used in conjunction.

By networking these theories, we developed a framework that enables a description of how students use different forms of thinking together in their problem-solving by blending them. The research questions to lead this study are:

- What heuristics do students employ as they attempt topology proofs?
- Did blending of the worlds of mathematical thinking occur in students' attempts at solving problems in topology? Was it a useful approach for problem-solving in topology?

Methods

This case study took the form of a single collaborative, structured problem-solving session where two graduate students were presented with three topology problems. The collaborative aspect of the design was intended to encourage the articulation of their thinking as they worked together. The participants of this study were two early graduate students in the researchers' mathematics department. Potential subjects were selected based on their proximity to the beginning of their time in graduate school and their responses to the opportunity. The study involved working on a whiteboard together, and it was audio- and video-recorded. The participants were also asked to construct proofs. The researcher (first author) wrote a problem on the board for the participants to attempt one at a time. Their attempts were examined, though the study was not focused on evaluating the accuracy or validity of their proof or the function of their teamwork abilities; rather, the principal focus was on the nature of their thinking and problem-solving, so they were encouraged to articulate their thoughts. The three topology problems are depicted in Table 1 alongside their motivation for inclusion in the study. These problems were selected to encourage different kinds of reasoning and thinking, thereby gathering

a variety of data from the students. This paper focuses on the students' attempt at the second question. The authors are in the process of analyzing the data from the students' attempt at the other questions for future studies.

Table 1. Interview problems and their reason for selection.

Topology Problem	Intention for Selection of the Problem
1. Provide a metric on (-1,1) that induces the usual topology but is complete as a metric space.	The most direct solution involves making a particular connection between spaces that is often associated with a graph, and the notion of a metric is associated with the idea of distance. Thus, the question is heavily influenced by the embodied world of thinking.
2. Determine whether R imbued with the lower-limit topology is path-connected.	Path-connectedness is typically considered in cases of topologies that can be perceived, yet the space in question is not a manifold that can be imagined easily. This might motivate the students to try to work in the embodied world, yet the proof does not directly follow from that perception.
3. Prove that (0,1) with the usual topology is not compact.	Compactness of a topological space is an abstraction of the notion of compactness in metric spaces, which typically benefits from embodied thinking.

After the interview, a transcript of the conversation was created, and images from the video were used to examine the work that the participants did on the board. This transcript of the data was coded with four themes in mind: Embodied, Symbolic, and Formal worlds of mathematical thinking, as well as Blending. The first three are in line with descriptions from Tall's Three Worlds of Mathematical Thinking, while blending was used to identify moments where the participants were considering different worlds of thinking in conjunction to elucidate a concept or make progress in their proof, according to the theory of cognitive blending. This is distinct from the students bringing up different forms of thinking simultaneously without engaging in any detectable interaction between them. Moments of potential blending were identified when different forms of thinking overlapped or followed each other. NVivo qualitative data analysis software was used to examine and code the video along with its transcript. These codes were analyzed further to determine whether they could be considered evidence of a cognitive blend.

Results and Discussion

The two students began this problem with the correct intuition that the space is not path-connected. They started their approach by defining each term they saw, beginning with their understanding of the lower-limit topology. They handled that concept by writing out the form of the basic open sets (intervals of the form [a, b), with a, b real) as seen in Figure 1. Then, to describe path-connectedness, Student 2 stated, "between any two points we can make a path," and Student 1 replied that he thought a path needed to be "between sets." So, Student 2 drew an image of a path in a space by drawing a circle, labeling points x and y, and then connecting those points with a curving line, then verified that path-connected means "between any two points we can make a path?" Student 1 then affirmed this, and Student 2 drew a second circle as he mentioned the notion of the components of the space. This prompted Student 1 to mention "since

connected implies path-connected…" which brought them to a discussion about the proper direction of the implication between those two properties. Ultimately, they agreed, mentioning the topologist's sine curve as the example, that path-connectedness implies connectedness, with Student 2 then writing on the board "C → PC," the wrong implication. They then considered whether the space is connected, with Student 1 having believed it is. This motivated students to focus on their definition of path connectedness, as they pondered what the definition of a path involves. After they defined a path, they revisited the correlation between connectedness and path-connectedness, realizing the mistake on the board. After correcting it, they realized that if they can find a separation of the space, then the space must not be path-connected. Student 2 suggested they could assume it is and try to arrive at a contradiction, with Student 1 then arguing that they could just consider what sets are open first to avoid that level of work. They began to ponder what the open sets in this space look like, with Student 1 having quickly decided he does not think that the space has a separation. They did not perform any detectable set theory, as they only wrote down the basic open sets before deciding that there was no open partition.

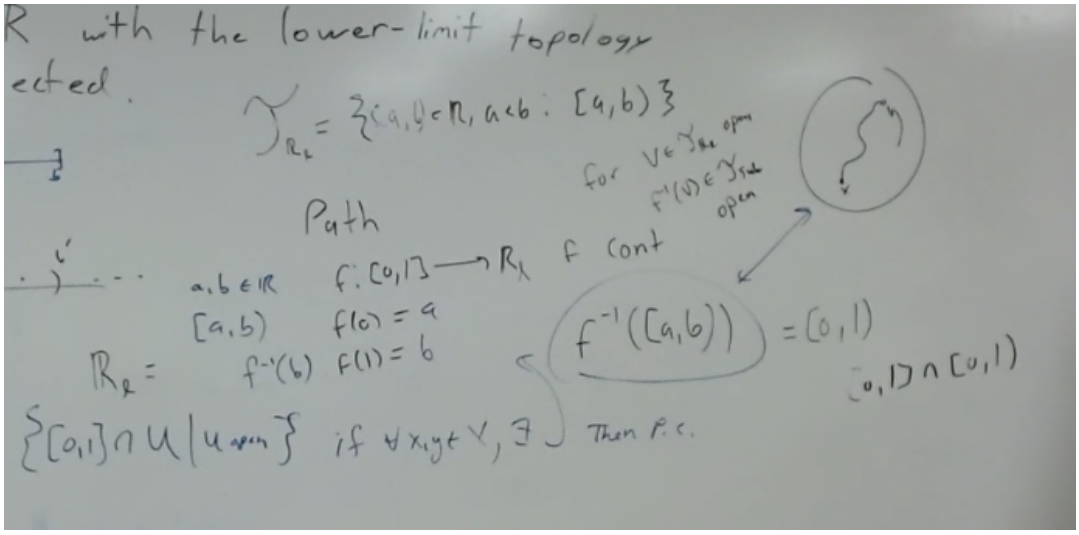

Figure 1. A portion of the students' board work.

The students then engaged in their approach of assuming that the space is path-connected and tried to find a contradiction. Student 2 then stated that he wants to understand what a path would look like between two points "in a basis element" as they decided they need a "continuous function that connects a to b." They began to consider what the preimage under some path of the basic open set [b,a) must "look like", before Student 2 replaced it with the closed set [a,b]. Student 1 then asked the researcher what the definition of a path is, and he asked in response, "How do you think of a path?" Student 1 then gestured a line in the air, then drew the same image that Student 2 drew before, claiming, "it's a continuous sort of connection that exists within the space." The researcher replied that a path is a continuous map from the interval into the space, with Student 2 adding that a space is path-connected if a path exists between "all the points." They then amended their existing definition of a path with quantifiers to extend it into a definition for path connectedness. Student 1 asked what the topology of the interval was, as the researcher affirmed his belief that it has the usual topology, the subspace topology of the real line with the usual topology. The pair thought in silence for a moment, then Student 1 resolved that they wanted to break the continuity of their supposed path. They tried to understand what the preimage of their closed set must look like, with Student 2 having noticed the difficulty in the

question coming from the fact that the path may "backtrack" on itself, in other words, the path need not be injective. This was essentially as far as they were able to take the proof on their own, as the rest of the progress was only made with significant interviewer intervention.

Afterwards, the researcher informed the students that they could find a separation of the space. They began to consider this as Student 1 struggled with the set theory, and the researcher guided them to consider explicitly taking the union of particular sets. This helped them realize that they could construct two open sets that are complements of each other, meaning the space is not connected, implying the space cannot be path-connected. This process of the students' attempt was coded, as Figure 2 depicts the codes as they appear in the transcript, with blue indicating the embodied code, red for symbolic, yellow for formal, and black for identified instances of blending.

Figure 2. The transcript's coding of embodied (blue), symbolic (red), formal (yellow), and blending (black).

Addressing the research question "What heuristics do students employ as they attempt topology proofs?", we note firstly that the participants used a significant amount of formal thinking and reasoning, as seen by the frequency of the yellow blocks in the coding of the transcript in Figure 2. They began Question 2 by defining each property and clarifying the relevant topological space by considering the basic open sets. Additionally, they used axiomatic reasoning with relevant theorems to decide which "path" to follow in their solution, recalling that if a space is path-connected, then it is connected, and applying the contrapositive/contradiction to arrive at their result. There was also an intentionality in what activities they considered productive, as at one moment Student 2 said, "Well… let's just maybe back off from this, since there's not an immediate separation standing out." Thus, the heuristics employed include the following: leveraging logical structures to establish and reframe objectives, considering the difficulty of the possible goals, and, as demonstrated in the next question, cognitive blending of various worlds of thinking as strategies to solve their problems.

Next, we consider the second portion of the research questions, "Did blending of the worlds of mathematical thinking occur in students' attempts at solving problems in topology? Was it a useful approach for problem-solving in topology?" Analyzing this recording yielded various references to Tall's Three Worlds, and some moments suggest a blending occurring between the worlds of thinking. Firstly, the students handled their concept of a path in such a way that exemplifies a cognitive blend. As they began the problem, the first written "description" they provided for path/path-connectedness was a picture meant to represent the concept of a path. This was also later used to resolve a moment of confusion where one student believed that paths needed to map "between sets." While the students initially disagreed about the verbal formal description, they immediately agreed on the picture's validity, and Student 1 used that to rectify his misunderstanding of the formal description. This is significant evidence of Student 1 having used single-scope blending as he interpreted this image into a formal understanding, agreeing that the path connects points, not sets. Also, Student 2 intentionally used this image instead of the formal definition to communicate the definition of a path, even though he had just stated that formal definition. Whether he thought the image was more convincing or it would be familiar to Student 1 in such a way that it would help him make that connection, it is clear that Student 2 has internalized the image in great conjunction with the formal definition of a path. It is as if, internally, the image and the definition are communicating the same idea to him, which supports

the idea of this cognitive blend between the embodied and formal worlds being a familiar tactic to him.

Blending appeared another time regarding Student 1's description of his concept of a path, as he gestured with his hands while stating that it is a continuous map, before drawing the picture on the board depicted in Figure 1 with the two-directional arrow between the image and the definition. Not only does his explanation describe a blend between his embodied gestures, but he also explicitly connected the ideas on the board with an arrow.

Lastly, while the students used the note "P → C" to reference the theorem that path-connectedness implies connectedness (as well as the converse and its shorthand), this is symbolism that has become common to the students to denote the formal theory. There is no evidence they are handling those icons in any way indicative of a symbolic form of thinking (i.e., there was no action taken on the terms). However, their solution to this confusion, referencing the topologist's sine curve, carried some information that enabled them to reconstruct the theorem without performing any formal tasks. This does suggest some form of blending occurred, though whether it is between any worlds of thinking or merely with their recollection of the topic is unclear.

Conclusions

Ultimately, this data provides evidence that blending the three worlds of thinking is a common and useful cognitive tool for students as they work on problems in topology. Blending was detected and analyzed in the context of successful moments of progress through the problem. It could be suggested that these instances of blending constitute comprehensible connections between mathematicians' different forms of thinking that are not only used in the contexts in which they are developed but may also be internalized into the broader cognitive body of the concepts. Additionally, while no blending was mentioned between the formal and symbolic worlds, this is certainly a possibility if one were to handle a problem by using symbolic logic to restructure the problem (e.g., using DeMorgan's law to "distribute/factor" a negation).

While this study presents compelling evidence that helps address the research questions, there are some limitations. For instance, as this study was task-based, we do not have precise descriptions concerning the students' thinking; we relied on the external evidence of their articulations and board-work to make conclusions about what was happening mentally. This could suggest that there is more blending that is not being detected. Additionally, while these students lack the language of our theoretical framework that would have enabled them to describe their own thought processes, asking them to understand the terms and use them causes an additional cognitive burden that could distract the students and form an unnatural environment for their proof attempt. While there is a larger curiosity regarding how students think about topological concepts in general, the typical class structure may not encourage students to think about their own internal conceptualization of those ideas. Instead, it seems that the majority of the mathematics curriculum focuses on developing students' ability to answer questions, which informed the design of this paper's research question. There are currently plans to develop this project further that involve interviews where the students are asked to describe their thought processes as they work and potentially explain their conceptualizations of topological concepts. As part of the first author's dissertation, we are continuing to refine this theoretical framework to develop a model to further guide our analysis of the data.

An Analysis of Performance, Standard Mastery, and (Re)assessment Behaviors in a Coordinated College Algebra Course

Derek Eckman
Idaho State University

Sam Haycock
Idaho State University

Collin Kress
Idaho State University

The purpose of this report is to identify specific content topics and assessment or reassessment behaviors to classify students' performance in a College Algebra course using alternative grading. Our data consist of students' individual standard mastery marks, reassessment frequency, standards reassessed, and final letter grades (which were primarily based on the number of standards mastered in the course). Our analysis involved constructing logistic models and a random forest to identify predictor variables that reduced the Akaike Information Criterion (AIC) and the mean Gini Index. Our results describe two content standards and reassessment behaviors whose attributes were central to our classification models, which can inform the instruction or revision of traditional- and alternative grading-based College Algebra courses.

Keywords: Alternative grading, College Algebra, reassessment, function composition, exponential and logarithmic functions

Alternative grading (AG) practices (e.g., standards-based grading, mastery-based grading, specifications grading, ungrading) are common in secondary (Guskey, 2008) and gaining momentum in undergraduate mathematics education courses (Lewis, 2022). More than 65 years after Bloom's (1968) introduction of learning for mastery, researchers have demonstrated this system's ability to improve both student and teacher perceptions of mathematical learning and coursework. For example, students in AG courses tend to exhibit lower test anxiety (e.g., Harsy et al., 2021; Henriksen et al., 2020; Lewis, 2022), consider assessments to be learning opportunities (Harsy & Hoofnagle, 2020), focus office hours conversations on constructing meaning for math topics instead of answer-getting (Zimmerman, 2020), and provide positive reflections on their experiences in their courses (Collins et al., 2019; Harsy et al., 2021; Henriksen et al., 2020). Instructors of AG courses often report increased feelings of responsibility, coupled with higher expectations for students, which lead to an overall improvement in their attitudes toward teaching their courses (Guskey & Gates, 1986).

Many of the reports cited in the previous paragraph describe (a) implementations of alternative grading, (b) affective advantages to students in courses using alternative grading, or (c) comparisons of students' experiences and perceptions of assessment in traditional and alternative grading courses (Swanson et al., 2025). In contrast, there has been minimal research on the use of student data to identify central topics in AG courses or behaviors that correlate with students' overall mastery of course content. The purpose of this report is to provide insights into such topics and behaviors in the context of a coordinated AG College Algebra course. To this end, we provide the following research questions (RQ) to guide our discussion:

1. Which mathematical topics are most correlated with student's mastery of course content in a College Algebra course utilizing alternative grading?
2. Which student study practices are most correlated with student mastery in such a course?

Theoretical Background and Course Structure

The AG College Algebra course instructors created the course in accordance with the Four Pillars of Alternative Grading (Clark & Talbert, 2023) and Collins et al.'s (2019) characteristics of Mastery-based Testing (MBT). We describe the course composition using the Four Pillars.

Pillar 1: Clearly Defined Standards

Clark and Talbert (2023) do not provide a rigorous definition of the term *"standard,"* leaving the decision on what constitutes acceptable student work open to the instructor's discretion. Still, Collins et al. (2019) state that whatever standards are determined, these standards must be clearly worded and communicated to students on study guides and assessments.

To determine the *standards* for the College Algebra course, instructors implemented a three-step procedure reminiscent of grounded theory (Strauss & Corbin, 1998). First, they analyzed the common final exam and compiled a list of skills they believed students would need to complete the questions (i.e., open coding). Second, they organized the skills into overarching topics that appeared (to them) suitable to serve as units within the course (i.e., axial coding). The instructors utilized the term *standard* to refer to each of the content topics that emerged from the organization process. The final, recurring, stage is to refine the list of standards through implementation iterations until it appears that the standards list encompasses the material conventionally covered in a traditional College Algebra course (i.e., theoretical saturation). The current iteration of the AG College Algebra course includes a list of 18 content standards, some of which are shown in Table 1 below. Students must show proficiency twice on a standard to achieve mastery of that standard. To facilitate this process, the course also includes feedback systems (Pillar 2), marks systems (Pillar 3), and a three-part assessment structure (Pillar 4).

Table 1. A sample of three standards from our AG College Algebra Course

Standard F8	Add, subtract, multiply, divide, compose, and decompose functions given in any of the four representations, and simplify when necessary/possible. Find the domain and range of the combined functions.
Standard EL4	Solve logarithmic and exponential equations. Solutions are either approximate or exact.
Standard EL5	Model and solve applications with exponential functions (compound interest, exponential decay and growth).

Pillar 2: Helpful Feedback

Instructors in the College Algebra course provide targeted, specific feedback on students' assessment and reassessment attempts in the course. The purpose of such feedback is to create a loop through which students know which ideas to revisit before reassessing. Collins et al. (2019) also recommend providing feedback to help students progress toward mastery of course topics, rather than as a penalty, which might disincentivize future attempts at mastery.

Pillar 3: Marks Indicate Progress

Instructors use a binary system to provide marks on students' assessments and reassessments: *pass* and *not pass yet* (Clark & Talbert, 2023). They also condition *passes* on conceptual mastery of a topic and use *not pass yet* marks to facilitate future student learning opportunities of course material, rather than penalizing (often computational) mistakes (Collins et al., 2019).

Instructors use a standardized system, based on the number of standards students master throughout the semester, to assign final letter grades. We show the number of standards corresponding to each letter grade in Table 2 below. The possible addition of a + or – modifier to a student's letter grade is contingent upon engagement activities, such as homework completion and course attendance. Consequently, students' final letter grade in the course is an indication of the amount of AG College Algebra content for which they have exhibited proficiency. When we describe productive predictors for classifying students by letter grade in the results section, we consider our claims to be synonymous with describing specific content or behaviors whose acquisition is associated with students' mastery of AG College Algebra material.

Table 2. The mastery-based grading scheme to determine final letter grades in AG College Algebra

Standards Mastered	0-8	9-11	12-14	14-16	17-18
Final Letter Grade	F	D	C	B	A

Pillar 4: Reattempts Without Penalty

A central component of all alternative grading strategies is allowing students to perform reassessments to demonstrate growth and mastery of course content (Clark & Talbert, 2023). College Algebra instructors provide three opportunity types for students to reassess course standards: (a) required weekly in-class assessments (which contain some instructor-chosen previously assessed standards), (b) optional weekly reassessments of student-chosen standards, and (c) optional reassessment opportunities on the final exam. In this report, we focus a portion of our analysis on reassessment opportunity (b), the optional weekly reassessments.

Methodology

In this section, we describe our data collection and analysis methods. We will use three statistical terms to organize our descriptions. First, we use the term *predictor variable* to refer to student behaviors or standard mastery for which we collected data. We have included a list of some predictor variables in Table 3 below. Second, we use the term *observation* to refer to the unit of analysis in our study, i.e., individual AG College Algebra students. Finally, we use the term *category* to refer to the response variables whose relationship with the predictor variables we attempted to determine (e.g., the final grade in the course).

Data Collection Methods

Population and data sources. The population we chose to study for this report consisted of all students enrolled in an Alternative Grading (AG) College Algebra or College Algebra Corequisite course at a mid-sized regional university in the Pacific Northwest. To construct a sample of students from this population, we collected internal and institutional data for the 134 students enrolled in one of the six Spring 2025 sections of traditional or corequisite AG College Algebra offered at the institution. The first author of this report was an instructor for one of the corequisite courses. We collected data from three sources. First, we imported data from a Qualtrics form used throughout the semester for students to schedule weekly reassessments in the proctor room. The information we imported from this form included students' names, the dates and times of reassessments, and the standards they intended to reassess at each appointment (a maximum of two standards weekly). Second, we collected students' individual standard mastery data from all but one instructor after the semester. Finally, we collected students' final letter grades and demographic data from the institutional research staff.

Predictor variables and sample refinement. In preparation for data analysis, we determined two classes of predictor variables to investigate in relation to students' final letter grade. First, we created three predictors for each standard according to possible mastery level (0 passes-not met; 1 pass-partially met; 2+ passes-fully met). This class of predictors aligned with the intent of RQ1, i.e., determining content concepts with explanatory potential for students' performance (e.g., final grade outcome). Second, we created predictors for behaviors related to the reassessment room, including (a) the total number of reassessment appointments made and (b) the number of standards reassessed throughout the semester. This class of predictors aligned with the intent of RQ2, i.e., determining behaviors that may help explain students' performance.

We used our focal predictors to restrict our initial sample to the set of observations (i.e., students) exhibiting both predictor classes. To this end, we removed 28 students from our initial sample. Of these students, 12 did not have assessment, reassessment, or standard performance data (typically students with early withdrawals), and 16 students were removed due to an instructor not providing standards mastery data. Our final sample consisted of 106 students.

Table 3. A selection of predictor variables guiding our data collection and analysis

F8	Categorical (binary) variable indicating whether the student mastered Standard F8 or not, i.e., achieved two or more passes.
Total.standards.scheduled	Discrete variable describing the number of standards students scheduled for reassessment throughout the semester.

Data Analysis

The second and third authors prepared the data for formal analysis and importation into the R studio platform. This process included (a) assigning identifiers across the disjoint data sources and (b) compiling three distinct spreadsheets into a centralized document containing the 106 observations to import into R studio.

Statistical Techniques. The second author of this paper led the data analysis for this project, which included techniques related to (a) stepwise selection on logistic models using the Akaike Information Criterion (AIC) and (b) creating and measuring the decision trees in a random forest by Gini Index to construct a variable importance plot. We explain these components of our analysis in the paragraphs below.

Statisticians use logistics models to predict the category (e.g., final letter grade) associated with a specific observation (e.g., student with a particular set of standard and reassessment properties). When building a logistic model, a common approach is to use forward or backward step-wise selection. This process involves starting with either no predictor variables in the model (forward selection) or all predictors in the model (backward selection) and then adding (i.e., forward) or removing (i.e., backward) predictor variables to determine how the change improves the explanatory power of the model to classify the observations correctly. A central component of determining a final logistic model is minimizing the AIC value, which reduces the predictors in the model while maintaining explanatory power. Although the forward and backward selection processes can identify different variables as important, any variables that appear in both models provide a strong argument for predictors of high-performing students. Our analysis involved creating both forward and backward selection logistic models to determine important standard mastery (i.e., RQ1) and reassessment behavior (i.e., RQ2) predictors that we could use to categorize our students' final grade performance (i.e., content mastery).

Statisticians use random forest (i.e., a collection of decision trees) as an alternative method to predict the category (i.e., final letter grade) associated with a particular observation (i.e., student performance and behavior). In our instance, we measured the Gini Index to determine the distribution of the predictor variables across the decision trees in the random forest. A low Gini Index (i.e., close to 0) indicates that a particular predictor variable (e.g., mastering Standard F8) produces the cleanest separation of observations into those that correspond or do not correspond with the category (e.g., students who master Standard F8 generally get A grades and those who do not master F8 generally receive lower grades). We used the data from the Gini Index measurements across the random forest to construct a variable importance plot, which shows the predictor variables that contributed the most to improving the tree's predictions throughout the forest. In this plot, the higher the importance score, the more the Gini Index is reduced (i.e., decreased) across all splits in a given decision tree. In other words, a high importance score (e.g., greater than 3) indicates an essential predictor variable for categorizing students' final grades in the College Algebra course. Through our analysis, we identified the two content standards (RQ1) and student behaviors (RQ2) that provided the most explanatory power for the students' final letter grades in the course. We describe these results in the following section.

Results

RQ1: Content Standards Corresponding with Overall Standard Mastery

Our initial logistic models indicated several important predictor variables, both from the forward and backward selections. Among these variables, we found two standards, F8 and EL4, with associated predictors that indicated high explanatory power for students' final letter grades in the course (i.e., mastery of course content; see Table 1 for the text of these standards). For instance, we determined that students' eventual mastery of these standards substantially lowered the AIC across our logistic models. Although only students' reassessment of Standard EL4 was a statistically significant predictor for students' final course performance ($p = 0.004$), we found that manually removing students' mastery of F8 and EL4 from our models led to a drastic increase in the AIC value (e.g., by a factor of 2 to 3 depending on the model). These results indicate that students' mastery of function composition topics (i.e., Standard F8) and ability to solve logarithmic or exponential equations (i.e., Standard EL4) are crucial predictors for students' final letter grades (and subsequent success) in AG College Algebra.

To further investigate the potential importance of standards F8 and EL4 in relation to student success in College Algebra, we created a random forest, measured the corresponding Gini Index, and constructed a variable importance plot. We share a sample decision tree from the random forest and our variable importance plot in Figures 1a and 1b below. We note that the first two branches in the sample decision tree (Figure 1b) are F8 and EL4, and each predictor has a mean decrease in the Gini Index above 5 (Figure 1a), indicating their importance in classification across the decision trees in the random forest. Taken together, the reduction in AIC and the strong decrease in the Gini Index confirm the central nature of standards F8 and EL4 as classification tools for students' letter grades in our course.

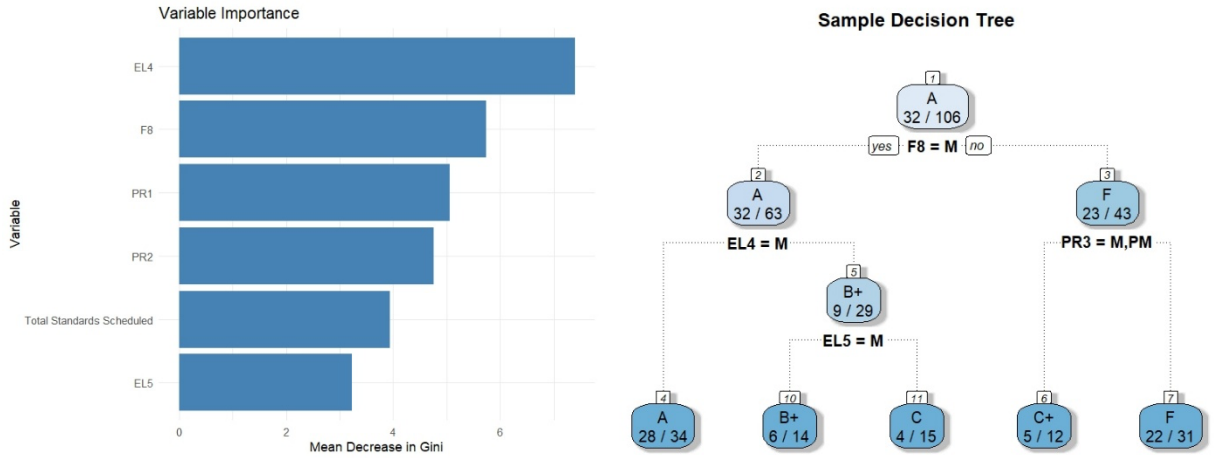

Figure 1. (a-left) A variable importance plot of the largest mean decrease in Gini Index. (b-right) A sample decision tree from the Random Forest method.

RQ2: Students' Assessment Behaviors Corresponding with Overall Standard Mastery

Our results related to RQ1 indicate that the predictors with the most explanatory power related to students' letter grade performance in the AG College Algebra course were content (i.e., standard) related. We anticipated that some students' (re)assessment behaviors might also function as crucial classification tools of students' final letter grades, due to the central nature of reassessment in the AG course. Through our analysis, we identified two predictors that served as useful classification tools. First, we found that the total number of standards that students reassessed over the course of the semester (a) reduced the AIC in both the forward and backward directions of the logistic models and (b) produced a reduction in the Gini Index above 3. Second, we found that the total number of reassessment appointments that students scheduled and subsequently completed also consistently reduced the AIC in logistic models and produced a Gini Index reduction above 3. We note that among our list of predictors, which included students' performance on all 18 standards and various (re)assessment behaviors, students' total number of standards reassessed produced the fifth most significant decrease in the Gini Index, and the number of completed reassessment appointments contributed the twelfth largest decrease. Taken together, these data indicate that the most important student (re)assessment behaviors for classifying students' final letter grades in AG College Algebra involve their reassessment actions. Specifically, students who complete scheduled reassessment appointments and reassess larger numbers of standards tend to achieve higher grades in the course.

Discussion

This report highlights our use of reassessment and student performance data in a coordinated AG College Algebra course to increase our understanding of students' achievement of particular letter grades (i.e., standard mastery) in the course. To this end, we proposed two research questions related to (a) the central course standards and (b) (re)assessment behaviors that could provide explanatory power for students' mastery of the content in the course.

Our data analysis related to RQ1 revealed that students' mastery of function arithmetic and composition (Standard F8), and algebraic fluency with solving exponential and logarithmic equations (Standard EL4) provided a framework for effectively classifying the letter grades of a large number of our students. Our findings reinforce those of prior researchers who claimed that building conceptual meanings for function concepts is not easy for students (Breidenbach et al., 1992; Thompson & Carlson, 2017), whether (a) learning function composition in preparation for

the chain rule in calculus (Clark et al., 1997), (b) building meaning for exponential functions (Ellis et al., 2016), or (c) reasoning about logarithmic functions (Kuper & Carlson, 2020). Additionally, our results extend these findings by showing evidence of the importance of composition, exponential, and logarithmic topics in students' success in a mastery-oriented College Algebra course.

From an instructional perspective, our results related to RQ1 imply that an increased focus, or at least increased attention to these topics, may lead to improved student success in College Algebra courses using alternative grading. Although our study does not include a comparison with students in traditionally-graded (i.e., weighted average) College Algebra or calculus courses, our results suggest that (a) traditional College Algebra course instructors might similarly profit from increased focus on composition, exponentials, and logarithms, and (b) addressing students' notions of function composition, exponential functions, and logarithmic functions may be a productive focus for diagnostic or remedial tools in higher mathematics coursework (e.g., calculus).

Our data analysis related to RQ2 question revealed that students' willingness to schedule and perform reassessments across various standards correlated with higher performance (i.e., increased mastery of content) in the course. Our findings provide empirical evidence that reassessments can be employed as learning opportunities (Collins et al., 2019) and that students who avail themselves of these opportunities often progress toward mastery. While we recognize that our results regarding reassessments may not be fully transferable to College Algebra or other courses using traditional grading systems, we use our results to highlight the possibility that all instructors can modify some (or all) of their assessments to create student learning opportunities (rather than penalizations or unchangeable marks of failure).

We are continuing to collect data on students' standards mastery and (re)assessment practices during the Fall 2025 semester. We anticipate that the analysis of this additional data in the coming months will provide further refinement of the results we presented in this report. Specifically, we plan to test whether our logistic models, in general (and Standards F8 and EL4, and students' reassessment practices in particular), continue to serve as effective classification tools for students' final letter grades. Our eventual results will serve to further the discussion of centrally important topics in College Algebra and the refinement of AG College Algebra courses.

Acknowledgments

We gratefully acknowledge the work of Idaho State University's Institutional Research, and Terren Hunt specifically, for the preparation of some of the data that we analyzed for this report.

Snowballing: The Unexplored Issue of Developmental Mathematics and Course Repetition

Katherine Burke
Temple University

In the developmental mathematics education literature, course failure typically leads only to attrition from the course sequence. That is, an overlooked, and not well-understood, experience in developmental mathematics, is course repetition. In this quantitative study, I aimed to investigate the incidence and impact of developmental mathematics course repetition. Specifically, I aimed to document how experiences with course repetition contributed to students' course taking patterns within and beyond developmental mathematics. Findings indicate that the consequences of experiences with developmental mathematics course repetition are significant and far reaching, influencing longer-term academic outcomes including program retention and degree attainment. The need for further investigation, particularly using qualitative methods to understand how and why observed relationships in a student's mathematics/academic trajectory operate and function, is well supported by the quantitative results of this study.

Keywords: Developmental math, course repetition, STEM students, graduation rates

While developmental mathematics (DM) education aims to resolve preparatory disparities and provide a path for degree attainment, research has consistently documented poor academic outcomes among DM students at both two- and four-year institutions (Bahr, 2010; 2012). Short-term outcomes include high rates of course failure and sequence attrition, while longer-term outcomes include longer times to and lower rates of degree attainment (Bailey et al., 2010; Chen, 2016; Fong et al., 2015). Furthermore, despite consistent empirical (e.g., Bailey et al., 2010; Bahr, 2012) and anecdotal (e.g., from instructor practitioners) evidence that DM courses suffer from high rates of failure, the significance and influence of DM course repetition[1] on these outcomes is unaccounted for in the extant DM education literature. In this study, the term *contextual force* refers to a phenomenon that is, in some way, inherent to the learning context, and that indirectly, though importantly, shapes the learning context. Given the high rate of failure documented in DM courses, experiences with course repetition are inherently a part of the DM educational experience. As such, this study asserts that DM course repetition is a contextual force that influences DM education and its outcomes by its direct impact on students and their learning experience.

Literature Review

In Bahr and colleagues' (2017) mapping of students' STEM course taking pathways, reported course outcomes (e.g., pass rate, failure rate, STEM pathway attrition, etc.) only concerned students' performance in their first attempt of a course, explicitly excluding students' performance during subsequent course attempts from analysis and reporting. According to Bicak and colleagues (2023), though more documented in K–12 education research, the rates and implications of course repetition are not well-explored in postsecondary education research. In

[1] *Developmental mathematics course repetition* is defined in this study as the enrollment in a course previously taken because the prior enrollment ended with a failing final grade, withdrawal from the course, or a final grade lower than what is needed to advance to the next course in the sequence.

particular, much of the research investigating DM education is anchored at two-year postsecondary institutions, meaning there is a need for DM education research conducted at four-year postsecondary institutions. Furthermore, while there is significant concern among developmental mathematics researchers regarding DM sequence attrition and completion, few, if any studies, have endeavored to conceptualize or understand the factors (including their functioning and underlying mechanisms) that contribute to attrition or completion. For instance, Bahr (2008) found that the likelihood of successful remediation–operationalized as passing college-level coursework–is inversely related to level of placement, or "depth of remedial need" (p. 444): The lower a student's placement, the lower the likelihood of the student passing college-level coursework. When discussing this finding, Bahr acknowledged that "the mechanisms that underlie the relationships between depth of remedial need and successful remediation are, as of yet unclear" (Bahr, 2008, p. 444). This underscores that the lack of a fundamental understanding of factors that contribute to observed outcomes relating to sequence attrition or completion inhibit the advancement of DM research.

To address this gap in knowledge, this study seeks to answer the following questions:

1. What are the rates and patterns of developmental mathematics course repetition?
    a. What are the mathematics course taking trajectories and longer-term academic outcomes of students who experience developmental mathematics course repetition?

Research question 1a is motivated by Hodara's (2019) finding that DM students are less likely to retain their STEM major than their non-developmental peers. While this finding was not discussed further, program retention is likely related to DM sequence attrition, given the findings regarding gatekeeper course enrollment and completion. As such, this study seeks to investigate how DM course repetition impacts program retention and graduation.

Methods

Data Collection

Data collection occurred at Temple University— a large, four-year, public research university in a large city on the East Coast. I obtained longitudinal student data from the Temple's Office of Institutional Research and Assessment for developmental mathematics course enrollees who entered Temple between the 2013-2014 (13-14) and 2023-2024 (23-24) academic years. The data set included course and program enrollment data, as well as graduation information. Data cleaning yielded an analytic sample of 14,942 students whose enrollment (e.g., campus of enrollment) and academic records (e.g., DM coursework was taken either in-person or virtually during the pandemic) met certain criteria, which ensured uniformity aligned with the scope of this study's investigation. I used subsets of this analytic sample for more precise analyses, which are discussed below.

The Temple mathematics department currently offers three algebra-focused courses—MATH 0701, 0702, and 1021—and one co-requisite laboratory course—MATH 1019—associated with the highest-level algebra course, MATH 1021. That said, given the purpose and functioning of DM education at Temple University—particularly the prior changes to MATH 0701 and the more recent addition of MATH 1019—MATH 0702 Intermediate Algebra and MATH 1021 College Algebra are the DM courses of primary interest in this analysis. Furthermore, this study is interested in the academic trajectory of DM students and their engagement with advanced/college-level mathematics courses, specifically the calculus sequence, which at Temple involves four calculus courses starting with Precalculus. Relatedly, I examined how and when DM students' program of enrollment shifted, if at all, during or after their DM coursework.

In particular, I was interested in DM students who enrolled in a STEM or STEM-adjacent program, referred to as *STEM (adjacent) programs* (e.g., Music Technology or Secondary Education), at some point in their time at Temple because calculus coursework is a requirement only for certain STEM (adjacent) programs.

Data Analysis

To answer research question 1 pertaining to rates and patterns associated with DM course repetition, I established enrollment trends, including most frequent DM course sequences, by analyzing the analytic sample of 14,942 DM students. I then analyzed a more uniform subset of DM students (n=10,482) to establish rates and frequencies of DM course repetition. Chen (2016) found high rates of continued enrollment among remedial students 6 years after initial enrollment, suggesting these students might take longer to complete their degree. As such, to answer research question 1a pertaining to the longer-term academic outcomes of DM students, I analyzed the 5,765 students who enrolled at Temple between the 13-14 and 18-19 academic years because their academic records span at least 6 academic years (Figure 1).

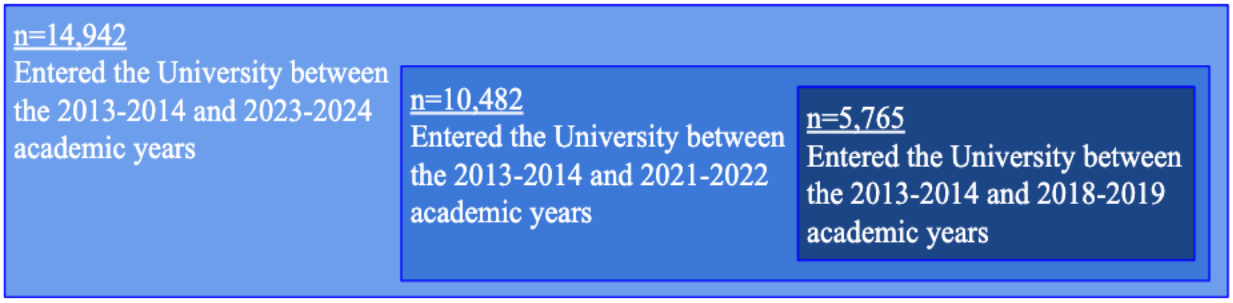

Figure 1. Analytic Samples

Results

Of the 14,942 developmental mathematics students of interest with initial enrollment data (n=14,279), 90.15% took their first DM course during their first year of enrollment, 97.76% within their first two years of enrollment, and 99.36% within their first three years of enrollment. 9,958 students enrolled in 1 DM course, 4,679 students enrolled in 2 DM courses, 302 students enrolled in 3 DM courses, and 3 students enrolled 4 DM courses. 14,932 students enrolled in course sequences of interest (Figure 2); The exclusions involved anomalous course sequences and too few enrolled students for analysis. 25.14% of DM students had to repeat at least one (and up to three) of their DM courses and 20.71% (n=778) of DM repeaters had to repeat one of their DM courses more than once. For instance, a student could take 3 DM courses, repeat two of those courses one time each, and have a DM sequence length[2] of 5 (referred to as a *singular repeater* or *repetition*), or a student could take 1 DM course, repeat the course four times, and have a DM sequence length of 5 (referred to as a *multiple repeater* or *repetition*). Thus, while singular repeaters have longer DM course sequences because of one course repetition per repeated course, multiple repeaters have longer DM course sequences because they repeated a course(s) multiple times. Such instances of multiple repetitions are highlighted in orange in Table 1, which summarizes DM sequence length according to how many DM courses students enrolled in and had to repeat.

[2] *DM sequence length* refers to a student's total number of DM course enrollments during their time at Temple.

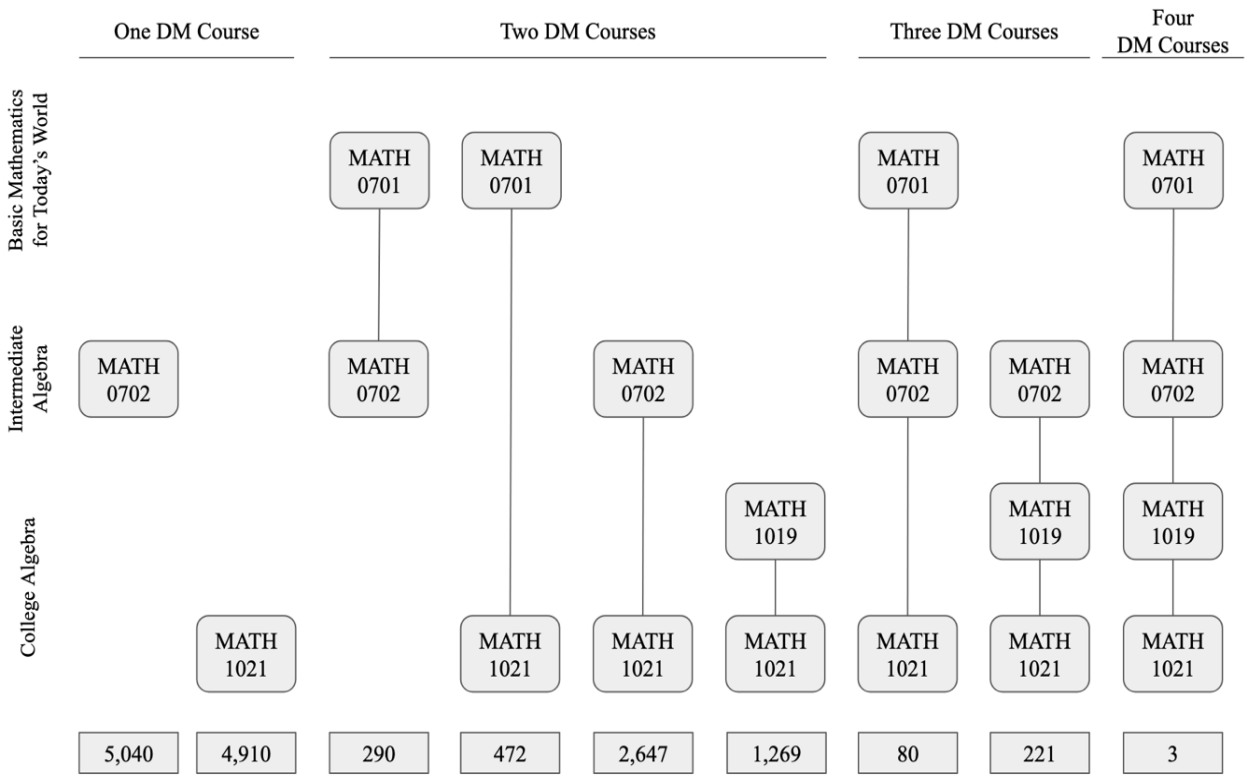

Figure 2. Most Frequent Developmental Mathematics Course Taking Patterns

Table 1. Developmental Mathematics Course Enrollments

Number of Enrolled DM Courses	Number of DM Courses Repeated	DM Sequence Length								**Total**
		1	2	3	4	5	6	7	8	
1	0	7,818	0	0	0	0	0	0	0	**7,818**
1	1	0	1,759	371	9	1	0	0	0	**2,140**
2	0	0	3,251	0	0	0	0	0	0	**3,251**
2	1	0	0	911	246	7	0	0	0	**1,164**
2	2	0	0	0	180	68	16	0	0	**264**

3	2	0	0	0	0	42	14	4	0	**60**
3	3	0	0	0	0	0	9	1	1	**11**
4	0	0	0	0	2	0	0	0	0	**2**
4	1	0	0	0	0	1	0	0	0	**1**
	Total	**7,818**	**5,010**	**1,397**	**513**	**159**	**39**	**5**	**1**	**14,942**

Of the more uniform subset of 10,482 DM students and across all their DM enrollments, 742 students withdrew from at least one of their DM courses, 2,510 students failed at least one of their DM courses, and 326 students experienced both at least one DM course withdrawal and at least one DM course failure. 34.05% of students who experienced both DM course withdrawal

and failure experienced more than one withdrawal and/or failure. Table 2 summarizes the passing rates in MATH 0702 and 1021 based on enrollment attempt. 16.83% of MATH 0702 students (n=5,756) repeated the course at least once and 20.84% of MATH 1021 students (n=6,709) repeated the course at least once. Of the 1,985 students who took both MATH 0702 and 1021, while the rate of MATH 1021 repetition among students with no repetitions of MATH 0702 was 21.91%, the rate of MATH 1021 repetition among students with at least one repetition of MATH 0702 was 45.69%. Of students' final DM course enrollment, 78.63% of students passed, 14.44% failed, and 6.36% withdrew from their final DM enrollment.

Table 2. Final Course Grade by Course and Attempt

	MATH 0702			MATH 1021		
	1st Attempt (n=5,756)	2nd Attempt (n=969)	3rd Attempt (n=146)	1st Attempt (n=6,709)	2nd Attempt (n=1,398)	3rd Attempt (n=271)
Pass [a]	69.96%	57.07%	50.00%	70.52%	63.16%	69.37%
Fail [b]	20.64%	30.65%	34.93%	22.58%	29.83%	25.46%
Withdraw	8.60%	11.87%	13.01%	6.68%	6.44%	4.43%

Note: Course attempts were included if enrollment was greater than 100. [a] Pass = A to C-. [b] Fail = D+ to F.

Of the 5,765 DM students who enrolled Temple between the 13-14 and 18-19 academic years, 3,023 were enrolled in a STEM (adjacent) program during their last DM course enrollment. Additionally, 1,933 of the 13-14 to 18-19 entering students enrolled in at least one calculus sequence course—referred to as *DM-to-calculus enrollees*—following their last DM course enrollment. While 57.07% of STEM (adjacent) students who did not experience DM course repetition became DM-to-calculus enrollees, lower rates of DM singular repeaters and DM multiple repeaters became DM-to-calculus enrollees—27.05% and 23.58%, respectively; Table 3 summarizes the final course grade of DM-to-calculus students' first calculus sequence course differentiated by the extent of repetition in DM coursework. 83.29% (n=1,610) of DM-to-calculus enrollees were enrolled in a STEM (adjacent) program during their last DM course enrollment and 65.09% (n=1,048) of these DM-to-calculus enrollees retained their STEM (adjacent) program enrollment throughout their time at Temple.

Table 3. Final Grade in First Calculus Course Following DM Course Sequence

	No Repetitions (n=2,842)	Singular Repetitions (n=504)	Multiple Repetitions (n=85)
Pass	58.09%	26.79%	14.12%
Fail	28.36%	46.03%	57.65%
Withdraw	12.91%	26.39%	28.24%

Of the 13-14 to 18-19 entering students, 3,804 (65.98%) graduated. The graduation rate among students who repeated 0, 1, or 2 DM courses was 68.12%, 58.97%, and 57.35%, respectively. Table 4 summarizes overall graduation rate by extent of DM repetition and further differentiates graduation rates by time to degree attainment. Of the 1,889 graduates who began their DM coursework enrolled in a STEM (adjacent) program, 47.70% graduated with a STEM (adjacent) degree, which suggests that the rate of STEM (adjacent) program attrition amongst graduates is more than 50%. The students who retained and graduated with a STEM (adjacent)

degree account for 81.54% of students who graduated with a STEM (adjacent) degree, suggesting that relatively few students transfer into STEM (adjacent) programs from non-STEM (adjacent) programs; The STEM (adjacent) program retention rate amongst non-graduates (n=1,189) was 74.10%. The rate of STEM (adjacent) program retention from initial enrollment through graduation varied based on experience with DM course repetition: While the program retention rate was 51.48% among students who did not repeat a DM course, the program retention rate among singular and multiple repeaters was 34.57% and 36.59%, respectively.

Table 4. Graduation Rate and Time to Degree Completion

		Years to Degree Completion				
	Graduation Rate	<4	4	5	6	6+
No Course Repetitions	68.12%	7.29%	57.47%	26.57%	6.69%	1.99%
Singular Repetitions	60.26%	4.43%	42.29%	38.63%	11.45%	3.21%
Multiple Repetitions	52.85%	3.08%	27.69%	41.54%	20.00%	7.69%

Discussion and Conclusion

In working to investigate the rates, trends, and long-term impacts of course repetition in developmental mathematics education, it became quickly evident that the consequences of repetition are numerous and cumulative. Analyses reveal that more than a third of students receive a non-passing final grade at some point in their DM coursework and that more than a fifth of students receive a non-passing grade in their last DM course. Furthermore, while prior research has documented the high failure rates of DM courses (e.g., Bahr, 2012), this study's analyses reveal that DM courses' passing rates decline across enrollment attempts. Taken together, these findings highlight the precarious pathway DM students must traverse to pass or advance further than their DM coursework.

It is clear from this study's results that the impact of DM course repetition extends beyond a student's DM coursework. In particular, the extent of a student's experience with DM course repetition appears to impact further mathematics persistence and performance. While these quantitative analyses do not and cannot provide much insight into how the former finding functions, it is nevertheless a meaningful finding that should motivate future efforts to reduce DM sequence and STEM (adjacent) program attrition. The latter finding that first-calculus course passing rates decrease with experiences with DM course repetition suggests that the efficacy of DM education wanes as students repeat courses. Experience with DM course repetition also appears to impact timely degree attainment, which is a reasonable finding given that multiple repetitions can double or even triple the length of a student's DM course sequence relative to the number of DM courses in which they enroll (e.g., taking 2 DM courses, repeating both twice, and having a DM course sequence length of 6). Furthermore, the findings regarding STEM (adjacent) program attrition and retention through degree attainment—that program retention is low, yet the rate of students transferring into STEM (adjacent) programs is seemingly lower—suggest that addressing the high incidence of DM course repetition could be an effective means of increasing STEM (adjacent) program retention, since there is evidence that DM course repetition is related to post-DM persistence. Specifically, by conducting this study at Temple—a STEM-focused, research institution, where DM coursework is a remedial prerequisite for more advanced mathematics coursework—this study not only contributes to the growing body of DM

education research conducted at four-year institutions, but it also provides insight into how DM education relates to and impacts STEM (adjacent) trajectories.

Implications, Limitations, and Next Steps

This study's findings underscore the significant financial, opportunity, and psychic costs incurred by students when they encounter this common, yet not well-understood, experience within DM education. Specifically, extended course sequences cost students time and money in pursuing their program, degree, and career path. Furthermore, considering the tenuous—though well-studied—relationship students have with mathematics, it is important to consider how students experiencing DM course repetition perceive their learning experience and potential. Thus, a major limitation of this study is that its quantitative methodology provides little insight into how the academic, mental, and tangible costs interact to compound the consequences of DM course repetition. Additionally, unexpected quantitative results made it difficult to conduct certain analyses. For instance, students' course sequences were occasionally regressive (e.g., taking MATH 1021 and then later taking MATH 0701), or students sometimes advanced to higher-level DM courses without having passed the prior prerequisite course. Taken together, this study's findings strongly warrant qualitative investigations of students' experiences with course repetition to understand how and why observed trends and quantitatively inexplicable patterns occur. Furthermore, narrative reflections from DM students who have experienced course repetition could help inform instructional practice, as well. For instance, understanding students' perspectives on their repeated DM course enrollments, both cognitively and affectively, could help instructors differentiate their lessons. Thus, exploring DM course repetition qualitatively will support the investigation of this phenomenon as a contextual force that influences the DM educational environment via its impact on DM students' and their learning experience.

A Learning Trajectory for Area Under a Rate Graph

Samuel Brienen
University of Idaho

Robert Ely
University of Idaho

Amy Ellis
University of Georgia

We made a short sequence of interactive tasks in which a student must estimate the total amount of water in a pool, given the water rate (gals/min) at a handful of moments. Through working on these tasks in a small teaching experiment, an undergraduate who had not seen calculus learned to conceptualize the area under a linearly increasing water rate graph as representing the total accumulated volume of water. From this we developed a learning trajectory, highlighting requisite and developing concepts, actions, and teacher-researcher interactions that were key to his learning. His learning trajectory, which entailed imagery of lower and upper Riemann sums, reveals ways to learn key calculus concepts while maintaining the relationship between rate and amount quantities as a central, rather than an easily jettisoned, part of students' understanding of 'area under a curve'.

Keywords: Calculus, Rate of change, Definite Integral, Accumulation

One of the two main questions of calculus can be summarized as the following: "you know how fast a quantity is changing and you want to know how much of it there is" (Thompson et al., 2013, p. 125). Equipping students to conceptualize the accumulation of an amount of a quantity given its varying rate of change has long been discussed as a significant challenge in the teaching and learning of calculus (e.g., Thompson, 1994). In the U.S., students typically emerge from a standard single-variable calculus class quite able to interpret a definite integral as a gestalt area "under" a curve, but in many cases, they struggle to attribute quantitative meaning to it in a context, and often cannot interpret it as a sum (e.g., Fisher, Samuels, & Wangberg, 2016; Jones, 2015; Sealey & Oehrtman, 2005; Wagner 2016). One recommendation for addressing this issue has been to teach the accumulation of an amount with minimal emphasis on 'area under a curve' (e.g., Thompson et al., 2013). Yet areas under curves are also powerful representations for accumulated amounts, and they can reveal important characteristics about how these amounts relate to their rates of change. Our broader goal is to study how to build a student's understanding of an accumulated amount as an area under a curve *through* leveraging their quantitative reasoning in a context. Our hope is that the relationship between rate quantities and amount quantities can thus become a central, rather than an easily discarded, element of their understanding of 'area under a curve'.

In this paper we develop a short learning trajectory of an important piece of this broader understanding, by conducting a short teaching experiment with a college algebra student who had not taken calculus. We chart out how he learned to interpret the area under a *linear* rate graph (flow of water in gals/min) as representing a total accumulated amount (of water in gallons), by engaging with a sequence of interactive tasks. In so doing he developed a method akin to lower and upper Riemann sums. We believe the linear rate graph case is a pivotal one from which a student could generalize this area-represents-amount idea to more general types of rate curves, while staying grounded in quantitative meanings of accumulation and rate.

Background and Theoretical Framing

Accumulating Amounts From Their Rates of Change

Much of the recent research about the teaching and learning of definite integrals focuses on how students learn to interpret integral notation in quantitative contexts (e.g., Greefrath, et al., 2021; articles in *ZDM* special issue: Ely & Jones, 2023). In some approaches to developing quantitatively-grounded interpretations of integrals, such as multiplicatively-based summation (Jones, 2015) and accumulation-from-rate (Thompson, et al., 2013), the integrand—i.e., the "$f(x)$" in $\int_a^b f(x)dx$—is always interpreted as a *rate*. Specifically, $f(x)$ is the rate at which some amount F changes as x changes, and the definite integral measures how much F accumulates over the interval (a, b). For a student using such an interpretation to imagine an integral in terms of area, the area is always then an amount accumulated under a rate graph (e.g., a graph of $y = f(x)$). Thus it is valuable to study how a learner could develop the idea that the area under a rate graph represents an accumulated amount, even independently of any definite integral notation.

Learning Trajectories

Researchers have defined and theorized learning trajectories in a variety of ways. Simon (1995) introduced the construct of a hypothetical learning trajectory as the learning goal, activities, and thinking in which students engage, and Clements and Sarama (2012) depicted it as a conjectured route through a set of tasks designed to engender the mental actions to support a developmental progression of understanding. For the purposes of this study, we follow Ellis et al.'s (2014) characterization of a learning trajectory as a tool that seeks to explain learning over time, in particular, "an account of changes in students' schemes and operations" (p. 2). This follows with Steffe and Olive's (2010) view that a learning trajectory is ultimately a type of model observers construct of a learner's knowledge. Ellis et al. treat a learning trajectory as including a sequence of *conceptual stages* that can account for a learner's observed activity. Each stage is characterized by the *concepts* or understandings that an epistemic student uses at particular moments of their activity (Ellis, 2022). Also included is the context of the student's activity, such as the *tasks* they performed, the *actions and representations* they reasoned with while doing so, their *interactions* with others, and the *teaching actions* that supported their shifts from one stage to the next. In particular, a learning trajectory seeks to account for how specific contextual elements mediated or facilitated the learner's conceptual changes. The learning trajectory distills the student's whole observed activity and its context into the parts that are key for accounting for how they learned.

Methods

We recruited four undergraduate students at a medium-sized university in the Northwest U.S. to work on a calculus-related activity. They were chosen because they were interested and available, and because they were currently enrolled in college algebra and had not taken calculus. We conducted one 2-hour teaching experiment session with each pair. This paper's results are from one of these pairs. One participant had to leave after 15 minutes, so our results are from the other participant, 'Ian' (pseudonym). Participants worked on a sequence of pool-filling tasks on an iPad. The main teacher-researcher, TR1, asked questions along the way to elicit explanations for their actions and comments, but did not explain concepts or help the participants solve the tasks. A second teacher-researcher, TR2, was present for the first part of both sessions also. Participants also used scratch paper, writing implements, calculators, and a large whiteboard.

The sequence of tasks was programmed using Desmos Classroom. Each task had a similar format and layout [Figure 1], including: (a) an animated video of a swimming pool being filled

with water, (b) a table displaying a sample of the water rates (gals/min) at a few moments in time, and (c) a graph of the water rate for the time shown in the animation video. The video had labels showing the rate at which the pool was being filled and the volume in the pool in real time. The number of values shown in the table could be changed.

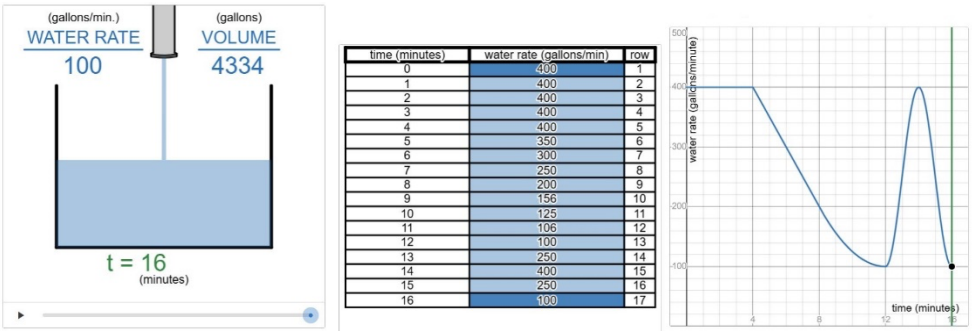

Figure 1. Pool activity, Task 0 (Orientation task): (a) pool animation, (b) rate table, and (c) rate graph

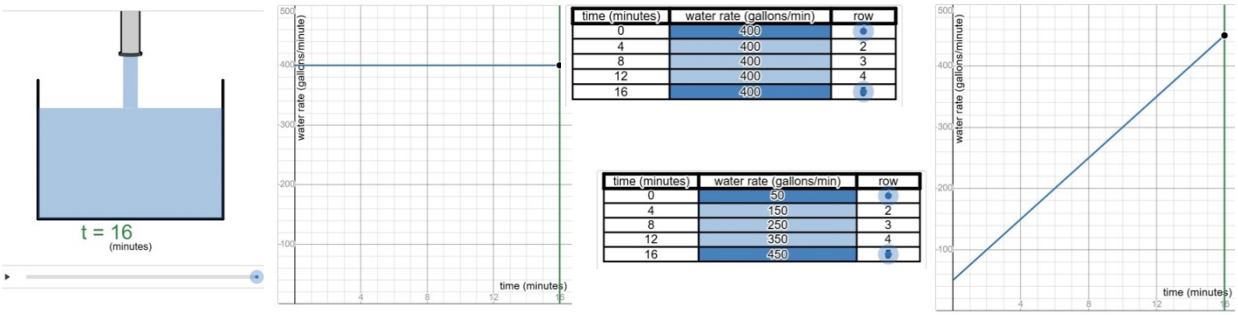

Figure 2. Pool activity, (a) animation, (b) Task 1 table, (c) Task 1 graph, (d) Task 2 table, (e) Task 2 graph

The introductory Task 0 was meant to quickly orient participants to the tools and displays. They were told that the water rate is fluctuating and that the values in the table are as if a picture was being taken of the water rate value at certain moments in time. For Tasks 1 and 2, participants had to extrapolate from just the video and the table the amount of water in the pool at the end of the video ($t = 16$). The water rate and volume readouts, as well as the water rate graph, began as hidden; these were revealed after six guesses or after one relatively close guess. Participants had unlimited guesses and were given general feedback about the accuracy (e.g., "really far below the actual amount"). In Task 1, the water rate was a constant 400 gals/min [Figure 2abc]. In Task 2 the water rate linearly increased from 50 to 450 gals/min [Figure 2ade].

Both sessions were video-recorded, screen-recorded, and transcribed. To analyze the data, we leveraged ongoing and retrospective analysis methods (Steffe & Thompson, 2000) to characterize Ian's changing concepts throughout their sessions. Prior to collecting any data, we formulated a learning goal: the concept that the area under the graph of a rate function measures a total accumulated amount. We developed a hypothetical learning trajectory based on extant research, and modified the tasks. Based on time constraints we narrowed the learning goal to just the area concept for the case of a linearly increasing rate graph, rather than any general rate graph. The hypothetical learning trajectory then served as a source of initial codes for identifying the participants' concepts; we determined as a group whether Ian's task responses provided evidence of a concept from the hypothetical learning trajectory. This initial round of coding also produced emergent codes (Strauss & Corbin, 1990), which we incorporated into a revised

learning trajectory for Ian. Given the challenge of understanding and characterizing a student's mental images, we triangulated evidence from multiple sources to infer Ian's thinking, including his written work, utterances, nonverbal gestures, and shifts in his problem-solving approaches. We then examined the interactions between Ian and the TRs, within the context of the task structure, to identify supports for Ian's emerging concepts.

Results

In this section we summarize Ian's activity and his interactions with the teacher-researchers on Tasks 1 and 2. We analyze the concepts, actions, and attention-directing interactions that we found to be key in his learning of the target concept: *The area under the rate graph measures the total accumulation* of, in this case, the volume of water. We identify two of these concepts that Ian already knew and were requisite to his successful learning through the tasks.

Task 1

When Ian began working on Task 1, he saw that the rate 400 appeared in the table five times, so he calculated the total amount of water to be 5×400 = 2000 gals. He was perplexed when the program told him this answer was 'really far below' the actual amount, and he played back and explored the animation. The TRs then directed his attention to the quantities in the table. TR1 said, "the second column gives the water rate," and Ian replied, "I see, okay." TR2 asked, "In what units?" Then Ian responded, "so we just multiply 400 times 16?" When inputted, the program confirmed this to be 'exactly right.' From that moment on, Ian consistently distinguished rates from amounts and attended to which of these he was representing when graphing or calculating. The primary role of Task 1 was not to enable Ian to significantly develop new concepts, but to invoke his understandings of rate (gals/min) in the context at hand. In particular we note a key concept and the intervention that elicited it in the pool context:

- Key (requisite) concept: *A constant rate times a duration of time gives a total amount accumulated over that time interval.*
- A key attention-directing intervention: TRs pointing out the quantity type, and units, of the outputs in the (rate) table.

Task 2

Developing and graphing an underestimate (lower staircase). In Task 2, the water rate linearly increases over the 16 seconds. Initially the table shows the water rate values at every 4 minutes [Figure 2ad], and the graph is not visible. Ian used these values to estimate the total amount of water as 50(4) + 150(4) + 250(4) + 350(4) = 3200 gals. He pointed out to TR1 that he did not need to use the last value on the table (450 gal/min when $t = 16$). The feedback from the program was that this was 'pretty far below' the actual amount of water. Ian said, "I was thinking just like steps from the way it appears," and sketched Figure 3a on paper.

At this point, Ian did several things that, in our analysis, were not crucial to the learning trajectory. He tried several ways to compensate for the lacking amount, trying to incorporate the final rate value 450 (at $t = 16$) somehow in the calculation. He made the program generate more rate values for smaller increments of time and noticed that he could do the same type of calculation. He said that "the more [steps] you have, the more accurate it is"—a valuable insight, but not key in his learning trajectory. He did use these values eventually to find an equation for the rate curve, initially trying a quadratic curve but ending up with the correct linear formula. He did not use the formula however, and after trying another several estimates, the program told him

the actual correct amount (4000 gals) and revealed the actual rate graph. This did not seem to surprise him, since he had already figured out the equation of that curve and knew it to be linear.

TR1 decided it would be beneficial to have as a referent on the whiteboard a large graph akin to what Ian sketched on his paper [Figure 3a]. He drew and labelled axes [Figure 3b] and asked Ian to draw a graph of his stairs and asked him how many he wanted to use. Ian said, "there's a number that's quite accurate while still not being massive." He drew his graph with four stairs [Figure 3c], and said, "the staircase I was kind've thinking would look something like that." Ian immediately added, "you just kind've imagine having either a line like that [straight line in Figure 3d] or in between the stairs that averages it [new line in Figure 3e]."

Figure 3a-e. A sequence of rate-vs-time graphs produced by Ian on Task 2.

These actions provided Ian with representations that were crucial to reason with. Ian's ability to represent and interpret his graph indicates that he already had the following complex understanding, and the following key actions enabled him to employ for Task 2:

- Key (requisite) concept: *A rate graph is a continuous record of how a quantity's rate of change varied over time, and each point on it is a multiplicative object* (Saldanha & Thompson, 1998) *representing the rate of flow of water at that moment in time.*
- Key actions: (a) estimating the total amount using constant rates over sub-intervals, and (b) graphing the corresponding (under-)estimating rate function as a 'lower staircase' on the same graph as the actual rate function [Figure 3d].

We briefly note that the other pair of participants we studied were unable to complete Task 2 because they could not consistently employ this concept.

Interpreting the rate graph between under- and over-estimate staircases. Ian noted that his 'lower staircase' underestimates the actual amount of water, and then he drew an 'upper staircase' [Figure 4a] overestimating the actual amount by, as he said, putting the excess "growth" at the beginning rather than at the end of the interval. He added, "This volume [tracing the larger rectangular path we have marked in Figure 4b with a solid line] is bigger than this volume [tracing the smaller rectangular path we have marked in Figure 4b with a dashed line]." Here Ian had begun to use the following new concept:

- Key (new) concept: *The area of a rectangular region under a constant rate graph* (where the rate is in gal/min) *measures a volume* (in gal).

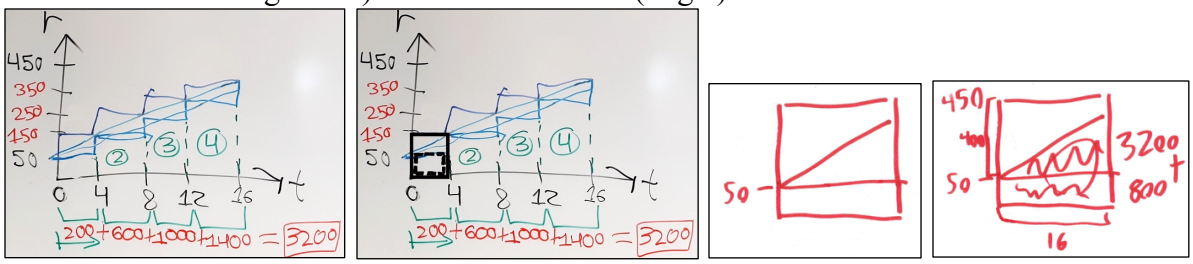

Figure 4a-d. Rate graphs and diagrams Ian used when reasoning with areas on Task 2.

Looking at the graph [Figure 4a], Ian then said there is something between the two staircases that was "more accurate, I guess, to the growth." TR1 asked where in between, and Ian replied,

"exactly in between, right?" Although he didn't say it at that moment, later Ian confirmed that this was when he strongly suspected the actual amount would be exactly halfway between his over- and under-estimates, once he saw the graph that displayed all three together (Figure 4a).

Ian then calculated that "exactly in-between" value. He determined the over-estimate amount from the upper staircase (4800), found the difference between that and the lower staircase underestimate to be 1600, took half of that (800), and added this to under-estimate. He got 4000, and since he already knew this to be the exact actual amount, he said, "Okay, so that method does work." His calculation, confirmed that the together with the earlier empirical correct answer feedback from the program, confirmed his geometrical inference from the graph.

When asked why, Ian explained by appealing to the geometry of how the rate graph cut in half the regions between the two staircases: "If you just draw any rectangle and have a triangle in it, it's half. So, I just thought since all of those are squares, it's just half. So, I just tried finding what half would be for that." Here Ian used the following new concept, which was enabled by the following key action:

- Key (new) concept: *The areas between the lower and upper staircases represent the difference in volume between the under- and over-estimates*.
- Key action: Generating the upper staircase overestimate on the same graph as the lower staircase and the actual linearly increasing rate graph.

Area under a linear rate graph. We interpret that Ian's combination of realizations enabled the following type of reasoning. Seeing that the actual volume is exactly halfway between the under- and over-estimates, and also that the region under the actual rate graph exactly splits the difference between the regions under the two staircases, together with his recent concept that the area in a rectangular region represents a volume, Ian was able to infer the following:

- Key (target) concept: *The area under the linear rate graph represents the actual exact water volume*.

This was confirmed by Ian's subsequent activity. TR1 asked if his idea allowed him to use a simpler way to find a volume just by considering the (rate) graph. Ian said, "If it's a straight line then yes," and he drew a simplified geometric diagram with just one large triangle atop a rectangle of width 16 [Figure 4c]. But then he said "No, that's wrong. I'm thinking of it as, that's rate of growth, not that it starts at 50 filled up already. Never mind. Discount that idea." This comment suggests that he was thinking through which aspects of his diagram represented amounts and which represented rates. With TR1's encouragement, Ian continued his geometric calculation [Figure 4d], getting the same answer of 4000 (referred to without units). He said, "that's interesting that it's as simple as that." "That you can just calculate the area and find the… Yeah. Right. Huh. That's pretty neat." This was an empirical confirmation for Ian of his new concept. The fact that he calculated the area of the entire trapezoidal region on its own indicates that he viewed the region as an object whose area measures the water amount, rather than just as a representational tool that suggests how to calculate that amount.

Role of Task 2 elements in Ian's learning trajectory. We have already described the role some key actions and interventions had in Ian's learning trajectory. We also noticed the role that several features of Task 2 had in this trajectory. Task 2 initially provided Ian only with the pool video and the table of linearly changing rate values, and not a rate graph. It required Ian to estimate an amount value, then gave him feedback about that value, and it let him do this six times before revealing the actual volume value and the rate graph. The limited information in the initial table afforded Ian's development of an underestimate of the true amount, since those values naturally appear as 'steps' in the table. The task led Ian to change the number of values in

the table, which allowed him to develop more accurate estimates of the rate. The delayed revelation of the actual water amount was important, because it gave him an amount value that he used to empirically confirm his developing concepts about areas as amounts. The delayed revelation of the rate graph may have been less important in Ian's case, since he happened to have already figured out the linear function that fit the table data, and he probably could have graphed it on his own if asked. Finally, we conjecture that Task 2's interactive structure in the first place made his staircases fundamentally situated within his active process of estimating the true amount, rather than simply becoming quantitatively untethered geometric objects.

Discussion

Through these interactive pool-filling tasks, Ian learned that the area under the linear rate graph represents the actual exact water volume. In so doing he used his own method of under- and over-estimating an actual accumulated amount by using lower and upper Riemann sums. Although we did not study what further learning was enabled by Ian's new concepts, here we discuss two promising affordances of his concepts. These affordances help justify why this pool filling task sequence could be more beneficial than another slightly more efficient sequence.

After all, to learn the target concept in just the linear rate case, it would likely be quicker for a learner to average out the increasing water rate over the whole interval, imagining that a pool filling constantly at that rate would end up with the same amount. Graphing could show this averaging geometrically, so they could imagine the areas serving as proxies for the amounts. In comparison with that hypothetical route, Ian's learning trajectory positions him much better to generalize his concept in calculus, because he has developed the key imagery used in calculus to conceptualize an integral as a limit of upper and lower Riemann sums.

A second affordance is that, unlike the students in studies we mentioned earlier, Ian's new area-represents-amount concept is conceptually anchored in the quantitative relationship between rates and amounts, and is not just something he noticed empirically about areas of regions. Yet there was an important part of Ian's learning trajectory that was empirical. In Task 2 he was told the actual amount accumulated in the pool. He noticed this value was halfway between his under- and over-estimates, just as the area under the rate graph is exactly halfway between the areas of the lower and upper staircases. Did he just *associate* the area with the amount, or did he develop any sense of necessity about why the area must measure that amount?

It is difficult to say from our data. Nonetheless we wonder exactly how much necessity is readily available for any learner in the process of constructing the area-represents-amount concept, through any learning trajectory. For instance, another path might allow a learner to more explicitly reason with 'canceling' units: gals/min × min = gals. But does that carry much more sense of necessity for them? Izsák (2025) proposes an approach that grounds quantitative area reasoning with integrals in a particular measurement interpretation of multiplication. This makes the units canceling feel much less like a magic trick, yet in that approach there is still fundamentally an association made between a unit square and a unit of the accumulating quantity (e.g., volume). With this in mind, our study highlights a question for further study: Is some degree of empirical association unavoidable when initially learning the concept that areas under rate graphs represent accumulated amounts? Is the concept's security based on how the learner experiences these areas as increasingly reliable tools for interpreting amounts?

GTA Perceptions of Precalculus Students' Graphing via Covariational Reasoning

Irma E. Stevens
University of Rhode Island

The success of any educational change requires the support of instructors, and at the introductory undergraduate mathematics level, up to 30% of those courses are taught by graduate teaching assistants (GTAs). Research has shown the prevalence and importance of covariational reasoning at the precalculus/calculus level, and this study examines how GTAs interpret and respond to students' attempts at graphing via covariational reasoning. Through engaging in a version of Carlson et al.'s (2002) Bottle Problem, and then watching and responding to two precalculus students' video responses to the problem, 11 GTAs had the opportunity to express their teacher decision making around student thinking. I analyzed their responses using Herbst et al.'s (2023) categories of perception teachers use when considering framed student contributions: normativity, serviceability, and responsiveness. The results indicate that GTAs primarily focus on serviceable and non-normative aspects of students' work. I detail these results and discuss implications for GTA training.

Keywords: GTA training, covariational reasoning, instructor decision making

Graduate Teaching Assistants (GTAs) are often each responsible for teaching hundreds of undergraduate students over the course of their graduate program, particularly in introductory level courses. Building programs and compiling resources support these instructors, but understanding how these GTAs think about and respond to their students' thinking is both a critical and needed component to ensure that these resources meet GTAs' needs. In this study, I focus on GTA's perceptions of undergraduate precalculus students' work on a graphing task – an adaptation of Carlson et al.'s (2002) *Bottle Problem*. GTAs received student work with both quantitative and nonquantitative attempts at covariational reasoning. I analyzed 11 GTAs' responses to the work using Herbst et al.'s (2023) categories of perception, a framework enabling a focus on GTA's attention to the normativity, serviceability, and responsiveness of the student work. Analysis was guided by the research question: What do GTAs perceive in undergraduate precalculus students' work on a task aimed to support graphing via covariational reasoning?

Literature Review & Theoretical Frameworks

In this section, I discuss literature linking covariational reasoning and graphing, literature linking instructional noticing and decision making, and I describe the state of GTA training in the U.S. The first two include descriptions of the theoretical frameworks used in this study: covariational reasoning (Carlson et al., 2002) and categories of perception (Herbst et al., 2023).

Covariational Reasoning and Graphing

Covariational reasoning – reasoning how two quantities change together – is a construct built from research on students' quantitative reasoning – reasoning about and operations with measurable attributes (Carlson et al., 2002; Thompson & Carlson, 2017). Researchers have demonstrated the importance of students' covariational reasoning to support productive meanings for a variety of topics in K-12 and beyond. Relevant to this study its importance in precalculus meanings for rate of change relevant to graphing linear, quadratic, and exponential functions (e.g., Ellis et al., 2015; Johnson, 2015; Moore, 2014; Tasova, 2021; Yu, 2022).

The *Bottle Problem* (Carlson et al., 2002), in particular, was the impetus for a covariational reasoning framework; it involved students reasoning about the relationship between the height and volume of water in a spherical bottle as water was being poured into it. Their study distinguished students' mental actions based on how students described quantities changing. For example, *directional covariational reasoning* involves students describing one quantity's values increasing/decreasing/staying constant as another quantity's values are increasing/decreasing, and *amounts of change covariational reasoning* involves students describing changes in a quantity's values as increasing/decreasing/staying constant as another quantity's values changes by equal amounts. Students can use graphs to represent these relationships and use covariational reasoning to justify their graph by attending to (changes in) quantities' magnitudes. For example, for a linear relationship, students can justify a Cartesian graph of a straight line as representing a linear relationship between quantities by highlighting equal magnitude changes in one quantity and identifying corresponding equal magnitude changes in the second quantity.

As researchers have attended to students' covariational reasoning with graphs, they have uncovered just how difficult this reasoning can be. For example, students may struggle to conceptualize changing quantities as varying *smoothly*, reasoning instead with *chunks* (Castillo-Garsow, 2013). Reasoning with *chunks* can lead to attempts at *amounts of change* covariational reasoning that consider intervals of change that are too big (e.g., the relationship between quantities may shift from an increasing to a decreasing rate of change within the chosen interval) (e.g., Stevens et al., 2023). Students may also have meanings for graphs that make it impossible for them to represent dynamic relationships traced out from right-to-left or straight up and down (e.g., the graph would no longer represent a function), even if doing so would appropriately represent the relationship they conceive in their context (Moore et al., 2019).

Research on students' graphing has also identified several non-quantitative ways of reasoning. *Iconic translations* (Monk, 1992) and *thematic associations* (Thompson, 2015), for example, involve students attending to shapes and phenomenon to justify shapes in their graphs. For example, a student might conclude a graph representing a rider going around a Ferris wheel is curved because a Ferris wheel is circular, regardless of the quantities under consideration. Or a student might focus on the phenomenon that a rider traveling at a decreasing speed results in a concave down graph, even if the graph is relating two different distances (rather than distance-time graph). Called pseudo-analytical behavior (Vinner, 1997), these types of reasoning are classified when particular mental actions are indicated without providing adequate evidence they "possessed an understanding that supported that behavior" (Carlson et al., 2002, p. 358).

Altogether, this research indicates a wide variety of students' reasoning with graphs. This study aims to begin researching what GTAs, not researchers, attend to when interpreting some of the same student work that inspired these researchers.

Instructor Noticing & Decision Making

What instructors do with their knowledge of student thinking depends on what instructors notice and what their instruction makes available to be noticed. Several researchers have attended to mathematics teacher noticing (see an overview in Sherin et al., 2011), but in this article, I adopt a framework designed to categorize teachers noticing around student contributions to a problem-based task. Herbst et al. (2023) describe three categories of perception: serviceability, normativity, and responsiveness. These categories, which also rely on the idea of framing, serve as the analysis framework for this study (heretofore SNR framework).

Herbst et al. (2023) used a task-based geometry lesson as the context for their categories' examples. This context is important in determining how the other categories are interpreted. That

is, framing is "the organization of events and individual experiences according to certain principles" (p. 403), and thus identifying an event as "task-based", "geometry", and a "lesson" results in certain expectations. Herbst (2006) has developed the notion of instructional situations to describe how teachers frame students' work on problems (e.g. "construction" and "proof" for Geometry). Thus, if a teacher frames a task-based geometry lesson as involving construction, based on their expectations of what that entails, it presents the teacher with opportunities to anticipate and observe students' actions on the task, and moreover, opportunities to scaffold students' work accordingly. With this lens in mind, the following constructs are the SNR categories of perception available for a teacher to notice student contributions.

Normativity. Based on how a problem has been framed, a student's contribution is deemed as more or less normative based on the extent to which it complies with or breeches what the teacher deems to be appropriate within the frame of an instructional situation. Thus, while a correct solution to a problem would certainly be seen as normative, a student who has an incorrect solution to a "construction" problem but who used construction tools (e.g., a compass) would still have a more normative contribution than a student who sketched a diagram correctly.

Serviceability. Serviceability attends to the extent to which a student's contribution fits within the teacher's instructional goal. For example, a student with a more serviceable solution may not have a complete solution or may have overgeneralized an observation, but they contributed an observation that is relevant to the teacher's instructional goal for the lesson. In contrast, a less serviceable contribution from a student could be one in which a student provided a method to solve a task that is not the same as the method included in the instructional goal.

Responsiveness. Responsiveness attends to the extent to which a student contribution relates to the question asked in the problem. For instance, the aforementioned student who sketched a diagram correctly responded to the question asked, whereas students who change the givens or do not entirely address the question (e.g., are missing components of the solution) would be providing contributions that are less responsive.

As mentioned, Herbst et al. (2023) framework detail these constructs using examples from teachers discussing student contributions for a task-based lesson involving construction in a high school geometry class. A teacher does not necessarily perceive any one of these during a given lesson. In this study, the focus will be on GTAs' perceptions when responding to student contributions of a task-based problem for precalculus students involving covariational reasoning and graphing.

Instructor (GTA) Training

Up to 30% of introductory undergraduate mathematics courses are taught by graduate teaching assistants (GTAs). Over the course of their graduate student career, GTAs may be responsible for instructing hundreds of undergraduate students. Training for these GTAs is often less extensive than traditional K-12 instructor training programs, and moreover, faculty members responsible for developing instructional materials for GTA training often find it challenging to locate instructional materials. Nevertheless, Kung and Speer (2009) have reported that GTA instructors want to place an emphasis on building GTA's skills in probing and using student thinking. Recent efforts by the *Mathematical Association of America* (MAA), such as the *CoMInDS* resource suite and the *Instructional Practices Guide* (Abell et al., 2022) have begun to address the need for instructional materials for college instructor/GTA training. Both also provide insights into how to support understanding and using student thinking in teaching, but more work is needed to understand how GTAs currently think about student thinking and how their classroom context influences their noticing and decision making.

Methods

In this section, I describe the population and context of this study, the process of adapting the *Bottle Problem Task* into a GTA training task, and the analyses I conducted.

Methodology

This study required two phases of data collection: precalculus student responses to the Bottle Problem and GTA responses to those students' responses. First, the *Bottle Problem* was adapted into a task given to 39 students in an Applied Precalculus class at a mid-size university in the Northeast. This task included students submitting video responses to the task. From the 33 students who consented to share their classroom data, we de-identified their videos and created transcripts of each of the students' responses. These responses were collected and analyzed for correctness and level of covariational reasoning. A subset of two student videos and transcripts were then provided a group of 11 graduate students who were enrolled in a one-credit hour seminar on teaching undergraduate mathematics. These 11 graduate students were in their first or second year of teaching, and some of these graduate students either had or were currently teaching different sections of the same Applied Precalculus course. These graduate students submitted their own video responses to (a) the same adapted Bottle Problem task as the precalculus students and (b) how they would respond to the two students from the subset of student videos and transcripts. All GTAs in the course consented to sharing their classroom data.

Task Design

In this section, I describe the process of adapting a research task using for assessing students' covariational reasoning to a classroom task and then again to a GTA training task (Figure 1).

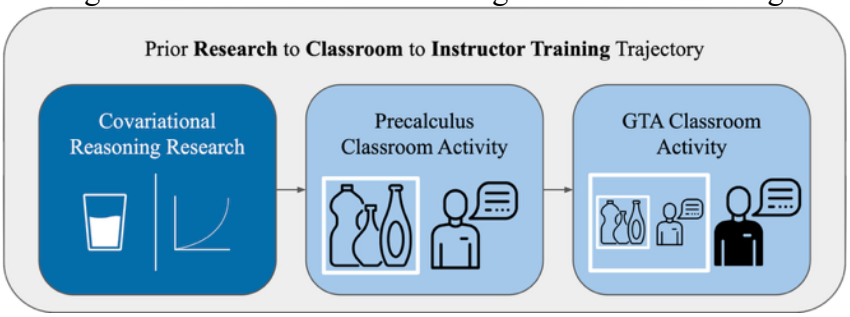

Figure 1. Transition from research to classroom to GTA training.

Adapted Bottle Problem Task. The original *Bottle Problem* Task asked students to graph the relationship between the height and volume of water poured into a spherical bottle. In Moore's *Advancing Reasoning Project*, his team adapted this problem to be used in a classroom activity for preservice secondary mathematics teachers by incorporating several differently shaped bottles. I adapted this version of the task into two parts. In Part I, students worked together in groups in class to get accustomed to creating graphs/bottles and to introduce the language of covariational reasoning to them. In Part II, students completed the activities outside of class and submitted 3-5 minute video responses of their solutions. Each part had different bottles/graphs, and in Part II, students had the opportunity to make their own bottles/graphs and needed specifically to recognize descriptions of quadratic and exponential relationships. In total, students completed 8 bottle-graph pairs.

GTA Training Task. The *Adapted Bottle Problem* video responses were analyzed according to their correctness and covariational reasoning (see details in Analysis section). For the GTA training material, the goal was to identify two videos for the GTA students to respond to. The

learning goals of the GTA activity was to (a) introduce them to procedural vs. conceptual thinking (b) introduce them to covariational reasoning and (c) respond to student thinking by attending to students' covariational reasoning. To do so, the GTAs first read an introduction to procedural and conceptual thinking, including an introduction to Carlson's Precalculus Concept Assessment (Carlson et al., 2010) and potential responses to the *Bottle Problem* (Abell et al., 2024). The GTAs were then given the same *Adapted Bottle Problem* task, including submitting their own 3-5 minute video of their reasoning.

Then, the GTAs watched the two selected videos and received the transcripts of the two precalculus students explaining their reasoning on Part II of the *Adapted Bottle Problem* task. One student exhibited *amounts of change* reasoning considering too large of intervals of change and another student used *thematic associations* with "speed." Neither exhibited entirely correct solutions. Kala's work, though incorrect, used amounts of change (serviceable), constructed expected representations (normative), and carefully color-coded and followed directions (framing/responsiveness). In contrast, Leonhard relied on language around speed to explain his reasoning (non-serviceable), constructed more than one graph for a unique bottle (non-normative), and did not follow instructions to color-code or only explained a subset of his bottles/graphs (framing/responsiveness). The GTAs then submitted a second 3-5 minute video on how they would respond to those students.

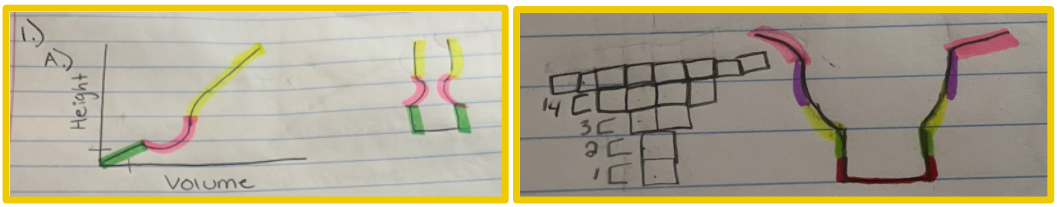

Figure 2. Sample of Kala's work on the Adapted Bottle Problem.

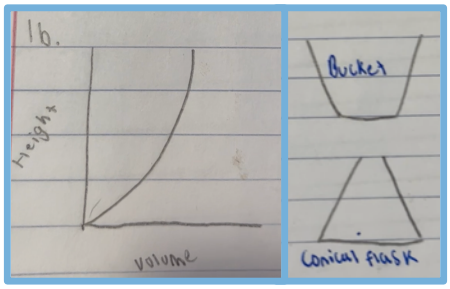

Figure 3. Sample of Leonhard's work on the Adapted Bottle Problem.

Analysis

The goal of the analysis was to attend to the GTA's responses to students' covariational reasoning. To do so, I engaged in a two-part analysis: on GTA responses to the *Adapted Bottle Problem* and on GTA responses to student solutions of the problem. In this manuscript, I focus on the latter part. In this part, I used the SNR framework from Herbst et al. (2023) to code the GTA responses to the student work. I used transcripts of the videos and referenced accompanying student work to code GTA utterances/pointers.

In particular, I created codes for each of the categories of perception. *Correctness* was coded based on the GTA's perception of a student's final graph shape. *Framing* was coded based on the GTA's perception of the prompt. *Normativity* was coded based on GTA's perception of student's production of reasonable responses. *Serviceability* was coded based on GTA's perception of a

student's covariational reasoning and/or discussing mathematical relationships, with specific codes pointing to *directional* and *amounts of change* covariational reasoning. However, because these GTAs were new to the construct of covariational reasoning and Kala's amounts of change reasoning was not entirely correct, to code for serviceability, it was only required for the GTAs to attend to quantities students identified and how those quantities were changing together. *Responsiveness* was coded based on GTA's perception of a student's response as a complete response to the problem statement, including color coding.

Moreover, the SNR framework enables the negation of each of these codes (non-normative, for example). Particularly given the open nature of the task, the line between the two can be difficult to define objectively, and so determinations were based on GTA's reactions. For example, one GTA may consider a graph correct as long as the general shape is appropriate (e.g., curved vs. linear segments) whereas another GTA might consider a graph incorrect if the relative steepness of lines in a graph are not considered. Thus, to code for students' responses to student work, an initial code of serviceability, normativity, responsiveness, and correctness was coded. Then, if the GTA's reaction to the work was positive (e.g., praising) the work based on that category, the code remained as is; if the GTA's reaction to the work was negative, the code was negated (e.g., correctness to incorrectness).

Results

In this section, I detail the results of the analysis on GTA responses to Kala and Leonhard's student work. The overall distribution of GTA comments are in Figure 4 below. These results indicate that GTAs largely attended to the serviceable and non-normative aspects of the student work. In the remainder of this section, I detail some of the findings and note what particular aspects of the student work the GTAs perceived.

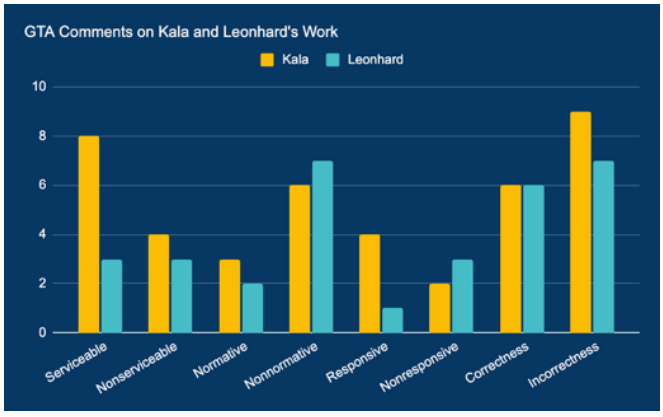

Figure 4. GTA perceptions of Applied Precalculus students' responses to the Adapted Bottle Problem.

GTA Responses to the *Adapted Bottle Problem* and Framing

Although not prompted, many (5) GTAs recognized how difficult the problem itself was, sympathizing with the students. For instance, one GTA remarked that the problems are "not like super intuitive at first glance". In particular, for one of the problems, a GTA remarked they would have preferred the axes to be switched because as is, it "kinda throws off a bit based on conventional [axes]." Two instructors noted that the framing of the problem would require additional instructor support. However, in general, GTAs still had a positive response to the problem, with one stating, "I'm all for it. I think it's good to keep them on their toes."

GTA Responses to Kala's Work

For Kala's work, one of the key perceptions from GTAs were that the work was non-normative. Four GTAs commented on the pink "dip" in Kala's graph in Figure 4 (left). One stated that Kala "dipped the pink part down and said that it decreases but she wasn't fully aware of the fact that she was talking about the decrease in the rate of change." The same GTA called the shape "kinda weird because that wouldn't happen on any of these graphs." These comments attend to the non-normative nature of Kala's solutions, specifically incorporating Kala's covariational reasoning in her description of Kala's contribution.

The second key perception from GTAs was that the work was serviceable. Seven GTAs praised Kala's attempts to use "blocks" (Kala's language) to support her reasoning (see Figure 4 right). One GTA stated "the way she approached it with the squares does demonstrate that she understands the concepts behind the assignment." Another GTA stated that she saw that Kala used this approach "so she can get an idea" of the problem. These comments attend to the serviceability of Kala's approach, specifically using the blocks to support not only constructing the graph but justifying her graph via amounts of change covariational reasoning.

Lastly, and somewhat surprisingly, three GTAs praised Kala's use of color-coding. It remains unclear whether or not the teachers saw color-coding as part of the framing, since Leonhard did not color code and the two GTAs specifically noted a need for him to do so were part of the three that praised Kala's color-coding.

Leonhard's Work

For Leonhard's work, the key perception from GTAs was that the work was non-serviceable and incorrect. One GTA thought Leonhard "did not seem to have as much of an understanding of rate of change" and just "throwing out a few terms." Another GTA noted that Leonhard himself remarked on wishing he had numbers, and stated "since he's given the relationship, you can certainly get numerical values like Kala did." Only three GTA specifically referenced the "faster/slower" speed language (and two praised it). These comments attend to the non-serviceable ways in which Leonhard justified his actions. Overall, GTAs noted some pseudo-analytic actions Leonhard took (even if viewed positively), but not thematic associations.

The second key perception from GTAs was that Leonhard's work was nonnormative. Six students commented that Leonhard produced *two* different bottles for the same graph (Figure 3), though one GTA praised it. As one GTA discussed, "he had a couple options for the bottle. He did say that both of them worked even though both of them were quite different." That is, the two bottles Leonhard produced represent two different rates of change between height and volume, making it impossible for Leonhard to have an appropriate solution. These comments attend to the nonnormative (and also incorrect and nonresponsive) nature of Leonhard's work.

Discussion

Using the SNR and covariational reasoning frameworks, this study showed both that GTA's perceptions span the categories of normativity, serviceability and responsiveness, and that these 11 GTAs primarily focused on the serviceable and non-normative aspects of undergraduate precalculus work on a graphing problem via covariational reasoning. Looking at GTA's comments more closely, it seemed that, even with little introduction to the constructs of covariational reasoning, GTAs were able to perceive and attend to students' covariational reasoning and pseudo-analytic actions in this task. Further research can look at the influence of the task including an instructional goal of covariational reasoning in GTA's perceptions and also the impact additional GTA training in covariational reasoning has on GTA perceptions.

Qualitative Analysis of Student Responses to Metacognition Prompts in College Algebra

Cynthia Farthing
University of Iowa

Jamie Tanas
University of Iowa

Michael N. Johnson III
University of Iowa

Students in a college algebra course completed reflective metacognition journal assignments about their studying and performance in the course. This paper is a thematic analysis of the qualitative data collected from those journal assignments and surveys about the effects of the journal assignments on their studying and performance in the course. We investigate how the journal assignments affected the study strategies they used in college algebra and what students learned about themselves as learners through these reflective assignments. Findings indicate that metacognition journals were effective in supporting students in reflecting and changing their study habits. Qualitative analysis is used to describe students' reflection and changes to study habits after engaging with journals embedded in a mathematics course.

Keywords: College Algebra, Metacognition, Developmental Math, Qualitative Analysis

The first year in university can be challenging for students academically. First year courses traditionally have higher rates of student failure or withdrawal and have a direct impact on student retention and degree completion overall (Flanders, 2017). Developmental mathematics courses like college algebra, which often do not serve to meet a degree requirement but rather prepare students for further university level mathematics courses, are no different (Tunstall, 2018). To support students in successful completion of college algebra researchers and instructors at several institutions have worked to redesign the course to include more active learning methods, revised curriculum, and innovative pedagogical approaches like modeling-based learning (Tunstall, 2018; González-Muñiz et al., 2012). While these reforms show promise, there is still work to do in supporting students in understanding mathematical concepts during a critical course in their first year at university.

One approach to improving student learning in mathematics is through supporting self-directed learning via metacognition. Metacognition is defined as "thinking about one's own thinking" or awareness or analysis of one's own learning or thinking processes (Tanner, 2017; Flavell, 1979). Although several frameworks exist to understand the process of metacognition, we conceptualize metacognition to include the skills of goal setting or planning, monitoring progress, and evaluating performance (Lovett, 2011; Tanner, 2017). While we know that acquiring and practicing these skills are critical to student performance in mathematics (Verschaffel et al., 2017), many students enter their first year of university without direct instruction or experience with planning, monitoring, and evaluating their mathematics learning. Within STEM, one approach to improving student learning is through incorporating metacognitive instruction alongside academic content within the course itself (Lovett, 2011; Tanner, 2017; Colrthorpe et al., 2019). These metacognitive supports may include reflection on learning through exam wrappers (Lovett, 2011), discussion prompts (Colthorpe et al., 2019), and questionnaires (Lucangeli, et al, 2019). These approaches are appealing to educators since "... metacognition continues to be a predictor of mathematics performance" (Desoete & De Craene, 2019, p. 556) and their implementation are a brief and manageable addition to a course for both instructors and students (LaCaille et al., 2019).

In this study metacognition journal assignments were embedded throughout a college algebra course. Students completed seven journals and a post survey regarding their experience with the journals. In this paper we analyze responses from one journal and the post survey. As we examined these student responses, we sought to answer the following research questions.

1. [RQ1] Did students report changing their study habits due to metacognition journal assignments? If so, how?
2. [RQ2] How do students define a productive study session? What can we learn from this about their study habits in college algebra?
3. [RQ3] What did students learn about themselves through metacognitive journaling in college algebra?

Methods

Metacognitive Intervention

The college algebra course was incrementally redesigned between 2020 and 2022. One of the key changes was the addition of metacognition journals to the course. These metacognition journals were graded assignments; students received full credit once they completed a journal assignment. There were seven metacognition journals throughout the semester and together made up 4.2% of the final grade. As part of the course redesign process, students were given surveys at the beginning (pre-surveys) and end of the semester (post surveys) to assess the effectiveness of the course changes. Beginning in Fall 2022, students who completed the surveys were asked to consent in a research study that would allow their survey responses, their course grades, and coursework to be analyzed. (They did receive bonus points for completing the pre and post surveys.) In this paper, we are analyzing and discussing responses of study participants on one of the metacognition journal assignments and questions from the post survey. This study was conducted over three semesters: Fall 2022, Fall 2023, and Spring 2024.

Data Collection

In Fall 2022, 473 of 754 students enrolled in the course (62.7%) participated in the study. The Fall 2023 semester had 538 of 672 students enrolled (80.1%) participating in the study. Enrollment in this course is much lower in the spring semesters. In Spring 2024, 107 of the 133 enrolled students (79.2%) participated in the study. Thus, the study had 1,118 participants.

The post survey asked students specific questions about the metacognition journals. One question asked students which of the metacognition journals was the most useful for them. According to this question, Journal 2 was the most helpful, and it is for that reason that we chose to analyze students' responses from that journal assignment. We also analyzed responses from two questions about metacognition journals from the post survey.

Coding and Analysis

Journal responses were coded through an iterative and collaborative process with three researchers. An inductive and comparative method (Mirriam & Tisdale, 2016) was used to develop themes from the data. During the first round, open coding (Saldana, 2016) was used by two researchers to develop initial codes. The researchers then refined those codes, coming to an initial agreement on definitions. These codes were tested on a sample of student responses and researchers met again to check coding agreement and utility of codes. During this second round of coding, definitions were refined and additional codes added when needed. A third and fourth round of sample coding was performed until agreement between researchers was reached on all

codes. The remaining student responses were then coded by a single researcher. After all responses were coded, researchers engaged in thematic analysis (Glesne, 2018) of student responses. Themes were developed by researchers through analysis of patterns within the coded data.

Data and Results

Journal 2

During the second and third week of the semester, students were asked to log when they studied for their college algebra course. Between the two weeks, students were given information about spaced practice and how it is shown to be more effective than studying all at once. After two weeks, students completed the metacognition journal assignment. We are investigating the open-ended responses students submitted on that assignment about how the classify productive study sessions and the changes about their study habits.

Productive study session. Students responded to the prompt "How do you define a 'productive' study session?" We created fifteen codes that were grouped into five themes.

1. Environment. This theme includes whether people studied alone or with others and the level of distractions within the environment.
2. Outcomes. This theme is characterized by what students finished in the study session; for example, did they learned something new, complete a task, or work efficiently?
3. Planning. This theme includes codes scheduling time to study or making lists of tasks to complete during their study sessions.
4. Self/Affective. This theme includes codes that describe students' ability to focus during a study session or feeling confident after the study session.
5. Study Habits. This theme is characterized by the types of study methods students used during a study session, e.g. explaining concepts to others or reworking examples.

The 1,116 responses produced 2,091 codes. To avoid double counting responses that contain two codes from the same theme, we are reporting the percentage of codes instead of percentage of responses. Figure 1 shows the percentage of codes for each of the above themes.

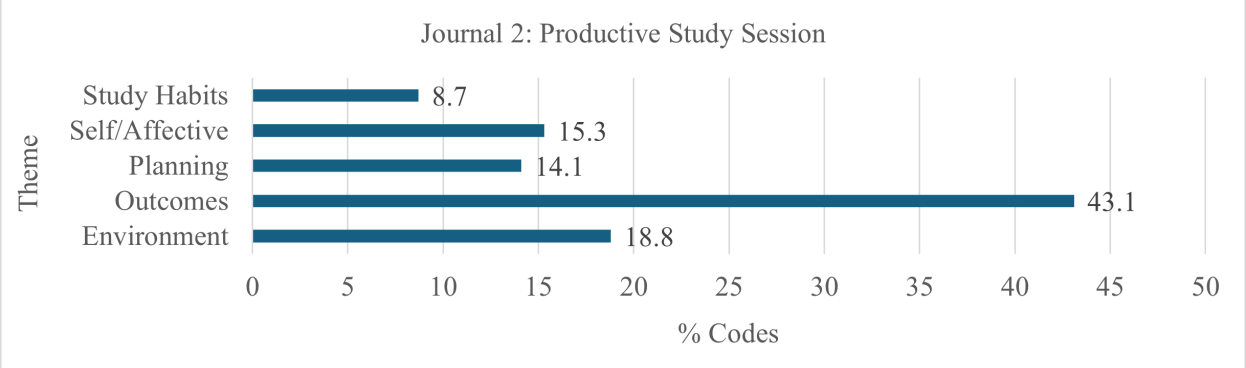

Figure 1. Theme vs. % Codes from Journal 2: Productive Study Session.

Study changes. Students responded to the prompt "Reflect on what we discussed in class about metacognition and what you discovered in the last couple of weeks about how you study and learn effectively. What changes will you make to your study strategies? What study strategies will you continue?"

We created twenty codes and categorized the codes into four themes.

1. Environment. This theme includes codes related to where students will study, how they will reduce distractions, and whether they will study alone or with a group.
2. Evaluating. The only code in this theme is "evaluating/reflecting" and was used when a student mentioned reflecting periodically on their study skills to see if they want to make additional changes.
3. Planning. Codes in this theme relate to students planning when they would have a study session, including if they intend to do spaced practice, or planning what topics they will cover in a study session.
4. Study Habits. This theme is characterized by study practices or habits students will use in the course. Habits range from general best practices like attending class to specific study skills like rereading notes or self-quizzing.

There were 1,117 responses which produced 2,182 codes. The percentage of codes for each theme is displayed in Figure 2.

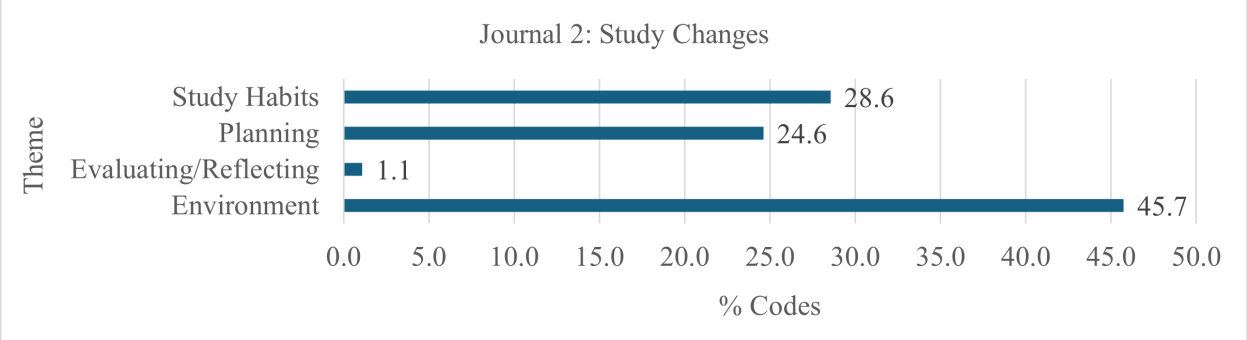

Figure 2. Theme vs. % Codes from Journal 2: Study Changes.

End of Semester Survey

At the end of the semester, students were invited to complete a post survey that included questions about their self-efficacy, their mathematical anxiety, and general course questions. The questions on self-efficacy and mathematical anxiety were direct parallels to questions asked during the pre-survey to track their progress over the semester. This line of inquiry is being explored within the same data (Preschel, 2025) but is outside the scope of this paper. The post survey included multiple choice and open-ended questions about students' experience with and the effects of metacognition journals.

Self as learner. We coded student responses to the prompt, "What (if anything) did you learn about yourself as a student through these metacognition journal assignments?" We generated a total of nineteen codes and grouped them into five themes.

1. Planning. This included codes where the student mentioned future-oriented practices like setting goals for a study session or a course.
2. Self/Affective. This theme included codes that referenced internal aspects of the student. Examples include mentioning how well they focus or that they learned something about how to motivate themselves.
3. Study Habits. This theme included codes that referenced habits, tools, or actions that would aid them in study, (e.g., using outside resources, or trying a new study skill.)
4. Evaluating/Reflecting. This theme included codes that showed students learned either to diagnose which material they needed to study or to reflect on how their studying was going.

5. Did not learn anything. This theme was a singular code where students mentioned that the journals did not provide them with anything.

This prompt provided us with 1118 responses with 1020 codes. See Figure 3 for the percentage of codes in each theme.

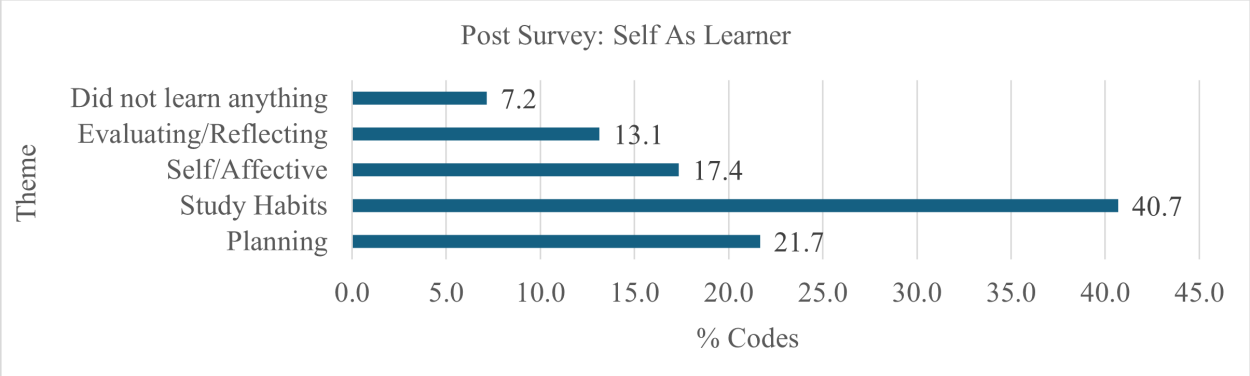

Figure 3. Theme vs. % Codes for Post Survey: Self as Learner.

Study changes. Students were asked to "Describe any changes you made to your study habits because of the metacognition journal assignments." A total of twenty-seven codes were sorted into five themes.

1. Environment. This included codes related to external factors to the student and the environment they studied in.
2. Planning. This included codes where the student mentioned future-oriented practices that do not occur within the moment of studying.
3. Study Practices. This included codes that pertained to actions that occurred while studying or events/actions that were considered studying.
4. Self/Affective. This theme included codes that referenced internal aspects of the student. Examples include increased confidence or activities to reduce stress.
5. Study Habits – General. This theme was for codes that gave vague statements about study habits that were not as specific as other themes (e.g., "No change" or "I changed my habits").

This prompt provided us with 1118 responses with 1101 codes; the percentage of codes in each of the five themes is in Figure 4.

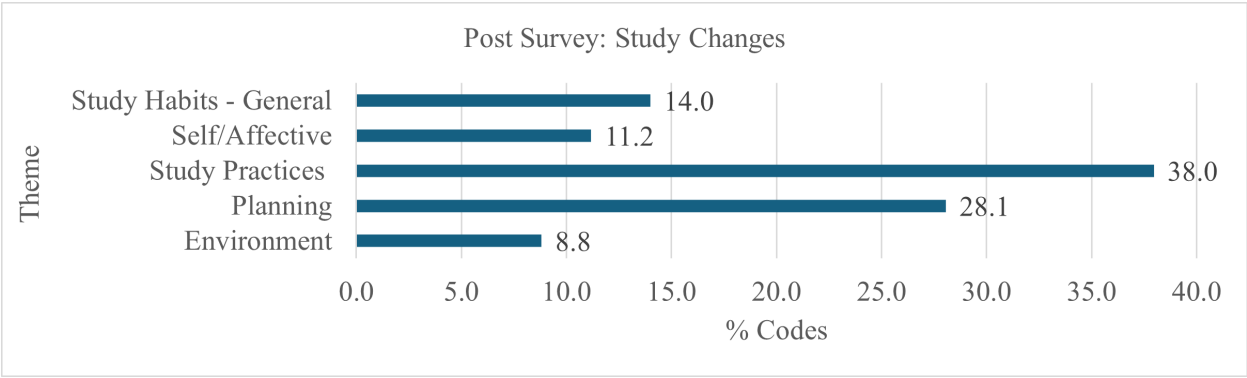

Figure 4. Theme vs. % Codes for Post Survey: Study Changes.

Discussion

Journal 2

In the discussion that follows, percentages reported for themes will indicate the percentage of total codes for the prompt, while percentages for reported codes will correspond to the percentage of student responses with that code.

Responses to the Journal 2 Productive Study prompt, which give insight into RQ2, fell into five thematic categories: Environment, Outcomes, Planning, Self/Affective, and Study Habits. The most prominent theme was "Outcomes" at 43% of coded entries. (See Figure 1.) The highest occurring codes in this theme were "Complete a Task" (40%) and "Understanding/Learning" (37%). While these two codes may provide students with a sense of productivity in their study session, we questioned if these measures indeed align with student learning. The least frequent theme, "Study Habits" (9%), included study habits that would give more concrete measure of student learning, including the codes "Retrieval Practice" (4%) and "Explains Concepts to Others" (2%). These practices would provide students with more direct measure of their learning but were much less frequently reported by students as part of a high-quality study session. Related, the theme "Self-Affective" (15%) reveals that students often rely on "Feeling Confident/Good" (8% of responses) or being able to "Focus" (20% of responses) as an indicator of a productive study session. As we know novice students frequently overestimate their skill or feel overconfident, this may or may not be associated with increased learning. Further, "Focus," without attention to high-impact study strategies, like reading over notes versus retrieval practice, may or may not align with learning. Lastly, we see that students often look to their "Environment" with 32% of students reporting "Limiting Distractions" as how they measured a productive study session.

For the Journal 2 Study Changes prompt, students described changes they would make to their studying after monitoring their habits for 2 weeks. Since this journal was assigned at the beginning of the semester, the responses give us a baseline measure for RQ1. The most frequent change reported by students was the theme "Environment" (46%) which included the codes "Remove Distractions" (35.5%) and Location (34.7%). Students understood the importance of the environment in relation to their studying after reflecting on their study sessions. Furthermore, students perceived the study environment as a significant barrier to their studying, and they planned to improve it by intentionally limiting distractions or moving to a location more conducive to studying. The second most frequent theme was "Study Habits" (28.6%) which included codes related to study habits students noted were useful in their studying including "Increasing Study Time" (8.8%), "Working/Practice" on problems (8.6%), "Taking Breaks" (6.7%), completing "Assignments" (8.3%), and "Office Hours" (6.1%). While adoption of these practices is positive, high impact study habits like "Spaced Practice" and "Retrieval Practice," were less frequently reported by students. Finally, "Planning" (25%) was another common theme within student responses. Students reported planning the time that they studied (19.2%), spacing out the timing instead of cramming (21.6%), and planning what they worked on during a session (2.1%) were all changes they would implement after monitoring their study sessions. Responses to the Post Survey Study Changes prompt indicate how successful students were in continuing these habits.

Post Survey

As noted in the Results, the most prominent theme for the Post Survey Self as Learner prompt was "Study Habits" with 40.7% of coded entries. This theme included responses where

students mentioned they "Learned to Study Effectively" (14.3%) or referred to their "Study Habits" (14.7%) or "Study Frequency" (4.5%). These findings address the second part of RQ1 ("If so, how [did their study habits change]?") by showing that students described their changes with increasing specificity. Many codes within this theme also carried an evaluative component. For example, "Time Management" (7.8%) included responses where students said they were good at time management or needed to improve. This not only helps to answer RQ3, but it shows students are identifying their strengths and weaknesses regarding study skills. While responses to the Post Survey Self as Learner prompt highlight students' broad perceptions about their study skills, the second prompt from the post survey offers a more detailed view of the specific changes students reported making.

The codes for the Post Survey Study Changes prompt provide insight into how students' study practices varied and what outcomes emerged. The three most frequent codes, each clearly separated from the rest, were "Increase Study Time" (11.2%), "Studied Earlier for Exams" (10.9%), and "Spaced Practice" (10.4%). These fall into two different themes: Planning ("Spaced Practice" and "Studied Earlier for Exams") and Study Practices ("Increase Study Time"). Overall, the themes "Study Practices" (38%) and "Planning" (28.1%) were the most common themes. This suggests that students not only adjusted the concrete ways they studied but also developed stronger planning strategies to support those habits.

In relation to RQ1, the Post Survey themes and codes added both detail and precision, while opening avenues for future inquiry beyond the scope of this paper. For example, future analysis could examine student outcomes associated with codes, explore connections across codes, prompts, and themes, or trace temporal patterns of change across the semester. Future work could investigate how to strengthen support for students. For example, a support that was implemented in this course (but its study was outside the scope of this paper) was Metacognition Mentors. Additional considerations could include adapting prompts and support to align more closely with the study habits revealed in this project.

Conclusion

Together, these findings suggest that the metacognition journals effectively introduced students to metacognitive practices and encouraged reflection on those practices. At a base level, 93.5% of students stated they learned something about themselves as learners through the metacognition journals. The responses show that students are beginning to think about what helps them learn best. However, students may not be good at evaluating how well they truly understand a concept. For example, students measured productivity in a study session by focusing more on finishing tasks, their environment, and how they felt while studying. Not surprisingly, when students planned on making changes, they primarily focused on removing distractions with a secondary focus on the study habits they implemented. At the end of the course, when students reflected on the study habits they changed, they were most likely to mention more time studying, study earlier for exams, and include more spaced practice. The frequent mention of spaced practice shows growth in students' awareness about high-impact study practices. Their end of course reflections also indicate that students knew what appropriate study habits for themselves would be, even if they did not meet their own expectations. Thus, it is important for instructors to discuss and model effective study practices and encourage students to continue to reflect and try new strategies.

Students' Mathematical Reasoning About the Period of the Sum of Trigonometric Functions

Ishtesa Khan
Arizona State University

This study investigates students' mathematical reasoning when determining the period of the sum of two cosine functions through exploratory teaching interviews. Two undergraduate students engaged with Desmos applets to explore the sum of two cosine functions. The analysis revealed output-oriented reasoning that focuses on identifying input values where function output repeats, and alignment-oriented reasoning that focuses on where the period of the sum function aligns with the periods of individual trigonometric functions to determine the period of a sum of two trigonometric functions.

Keywords: trigonometric functions, periodic functions, mathematical reasoning

Introduction

The periodic nature of trigonometric functions is often highlighted in mathematics education (Weber, 2005; Ortega, 2017; Brown & Rice, 2011), although relatively few studies examine how students understand the periodic behavior of these functions. This paper presents findings from exploratory teaching interviews (Steffe & Thompson, 2000) aimed at exploring students' reasoning about the sum of two cosine functions. The study is driven by an interest in how students develop foundational knowledge relevant to Fourier series. Fourier analysis is an interdisciplinary topic connecting mathematics, physics, and engineering education. Although the Fourier series is a significantly advanced mathematical topic, it is often missing from standard undergraduate curricula. When learning Fourier series, the importance of periodic functions is recognized as central (Leith, 2024; Mays and Loverude, 2019; Jia et al., 2011). Fourier series breaks down complex periodic functions into sums of sine and cosine functions, which are used to analyze, design, and optimize models in physics and engineering. The initial phase of the study suggested the need to investigate students' progression of thinking as they learn about the periodic behavior of sums of sine or cosine functions. Therefore, this paper addresses the research question: *What mathematical reasoning do students use to determine the period of the sum of two cosine functions?*

Literature Review

While many studies (Blackett & Tall, 1991; Doerr, 1996; Brown, 2005; Weber, 2005; Steckroth, 2007; K.A.Thompson, 2007; Moore, 2014) have investigated various aspects of trigonometric functions, their periodic behavior remains underexplored. Educators and practitioners (Miller, 2001; Martinez Ortega, Preciado Babb & Velasco, 2017) emphasize innovative teaching strategies incorporating physical movement to deepen students' understanding of periodic functions. Stupel (2012) advocated for connecting the periodic properties of trigonometric functions with fundamental number theory concepts, particularly through dynamic visualization tools like GeoGebra that enable students to explore how changes in parameters of a function affect the pattern and periodicity. Studies by Buendía and Cordero (2005) and Shama (1998) explored how students understand the periodic nature of functions and periodicity in general. The findings suggest a disconnect between recognizing periodic behavior in situations and relating this periodic nature to a formal mathematical context. Recent research (Khan, 2025) examined an undergraduate engineering student's conception of periodic functions,

finding that students conceptualize a function's period as the distance between two distinguishable points, such as maxima, where output values repeat, and patterns repeat through the domain. However, despite this saturated work on periodic function understanding, there remains a significant gap in research investigating how students develop mathematical reasoning about the periodic nature of the trigonometric sum, particularly using graphing technology like Desmos.

Theoretical Perspective

Constructivism serves as the foundational learning theory for this research. According to constructivist theory, knowledge is not passively received but actively constructed by an individual. Resnick and Glaser (2016) describe constructivism as a framework in which learners build understanding by integrating new information with their existing knowledge. This paper explores how students develop mathematical reasoning about the periodic nature of the sum of two cosine functions. The exploratory teaching interview (Steffe & Thompson, 2000) rooted in constructivist principles, provided the necessary framework for this investigation. This approach allowed the design of strategic perturbations through researcher prompts and tasks that reveal students' evolving conceptions as they work through the tasks. Khan (2025) reported a student's thinking of periodic functions. The findings enabled the formulation of a hypothetical framework (Table 1) describing students' reasoning about periodic functions and guided the methodological approach of this study.

Table 1. A hypothetical framework of students' thinking of periodic functions.

Setting/Context	Aspects of Concept Image
General conception of periodic functions	A student thinks that a periodic function has repeating and unchanged pattern in a graph.
	A student thinks that a periodic function has same output values after a certain interval.
	A student thinks that a periodic function has repetitive output after a period throughout the domain.
To determine whether a function is periodic	A student thinks that a periodic function has same output values for two reference points and there is an unchanged pattern within these two points. And the pattern keeps repeating throughout the domain.
	A student thinks about an unchanged pattern as a chunk that is repeated throughout the domain.
	A student thinks about a function being periodic in terms of function formula. If there is a horizontal shift P, then $f(x+P)=f(x)$.
Understanding of 'a period' of periodic functions	A student thinks about a period as the distance between two maximum or minimum points of the function.
	A student thinks about a period as the interval for which the function's graph remains unchanged throughout the domain.
	A student thinks about a period as a constant value p. For a horizontal shift p, the function produces same output.

Methodology

This study employs exploratory teaching interviews with two participants to investigate how students use their conception of the period of a trigonometric function in developing their understanding of the period of the sum of two trigonometric functions.

Two volunteer participants, Eloise and EL (pseudonyms), were recruited from a pool of students who participated in another interview that explored their conception of periodic functions. Both participants had prior exposure to trigonometric concepts and functions.

Data were collected through interviews conducted via the Zoom video conferencing platform. The interviews were scheduled as one-on-one sessions and video recorded in full to capture both the participants' verbal explanations and on-screen interactions. During the interviews, participants engaged with a dynamic task using Desmos, a web-based graphing calculator.

In this interview, the participants worked on four tasks that were designed to explore the progression of their thinking about the period of a function that represents a sum of two or more trigonometric functions. In this paper, we report on Task B, where participants were presented with two cosine functions, $\cos(mx)$ and $\cos(nx)$ where m and n were integer parameters ranging from 1 to 10. In addition, a summation function $h(x) = \cos(mx) + \cos(nx)$ was defined. Using the Desmos applet, the participants were able to graph either the individual functions or the combined function h. The Desmos environment provided interactive sliders for the parameters m and n, allowing the participants to dynamically adjust the values and observe the resulting changes in the graph(s). The following figure is a snapshot of the Desmos applet.

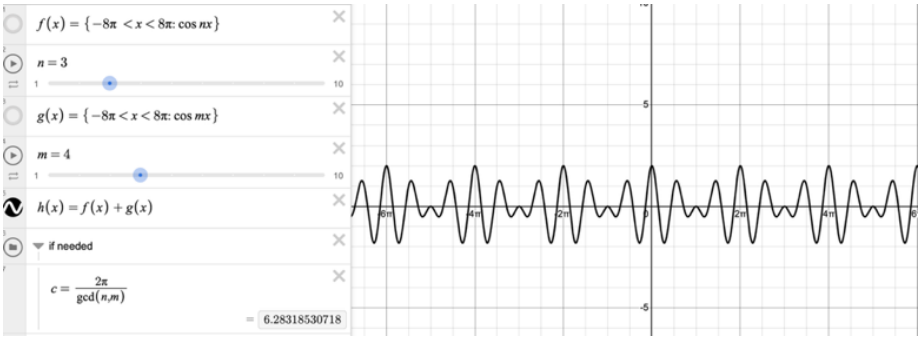

Figure 1. A view of Task B in Desmos

To analyze the data, the qualitative data analysis method (Saldaña, 2021) was implemented. I first transcribed using Adobe Premiere Pro and then manually corrected auto-transcription errors. I read through the data and named codes based on themes. I labeled the data into discrete parts based on the codes I created. Next, I compared similar events in the data and collated excerpts that were labeled with a particular theme. Then, I drew connections between the codes to find how the codes can be grouped into categories to answer the research question.

Results

In this section, I report on Eloise and EL's evolving thinking process in exploring the period of $h(x) = \cos(mx) + \cos(nx)$. Before task B, Eloise and EL were introduced to Task A, where they explored the periods for the functions $y = \sin(3x)$ and $y = \cos(5x)$. First, Eloise determined the distance of a pattern that repeats within a graph of these trigonometric functions with different frequencies, then she tried to choose input values for which the output values

repeat. She mentioned the numerical difference between these input values as the period of the functions. EL, on the other hand, approached the same task differently. She used proportional reasoning to rationalize that the period of $\sin(3x)$ would be $2\pi/3$. First, she pointed towards the length of one period of $2\pi/3$, then mentioned that as she knew the period of the sine function is 2π, the period of $\sin(3x)$ would be $\frac{2\pi}{3}$ because if she changes the input for the function within the length of 2π, there are three times as many periods for $\sin(3x)$ compared to $\sin(x)$. The interviewer then asked the participants to think about the period of $y = \sin(3x) + \cos(5x)$. Eloise imagined a graph with some oscillations but was unsure about whether it was periodic. However, after the interviewer presented the graph of this sum function, Eloise again looked for the distance between input values for which the output values are the same. In response to the same question without any probing, EL initially imagined the sum of $\sin(3x)$ and $\cos(5x)$ as a periodic function with a period that would be common for both functions. In her words-

> "If the period of A ($\sin(3x)$) is $2\pi/3$ and the period of B ($\cos(5x)$) is $2\pi/5$, then the period of the combined one will have some integer times $2\pi/3$ and also some possibly different integer times $2\pi/5$. And from what I know $\frac{1}{3}$ and $\frac{1}{5}$, these are not multiples of each other, and their least common multiple, I think, is 1. So, I would say the period would be 2π".

Task B is designed to explore the reasoning students' use in determining the period of the sum of two trigonometric functions. Eloise and EL were presented with the Desmos applet, and they initially explored the applet on their own. After interacting with the applet, Eloise initially perceived that as m and n gets larger, the graph of $h(x) = \cos(mx) + \cos(nx)$ may have a similar pattern to $\cos(x)$ with many peaks in between intervals. While exploring the applet, EL noticed that a regular cosine function with a frequency m makes the period smaller as the value of m gets larger. She also mentioned that the period of the sum of two cosine functions with different frequencies depends on the multiple of the periods of each regular cosine function with frequencies m and n.

Next, in this results section, I will present Eloise and EL's thinking to determine the periods of the function $h(x) = cosmx + cosnx\ where\ 1 \leq m \leq 10, 1 \leq n \leq 10$ for different combinations of m and n.

For Cases $n \neq m$, With no Common Multiple

The interviewer asked Eloise to list the periods of the function h, for different combinations of (n, m) as n, m takes integer values between 1 and 10. Eloise relied on the graph of h to see for which x values the output repeats, focusing on the peak-to-peak distance of the interval. She used this reasoning to find periods of h for combinations like $(1,2), (2,3), (1,10)$. She thought that for (n, m) combinations that $n \neq m$ have no multiple in common, the function repeats every 2π interval. EL, in contrast, for the same situation imagined that the function h will start repeating at 2π, as each $\cos(mx)$ and $\cos(nx)$ need to meet at a place where the period of h is a multiple of both the periods of $\cos(mx)$ and $\cos(nx)$. When (n, m) are different with no multiple in common other than 1, the period of the sum would be 2π. Although Eloise relied on the function formulas, EL conceived the period of h as the distance between points where the individual periods of $\cos(mx)$ and $\cos(nx)$ '*meet*' or coincide.

For Cases Where $n = m$

When $n = m$, EL continued to demonstrate her focus on underlying relationship between the period of h with n and m. However, Eloise initially imagined the period of h would be 2π. To verify her assumption, she utilized the graph of h, and noticed that the period is π. She paused to reconsider and reflected on what the output of h looks like for $n = m$. Eloise realized that if $n = m = 2$, then $h(x) = 2\cos(2x)$, and the period would be half of $2\cos(x)$ which is π. For $n = m = 3$, Eloise focused on the pattern to determine the period of h. She thought $2\cos(x)$ as the base function and compared the period of $2\cos(3x)$ with $2\cos(x)$. She mentioned that the period of $2\cos(3x)$ would be $1/3$ of the period of $2\cos(x)$. At this point, Eloise started recognizing the multiplicative aspect of the pattern of change in the period of h with the changes in n and m. The following figure shows that she wrote a hypothesis. She thinks that when $n = m$, the period of h would be $2\pi/n$.

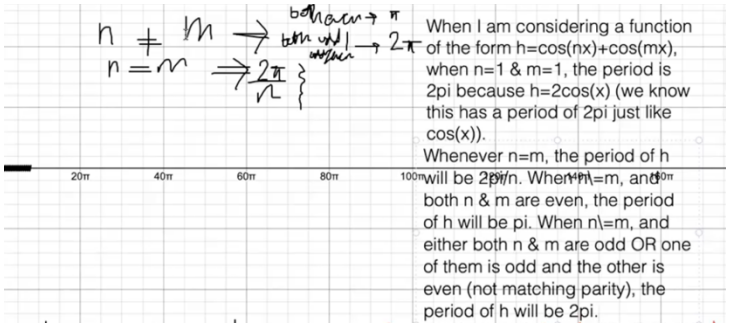

Figure 2. Eloise's initial hypothesis for the period of h, when n=m and $n \neq m$

For Cases $n \neq m$, With Common Multiple

After finding some periods of h for different combinations of (n, m), Eloise also came up with a hypothesis that for cases when $n \neq m$ and n, m are both even, the period of h would be π. When $n \neq m$, and either both n and m are odd, or one of them is odd and the other is even, the period of h would be 2π.The interviewer then offered Eloise to consider periods of h for combinations like $(6,4), (8,4), (3,9)$. Her hypothesis failed when she determined the period $\frac{\pi}{2}$ from the graph of $h(x) = \cos(8x) + \cos(4x)$. Using the graph Eloise demonstrated that the period of a function is the distance of an interval between two repeated outputs of the function for $(n, m) = (8,4)$. She looked for the inputs of h for which she could get the repeated output values. For instance, she thought that if the input for $h(x) = \cos(8x) + \cos(4x)$ is $\pi/2$, then $\cos\left(8 * \frac{\pi}{2}\right)$ and $\cos\left(4 * \frac{\pi}{2}\right)$ both have even integer multiples of π, and the output is 2, the same as the output of $h(0)$. She rechecked the process with an input $\frac{\pi}{4}$, but realized that in this scenario $\cos(4 * \frac{\pi}{4})$ had an odd integer multiple of π and did not return the same output value as $h(0)$. She concluded that as she started with an initial input 0 of $h(x)$, for another input $\pi/2$ of $h(x)$, there exists the smallest interval for which the output of $h(x)$ repeated. Throughout the interview, to determine any period of the sum of trigonometric functions, Eloise strictly focused on getting repeated outputs. She assumed the periods of h are related to (n, m) being the same, even, or odd, and she focused on verifying her assumptions by finding the smallest intervals between two same outputs. Then the interviewer probed her by asking whether the period of h is related to having any common factor between n and m. She quickly comprehended that the period of h would be 2π divided by the greatest common divisor of n and m.

For cases when n and m are multiples of the other, EL continued to compare the periods of $\cos(mx)$ and $\cos(nx)$ individually with the period of $h(x)$. She was thinking about the ratio of 2π and the common multiple of n and m to be the period of h. She thought that if $\cos(2x)$ has a period of π, and $\cos(4x)$ has a period of $\pi/2$; then the period of $h(x) = \cos(2x) + \cos(4x)$ would be the π as there are two of $\pi/2$'s in π. EL also graphed $\cos(2x)$, $\cos(4x)$, and $h(x)$ together and showed that at $x = 0$ and $x = \pi$, all these functions have maximum values and '*they meet at these points.*' Figure 3. below shows that EL marked the outputs for $\cos(2x)$, $\cos(4x)$, and $h(x)$ when the inputs are 0 and π.

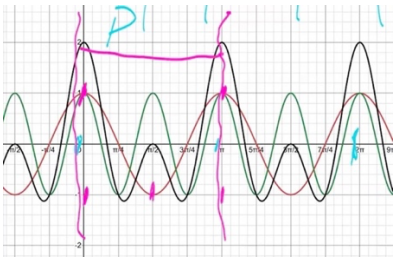

Figure 3. EL shows the periods for the sum function h when n=2, m=4

At this point, EL generalized that the period of $\cos(nx)$ would be $P_1 = \frac{1}{n} * 2\pi$, and the period of $\cos(mx)$ would be $P_2 = \frac{1}{m} * 2\pi$. She thought that the least common multiple of $\frac{1}{n}$ and $\frac{1}{m}$ plays a role in determining the period of h. The interviewer then asked EL to consider $n = 6$ and $n = 9$ to determine the period of h. EL found this combination unique as these are not multiples of each other, but in her words, *'they do combine'*. The following excerpt suggests that EL was referring to the least common multiple in determining the period of h.

Interviewer: What do you mean by they combine?

EL: Do they combine? We have $\frac{1}{6}$ and $\frac{1}{9}$…. So if we have something divided by 6 and we have some other thing divided by 9 (she wrote $\frac{x}{6} = \frac{y}{9}$). Do these ever line up? I think if we do $\frac{3}{9}$ and $\frac{2}{6}$, these are the same. So then, I think this (the period) will be $2\pi/3$

Interviewer: What exactly did you try to get from writing $\frac{2}{6} = \frac{3}{9}$?

EL: I was thinking if we have $\frac{x}{6}$ as some number of periods of the first function, and $\frac{y}{9}$ as some number of periods of the second function. And we want them both to line up at 2π. So if we find two numbers x and y that make this work, then we get the period of the larger function.

Interviewer: Okay.

EL: And then I found 2 and 3 that made this ($\frac{2}{6} = \frac{3}{9} = \frac{1}{3}$) work, and we get $\frac{2\pi}{3}$.

EL was thinking about the least common multiple of n and m as the input within the interval $(0, 2\pi)$ where the output starts repeating for all three functions, $\cos(mx)$, $\cos(nx)$, and h. As she exhibited her thinking of the least common multiple of (n, m) playing a role in determining the period of h for different combinations of n and m, the interviewer asked whether she could generalize her thinking about the period of the sum of two cosine functions. EL spontaneously mentioned that it would be related to the greatest common divisor of n and m. She thinks about the least common multiple of $(\frac{1}{n}, \frac{1}{m})$ as the same as the reciprocal of greatest common divisor of

(n, m). Figure 4. shows EL's formula to determine the period of the sum of two cosine functions.

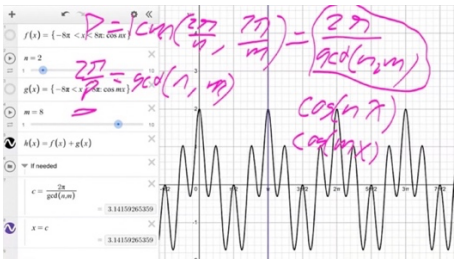

Figure 4. EL's formula to determine the period of h.

Discussion and Limitations

The results of the study suggest two distinct types of reasoning that students use to determine the period of the sum of two cosine functions. The constructs *output-oriented reasoning*, and *alignment-oriented reasoning* represent different ways students utilized their existing mathematical knowledge to make sense of the period of a trigonometric sum.

Eloise's approach of *output-oriented reasoning* focused on interpreting visible and numerical results from the graph. She identified periodic nature of the function by seeking repeating, unchanged patterns and verified the period by finding the smallest input interval producing the same output. Her hypothesis relied on characteristics like evenness or oddness of parameters, verified with graphs rather than focusing on the foundational number theory concepts. This approach is effective in most cases as it aligns with her conceptions of periodic functions but required support to understand the role of the common factor of the parameters n and m in generalization of the period of h.

EL's *alignment-oriented reasoning* centers around the understanding of the multiplicative and proportional relation between frequency and period, recognizing that for $\cos(nx)$ the period is $2\pi/n$. This understanding allowed her to see that for larger frequencies, the trigonometric functions produce smaller periods. She also recognized that the periods of individual functions relate multiplicatively when combined and that their frequencies coordinate to form an aligned period. She thought about how individual cycles 'line up' or 'meet', seeking points where the periods of $\cos(nx)$ and $\cos(mx)$ align with the period of the sum of these functions. EL consistently demonstrated the proportional aspect while comparing the periods. She thinks that if $\sin(x)$ has period of 2π, then $\sin(3x)$ has period $2\pi/3$ because there are "three times as many periods" in the same interval. Using the multiplicative and proportional aspect with the alignment of the periods in her reasoning, she was able to generalize a rule for the sum's period, linking it to the greatest common divisor of the frequencies of the individual cosine functions. This reasoning reflects a robust concept of periodicity, allowing EL to derive a generalizable formula of the sum of two cosine functions.

The distinction between *output-oriented* and *alignment-oriented* reasoning has key pedagogical implications. Both forms of reasoning reflect active engagement in learning; *output-oriented* reasoning emphasizes concrete, visual evidence, whereas *alignment-oriented* reasoning fosters the ability to generalize the foundational mathematical idea. A limitation of this study is that the generalization of the period of h as presented does not hold mathematically when either n or m is an irrational number. Although the interview protocol included tasks designed to explore students' understanding of such cases, the results of these explorations are not included in this paper.

Teaching Logic for Social Justice: How Students' Activity Identifying Mathematical Assumptions Can Support Their Reasoning Around Prisons and Abolition

Megumi Asada
Rutgers University

Mathematics and mathematics education are implicated in broader societal inequities. These inequities can manifest in racialized and gendered classroom experiences and are perpetuated by the very practices students are encouraged to employ. While some scholarship in undergraduate mathematics describes possibilities for using mathematics toward social justice, this area has been largely limited to algebra, statistics and calculus, leaving proof unexplored despite its critical role within K-16 mathematics. The aim of this study was to develop an instructional theory for how students can productively discuss and debate sociopolitical issues through practicing competencies from proof-based mathematics. I report data from the first cycle of a constructivist teaching experiment with two undergraduates designed to help them use logic to support their sensemaking about prisons and abolition. Ultimately, students' successful activity attending to definitions and identifying assumptions in a geometric context supported their ability to identify commonplace assumptions about prisons.

Keywords: teaching math for social justice, logic, equitable instruction

Introduction

Undergraduate mathematics has long upheld and perpetuated societal injustices (Adiredja & Andrews-Larson, 2017). Some scholars argue that the very practices students learn in their math courses can amplify existing societal inequities (e.g. B. Martin, 1997). In particular, the disciplinary values of decontextualization and objectivity can permit mathematicians to draw harmful conclusions while receiving little scrutiny (Leyva et al., 2022; D. B. Martin, 2009). When mathematicians *decontextualize* data, they disregard social context and can draw conclusions based on their subjective choices of which variables to foreground or background. For example, 'achievement gap' scholarship uses statistics to draw deficit-based conclusions about Black and Latin*[1] students without attending to important factors such as school funding or racialized tracking patterns (Gutiérrez, 2008). Thus, a finding that reflects deeply entrenched societal injustices was misinterpreted as an indication that historically marginalized students in mathematics are less capable. Furthermore, the belief that mathematics is *objective* adds weight and influence to these inaccurate and biased conclusions (D. B. Martin, 2009). There is seemingly no room to argue with an objective finding, especially if its subjective nature is hidden in plain sight.

Just as mathematics can be used as a tool to support inequities, mathematics can also be used as a tool to fight them. Prior work describes possibilities to teach students to analyze, critique, and change societal injustices using mathematics (e.g. Gutstein, 2003). However, this work relies on statistics and computation (Harper, 2019), drawing connections between math and social justice that are not generalizable to more abstract areas of mathematics, such as proof. This is notable as proof plays a critical role throughout K-16 mathematics. In fact, the National Council of Teachers of Mathematics (2000) lists reasoning and proof as one of its five process standards,

[1] Salinas (2020) promotes the use of the term *Latin** to refer to Latinx/a/o people as a collective. Salinas advises reserving the term *Latinx* for gender-expansive *Latin** individuals.

arguing that K-12 instruction should enable students to "recognize reasoning and proof as *fundamental aspects* of mathematics [emphasis added]." I propose, however, that proof can be modified to honor the goals of teaching math for social justice and subvert the math disciplinary values of objectivity and decontextualization.

Advanced undergraduate mathematics serves as an important setting for teaching logic and proof for social justice. All secondary math teachers are required to take courses in proof, and these courses are where teachers form their opinions about proof-based mathematics (Knuth, 2002). However, these courses are currently taught in a manner that amplifies the disciplinary values of objectivity and decontextualization (Leyva, McNeil, et al., 2022). These instructors then bring a perspective of proof as decontextualized and objective into their K-12 classrooms. In the realm of proof, mathematical arguments rely on axioms, the taken-for-granted assumptions and logical starting points in a mathematical theory. Further results are then deductive consequences of these axioms. Traditionally, axioms were intended to reflect self-evident or empirical truths, and thus, proof was considered a means for drawing conclusions about objective reality (Dutilh Novaes, 2020). Unlike traditional axiomatics, however, modern axiomatics is agnostic towards whether axioms or the theorems that rely on them are true in an absolute sense (Dawkins, 2014). Theorems instead hold a conditional status, where the emphasis is placed instead on assuming the necessary axioms and constructing a valid proof (Dutilh Novaes, 2020). Thus, the modern perspective towards axioms subverts the problematic view of proof-based mathematics as objective, without recourse for critique. I also argue that the attention to axioms, or mathematical assumptions, can enable students to identify assumptions underlying their sociopolitical beliefs. This is noteworthy as K-12 teachers are explicitly expected to help students use and attend to mathematical assumptions (CCSSM, 2010). Yet, these approaches to applying logic and proof to students' sociopolitical views have been unexplored in the literature despite the impact they would have on K-12 math instruction.

This study's research goal was to develop an instructional theory for how students can productively discuss and debate sociopolitical issues through practicing competencies from proof-based mathematics. The instructional theory was developed via two cycles of constructivist teaching experiments (Steffe & Thompson, 2000), each with a pair of undergraduate math students. Students' activity identifying and relaxing mathematical assumptions, or axioms, in a geometric setting was designed to parallel their activity identifying and relaxing assumptions about prisons and prison abolition. The goal of this study was to develop a theory for how advanced mathematics can support students in discussing social justice issues. Accordingly, this study addresses the following research question: In what ways can students' reasoning about logical assumptions in advanced mathematics support their reasoning about assumptions in a sociopolitical setting?

Literature Review

I describe prior work that links math to social justice and scholarship that describes the role of sociopolitical assumptions, or logics, in oppressive systems. Teaching Math for Social Justice (TMSJ) encompasses a range of curricular interventions that enable students to both "read" and "write" the world using mathematics (e.g. Gutstein, 2003). These studies have been successful in increasing interest in mathematics (Rubel et al., 2016; Turner & Front Strawhun, 2013), providing opportunities for students to use mathematics to critique oppressive systems (Gutstein, 2003; Kokka, 2019; Rubel et al., 2016; Turner & Front Strawhun, 2013), and creating opportunities for students to engage in social change (Stocker, 2012; Turner & Front Strawhun, 2013). However, TMSJ implementations can also be constrained in their ability to sufficiently

cover either the social justice or the mathematics content. In some cases, lessons are entirely divided into two distinct halves covering mathematics or social justice content (e.g. Bartell, 2013). In other cases, eliciting understandings of the mathematics and of the political topics encompassed conflicting pedagogical goals. For instance, Gutstein (2003) occasionally had to tell his students how to find the answer or substantially simplify the mathematics. He also struggled to balance providing sufficient historical context with giving students opportunities to explore the mathematics. These trade-offs can be inherent to the added complexity that real world data sets can have relative to the nicer quantities students are used to working with in traditional school mathematics.

Harper (2019) describes Gutstein's difficulties negotiating conflicting disciplinary commitments as a theme that extends across TMSJ. Furthermore, many TMSJ scholars rely on data science to connect mathematics to social justice issues (e.g. Gutstein, 2003; Rubel et al., 2016; see Simic-Muller, 2019, for an example in the undergraduate context), which is notable as data science occupies only one category of the mathematics students are expected to learn in school. In fact, Harper (2019) comments that TMSJ work has generally struggled to connect social justice content to mathematics content standards at the secondary level. It is thus unclear to what extent TMSJ is even possible in more abstract areas of mathematics, including proof-based mathematics.

Prior work also describes the role that *math logics,* or the assumptions, norms and values shaping how society views mathematics (Battey & Marshall, 2023), play in perpetuating inequities in mathematics education. The notion of *logics* (Acker, 1990)*,* or organizing assumptions that justify and uphold certain systems, is widely used throughout scholarship that seeks to critique different ideological instantiations of injustice. For example, Leyva, McNeil, et al. (2021) draw connections between racialized and gendered events in an undergraduate calculus class and their associated math logics. They described how the logic that calculus should operate as a weed-out course inspired an instructor to tell his students to drop his course if they were struggling. Participants in this study indicated that this seemingly neutral event was racialized and gendered. Leyva et al. argue that when left unaddressed, math logics can continue to preserve inequities in math classrooms. This study makes use of the analogous roles of axioms in mathematical arguments and assumptions or logics in (political) arguments. By teaching students to analyze assumptions, or logics, across disciplines, this study addresses a limitation of prior TMSJ work by unifying the social justice and mathematical goals. Students' cross-disciplinary reasoning about geometric assumptions and carceral logics will serve as a guide for how proof can help students question oppressive logics more broadly.

Theory

Abolitionist theory framed the design of students' sociopolitical activities and served as a means for analyzing students' assumptions about prisons. Abolitionists contend that abolishing prisons requires dismantling the structures and ideologies, or pro-prison assumptions, that support them while building systems that address the problems prisons claim to solve. I describe a key construct from abolition, carceral logics (Gruen & Marceau, 2022), that played a central role in the study design. *Carceral logics* account for the everyday, taken for granted understandings people have about prisons and punishment (Gruen & Marceau, 2022). I anticipated that participants would initially rely on carceral logics without realizing they were doing so. In fact, even movements in support of prison reform can employ carceral logics. For example, some advocacy for removing the death penalty has relied on the assumption that a life sentence provides a satisfactory alternative (Davis, 2003). In this case, reformists inadvertently

evoke the carceral logic that incarceration is a sufficient solution to crime or violence. The goal of the study was not for the participants to take on abolitionist views or discard their initial perspectives but rather to identify and question carceral logics.

Methods

Data Collection

Data collection for this study consisted of two phases, both taking place over 10 weeks, consisting of an entrance interview, 7 teaching experiment sessions, and an exit interview. The data corpus includes interview transcripts, artifacts (student work), and video data from the teaching experiments. I recruited two participants per teaching experiment cycle. The present analysis covers data from the first of the two teaching experiments. My participants were a South Asian man (P1) and a Latina woman (P2), both of whom had taken multiple proof-based courses.

The goal of these experiments was to develop a theory of how students may use competencies from advanced undergraduate mathematics to support their discussions of prisons and abolition. To enable students to practice these competencies, I constructed a series of exercises that were designed for them to practice specific mathematical skills in a geometric setting then apply them to analyzing arguments about prisons and abolition. I used conjecture mapping (Sandoval, 2014) to develop hypotheses for how these exercises would enable students to engage in the three desired learning outcomes: identifying underlying assumptions of claims, relaxing these assumptions, and imagining different worlds or systems. This analysis focuses on the first learning outcome. These learning goals were participatory as the intention was for students to engage in authentic and productive discussion rather than perform well on a post-test. The starting set of conjectures were preliminary in nature, with the expectation that they would be incorrect in important ways.

As a facilitator, I generally guided students towards accurate mathematical interpretations and toward identifying the underlying commitments behind their political beliefs. However, I avoided imposing my own political beliefs onto the students. I encouraged participants to relax or question the assumptions they held *to a degree.* I did not ask participants to relax or replace assumptions that were fundamental to their identity or that involved the respect and inclusion of historically marginalized groups.

Analysis

I engaged in two types of analysis: ongoing and retrospective. Between sessions, I engaged in an *ongoing analysis.* I took note of whether and to what extent students identified or relaxed the assumptions included in the given session. I also identified instances in which the cross-disciplinary connections were successful or unsuccessful and developed preliminary conjectures regarding the relationship between students' reasoning across disciplines and the type of mathematical activity that could support student reasoning. I adjusted the exercises based on these revised conjectures. The ongoing analysis yielded tentative conjectures that account for how students would respond.

The retrospective analysis commenced after each experiment had concluded and involved a preliminary analysis to update the conjecture map. I identified episodes from the experiment that suggested the students successfully identified an axiom or a political assumption. I then worked backwards to identify mediating processes and conjectures that account for their successful activity. I coded for mediating processes, both those that were originally conjectured and ones that were unanticipated.

Results

The following excerpts are from Session 4 of the teaching experiment, which was the last session focused on having participants identify axioms and assumptions. Specifically, participants were given multiple examples of circles in non-Euclidean geometries and asked to identify what kinds of assumptions about circles these non-Euclidean circles brought up. They were then asked to critique a series of claims about prisons, with the goal that the participants would identify specific key carceral logics.

In the first half of the session, participants were asked to produce a definition of a circle and based off this definition, draw a circle in a series of non-Euclidean geometries. The participants first drew a circle in the Taxicab Geometry, a modification of the Euclidean geometry with a different distance metric. The taxicab circle resembles a Euclidean square and I had anticipated that participants would be hesitant to accept it as a circle. Ultimately, both participants accepted it. They were then asked to construct a circle in the Gap Geometry, a modified version of Euclidean geometry with a deleted strip, which produced a discontinuous, unbounded curve. Both participants rejected this curve as a circle and appealed to a definition of a circle that included the stipulation that circles were "closed and continuous:"

Author: And so for the 'closed and continuous,' is this something that to your knowledge, is canonically part of the definition of a circle? Or is this something that you've added in now that you've noticed this, and you're like, "that shouldn't be a circle."

Participant 1: I think it's always been part of the definition, but we exclude it because it would be superfluous in the Euclidean geometry.

Participant 2: Yeah, I think I'm assuming that it's in the definition. But I don't think I've had a definition that wasn't exclusive to the Euclidean geometry.

Participant 1: All the circles in Euclidean geometry are closed and continuous, we just don't say it because we just assume that it is.

Author: Out of curiosity, what's the difference between this and the not-round [taxicab] circle we had? Because it's also true that all of our circles in Euclidean are round, and we don't say that in the definition, but that's something that we're used to. What's the difference between a circle being round versus circle being continuous? Is there one that seems more wrong than the other?

Participant 2: I guess that we're holding the implication that it has to be closed and we're seeing that as more of a priority, carrying over the definitions in the different geometries.

Participant 1: I agree, I think that makes sense.

Both P1 and P2 acknowledged that they had never encountered a definition of a circle that included the stipulations "closed" and "bounded;" however, they maintained that these were both implied in the definition and were only omitted because they had previously only worked in Euclidean space. Interestingly, when I asked them to distinguish between their receptiveness towards accepting the Taxicab circle and their reluctance to accept the Gap Geometry circle, P2 suggested that it came down to a subjective decision. Namely, P2 saw the properties of being closed and continuous as "more of a priority." While both participants were unwilling to accept the Gap Geometry circle, they were consistent in their application of definitions. They agreed that the Gap Geometry circle would indeed count as a circle if "closed" was removed from the definition of a circle.

In the second half of the session, I asked the participants to assess various commonplace stances towards prisons. After introducing them to each claim, I asked them if they had any clarifying questions about it, without explicitly asking them to attend to definitions in particular:

> *Author*: So our first claim is that "prisons keep communities safe by incapacitating people who commit crime." So what are some initial questions you have about this perspective? This can include clarifying questions or things you'd want to know to assess the validity of the statement.
>
> *Participant 1*: Oh, well, I think we need some definitions. What do you mean by 'incapacitating people,' what do you mean by 'communities,' and also what do you mean by 'safe?' So for 'incapacitating people,' does that mean just sequestering them from society? Does that mean rehabilitating people? Does that mean keeping their freedoms at a minimum, so they have a much smaller change to commit the crime again in their current state? Which definition of 'incapacitating' are we meaning? Communities... does that mean the non-prison population, does that mean any susceptible parts of society we need to keep from harm's way? What do we mean by 'safe'? Are we just getting rid of crime altogether by sequestering those who've committed crime? Are we just reducing the amount of danger as opposed to getting rid of danger altogether? Are you saying there is no chance prisoners could harm society if they're put into prison? Are you saying there's no chance of them getting out or there's no chance of them still committing crimes while in prison?"

P1 immediately identified the need to define the terms: communities, safe, and incapacitation, and subsequently outlined various logical consequences for utilizing certain definitions (e.g. "Are you saying there is no chance prisoners could harm society if they're put into prison?"). When later asked to identify assumptions of the same claim, P1 again evoked the definition of 'safe:'

> You're assuming the prison has no adverse effects on the community. For example, if you have a lot of well-known members of this society in prison, how would that affect the community? Yes, they are safe from the crimes, but does that mean they are safe? Does that mean they are doing okay? Does that mean they are handling... Let's say there is a group of 10 family members, 9 go to prison. What's happening to the other one? Are they safe from crime? Would they have been safer with those family members on the other side? There are many effects of imprisoning people committing crime that extend beyond making the community safe. So that needs to be included in your assumption, that you are making it safe. Because 'safe' implies 'better.' Those might not be intertwined in this definition.

Ultimately, P1's attention to definitions when considering various definitions of circles extended to considering definitions related to prisons. Considering definitions ("those might not be intertwined in this definition") then became a resource that enabled him to identify a carceral logic, that prisons have no harmful effects on communities.

Discussion and Implications

Ultimately, the participants' activity developing a general definition for a circle outside of Euclidean space, and observing the consequences of this definition, primed P1 to spontaneously consider definitions when discussing assumptions about crime. While by the end of the experiment, he ultimately argued in favor of using prisons in some cases, P1 was successfully able to both identify and question a key carceral logic, namely that prisons have no adverse effects on communities. He also hinted at a few other commonplace assumptions: that

incarcerated people are not part of any community, that people are necessarily safer when their community members are incarcerated. The identification of these assumptions was borne out of an attention to definitions, first in a geometric setting, and later in a setting that discussed prisons.

Participants' activity with definitions in some ways reinforced and in other ways subverted what McNeill et al.(2022) refer to as the objectivity discourse, or the idea that mathematics is inherently objective. In their geometric activity, both participants maintained that circles needed to be closed and continuous, that this had always been part of the definition but had simply been omitted because it was "superfluous" in Euclidean geometry. This contrasted with their earlier acceptance that circles did not have to be round and that their circle construction in the taxicab metric counted as a circle. While P2 seemed to suggest that her own subjectivity was playing a role, both participants characterized their definition of a circle as standard. In contrast, P1 spoke directly to the subjective nature of how someone might define the terms: incapacitation, safety, or communities and the different downstream implications of some of these choices. While neither participant explicitly evoked nor refuted the discourse that mathematics is neutral (B. Martin, 1997; McNeill et al., 2022), their activity did subvert it by illustrating the very consequential differences that arise from how concepts like 'community' or 'safety' are defined. Of course, while it was a goal of this study for students to use skills from advanced mathematics to reason about a social justice issue, these activities were not explicitly designed with the intention of subverting specific math logics. Future work may attend more directly to the possibilities for advanced mathematics to help students subvert their problematic assumptions about mathematics.

Finally, this study builds on prior work describing TMSJ implementations. In contrast with prior TMSJ work, this study provides a potential example of how mathematics can aid in students' *interpretation* of sociopolitical issues. Much of the prior work in teaching math for social justice involved analyzing data or mathematical phenomena and bringing in an external political perspective to serve as a means for interpretation. This is necessary because data can be interpreted in myriad ways depending on the assumptions and commitments people are bringing in. In those cases, it is the interpretation that influences the data; the mathematics itself has little bearing on the development of a political interpretation. Indeed, this created conflict between the mathematical content students needed for a given lesson and the important social justice background that was required (e.g. Gutstein, 2003). However, in this teaching sequence, the attention to and manipulation of definitions was used to support students in questioning commonplace perspectives and interpretations of prisons and incarceration. Future work may consider other avenues, beyond analyzing definitions and assumptions, through which proof and logic can support students' reasoning about social justice topics.

Limitations

As a teaching experiment with four participants (two in this report), it was not a goal of this study to generalize from these specific participants' starting points, trajectories, or reasoning. Additionally, as a series of activities that took place outside of a classroom, the specific context of this learning environment differed substantially from that of a typical undergraduate class. Thus, while this study may be viewed as a starting point for the *possibilities* of integrating advanced mathematics and social justice mathematics, there are real barriers and limitations specific to the classroom setting that did not apply to this study and would need to be studied in future work.

Passaic County Community College

Given declining numbers of undergraduate students choosing to major in mathematics, research in undergraduate mathematics education seeking to understand the motivations and perceptions of math majors is more important than ever before. Of particular interest in this report are community college mathematics majors—they make up a significant proportion of math majors in any given year and yet existing research on recruitment and retention in STEM has been conducted almost exclusively at four-year colleges. We report findings from in-depth interviews with eight community college math majors regarding their motivations to major in mathematics. We then examine the ways in which such motivations interact with institutional and departmental structures traditionally noted to influence persistence in STEM majors. We discuss implications for improving math major retention and advancing the field's understanding of the influence of collegiate context on perceptions of mathematical culture.

Keywords: community college, math major, motivations

The declining number of undergraduate students choosing to major in mathematics—and ultimately graduating with a mathematics degree—has been cause for increasing concern both within U.S. mathematics departments and worldwide (Hall et al., 2022; Musu-Gillette et al., 2015; Seymour & Hewitt, 1997; Seymour, Hunter & Weston, 2019). However, most research collapses math majors within the umbrella of "STEM" or "math and science majors" (see Seymour, Hunter & Weston, 2019 for an overview) and thus is too broad to describe challenges specific to the mathematics major. Some research on STEM majors investigates the influence of high school mathematics achievement (e.g. Wang, 2013; Trusty, 2002) or specific first or second-year mathematics courses on student persistence (e.g. Ellis, Fosdick & Rasmussen, 2016); however, such information is likely not enough to understand phenomenon regarding recruitment and retention of mathematics majors specifically (Hubbard, 2023) given that they interact far more frequently with mathematics departments compared to other STEM majors.

Moreover, the majority of research on recruitment and retention in STEM fields has been almost exclusively conducted at four-year colleges. Little is known about community college STEM majors, and even less about community college mathematics majors (Mesa, Wladis & Watkins, 2014). This is problematic given that almost half of all mathematics majors in a given year are enrolled in community colleges (NCES, 2020), and roughly half of all graduates from four-year colleges at started at a community college (Foley, Milan & Hamrick, 2021). Thus, community colleges are a critical yet understudied part of the math major pipeline.

Of particular interest to recruitment and retention of community college math majors are students' motivations for majoring in mathematics, and how these motivations are influenced by institutional experiences (Wang, 2013). In this report, we asked:

1. How do community college math majors describe their motivations for majoring in math?

2. In what ways are institutional and departmental structures in alignment or tension with these motivations?

The data from this report comes from eight in-depth interviews with students majoring in math as of summer 2024 and enrolled in a two-year college within the City University of New York (CUNY) system. This data is part of a larger mixed-methods project that seeks to identify factors that impact community college math major recruitment and retention, and to create the first retention model for community college mathematics majors. In answering the research questions noted above, we seek to contextualize the field's understanding of the motivations of math majors for pursuing mathematics, and to provide hypotheses regarding the mechanisms by which such motivations might interact with larger structural factors within a math department.

Literature Review

Tinto's model of student departure (Tinto, 1987) is arguably the most influential existing model of college student retention in the literature. Tinto posited that family background, pre-college schooling, and individual student attributes influence student persistence via two "integration" variables which impact a student's decision whether or not to drop out. These variables are 1) academic integration, often measured by course grades; and 2) social integration, often measured by frequency of interaction with other students and faculty. However, subsequent literature has critiqued the relevance of Tinto's model for community college students and other "non-traditional" students (Bean & Metzner, 1985; Ashar & Skenes, 1993; Borglum & Kubala, 2000; Karp, Hughes & O'Gara, 2010; Stuart, Rios-Aguilar & Deli-Amen, 2014).

Bean and Metzner (Bean & Metzner, 1985) developed a model for retention of "non-traditional" adult learners (either over 24 years old, a commuter student, and/or a part-time student) that primarily focused on an institution's academic utility rather than its social environment. The authors contend that social integration is significantly less influential for such students, given that they likely enter higher education with their own support systems and social networks. Their model of student attrition contains three main variable categories: environmental, academic, and background, and these variables then influence academic and psychological outcomes, which in turn determine a student's decision to persist. While this model may be more relevant for groups of community college mathematics majors, it still is not designed to examine the particular interactions between students and mathematics departments and courses that are likely to be relevant to improving math major retention specifically.

Given the limitations of both existing models described above, we focus our review of the literature on variables relevant to retention of mathematics majors. Literature specific to retaining mathematics majors is slim, so we supplement the current review with literature on the more general category of STEM major retention. Within this literature, there are several key factors noted to influence STEM major retention. Most of this work has been conducted in four-year contexts (Wang, 2021), which focuses on factors such as grades and disposition towards mathematics in high school (Musu-Gillette et al., 2015; Shaw & Barbuti, 2010; Wang, 2013; Trusty, 2002; Evans, Chen & Hudes, 2020) and perceptions of mathematics self-efficacy or self-concept once taking college courses (Ellis, Fosdick, & Rasmussen, 2016; Wang, 2013). Though we do not attempt a comprehensive overview of all relevant factors here, we see three overarching categories from existing literature as relevant to our core constructs: sense of belonging and social integration (Rainey et al., 2018; Tinto, 1987; Rodriguez, & Blaney, 2021; Good, Rattan & Dweck, 2012); engagement with undergraduate research opportunities (Russel, Hancock & McCullough, 2007; Eagan et al., 2013; Seymour et al., 2004; Hunter, Laursen &

Seymour, 2007); and mentorship (Apriceno, Levy & London, 2020; Atkins et al., 2020; Chelberg & Bosman, 2019).

In general, the presence of each of these three factors has been associated with increased persistence in STEM degree attainment, while their absence contributes to attrition. Research in the area of sense of belonging notes how both institutional cultures and student-to-student interactions can influence students' perception that they fit in or belong within their chosen STEM major. The underrepresentation of women and students of color in STEM, in particular, can reduce their sense of belonging which can be improved or exacerbated by the institutional and pedagogical environments at the college (Rainey et al., 2018; Rodriguez & Blaney, 2021; Good, Rattan & Dweck, 2012).

Research on participation in undergraduate research experiences (UREs) and engaging with faculty mentorship has also consistently reported positive impacts on STEM major retention and subsequent interest in STEM careers (Seymour et al., 2004; Eagan et al., 2013; Apriceno, Levy & London, 2020; Atkins et al., 2020; Chelberg & Bosman, 2019). For example, Russell, Hancock & McCullough (2007) surveyed over 4000 STEM majors concerning their experience with UREs associated with the National Science Foundation and found that participation in such programs was associated with increased interest in STEM careers and graduate school. Participation in UREs and involvement with mentorship are also likely to contribute to students' sense of belonging. For example, Hunter et al. (2007) reported that UREs fostered a sense of belonging to students' desired scientific discipline and helped them to "[feel] like a scientist," (p. 53). However, given that the majority of existing research was conducted with STEM majors in four-year institutions, it remains an open question the extent to which community college math majors may perceive such resources as useful or accessible within their institutional context. The current study aimed to investigate exactly this question.

Theoretical Framework

To structure our investigation of community college math majors' motivations and the interaction of those motivations with institutional and departmental features, we turned to Critical Bifocality as it has been conceptualized and operationalized for use in mathematics education research (Chen & Horn, 2022). Traditionally, Critical Bifocality is a theoretical perspective that posits that investigations into social processes of marginalization or oppression necessitate a bifocal approach-focusing on the relationship between individual agency as well as structural features of environment. While we do not claim that the experience of being a math major in a community college context must necessarily entail marginalization or oppression, community college students are more likely compared to four-year college students to belong to groups not historically represented in higher education (Goldrick-Rab, 2007) and community colleges (and the students who attend them) have traditionally been stigmatized within higher education (Gauthier, 2020). Combined with the fact that we were interested in examining interactions between individual motivations and institutional/departmental structures, this led us to believe that utilizing the lens of Critical Bifocality would allow us to attend to the most relevant constructs for our student population.

Chen and Horn (2022) provide four principles that characterize research in mathematics education that take such an approach. Although all four principles were instrumental in informing the larger project, for the sake of space we focus the current discussion on two of the principles that were most useful for informing the data discussed in this report. They are, "(1) analyzing interactions between structures and lives; while (2) recognizing the pervasiveness of oppressive structures," (p. 802). Here, we report findings that speak to both of these principles—

individual student motivations for majoring in mathematics and influences from interactions with departmental and institutional structures.

Methods

In summer 2024, we invited all current math majors enrolled in any community college within the City University of New York (CUNY) system to participate in a paid one-hour interview about their experiences in the major. Eight agreed to participate; they varied on a range of characteristics including age, whether they were enrolled part time (PT) or full time (FT), and whether they had ever transferred from another college prior to the interview (see Table 1).

Table 1. Descriptive Characteristics of Interview Participants

Participant ID	Age	Gender	Last math course(s) completed prior to interview	Enrollment intensity	History of transfer
1001	44	Man	Calculus I	PT	yes
1002	29	Man	Calculus III, abstract algebra, differential equations	FT	yes
1003	24	Woman	Calculus I	FT	yes
1004	26	Woman	Precalculus	PT	yes
1005	22	Man	Calculus I	FT	yes
1006	25	Man	Abstract algebra	PT	yes
1007	21	Man	Calculus III, linear algebra, abstract algebra	FT	no
1008	23	Man	Calculus I	FT	no

Each interview was guided by a semi-structured protocol that consisted of the following topics: rationale behind major choice; course-taking (including placement); perceptions of quality of instruction in college math courses; influences of external life factors such as work, family, and health/disability; and influences of institutional culture, structures and resources on persistence within the major. The data for the current analysis is drawn from questions regarding students' motivations to major in mathematics as well as a segment of the interview in which students were specifically asked to comment on their use and perceptions of institutional features commonly noted as influencing persistence in STEM majors in the broader literature (undergraduate research opportunities, mentorship, and community involvement). Influences from students' environmental life factors were also important, but are beyond the scope of this report.

Analysis

Each interview was recorded and transcribed, then coded in several stages using thematic content analysis (Braun & Clarke, 2006). First, five researchers read all transcripts and met to generate common emergent themes. For example, at this stage researchers agreed that there was an important theme regarding students' motivation to major in mathematics and the notion of "real world applicability"; however, the exact definition of "real world" was not yet precisely specified. Then, two researchers took the generative initial themes, reviewed and refined them, and developed a more nuanced set of subcodes. For example, some students were motivated to major in in mathematics due to advancements that such a degree would provide for them in their current or former job. Still others noted that their motivation stemmed from a broader

appreciation for the relevance of mathematics in explaining phenomenon occurring outside of college classrooms. This was carried out in a number of cyclical rounds until consensus was reached between the two coders about the subcodes and the definitions of the overarching themes. Then the final list of themes was shared with a third researcher (another of the original five) for further discussion and refinement, leading to final thematic analysis results presented here.

Results

One prominent theme that emerged from the student interviews was that most community college math majors in the sample were interested in mathematics primarily for its utility, often favoring applied over pure mathematics. Seven of the eight participants shared that they felt that majoring in mathematics would be beneficial because it would facilitate advancement in their current careers (1001, 1003, 1004, 1005) or prepare them for success after transferring to a bachelor's or graduate degree program (1002, 1005, 1007). In contrast, one participant (1006) reported choosing the mathematics major because they aspired to become a mathematician. Overall, participants expressed greater appreciation for applied or "practical" aspects of mathematics than for purely theoretical ones.

However, students frequently felt conflict between their orientation around the practical aspects of mathematics and their experiences of the structure and culture of mathematics departments and classes, where they felt that pure mathematics was the prevailing norm. Two subthemes emerged within this broader theme: one concerning how students experienced this mismatch within their mathematics courses, and another addressing how the mismatch was perceived in extracurricular mathematics contexts, including math clubs, research opportunities, and internships.

Conflict Between Students' Motivation and Course Structures and Culture

1005 illustrated this conflict when describing what an ideal experience would be like within the math major, stating that most of what he would learn would be about, "not just solving maths, they will be able to teach you how to apply this mathematics into the work field...Because like I said, learning how to solve [for] x and y is not enough...I want to know how to use this stuff out there [in the workforce]." In this way, 1005 contrasts purely theoretical aspects ("just solving maths") with those practical aspects that would support him in his transition into the workforce.

Although career relevance is a motivation that has been reported by retention literature focusing on non-traditional students (e.g. Bean & Metzner, 1985), participants occasionally provided evidence that they viewed this common practice-orientated motivation for majoring in math as contrasting with the motivations of a "typical" mathematics major or of the mathematics instructors they have interacted with. This contrast was well-illustrated by 1002, who was set to graduate with their associate's degree in mathematics after the semester in which they were interviewed. When asked about what kind of mathematical activities they enjoyed, they responded, "There are people who love math ... I am not one of them, for sure... The people who love math, who are deep into the most abstract imaginary concepts that are applicable maybe in like 500 years or something… that's just not me." Although 1002 went on to say they do like mathematics, they saw this form of liking as outside of the norm for the motivations of a typical mathematics major because it does not privilege abstract ways of thinking.

1007, who was also set to graduate with their associate's degree in mathematics that semester, expressed similar views. They stated, "I guess I'm not really like those kind of

mathematicians where they...see this simple thing and then they'll just devote their couple years to that thing. And in the end, it's just for curiosity... I actually wanted to see something, how I can use math in the real world." Here, 1007 draws a contrast between himself and "those kinds of mathematicians" in which his interests in more broad applications of mathematics are seen as distinct from topics that would be of interest within a dissertation or academic research article. These findings both align with existing literature (which have noted the importance of real-world relevance and applicability to community college students) and add nuance specific to mathematics majors. In particular, students appeared to make sense of their belonging within a departmental culture they perceived as privileging pure and theoretical mathematics over practice-oriented, applied mathematics. This perception, in turn, seemed to undermine students' sense of belonging in the major. Whether and to what extent such departmental cultures contribute to students' decisions to leave the major remains an open question that we focus on in future phases of this project.

Conflict Between Students' Motivation and the Structure and Culture of Extracurricular Mathematics Activities

Beyond their coursework, many students noted that extracurricular mathematics opportunities also conflicted with their mathematical interests, and subsequently influenced their sense of belonging in the major. Among the seven who reported motivations for majoring in mathematics relating to practicality or their interest in applied fields, it was common for participants to report a feeling of misalignment with institutional resources such as internships, or departmental resources such as social math clubs and undergraduate research projects. For instance, both 1007 and 1003 reported having an initial interest in joining a social math club, but each mentioned a hesitation in participating because they felt these clubs were intended more for students interested in pure mathematics. For 1003, the computer science club felt "more accessible" than the math club, and so she chose to "attack [math] from the lens of computer science" instead. Likewise, 1007 expressed reservations about the mathematics faculty member leading the math club as someone who graduated from an elite institution of higher education with a mathematics degree. He felt that he was more easily able to communicate with a different math club facilitator, who, "might not be the most intelligent or like most successful who graduated from, I don't know, MIT, Caltech, NYU, but the way they communicate with students, the way they engage with students are the best...I guess those kind of professors at math clubs, I think those would be really enjoyable." In this way, we see students' perceptions of their own motivations interact with this structural feature of their mathematics department. In this case, these motivations are perceived as being in conflict with their perceptions of these opportunities, which thus influences students' sense of belonging and subsequently their participation.

In contrast, 1006, who was motivated to major in math in order to become a mathematician, utilized a variety of departmental resources, including his institution's math club and a summer research experience for undergraduates (REU). 1006 reported engaging in these opportunities due to the connection he felt to the other students and faculty members that participated in them. He perceived these individuals as those who, like himself, "also want to talk about [math] problems for the sake of just talking about the problems instead of just going to get the grade." He explained further, "you find people like that sometimes in your classes as well. So, Math Team, certain classmates in my classes who also actually enjoy what they're doing make me feel like I belong." 1006 described math team as "where the mathematician math majors go" in contrast to math majors interested in other applied disciplines. In this way, 1006 saw his motivations as in alignment with his perceptions of these departmental resources, which

further supported his perception of belongingness within the major. We see such findings as in alignment with other work demonstrating the potential for mathematics departments to reinforce exclusionary assumptions of not only who is welcome in mathematical spaces, but what kind of mathematics is welcomed into those spaces (Rodd & Bartholomew, 2006; Battey & Leyva, 2016).

Conclusions and Implications

The broader project from which these data were drawn aimed to generate hypotheses about ways that existing retention literature may fail to fully capture the experiences of community college mathematics majors. Our first finding indicated that students were frequently interested in mathematics because of its perceived utility and applicability to applied problems. Students described this practicality in multiple ways, including the utility of mathematics for career goals or future fields of study, as well as the applied, problem-solving aspects of mathematics courses themselves. In particular, students often viewed this preference for utility as in conflict with a dominant mathematics higher education culture that they perceived as prioritizing pure mathematics, done for its own sake, as a core ideal. This feeling of conflict with mathematical norms appeared to reduce many community college mathematics majors' sense of belonging.

This sense of conflict and misfit occurred both within students' mathematics courses, and within extracurricular mathematics activities offered by the mathematics department, such as the math club, the math team, and undergraduate research opportunities.

These findings illustrate how students' motivations for majoring in mathematics may interact with structural features of mathematics departments in ways that generate either conflict or alignment. This highlights a potential mechanism through which college mathematics culture may play a critical role in shaping community college mathematics majors' sense of belonging, both within the major and the broader mathematical community. We view the cases presented here as an example of Critical Bifocality, illustrating the relationship between individual experiences and departmental structures that may be uniquely intensified in the community college context.

Using Mathematical Knowledge When Learning to Program: The Case of Jack

Zackery Reed
Embry-Riddle Aeronautical University Worldwide

Elise Lockwood
Oregon State University

Students seeking careers in STEM will increasingly be required to develop proficiency with computational tools. As such, many students will be at least incentivized, if not required, to learn to program early on in their undergraduate careers. We hypothesize that, though many opportunities exist in which students can learn programming skills, providing undergraduate students with opportunities to program in the context of mathematics courses will be advantageous for students. We report on interviews conducted with students as they learned to program in the MATLAB language, undergraduate mathematics problems. We discuss how a student's mathematical knowledge mediated his programming practices.

Keywords: Undergraduate Mathematics, Programming, Computation, Digital Tools

There have been several recent calls for investigations into the role of digital experiences, including programming and computational activity, at the undergraduate level. In a recent special issue in the International Journal of Research in Undergraduate Mathematics Education, guest editors noted that "further research on digital experiences at the university level is definitely needed" (Geraniou et al., 2024, p. 688). They included "computational thinking and programming instructional design and policies" (p. 688) in university mathematics in a list of topics to be investigated. In addition, Lockwood and Morken (2021) explicitly call for "more studies in undergraduate mathematics education that explicitly explore relationships between computing and the teaching and learning of mathematics" (p. 404), saying that "much more needs to be investigated about the role of computing within RUME, including identifying and exploring potential benefits, affordances, challenges, and problematic issues" (p. 405).

In response to these calls, we conducted a teaching experiment (Steffe & Thompson, 2000) in which the solving of undergraduate mathematics problems was leveraged as a context in which the students might learn to program. We briefly report on initial instances of a student leveraging mathematical knowledge to mediate his programming activity. That is, we are interested in addressing the following research question: *In what ways might students' mathematical knowledge mediate their early engagement in machine-based computing?*

Literature Review

In mathematics education, there is a rich history of exploring the role of the computer in supporting students' learning. Papert (1980) argued that the computer provided opportunities for enriching students' mathematical thinking and activity. Many studies have featured students' use of programming to solve problems in various mathematical contexts including elementary topics (e.g., Benton et al., 2018; DeJarnette, 2019), and specific topics in undergraduate settings (e.g., Buteau et al., 2020; Lockwood & De Chenne, 2020). Our work continues in this vein, focusing on the domain of first year undergraduate mathematics.

Researchers have also focused on the intersection of computational thinking and domain-specific thinking. For instance, multiple studies (Lockwood & De Chenne, 2020; 2021; Medova and Certkova, 2021) reported on affordances of writing and running code for students' combinatorial thinking. In line with these studies, there is a growing literature base exploring

computing and computer programming in STEM and mathematics education (e.g., Caballero et al., 2019; Weintrop et al., 2016; Benton et al., 2018; Sinclair & Patterson, 2018).

We situate our study within this body of work and specifically examine novice coders' experiences learning to code while solving problems in mathematics. That is, "programming" as a practice is applicable to a wide variety of domains beyond computation in STEM fields, and one can learn to "program" in a variety of contexts. We are primarily interested in STEM-intending students initially learning to program in the context of mathematical problem solving. We hypothesize that such contexts can be leveraged effectively to provide students with an increasingly important skillset for the modern workforce.

Theoretical Framing

Our research question focuses on the interactions between students' mathematical knowledge and their engagement in the activity of machine-based computing (Lockwood & Morken, 2021), particularly as they learn to code for the first time. As such, we theoretically ground both the activity of programming and also mathematical knowledge.

Machine-based Computing

While framings of computer-adjacent activities such as programming, computing, and algorithmic thinking abound, we are primarily interested in early coders' experiences and activity when learning to utilize computational software to solve math and science problems. We thus focus our account of programming within the broader frame of machine-based computing. Lockwood and Morken (2021) characterize machine-based computing as "…the practice of developing and precisely articulating algorithms that may be run on a machine" (Lockwood & Morken, 2021, p. 405). Programming is an example of machine-based computing as it involves writing structured syntax that makes calls to underlying algorithms (e.g. via variables and functions) to be run in sequence through an interpreter to enact a computation and produce a result.

Importantly for our purposes, the activity of programming involves: a) writing, organizing and structuring specific syntax to be read by the interpreter, and b) making sense of the products of the computations in reference to the task or problem to be solved. These components align with Weintrop et al.'s (2016) characterization of programming, a computational thinking practice that "consists of understanding and modifying programs written by others, as well as composing new programs" (p. 139). We view the "understanding", "modifying" and "composing" aspects of Weintrop et al's characterization as features of programming on which we wish to focus.

Mathematical Knowledge

We employ a radical constructivist (Glasersfeld, 1995; Piaget, 2013) perspective to characterize students' understandings and infer aspects of their cognition by observing their utterances and mathematical activity. We conceptualize students' development of understandings in terms of their assimilations to schemes (Thompson et al., 2014) and draw from the fundamental constructs of accommodation and abstraction as the underlying mechanisms of learning and knowing. While we only have space to report on broad themes observed across many instances of students' uses of programming to solve mathematics problems, our built models (see the Methodology section) of the students' mathematical understandings that inform these broader themes are rooted in the fundamental constructs of radical constructivism.

Relevant to our analyses are Thompson and colleagues' (2014) notion of meaning and understanding. An understanding is a "cognitive state resulting from an assimilation" and a

thinker's associated meaning is the "space of implications existing at the moment of understanding" (p. 13). Importantly, as we discuss in the Methods section below, the students were leveraging programming to solve problems in mathematics content for which they had already received instruction. As such, the students were drawing from "stable" mathematical meanings (p. 13), that is, meanings for which the related understanding resulted from assimilation to a scheme. This contrasts "in the moment" understandings (p. 13) which still result from assimilation but may be fleeting because of memory constraints or are only momentarily attained in the process of accommodation. Thus, we both examine the salient aspects of the students' stable mathematical understandings being drawn from in the moments of programming, and we also note inferable features of the students' in-the-moment understandings of the logical mechanisms of computation and the workings of the computational interpreter that produced the outputs they observed.

Methods

We employed Steffe and Thompson's (2000) teaching experiment methodology to examine salient aspects of the students' learning of programming. For this report we focus on the results of individual teaching experiments with students enrolled in mathematics courses at a university in the United States. The teaching experiments entailed 90-minute sessions in which a student utilized MATLAB (Mathworks, 2024) live scripts[1] to solve mathematics problems.

Because of spacing constraints, we report on multiple interviews with a single student, Jack (pseudonym). Jack was in an engineering program and had previously taken the calculus sequence. The selection criterion for the interviews was that the students did not have (or had little) prior experience with programming and were willing to discuss their thoughts as they engaged with the live script.

The interviews took place via Zoom. Participants shared their screens while working in the live script, and the sessions were recorded using the built-in recording feature on Zoom. Participants read (within the livescript) provided textual, diagrammatic, and applet-based teaching elements to learn the syntax, structure, and formatting of code to perform computations in MATLAB. Throughout each live script were frequent goal-orienting prompts to enter code in cells to practice running code to solve problems. Students were free to ask the interviewer clarifying questions and were often prompted to anticipate what they expected the code to produce before running the MATLAB interpreter.

In line with the "responsive and intuitive interaction[s]" (Steffe & Thompson, 2000) common to teaching experiments, the interviewer frequently asked hypothesis-confirming questions while and after students produced and ran code, thusly exploring the participants' reasoning through interaction in the sessions. If the students, after long periods of trial and error, professed to be stuck, the interviewer would aid by providing a hint or parts of the code or syntax.

In retrospective conceptual analysis (Steffe & Thompson, 2000; Thompson, 2008), the research team reviewed the records to build models of the students' thinking using theoretical constructs to explain the observed mathematical activity. The researchers drew from foundational constructs of radical constructivism to infer features of the students' mathematical knowledge being activated and drawn from as they programmed. For this report, the research

[1] Many computational environments have accompanied "notebook" features where code can be structured and formatted alongside text and figures, can be organized into sections, and the output of the code can be viewed within the notebook. Jupyter notebooks are the well-known notebooks for Python. MATLAB's version of this is called a "live script".

team attended to Jack's evolving programming activity, searching for instances where his mathematical knowledge mediated his writing, running, and reviewing of code based on outputs given within the live script. We constructed narratives of episodes in which there were clear or important interactions between Jack's mathematical activity and his programming activity. The episode reported on is exemplary of larger themes taken from the data narratives.

Results

We present an episode featuring Jack's construction of for loops while solving kinematics-related problems. This episode features both smaller-scale and larger-scale instances of Jack' use of mathematical knowledge while engaged in programming activity.

"Distance is velocity times time"

In a multi-session activity centered on loops, Jack was tasked with approximating the distance traveled by car when given velocity and timestamp[2] measurements throughout a car's journey. The velocity information was stored in a 1x8 array called "velocities" and the timestamps corresponding to the velocities were stored in a 1x8 array called "times".

The two tasks in this section were to: 1) create a "distances" array with a for loop and use it to approximate the length of the windy road, and 2) create an "accelerations" array giving the average acceleration of the car over each time interval of travel.

Figure 1 gives Jack's first attempted loop[3] to create and use the distances array:

```
velocities=[13 9 10 4.5 2.2 13 6.7 5.4]
times=[0 120 375 447 807 867 959 1079]
%v=d/t
%d=vt
distances=[]
for i=1:8
    distances=velocities.*times
end
sum(distances)
```

```
distances = []
   ⋮
distances = 10^4 × 0 0.1080 0.3750 0.2011 ...
   ⋮
ans = 3.2140 e + 04
```

Figure 1. Jack's initial loop to produce a distances array.

Jack noted that this didn't seem correct because the loop gave the same output each time. He then was prompted to explain the output and said the following:

> *J:* So we're doing 13*0, 9*120, 10*375 … so on and so forth. So it's outputting that [i.e. the array output is performing those multiplications.] and then sum(distances) is adding that up.

Jack then noted that the loop was not needed to create the distances array via the calculation distances=velocities.*times, and that the loop was simply performing that calculation multiple times over. Jack then spent some time attempting to alter his code to progressively construct the distances array within the loop, eventually attempting the following:

[2] By "timestamp" we mean the time values at which the corresponding velocity measurements were observed.

[3] In the prior live script, Jack had performed arithmetic on arrays, including using the element-to-element array operation ".*", which multiplied the entries of arrays that share indices.

Figure 2. Jack's second attempt creating the distances array.

Jack quickly abandoned this approach. While moving his cursor progressively over the entries in the "times" array he described that for each index i, the loop "… multiplied [the velocities array] by [the time at index] 1, 2, 3, 4, … across times.". We note that Jack was interpreting the structure of the given outputs MATLAB by performing mental arithmetic. Also, implicit in this process was Jack drawing from an in-the-moment understanding of the ordered operations imposed by the MATLAB interpreter that would produce the given outputs. Jack then leveraged this in-the-moment understanding to re-structure his code in a way that reflects the ordered operations to produce the outputs he was expecting.

After another similar attempt, Jack articulated that his loop needed to, at each step, multiply the numbers in the velocities and times arrays that shared an index. After receiving help recalling previously learned syntax, Jack produced a for loop that achieved his stated goals. Importantly, this approach does not accurately approximate the length of the windy road, which was the goal of the task. Jack noted that his results did not match the provided final answer, but he did not act on this discrepancy nor attempt to revisit his code, being confident that the code had achieved his intended calculation. The interviewer chose to move on to the accelerations portion of the task, waiting to see if this discrepancy would surface again.

Jack was then asked to summarize his work on the distance approximation task and write down a formula that would calculate the distance for an arbitrary velocity v and time data t. Jack wrote "D=sum[v1*t1+v2*t2+…]" and said:

> *J:* Distance equals the sum of velocity 1 times time 1 plus velocity 2 times time 2 and so on and so forth … through the whole data set.

We note now (and will elaborate later) that Jack's stated distance calculation matches the calculations that Jack intended to (and eventually did) create with a loop. Jack's distance approximation entailed multiplying the velocity data by their corresponding timestamps, expanding the standard model $d = v * t$ to be enacted with velocity-timestamp pairings.

"Acceleration is velocity divided by time"

Moving on, Jack employed a very similar strategy to generate an array that would calculate the approximate accelerations of the car over the intervals of time, saying "Same thing as before … just tit for tat position 1 divided by position 1 in the array, and then 2 and 3 and so forth." Running the interpreter, Jack realized that there was an error somewhere in his code (Figure 3), as the first entry in the accelerations array was Inf (for "infinity").

> *J:* That can't be right … So we have 0 on the first value of "times", so it should be undefined but we're getting infinity for some reason? … So, I mean that's our starting point so our acceleration is 0, I mean but we have a starting velocity … so really we shouldn't be counting that first value I'm thinking. … So I mean acceleration is the velocity minus the original velocity over the delta of time … if we're starting at 13,

that's our velocity original, and then t is still just 0 … so a starting acceleration of 0 so that makes sense. … we're staying at a constant speed.

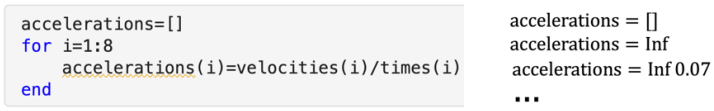

Figure 3. Jack's first attempt creating an accelerations array.

Here, we see Jack attempting to justify the "Inf" result by conceptualizing the start point of the data, as if the car had started without acceleration. Jack had suggested that we could ignore the first entry in accelerations, and the entries afterward would capture the "time delta" accurately and so the rest of the array was correct. Following up, the interviewer asked:

I: Now you just mentioned that for acceleration you want the delta of the velocities over the delta of the times, and so I'm wondering if in your mind the deltas of the velocities is just the same as the velocity itself in the time slot.
B: Yeah I mean acceleration is just velocity over time at that point in time. I guess we could put it that way.

After some time exploring what he meant by "delta" and returning to some of the calculations to examine whether his code was measuring the "delta"s, Jack eventually produced the following loop to calculate the accelerations.

Figure 4. Jack's final accelerations loop

We see two different and important instances of Jack's mathematical knowledge mediating his programming practice. First, as Jack built the distances array, he was able to envision element-to-element multiplication operations occurring in multiple structural configurations and make inferences about the MATLAB interpreter and the logic behind the outputs he was seeing. Jack was not only able to parse when an array resulted from one-to-one multiplication across two arrays but also was able to infer the impact of his syntax on the order imposed by the loop.

On a larger scale, Jack's first chosen model for approximating traveled distance was an expansion of the basic model d=v*t to be enacted on each velocity-time pairing in the dataset. This expansion was similar to those of problems in prior lessons of the teaching experiment, where a major theme was the gained ability from MATLAB to make many calculations at once. Supported by Jack's multiple statements such as "distance is velocity times time" and "acceleration is velocity divided by time" and his work on other similar modeling problems, we infer that this notion of making many calculations at once was an underlying goal taken on by Jack that mediated not only his writing of the code, but his interpretation of the validity of the code output. This differs from other possible goals he might have taken on, such as conceptualizing the construction of quantities (Thompson, 1990) necessary for the solution of the problem and then attempting to enact the quantitative operations programmatically, Jack was primarily concerned with making repeated calculations in the form of loops or array arithmetic.

Moreover, Jack required explicit guidance from the interviewer to become aware that his acceleration loop captured point-by-point division but did not capture his stated "delta"s necessary for typical rate of change formulas.

Discussion and Conclusion

There are two primary takeaways from these results and analyses, both related to the ways that Jack's mathematical understandings mediated his programming activity. The first is that, in these early instances of coding, Jack was developing and leveraging in-the-moment understandings how the program interpreter read his written code. That is, particularly apparent in his for loop refinement, Jack was generating and testing hypotheses about the relationships between their structure of the code and the structure of the resulting output. More than just parsing syntax and debugging errors, there was a cognitive element of inference on Jack's part where he made conjectures about how the code interpreter must be using his written code to produce outputs structured in the ways he observed.

Unlike other contexts in which the results of coding might be interpreted, to parse and interpret the structure of his outputs Jack was engaging in mathematical thinking not unlike the thinking involved in other tasks in the undergraduate curriculum. Students attempting to parse, understand, and leverage formulas such as the distance formula $\sqrt{x_1^2 + x_2^2 + \cdots + x_n^2}$ or sums such as Riemann Sums, partial sums of series, or infinite series similarly have to generate an understanding of the structure and mechanics of the formulas, but also develop an understanding of the appropriate and expected result of the calculation. Unlike these more traditional instances of envisioned sequences of operations, in computational software the results of many sub-stages of the process are viewable, interpretable, and thus able to provide more figurative material from which a student might mediate their programming or mathematical practice.

Contrastingly, the instances reported on in this study were of basic arithmetic operations. One might imagine similar tasks where the sub-stages are themselves complex and would not bring the same affordance to a novice programmer. Finally, these episodes also highlight potentially important considerations for task design in math-based introductions to programming and computation. Jack's successful structuring and writing of the loops were in some ways independent of the problem's quantitative reasoning requirement for the successful approximation of distance and accelerations. That is, the programming-specific goal of the task was to give students opportunities to flexibly navigate the subtleties of loop construction to produce variables of different types. We saw that Jack was able to achieve this goal even though he did not attend to the quantities in a way that would accurately measure the desired approximation. Rather than making recommendations one way or another, we simply note that future research should further investigate the complexities of the requirements on students to leverage particular understandings or ways of thinking as a precursor to successful program-writing. We consider that one eventual goal would be for students to develop enough flexibility and familiarity with coding to then enable computation to be leveraged as a tool for effective quantification and mathematical reasoning.

Setting and Sustaining Intentions: Two Stories of MGTAs' Growth as Instructors

Kelsey Quaisley
Oregon State University

Mary Beisiegel
Oregon State University

Mathematics graduate teaching assistants (MGTAs) often teach or support undergraduate courses and can have a significant impact on learners' experiences in mathematics. However, professional development (PD) programs rarely provide MGTAs with supportive, extended opportunities to learn about, enact, reflect on, and grow in evidence-based teaching practices. We designed a multi-year PD program for MGTAs focused on engaging students in mathematics and enacting equity-focused practices. We analyzed multiple sources of data to investigate shifts in MGTAs' teaching practices using principles of the PD. Applying the Theory of Planned Behavior, we describe the growth of two participating MGTAs. Both participants set and sustained intentions, modified their behaviors to align with their intentions to support engaging group work and empower women, respectively, and experienced positive shifts in their attitude and perceived behavioral control. Key implications include the importance of opportunities for MGTAs to reflect on their intentions and teaching practices in long-term PD.

Keywords: mathematics graduate teaching assistants, equity, active learning, teaching practices, theory of planned behavior

Mathematics departments in the United States rely heavily on mathematics graduate students (also known as mathematics graduate teaching assistants or MGTAs) to teach or to support large lecture-based courses such as Pre-Calculus and Calculus. MGTAs might lead problem-solving sessions associated with lecture courses or be assigned to teach a course as the lead instructor. In some doctorate-granting institutions, MGTAs teach up to 68% of Calculus I courses (Selinski & Milbourne, 2015). Yet, MGTAs rarely receive substantive preparation for teaching mathematics (Deshler et al., 2015; Ellis, 2014; Speer et al., 2017). Professional Development (PD) programs that exist do not typically extend beyond the MGTAs' first year in graduate school (Bookman & Braley, 2022; Deshler et al., 2015; Ellis, 2014; Harris et al., 2009; Kung & Speer, 2009). Preparation for a broad scope of evidence-based teaching practices (e.g., active learning, supporting student engagement in mathematical practices, facilitating collaboration) is crucial as many MGTAs represent future faculty and play an important role in teaching practices at post-secondary institutions (Ellis, 2014; Golbeck et al., 2016; Speer et al., 2017).

The proliferation of PD programs for MGTAs, although slow-going over the past fifty years, has more recently gained speed, as researchers have begun focusing on MGTAs' development as teachers (e.g., Beisiegel et al., 2019; Belnap, 2005; Speer, 2001). In a study of mathematics graduate programs in the U.S., Braley et al. (2023) observed that a greater number of graduate programs now offer some form of PD, such as an orientation to the department and teaching duties (79%) and/or a term-long teaching seminar (75%) as well as occasional workshops (73%). As the field has turned its attention to issues of equity (Brown, 2018), we see a similar focus in PD programs for MGTAs, with 65% of programs now offering some PD about equity (Braley et al., 2023, p. 1046). However, little is known about the equity-focused content in these programs.

Engaging in equitable mathematics teaching practices means accounting for students' identities in the classroom (Gutiérrez, 2009). For instance, a wealth of research demonstrates that active learning teaching practices do not inherently support female students in collegiate mathematics courses (Johnson, 2024). Rather, equitable instructors offer deliberate opportunities

for women to explain and justify their mathematics solutions uninterrupted (Johnson, 2024). While some PD has supported MGTAs in increasing their use of equity-focused teaching practices (Coles & Piccolo, 2025; Pilgrim et al., 2025) few studies have investigated MGTAs' general understanding of teaching practices (Beisiegel, 2017; Miller et al., 2018; Speer, 2001; Speer et al., 2010) and, more specifically, how PD programs can help MGTAs learn about and enact teaching practices that contribute to improved student outcomes.

Theoretical Framework: Theory of Planned Behavior

Despite MGTAs' impact on learners, only a handful of studies have investigated their understanding of and growth in teaching practices. As one example, Miller (2018) conducted a case study of experienced MGTAs, most of whom had experienced a year-long PD program focused on active learning and were teaching a Pre-Calculus course for the third time. While the MGTAs were provided lesson guides that emphasized active learning, Miller found that they often reverted back to lecturing when students were not engaging in group work. Another example (Beisiegel et al., 2019) investigated MGTAs' growth in their knowledge of teaching over the course of five years. They found that novice MGTAs were often unable to consider teaching practices that support active engaged learning as they needed time to adjust to routines of teaching (e.g., lesson planning) before adopting practices they had not yet experienced.

Our research investigates MGTA growth through the lens of Theory of Planned Behavior (Ajzen, 1991), which focuses on *behavioral intention*, *attitude toward the behavior*, *subjective norms*, and *perceived behavioral control* (see Fig. 1). In the context of the PD program, *behaviors* refer to the teaching practices that MGTAs use in the classroom and *intention* is an MGTA's plan to use certain teaching practices. While intention directly impacts resulting behavior, an MGTA's perception of their ability to employ teaching practices influences their pedagogical choices (i.e., their perceived behavioral control).

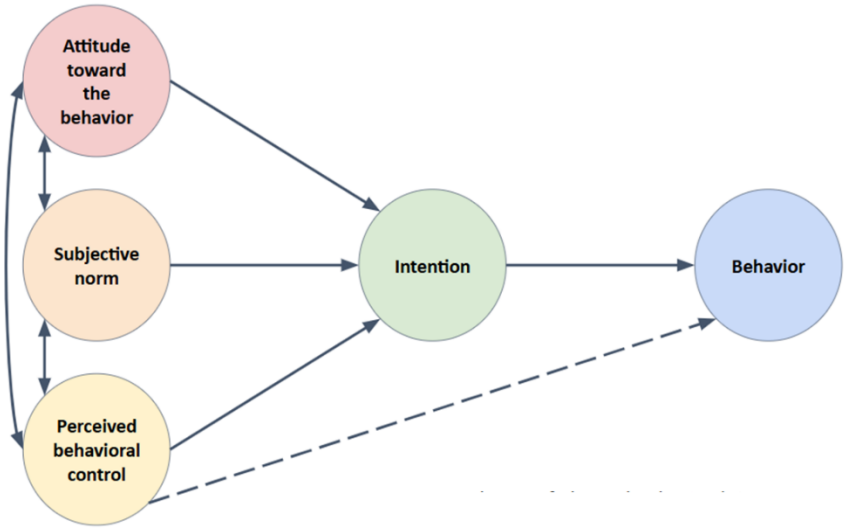

Figure 1. Theory of Planned Behavior (Ajzen, 1991, p. 182)

We implemented a PD program to support MGTAs in engaging students and enacting equity-centered teaching practices. In this report, we focus on two participants because of their commitment to setting and sustaining intentions in terms of active learning and equity. Our research question is: What change in behaviors, attitudes, and perceived behavioral control do MGTAs who set and sustain intentions in teaching experience during a two-year PD program?

Context of the Study and Methods

ELITE PD consists of five elements. In the first year of the graduate program, ELITE PD offers a three-day fall orientation as new MGTAs arrive at the university (topics include: the department and MGTAs' roles, community building with their peers, develop introductory knowledge of teaching practices focused on active group learning and dynamics) and a fall graduate teaching seminar (GTS) that is focused on their first term as an MGTA (topics include: more information about the department, the university's teaching support resources, classroom management, and how to implement small-scale instructional practices with attention to equity and active learning). The second year of the ELITE PD program offers a fall-term seminar Introduction to Active Learning and Equity (IALE; MGTAs build upon their understanding of and facility with active learning and equitable teaching practices) and a winter-term seminar Advanced Active Learning and Equity (AALE; MGTAs engage with specific research-based pedagogical approaches as well as equity research associated with teaching). We expect MGTAs to complete these seminars in the second year of their graduate programs, but some choose to focus on passing qualifying exams before taking IALE and AALE. The fifth element of ELITE PD has the MGTAs who have completed the first four elements become teaching mentors to new MGTAs. During each year of the ELITE PD program, we interview participants twice (fall and spring), video record them teaching three times (exceptions to this are when the MGTA is on a research fellowship or has an assignment as a grader for a course), and also survey their students. In IALE, the MGTAs complete journal reflections that are also used to understand their growth.

We explore the growth of two participants, Ayla (pseudonym), in incorporating group work practices, and Athena (pseudonym) in empowering women in the classroom. We chose to report on Ayla's growth because of her choice to repeatedly reflect on a salient struggle with engaging students in group work, as well as perseverance in their efforts to modify their teaching practices. We chose to report on Athena's growth because of her awakened intention to empower women and their notable shifts in teaching practices to realize this intention.

For Ayla, we analyzed five classroom observations (O2-6) and post-observation debriefs (D2-6), two interviews (I1-2), five reflection journals (R1-5), and an exit ticket from the IALE (ET). Note that each of O2-6 and D2-6 occurred once per term from winter of their first year in ELITE PD to spring of their second year, I1 occurred during GTS, R1-5 and ET occurred during IALE, and I2 occurred during the AALE. For Athena, we analyzed three classroom observations (O1-3) and post-observation debriefs (D1-3), and two interviews (I1-2). Note that each of O1-3 and D1-3 occurred once per term from fall of their first year in ELITE PD to spring of their first year. I1 occurred during IALE and I2 occurred at the end of the spring term. We analyzed these data by identifying each MGTA's intentions, and then identifying the components of the Theory of Planned Behavior relevant to their intentions.

Findings: Ayla's Growth in Supporting Group Work

In the first year of ELITE PD, Ayla's teaching practices centered on answering the questions of students with raised hands, without specifically instructing students on how to work on mathematics, e.g., in groups, pairs, or individually (O2, O3). Primarily, Ayla's intention for teaching was to "just let them work and then answer their questions when they pop up" (D3). However, Ayla's intentions for students to collaborate and talk with each other also started to percolate in her first year. She stated that her plans were "to try to make sure every student feels heard…and then try to encourage them to ask their group mates, if possible" (D2).

During IALE, Ayla's desire for students to work in groups increased; she wanted to "inspire collaboration" (R4) and get them "talking and participating" (R5) but she faced too many

challenges to change her practices the ways she wanted. First, Ayla expressed that "forcing students to work in groups feels uncomfortable" (R1). Second, Ayla felt pressure to avoid asking students to work in groups because of perceived resistance to changing norms mid-term: "I have already set the norm [to not do group work], so I am not sure how the students will react to it" (R1). Third, Ayla indicated a perceived lack of behavioral control, stating that it's "hard to get them to work in groups" (D4). At the same time, Ayla managed to make incremental progress towards her goal by asking every pair or group of students to check each other's answers (O4).

By AALE, and in the subsequent term, Ayla had experienced shifts in attitude, subjective norms, perceived behavioral control, and she began to incorporate co-constructing and revisiting group work norms (O5, O6). Ayla felt "empowered to try new things with students" (Fall ET), believed that she encouraged students to get "into groups pretty easily" and have "lots of conversations" (D6), and exuded confidence in describing her new teaching practice:

> My favorite one was the norms… like, 'these are the norms' and 'are there any other norms that you as students wanna add?'...it is one of the big reasons why I went from having almost no group work in the last term to really great and productive group work this term. (I2)

Table 1 shows an overview of Ayla's shifts towards supporting group work throughout years one and two of ELITE PD, which she ultimately credited for much of her growth:

> I've taken a lot of things from our seminar and tried to incorporate them into my classes…at the beginning of the term, I did group work norms, and I did it in the first class…and then I did it again when we came back from the snow day. Because I was like, 'I wanna remind everyone of the norms that we agreed on.' And I really think that helped develop equitable work and group activities. Because part of my norms were 'no one's done until everyone's done', making sure people don't get left behind...there's no dumb questions…And I think just doing that at the beginning of the term, really helped develop my, like, facilitating the group work that's been going on in my class. (D5)

Table 1. Ayla's Growth in Supporting Group Work

	Year 1 of ELITE PD			Year 2 of ELITE PD		
	GTS			IALE	ALE	
	Fall	Winter	Spring	Fall	Winter	Spring
Attitude				Uncomfortable with forcing group work (R1)	Empowered to try new things (Fall ET)	Frustrated but confident (O6)
Subjective Norm	Students may resist group work given that no group work norms have been established (R1)				Students easily work in groups when norms are set (D6)	
Perceived Behavioral Control				Hard to get students to work in groups (D4)	Confident in supporting productive group work (I2)	
Intention	Wants students to collaborate and talk with each other					
Behavior		Not promoting group work (O2, O3)		Asks students to check other's answers (O4)	Co-constructs and revisits group work norms (O5, O6)	

Findings: Athena's Growth in Empowering Women

After the first interview with Athena, it was clear that she was sharply aware and growing in awareness of gender (in)equity. When asked how she first learned about gender equity, she immediately responded that she learned about it "because I'm female, and the science field is dominated by men" and reflected on how her unique background and experiences moving to the U.S. for graduate school made her realize that women deserve more:

> I come from [Anonymized Country], so the women just have less, you know. So there's… not too many expectations. Not until I came to the US, and I'm like, 'Okay, equity is something to think about.'…it has become important to me, especially as I go through a lot of stress right now in my PhD…it wouldn't be fair to, um, just not get the same treatment a man would get, or the same recognition… (I1)

Athena's lived experiences seemed to motivate her awakened intention to empower women in mathematics. However, her shift to enacting behaviors in alignment with her intention was not immediate. Rather, her shift followed deliberate reflection on her teaching. When asked what she learned about her teaching from the first observation, she said, "I really approach this teaching thing in a very different way, in a wrong way…I don't even go to learn. I go to do my work and just, just get home….I'm not focusing on learning…that's not great" (D1).

Although Athena may not have focused on learning from her teaching that day, she reflected on her teaching during the post-observation debrief interview. When asked about unforeseen challenges with regard to equity and inclusivity, Athena's reflection included perceived behavioral control related to opportunities for women to present on mathematics:

> One of the group's that's only girls…they're like, 'Oh, is it okay to present something like that?'...I think they had the harder problem…I was very like, 'Okay, I get it. It's a hard problem. I'll do it on the board for everybody'…I did not have a problem with it, because they were just unlucky that day. (D1)

Athena's reflection appeared to prompt changes in her teaching practices, because in the next two terms Athena adjusted the ways she enacted group work to provide more opportunities for women to present mathematics. In the fall, Athena had permitted groups to self-select individuals to go up to the board and present solutions, which did not guarantee that women would present solutions (O1). But in the winter, Athena specifically encouraged women to talk about mathematics with the whole class listening (O2). For instance, during the second observation, Athena persisted in encouraging a woman to answer a question despite this student's shyness and lack of confidence, and despite seeing another raised hand from a man sitting in the front of the classroom (who would later present his work at the board):

> *Athena*: How are we doing on 1C? Did we get an answer? Um, does anyone have the answer for 1C, or…? [Athena nods head and looks with a smile to a woman near the back] What's your answer? [Student laughs a bit nervously] It could be right, you know? [Student(s) mumbling] Huh?
>
> *Student (woman)*: We did it but we're not feeling, like, confident.
>
> *Athena*: [Man near front raises hand, and Athena looks his direction, then looks back to woman, raises eyebrows in earnest, and gently waves her hand downwards towards the man, which prompts him to lower his hand. Athena continues to make eye contact with the woman.] One sec… What answer did you get?

Athena additionally offered opportunities for women to present mathematics at the board. She later reflected on this choice, revoicing her intention: "the girls should also get involved…not

just the guys" (D2), and expressing a happy attitude as she excitedly relived the moment when one of the women got an answer right:

> The guys were coming to the board to share their answers, and I just offered a girl, and she got the right answer. But she was so shy, you know…I gave her the morale and the motivation she needed to go to the board. Because she got it right, you know?…the worst part was that she got it first before the guys…they're not shy, you know…Yes, I felt good about it and she did feel good. I noticed she was happy. I looked at her, you know, because she felt like, I don't know why. I just felt she was happy, and I liked it. (D2)

By the spring term, Athena had modified presentation norms so that the individual(s) presenting within a group would rotate from one class to the next (D3). By making these changes, Athena ensured that women in groups of men would also have the chance to present their work, and furthermore, that every student would have a chance to talk about mathematics. Additionally, Athena continued to verbally encourage women presenters. For instance, Athena encouraged two women to discuss their solution at the board, saying, "you can teach us" (O3).

During the third debrief, when asked what went well in terms of equity, Athena first described how she ensured that everyone would get a chance to present and how she scaffolded solutions with some women to prepare them to present their work. She said, "if I did not do that they might have not been able to present their work on the board, and they might have just been left out" (D3). The interviewer then asked a follow-up question, saying, "I remember from the last time I did a debrief interview with you, you mentioned having the girls and women in your class feel really included. Do you have thoughts on how that's going this term?" (D3). In response, Athena again articulated her intention to provide opportunities for women and expressed confidence in doing so:

> I pretty much have learned how to navigate that…it's no longer a problem for me. I just treat everyone equally. I also make the ladies present their work, even if they are in, like, a group of men, for example. Like, it's okay if you, if there are, like, four guys and two girls. It's not okay for just the guys to present. The girls can also present the answer. You know what I mean? Like, on the board, not just the guys (D3).

Along with Athena's shifts in behaviors and perceived behavioral control, Athena's attitude towards teaching more generally shifted in positive directions over the course of the year. By the third debrief interview, Athena described enjoying and looking forward to teaching, saying she was "beginning to enjoy the process," "meeting my students makes me happy," and "I fell in love with a pattern I've been using, and that's been working" (D3). Similar to Ayla, Athena credits ELITE PD for her growth in enacting equitable teaching practices:

> Before I joined ELITE PD program, I was not very aware of inclusivity and equity, like, I just designed, I just did my job, you know what I mean? I just showed up to class to do my job, irrespective of how the student felt, or, like, I did not think about 'Oh, I should think about my students' feelings, or who they are.' You know what I mean, I just did my job. But having been part of ELITE PD, I'm able to understand that every student is different, and so are their needs. (I2)

Table 2 shows an overview of Athena's growth in empowering women in her classroom in year one of ELITE PD.

Table 2. Athena's Growth in Empowering Women

Year 1 of ELITE PD			
	IALE	AALE	
	Fall	Winter	Spring
Attitude	Tired after teaching, generally (D1, D3)	Likes to see shy women happy they are right (D2)	Excited for teaching and students, generally (D3)
Subjective Norm		Men always raise hands or present solutions at the board (D2, D3, I2)	
Perceived Behavioral Control	Challenging to support women in presenting difficult solutions (D1)		Confident in supporting women to present solutions (D3)
Intention	Empowering women in mathematics		
Behavior	Groups self-select student presenters (O1, D1)	Chooses women to talk and present when raising hands (O2, D2)	Rotating who presents within groups (D3) Preparing women to present (O3, D3)

Discussion

The Theory of Planned Behavior (Ajzen, 1991) helped us to observe shifts in MGTAs' attitudes, thoughts, intentions, and behaviors. Regularly interviewing and inquiring into each MGTA's experiences provided us with opportunities to follow their narrative threads–the major changes in various components of the theoretical framework, and the reflections and classroom experiences that instigated those changes. Ayla's attitude of discomfort with group work shifted, as she maintained her belief in its benefits for students, and persevered in her intention to enact, and ultimate enactment of, engaging group work strategies. Further shifts of her perceptions of students' perceptions of group work (subjective norms), as well as increased confidence (perceived behavioral control), influenced Ayla to grow in enacting group work strategies in subsequent courses. In contrast, Athena began her year in the program with a strong desire to empower women, which was sparked in terms of her intentions for teaching in the fall. Having set her intentions on empowering women by providing them with opportunities to talk about mathematics, Athena enacted new teaching practices in the winter and sustained her intention with further modification to her behaviors in the spring. Together, Ayla and Athena's stories of growth suggest implications for the potential benefits of reflection and extended PD.

The lessons we learned from analyzing Ayla and Athena's experiences and observing their growth have implications for other PD providers. In particular, regular observations and post-observation debriefs have the potential to sustain MGTAs' attention to their teaching. In addition, we find it noteworthy that reflection journals in IALE and observation debriefs provided opportunities for MGTAs to consider their values and intentions for teaching and whether or not their teaching practices are in alignment with those intentions. Specifically, reflection on challenges and successes with teaching supported both Ayla and Athena to consider ways to develop engaging and equitable teaching practices. This finding aligns with other research on the benefits of deliberate reflection for MGTAs and instructors of mathematics, more generally (e.g., Quaisley, 2024; Rogers, 2014). Future analyses will investigate patterns of growth across additional participants.

Student Experience With Collaborative Teamwork in Post-Secondary Discrete Mathematics

Shandy Hauk
San Francisco State University

Paul Carmody
San Francisco State University

Rebeca Hernandez
San Francisco State University

As part of a project developing and researching the use of team-worthy lessons in discrete mathematics in two- and four-year colleges, we conducted a study of three instructors and their 105 students. Classroom observations indicated that the use of team-worthy lessons changed the structure of classroom activity from primarily didactic lecture to at least 75% student-centered activity (e.g., group work, student presentation). However, a change in observed structure is only evidence of an affordance, not of students' experience of it or how it might have been productive for students. After each team-worthy lesson, students completed surveys about what went well (and not). Analysis of student responses used a framework based on social learning theory. Here we present results about students' self-reported experiences in terms of agency, authority, creativity, and self-efficacy.

Keywords: discrete mathematics, professional development, team-worthy lessons

Background

For many students, discrete mathematics is a first exposure to formal logical reasoning, proofs, and proving. Undergraduates entering discrete mathematics have many experiences with procedural problem solving and often attribute the authority for sense-making to textbook, instructor, or software (Herbel-Eisenmann, 2007). Like calculus, discrete mathematics shares a history of enormous disparities in outcomes correlated to demographic variables (Campisi et al., 2024). Research in undergraduate mathematics education, notably in calculus, has indicated that disparities can be addressed by linked changes in student materials and instructional methods (Bressoud & Rasmussen, 2015). This literature has also indicated that group-worthy learning opportunities for students combined with use of socio-culturally informed instructional approaches can build positive relationships among students, between students and instructor (and institution), and foster engagement in and outside of class (Archie et al., 2022; Laursen et al., 2014; Leyva et al., 2022; Yoshinobu et al., 2023).

The research reported here comes out of a multi-year project leveraging lessons learned from calculus reform to develop and research use of team-worthy activities in discrete mathematics (Discrete Mathematics Project, 2026). The project's research aims are to (a) explore how use of team-worthy lessons to replace lecture perturbs/enhances student opportunities for engaging in the intellectual work of discrete mathematics and (b) refine professional learning materials and processes to help faculty incorporate student-collaborative methods into their teaching. This report focuses on a subset of the data collected in the larger project to explore the research question: *What evidence is there from classroom observation and student survey that the use of team-worthy lessons creates opportunities for students to develop self-efficacy, authority, agency, and creativity, as components of their learning experience?*

Theoretical Perspective

Our approach was anchored in social cognitive theory and its attention to self-efficacy, agency, and authority (Bandura, 1997). The conceptual framing also drew on educational equity (Gutiérrez, 2009) and mathematical creativity (Regier & Savic, 2018). The framework we used included five categories (Carmody, 2024):

- **self-efficacy** (self-perception of one's own abilities for a given task),
- **authority** (perception about a source of information that has power for validation, verification, or legitimation of a student's or a group's work in mathematics; can be ascribed to a live human in the room or to others (e.g., in a textbook))
- **agency** (self–perception that is both personal and an aspect of interplay between teacher and student regarding who the agent of action is in doing mathematics),
- **mathematical creativity** (components in the process of intellectual work in mathematics),
- **equity** (in the narrow context of the meeting of student needs for access to ideas and identity development in the classroom, more on this below).

Agency involves both a willingness to act and a readiness to act (Bandura, 1997). Creativity, the use of imagination or inventiveness, influences what a learner may act on (and how they will take action). Agency is a co-requisite for experimentation related to how and what to act on (Regier & Savic, 2018). Beyond creativity and the ideas in social cognitive theory (self-efficacy, authority, agency), are the self-conceptions that make up mathematical identity and contribute to who students see themselves to be as learners and doers of mathematics. The framework offered by Gutiérrez (2009) involves interactions among mathematical identity, power, access, and achievement as aspects of educational equity. Gutiérrez noted, "equity is ultimately about the distribution of power, power in the classroom, power in future schooling, power in one's everyday life, and power in a global society" (p. 5). Note that we do not attempt to define equity here. Rather, we give background for what shaped the narrow use of equity concepts in the study in our attempt to document student experience.

When analyzing what made successful schools successful, Gutiérrez (2012, p. 26) found "a key feature of this successful context lay in teachers placing student needs, not just mathematics, at the center of their work." Whose needs are met and who decides they have been met depend on context. Some needs are established by and for an institution by majority society expectations (as defined in the curriculum and requirements for graduation or certification) and other needs are established by students themselves (e.g., needs behind why they chose to gain an education, seek certification, take a particular course). Needs being met for students is, therefore, part of a personal experience, established by the student's own background and supported by the institution in its practices, environment, and standards — including what happens at the intermediate level of the classroom. Thus, the analysis for this report centers on the key feature of the fulfillment of a student's asserted educational needs. Unlike Gutiérrez, who considered schools in the context of society, the focus here is students in the context of the classroom. Equity is far more than meeting a student's needs; it includes how this fulfillment is achieved. This report is not an attempt to address the broader issues of educational equity but to exemplify a means of documenting evidence for the particular aspect of equity related to students' perceptions of their needs being met and the openings offered to students to build personal agency, authority, self-efficacy, and mathematical creativity in the classroom setting.

Methods

Setting and Participants

The data for this study were collected from multiple visits to discrete mathematics classes at two- and four-year colleges. Conducted with appropriate institutional review board approval, data gathering and analysis included three instructors (pseudonymously: Antilles, Peter, and Miles) and the 105 students enrolled in their classes. During the study semester, the three

instructors themselves engaged in a short-course for professional learning about the student-centered methods for which the lessons were designed. The short-course focused particularly on noticing student thinking and strategies for orchestrating classroom discussion. Instructors had access to both a user guide giving an overview of how to teach with the activity-based lessons and detailed instructor roadmaps for each lesson. Instructional resources included:

- basic principles of team-worthy tasks and role-taking by students in team groups (Facilitator, Reporter, Documenter, Questioner)
- guidance on how to form, structure, and manage student teams
- lesson materials (e.g., student handouts) and recommendations for lesson preparation
- suggested questions to pose during instruction
- commentary on common student difficulties and strategies for addressing them
- written-out sample solutions for each task, including optional assessment items.

All three campuses were designated as Hispanic serving. Attendance in the on-campus classes varied, with an average of 80% of enrolled students present for observed classes. We visited at least two different team-worthy lesson uses for each of the instructors, each lasting 60 to 75 minutes (4 for Miles, 3 for Antilles, and 2 for Peter) in addition to at least 150 minutes of typical classroom teaching for each instructor (i.e., not using team-worthy lessons). Instructors interspersed team-based lessons with typical lecture across the semester, at least 1 lesson per month. Students completed a short survey after each team-worthy lesson (average $\leq$ 10 minutes). The descriptive statistics presented here were the result of quantitative analysis of observation protocol details across all observed classes, summary statistics from selected survey responses, and relative frequencies from qualitative coding of open-ended responses.

Observation

The observation method used for documenting classroom activity was based on the *Toolkit for Assessing Mathematics Instruction - Observation Protocol* (TAMI-OP; Weston et al., 2023). The TAMI-OP tool divides a classroom experience into two-minute intervals where checkmarks for a variety of actions by instructors and by students are recorded in a spreadsheet. Once documented, the actions can be grouped into four profiles based on the predominant actions that were checked: interactive lecture, group work, student presentation, or didactic lecture. An "interactive lecture" environment is teacher-centered yet includes questions and answers being exchanged between the teacher and one or more students in a whole class setting whereas the "didactic lecture" environment is teacher-centered and has little or no expectation of feedback from students to teacher or vice versa. The other two profiles are made up, respectively, of actions involved in "group work" (e.g., students work together in small groups, the instructor moves through the room guiding group activity) and "student presentations" (e.g., a student presents on their own or as a reporter for a group).

Survey

Two open-ended items on the survey asked students to:

O1. Share at least one aspect of your experience today with math teamwork that NEEDS IMPROVEMENT

O2. Share at least one aspect of your experience today with math teamwork that was POSITIVE.

Four Likert scale items on the survey asked students to rate aspects of their class session experience (see Table 1). The first two prompts are proxy measures for student sense of belonging and efficacy for engaging in the face of the challenge of working with others. The pacing questions are a proxy for identifying access to intellectual work experienced by students.

Table 1. Likert-like Rating Items on the Survey

Question	Scale
L1. Overall, how would you rate your experience of class today?	1=Satisfying to 5=Not Satisfying
L2. Overall, how would you rate your experiences today in working with others?	1=Fantastic to 5=Terrible
L3. How would you rate the pace of today's activities?	1=Too Slow to 5=Too Fast
L4. Thinking about all class meetings, including today, how would you rate the pace of the class so far?	1=Too Slow to 5=Too Fast

Qualitative Coding

Inductive analysis of students' responses began with the framework. Through three rounds of coding (open, thematic, categorical), the definitions of each subarea were refined. Distinguishing evidence of authority and of agency in student reporting was challenging. A student's reported actions might arise from being an agent in mathematics or might be more connected to their own sense of authority (e.g., validating or verifying their own legitimacy). A further complication, in a group setting, is that students participating in discussion may show agency or authority together (e.g., as a group collectively) and individually. In fact, the authority of the group may yield to any one person. Thus, for the purposes of this report, authority was considered a personal exercise. Consequently, in coding student's responses we distinguished between agency (acting on one's own work) and authority (verifying the legitimacy of one's or others' work).

Results

The first two rating questions were about overall experience and experience working with others. These were proxy measures for student sense of belonging and for engaging in working with others. For both items, the vast majority of responses were in the top two positive categories, with 98% in the top three (i.e., fewer than 2% of student responses in negative categories, see Figures 1 and 2).

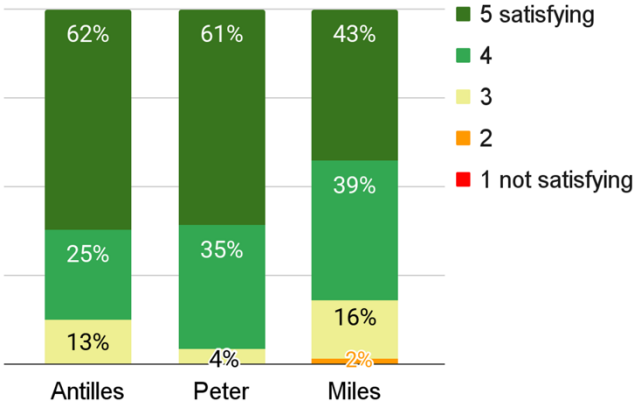

Figure 1. Student rating of overall experience today.

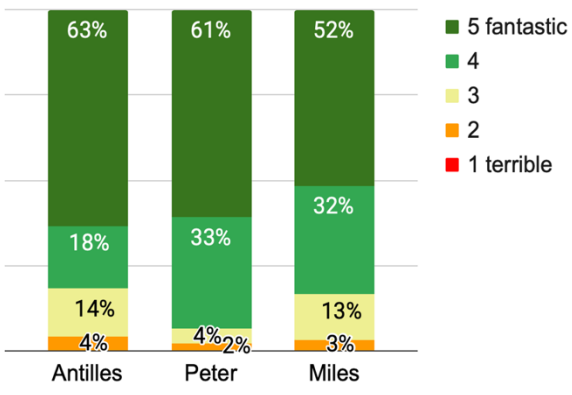

Figure 2. Student rating of experience working with others on mathematics today.

The questions about pace of the day's team-worthy lesson activities and for the class so far, were a proxy for identifying the access to intellectual work experienced by students. If pacing is about right (in the middle), that suggests students felt the work was accessible. For both items, most responses were that pacing was reasonable (not too fast, not too slow, see Figures 3 and 4).

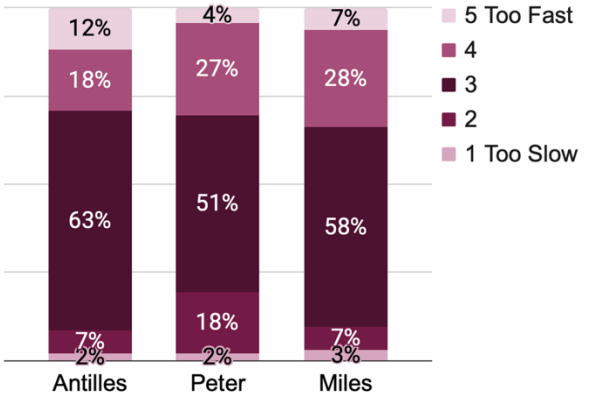

Figure 3. Student rating of pace of activity.

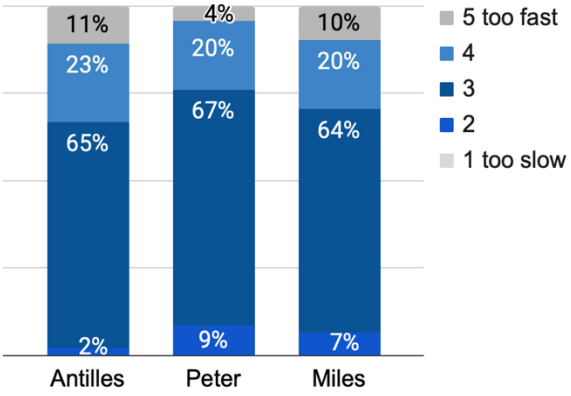

Figure 4. Student rating of pace of class so far.

Analysis of observation data indicated that the use of team-worthy lessons changed the structure of classroom activity from primarily didactic lecture (see Figure 5) to at least 75% student-centered activity (e.g., group work, student presentation; see Figure 6). Figures 5 and 6 suggest that the professional learning opportunities offered as support for instructor use of the materials was sufficient for a change in classroom practice when lessons were substituted for typical practice. However, a change in observed structure is only evidence of an **affordance**, not of students' experience (i.e., if and how the much larger proportion of group work and student presentation time was productive for students' engagement or learning). The examination and coding of written self-reports from the student surveys shed light on what went well (and not).

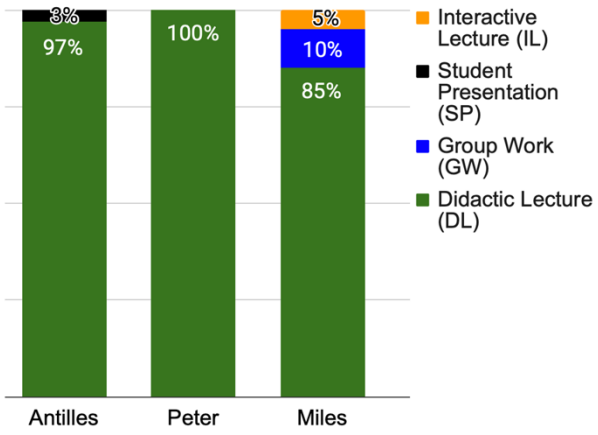

Figure 5. Distribution of instructional formats during typical classes.

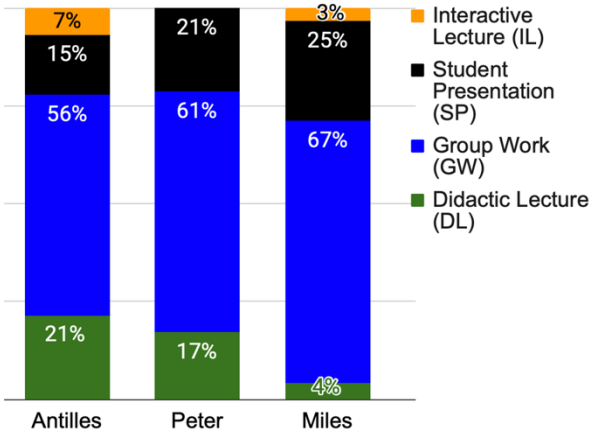

Figure 6. Distribution of instructional formats during team-worthy lessons.

The distribution of coded categories in responses to the question about what was positive differed across instructors (Figure 7, next page). For this report, only one primary code was assigned to each student's response, thus the columns sum to 100%. The code of *creativity* was the primary code in fewer than 6% of responses for any instructor. Similarly, the equity-related

category of *no unmet need* was explicit in only a few responses in each class. Students commented on a positive experience of *agency* by remarking on their pleasure with exploring mathematical ideas and engaging with teammates. A primary code of *authority* arose when a student reported satisfaction with their own or their group's competence or legitimacy in mathematical reasoning. In about 10% of responses in each class, students reported a positive experience of calibration of *self-efficacy*, in understanding the mathematics in the lesson. Finally, the most notable positive experience for many students was that they *worked together* in coming to a deeper understanding of the mathematics at hand (more on this new category, not in the original framework, below).

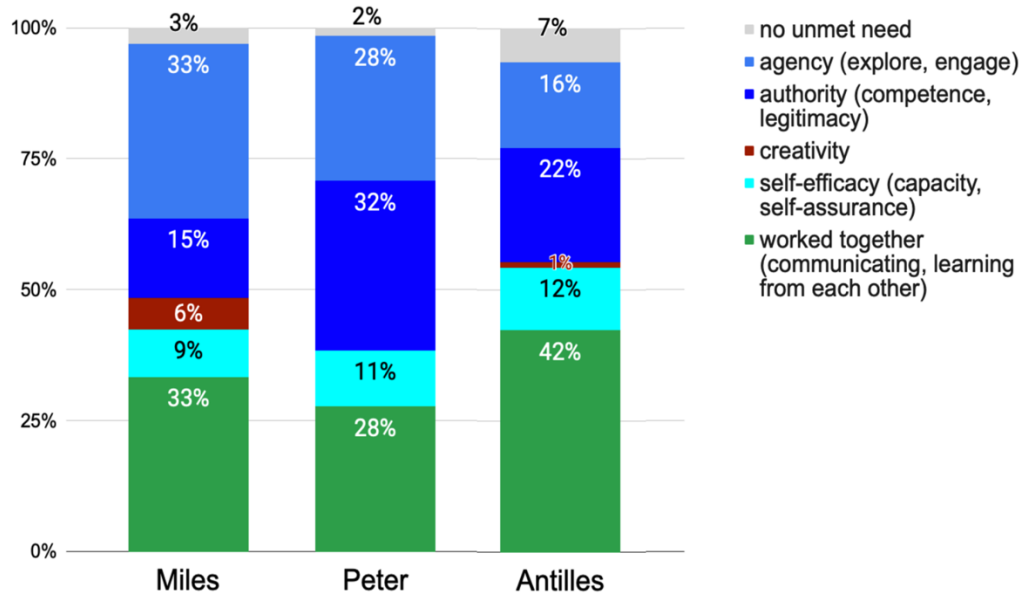

Figure 7. Distribution of percentage of coded student response across all activities, by instructor for "Share at least one aspect about your experience today with math teamwork that was POSITIVE."

Comments about what needed to improve to meet students' felt needs also varied by instructor (Figure 8, next page). As with the positive responses, each student comment got one primary code. Students sought better *access to tools* (e.g., whiteboard pens) or *directions* (e.g., details from the instructor about what was expected for success). Students also reported a feeling of not being clear on if/how they might have *choice* or make *decisions* related to questioning others within their group or on other teams. For each instructor, nearly 20% of students had concerns about how to behave to engage in *collaboration* so that all in the team were involved in interpretation, problem-solving, and/or communication of ideas. The phrase *no suggestions* indicates students commented that all was well or left the answer blank.

Noteworthy in Figure 8 is the smaller proportions of Miles' students who indicated a need for improvement in *choice/decision* or *access to tools/directions*. Miles regularly referred to group roles and reinforced students enacting those roles when he visited groups. The other two instructors used the roles mostly for the launch (facilitator come get supplies) and wrap-up (reporter share group's conclusions). Miles encouraged students to attend to their roles and be purposeful in participating in the team roles (e.g., during a visit to a group Miles sometimes suggested a Questioner visit other groups to ask about ideas).

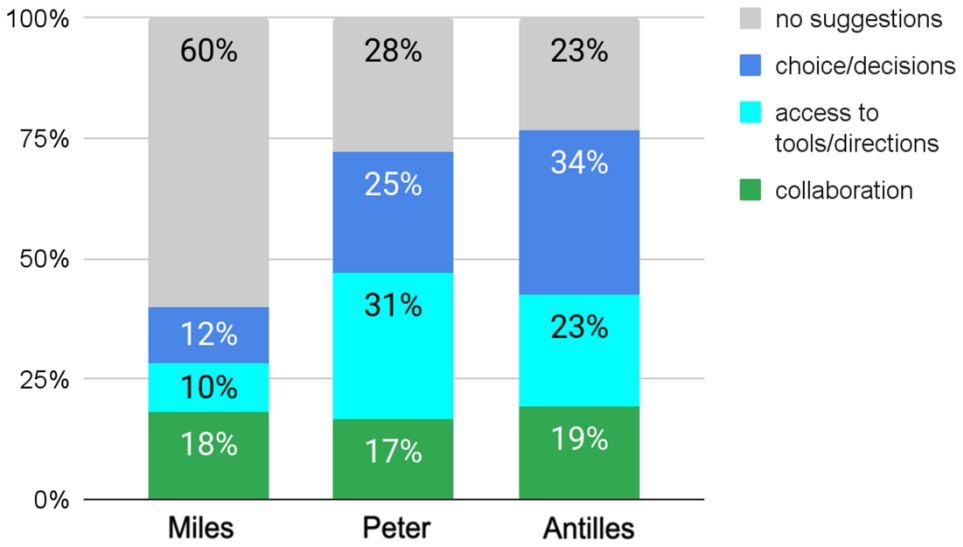

Figure 8. Distribution of codes for student post-lesson survey comments about what needed to improve.

Students generally enjoyed the teamwork and felt it helped them grow as users and doers of mathematics. At the same time, student survey responses suggested that more scaffolds for instructors to implement and orchestrate structures within and across teams for working together well would make student collaboration more effective.

Discussion

In addressing the research question, the findings do indicate there is evidence from classroom observation and student survey that the use of team-worthy lessons creates opportunities for students to develop and demonstrate self-efficacy, authority, agency, and creativity, as positive aspects of their learning experiences. For the "needs improvement" question, most students in Miles' class indicated no suggestions while Antilles' and Peter's students highlighted needs for clearer instructions, improved participation, and better collaboration. For the "positive" question, collaboration emerged most frequently of all positive characteristics noted by students, with at least 28% for each instructor. In future work we plan to add this category to the analysis framework. The distributions in Figures 7 and 8 reflect students' reports of their needs, both met and unmet, for creating and sustaining team-based learning.

Though the extent to which those experiences were equitable was not the focus of the student survey, there seems to be evidence that student needs for engaging in the intellectual work of discrete mathematics were being met in many ways. The majority of students indicated collaboration as an aspect they deemed positive. Yet, collaboration was also the area they felt needed the most improvement! A clear next step is revising the instructor short-course to share with instructors the results of this study and to build up supports for instructor learning in the areas students indicated need improvement.

A next research area is: What (re)balancing of instructor skills is needed to realize the potential of the (re)balancing of activity structures afforded by the lessons? Future work can examine how instructional skills, combined with the affordances of lesson content, contribute to the development of agency, self-efficacy, authority and additional aspects of equity (e.g., belonging) in mathematical sense-making among discrete mathematics students. Research on impact in terms of student mathematical knowledge growth is part of future work.

Acknowledgments

Based on work supported by the California Educational Learning Lab Grant #00005921. We are grateful to the piloting instructors and students who invited us into their classrooms and who provided feedback on their lesson experiences.

Beyond a Single Name: PVEST and Intersectionality in Multilingual Women's Identity Formation in a U.S. Mathematics Ph.D. Program

Jihye Hwang
Korea University

The experiences of multilingual women in U.S. mathematics Ph.D. programs are shaped by intersections of language, race, gender, and nationality. This narrative inquiry examines the identity formation of three women from Korea, Colombia, and Mexico, employing a combined framework of intersectionality and Phenomenological Variant of Ecological Systems Theory (PVEST). Findings identify three distinct pathways: the carryover of prior gendered invalidation, leading to impostor syndrome despite high commitment; context-dependent coping across bilingual ecologies; and the consolidation of an advocacy identity in a more protective environment. Theoretically, the study extends PVEST to Asian and Latin populations and clarifies a dual-function coping mechanism where strategies can be both adaptive and costly. Findings call for strengthening protective factors and identity-inclusive instructional designs in mathematics education is necessary to support this growing student population.

Keywords: Multilingual, PVEST, Intersectionality, Narrative Inquiry

Multilingual students constitute a significant portion of post-secondary mathematics classrooms (Data USA, n.d.). Recent research has begun to examine their experiences, although much of this valuable work has focused on multilingual students under a single name (e.g., Hwang et al., 2022; Rios, 2022, 2024). While this research has provided important insights, there remains an opportunity to explore how these multilingual students enter classrooms with diverse backgrounds and multiple social identities–including but not limited to race, gender, and nationality–that intersect in complicated ways (Hwang, 2023; Leyva & Joseph, 2023; Rios, 2022, 2024). These identities do not operate independently. They interact with one another and with students' multilingual status to create distinct lived experiences (Hwang, 2023). Although analyses examining single identity categories are informative, they may not fully capture the specific challenges that emerge from these intersections (Hwang, 2023; Leyva & Joseph, 2023; Rios, 2024). That is, there remains potential to further understand how students interpret experiences, navigate challenges, and develop their identities in mathematics education.

This study builds on existing work by examining the lived experiences of three multilingual women in a mathematics Ph.D. program: Helena, Jihyun, and Maria (pseudonyms). To analyze these stories, I adopt narrative inquiry, which focuses on how individuals make sense of their lived experiences (Clandinin & Connelly, 2000; Connelly & Clandinin, 1990; Polkinghorne, 1995). Within this approach, I employ a theoretical framework combining intersectionality (Crenshaw, 1991) and Phenomenological Variant of Ecological Systems Theory (PVEST; Spencer et al., 1997; Spencer, 2006). In this study, intersectionality is used as a lens to analyze how students' multiple social identities create unique structural contexts (Crenshaw, 1991; Gholson & Martin, 2019; Graham, 2022; Leyva, 2016; Leyva et al., 2022). PVEST then provides a framework to analyze how each student interprets and reacts to their experiences within that context, leading to the formation of their emergent identities (Spencer et al., 1997; Spencer, 2006; Velez & Spencer, 2018). Following the PVEST framework, I view identity as dynamic and contextually situated, emerging through the navigation of challenges arising from one's intersectional positions (Spencer, 2006; Velez & Spencer, 2018).

This study addresses the following research questions:

1. How do intersecting identities (language, race, gender, nationality) shape each student's lived experiences and stressors?
2. How does the five-stage PVEST model explain the processes through which each student copes with stress to form an emergent identity?
3. What do the narratives of these three students reveal about their life-stage specific outcomes?

Theoretical Framework

Intersectionality

I use intersectionality to analyze the structural context that shapes each student's experience. Emerging from Black feminist scholarship, intersectionality explains how interlocking systems of power–such as racism, sexism, and nationalism–create unique contexts of oppression and privilege (Crenshaw, 1991; Leyva, 2016). This lens is critical for this study because it moves beyond analyzing single identity categories in isolation and instead focuses on how their convergence shapes a person's lived reality.

For the multilingual women in this study, their positioning in U.S. higher education often frames them through a deficit lens as 'non-native English speakers.' I intentionally use the term 'multilingual' to recognize the linguistic resources these students possess, but it is the societal label of 'non-native' that often forms part of their structural reality that privileges English. This label intersects with their identities as women and as Latina or Asian, creating a unique structural context where linguistic ability can be conflated with intellectual competence (Leyva & Joseph, 2023). Intersectionality provides a tool for examining how these overlapping systems shape students' experiences.

Table 1. The Five Stages of the PVEST Model (Spencer, 2006).

Stage	Explanation
Net Vulnerability	The balance or imbalance of risks (e.g., social stereotypes, discrimination) and protective factors (e.g., educated family, role models)
Net Stress Engagement	The balance or imbalance between stressors (i.e., actual experiences of challenge) and available supports
Reactive Coping Methods	Problem-solving strategies an individual uses to manage the stress they are experiencing. These can be adaptive or maladaptive.
Emergent Identities	The stabilization of repeatedly used coping strategies into a predictable, yet fluid, pattern of response that forms an aspect of one's identity–how individuals perceive themselves within their context.
Life-Stage Specific Coping Outcomes	Resulting behaviors and outcomes of an emergent identity, which can be productive (e.g., academic achievement, well-being) or unproductive (e.g., psychological distress, dropout)

Phenomenological Variant of Ecological Systems Theory (PVEST)

To analyze how students navigate their experiences shaped by intersectionality, I use PVEST (Spencer et al., 1997; Spencer, 2006; Velez & Spencer, 2018). PVEST models how individuals form identities through a cyclical process that begins with *Net Vulnerability*, and is followed by *Net Stress Engagement, Reactive Coping Methods, Emergent Identities*, and *Life-Stage Specific Coping Outcomes*. Table 1 summarizes each stage.

These stages are not linear but cyclical. One's subjective interpretation of a challenge shapes their reactive coping method. When the person feels a particular coping method is producing desirable results, that coping method stabilizes into an emergent identity. This identity then leads to life-stage specific coping outcomes that create a feedback loop, altering the students' initial net-vulnerability for the next cycle of stress engagement (Spencer, 2006). In this study, the model allows me to trace how each student's net vulnerability translates into their emergent identity.

Method

In this study, I employ a qualitative research design using narrative inquiry, a methodology that focuses on understanding one's lived experiences through what they tell (Clandinin & Connelly, 2000; Connelly & Clandinin, 1990; Polkinghorne, 1995). This approach was chosen because it allows for an in-depth exploration of how participants make sense of their lives and construct their identities over time. The focus on subjective, lived experience aligns with the phenomenological perspective of PVEST, which argues that an individual's perception of events is central to their development. In this study, narrative inquiry provides the method to access and understand these phenomenological processes.

Researcher Positionality

As the researcher, I share several social identities with the participants. I am a Korean woman who received her K-16 education in Korea and is now a multilingual international student in a U.S. mathematics education Ph.D. program. My own experiences with linguistic challenges and feelings of incompetence have shaped my interest in this topic. This shared positionality helped build rapport and trust with the participants, which allowed for more open sharing of their stories. At the same time, I was mindful of my tendency to attribute my own challenges to personal deficits. Throughout the research process, I engaged in reflexivity to avoid imposing this deficit perspective on the participants' experiences and instead sought to understand the broader context of their stories.

Participants and Data Collection

The participants for this paper–Maria, Helena, and Jihyun–were first-year Ph.D. students in mathematics at a large Midwestern university in the U.S. All are multilingual international students whose K-12 education was primarily not in English. Maria is from Mexico, Helena is from Colombia, and Jihyun is from Korea. All names are pseudonyms.

I collected data in three stages to capture each participant's experiences: Participants first wrote an autobiography, "Me and Math: My relationship with mathematics up to now," about their relationship with mathematics based on the idea from Di Martino & Zan (2010). After that, I conducted one 60–90 minute semi-structured interview with each participant to explore events from their autobiography in more detail and to ask further questions. Lastly, a series of follow-up interviews was conducted via email or shared documents, allowing participants time to reflect on their responses.

Data Analysis Procedures

The data analysis was conducted in two main phases: narrative construction and theoretical cross-case analysis, respectively, narrative analysis and analysis of narrative according to Polkinghorne (1995). I first analyzed the collected data to construct a first-person narrative for each participant. This process involved coding for specific experiences, identifying themes, and organizing them into a plot. Each constructed narrative was then sent to the participant for member checking to ensure the representation was fair and accurate. In the second phase, the finalized narratives of Helena, Maria, and Jihyun were treated as the data for a cross-case analysis. I applied the theoretical frameworks of Intersectionality and PVEST to this data. First, I used intersectionality to analyze how each participant's intersecting social identities shaped their experiences. Then, I used the PVEST 5-stage model to analyze the process of identity formation for each student, tracing how their different backgrounds led to different vulnerabilities, stressors, coping methods, emergent identities, and life-stage specific coping outcomes.

Findings

This section presents the analysis of each participant's narrative. The order of cases presented here demonstrates three key mechanisms through which contexts influence emergent identity: how past environments become internalized and continue to shape coping methods, how individuals navigate multiple environmental demands, and how environment transitions can catalyze emergent identities.

Jihyun: "I decided to study science harder and show that I could do better than these boys"

Jihyun's story shows how gendered invalidation from earlier schooling can continue to shape her academic experience. As a Korean woman in a U.S. mathematics Ph.D. program, her current academic experience is shaped by a worry about being perceived as incompetent, which is rooted in sexist treatment from her past educational experience in Korea.

Her net vulnerability combines significant risks from past trauma with current pressures from the model minority myth demanding mathematical excellence for Asians. The following is one of the quotes from the narrative that shows her experience of sexism.

> .. [a] teacher in that class said something like, "A girl makes the water cloudy [translated from Korean saying]," which is similar to "A rotten apple (=a girl = me) spoils the whole barrel" in English. I decided to study science harder and show that I could do better than these boys.

Jihyun described that such experiences contributed to her perfectionism. In addition to those risks, she felt pressured to meet the standard based on the model minority myth: "Sometimes I feel I am representing Koreans… If I do something wrong… I am afraid they would think every Korean is neither good at mathematics nor nice." At the same time, she wanted to contest the common bias that "Asians are not good at English." These pressures are internalized and shape her net stress engagement and reactive coping methods.

After moving to the U.S., she faced a different environment where lectures were rapid in English and on-the-spot participation and responses were normative. Combined with the vulnerability that she had, in response, she monitored and censored herself (e.g., "I need to think at least three times before I verbally say something" or "I try to erase my Korean accent"). At the same time, she found some strategies, such as relying on written materials rather than verbal conversations.

These repetitive coping methods have been stabilized as a commitment-centered identity (i.e., "Mathematics is my life. Mathematics is who I am.") while retaining imposter syndrome.

As life-stage outcomes, she retained high achievement as a trade-off for greater cognitive load and self-doubt. However, there was an important advance: she discussed her imposter syndrome and concerns about English with her advisor, and the advisor agreed to provide some support, which would increase protections and hopefully reconfigure net vulnerability in the next cycle.

Helena: "Don't get me wrong. I am glad that I speak English, but Spanish is my language."

Helena's story illustrates context-dependent coping across multilingual ecologies: how she adapts by strategically using Spanish as the language of her inner world and community, while treating English mainly as a professional tool. She is a Colombian Ph.D. student in mathematics in the U.S. Helena's net vulnerability is relatively low due to strong protective factors, including a supportive cohort, Spanish-speaking Latina roommates, and a Catholic community, which buffers the linguistic risks she faces as a multilingual student. Her net stress engagement is situational: stress spikes when comprehension depends on real-time oral English, such as fast speech, unfamiliar accents, multi-party talk, which makes it more challenging; but in mathematics, it is buffered by written channels, such as notation, boardwork, and slides.

Helena employs two distinct reactive coping methods depending on the context. Within her cultural community, she finds emotional regulation and strength, stating, "having Latinas around me and speaking Spanish with them is important to me." In academic settings, she uses a different but equally adaptive strategy to manage cognitive load and stress: choosing to be quieter. Her statement, "I tend to be quieter in English than in Spanish," reflects a strategic choice to conserve energy and avoid the high stakes of real-time verbal processing in a second language. The stabilization of these context-dependent coping methods results in an emergent identity that is confident and leading in Spanish-speaking contexts but more reserved in English-speaking academic ones.

Her life-stage specific coping outcomes are currently productive, marked by successful adaptation to her first year. However, a potential challenge arises from the interplay between her adaptive coping (being quieter in English) and future professional demands. Her anxiety about teaching–"I am scared that I am not explaining myself well"–reveals a potential unproductive outcome. The issue is not that her coping strategy is deficient, but that a strategy that is highly adaptive for learning may not be sufficient for the demands of teaching, highlighting a tension she must navigate in the next cycle.

Maria: "I know the answer, but why I don't have the courage to raise my hand and say it?"

Maria's narrative illustrates how a supportive new environment can facilitate the transformation of an identity shaped by past intellectual suppression, as evidenced by her experiences in Mexico and the U.S. As a Mexican woman in a U.S. Ph.D. program, she works to overcome earlier invalidation coming from her gender and redefine her place in mathematics.

Maria carried a risk of gendered invalidation in her undergraduate studies in Mexico. In Mexico, as the only woman in the cohort, her contributions were often ignored (e.g., "Maria got a good grade because the professor just gave it to her," or "Maria did well on the exam because her exam was easier than ours"). The silence of peers, as she noted, "none of the other classmates said anything," reinforced the isolation. In response, she developed a reactive coping method that was twofold: she used silence as a protective strategy while internally reframing her struggle into a purpose. She came to see her persistence in mathematics as necessary "for a woman to be represented in this profession," believing she had been "breaking the stereotype and making it possible for another woman" in her hometown. This sense of purpose became an emergent identity that she carried into her next academic environment.

When she moved to the U.S., the new environment with a cohort of six other women served as a protective factor. While this supportive community reduced her net vulnerability, she still faced academic stressors. Despite her fluency in English, the rapid pace and accents of U.S. classroom communication were challenging. In response, she developed coping methods such as relying on mathematical symbols and written work rather than verbal participation. Despite some challenges, the supportive social context provided the safety needed for the emergent identity she had begun to build in Mexico, as an advocate for women in mathematics, to be validated and reinforced. This validation led to productive life-stage-specific coping outcomes. She successfully passed her qualifying exams and now feels a sense of belonging. This success could serve as a new protective factor, reducing her net vulnerability for the next cycle.

Across these three cases, this paper presented how past environments, present supports, and transitional contexts interact with students' identities in distinct ways. Together, these narratives demonstrate the mechanisms of PVEST in practice–how vulnerabilities are internalized, how coping strategies stabilize, and how emergent identities take shape.

Discussion

This study analyzed the narratives of three multilingual women in a mathematics Ph.D. program to understand how their social identities intersectionally shape their emergent identities in the U.S., a different context from their home countries. Across cases, real-time English discourse demands, such as pace, accent/intonation, and multi-party talk, were common, yet their meaning and impact differed: Jihyun carries forward legacies of gendered invalidation under a model-minority myth, increasing her worries about evaluation; Helena navigates a split present–socially well supported while academic English remains demanding; Maria's move into a more protective environment enables the consolidation of a purpose to represent women in mathematics.

PVEST clarifies how these vulnerabilities become integrated into identity through a cycle of stress, engagement, developing coping methods, and stabilization of those coping methods. Through their coping methods, Jihyun developed an identity committed to mathematics with imposter syndrome, Helena developed an identity responsive to bilingual contexts, and Maria developed an identity as an advocate for women in mathematics. The density and fit of protections influenced these trajectories towards identities and more or less productive life-stage specific outcomes. For instance, Maria's supportive cohort reinforced her advocacy, while targeted supports for Helena and Jihyun showed the potential to reconfigure their net vulnerability for current or future challenges. Across these cases, protective factors were powerful enough to change the direction of each student's academic and personal journey.

This study's findings make four theoretical contributions to the literature on the identity development of multilingual students. First, this study provides an empirical demonstration of PVEST's applicability to Asian and Latin students in mathematics education, extending the framework beyond its primary application. While PVEST offers a lens for understanding identity formation in context (Spencer et al., 1997; Spencer, 2006), its use in mathematics education has predominantly focused on the experiences of the Black community (e.g., Graham, 2022; Gholson & Martin, 2019). This study contributes to the understanding of the framework's usefulness for other marginalized populations, illustrating how the interaction of risks, supports, and coping mechanisms also shapes the identity processes of multilingual Asian and Latin women.

Second, this research provides an empirical demonstration of intersectionality and PVEST. In this study, intersectionality explains what constitutes each student's unique net vulnerability (Velez & Spencer, 2018). It reveals that the experience of multilingual students is not

monolithic, but rather a specific structural position created by the intersection of language, gender, race, and national origin. PVEST, in turn, explains how students navigate these structural realities (Velez & Spencer, 2018). It traces the process through which their specific vulnerabilities are linked to reactive coping methods–such as Jihyun's perfectionism, Helena's strategic silence in English, and Maria's reframing of challenges–which then stabilize into their Emergent Identities (Spencer et al., 1997; Spencer, 2006).

Third, this research empirically clarifies the complex mechanisms underlying core PVEST concepts. While PVEST is a non-deterministic framework that anticipates diverse and nuanced outcomes (Spencer, 2006), Jihyun's case provides an example of this principle by demonstrating a clear dual-function mechanism. Her perfectionism is adaptive, producing the desired productive outcome of high academic achievement. At the same time, the same strategy can be mentally draining, causing negative effects like self-censorship and imposter syndrome. By explaining this complex process in detail, this research extends beyond theory to provide an empirical account of how a single coping method can simultaneously lead to both positive and negative outcomes.

Finally, this study contributes to the understanding of the role of ecological transitions in identity development. Maria's case shows that a supportive new environment does not just create a new identity. Instead, it can serve as a space to validate and reintegrate a resilient identity that was already developed in response to a previous hostile environment. This finding highlights the interplay between individual agency–Maria's prior efforts to reframe her struggle into a mission–and structural support. It suggests that environments serve as catalysts that can unlock and reinforce the potential of an identity already in progress.

The findings from this study call for attending to students' complicated cognitive and affective efforts and challenges that are not visible behind high achievement. Additionally, it is essential to acknowledge students' plural ecologies, recognizing that they may have developed different identities across various contexts. This implies that mathematics educators must devise strategies to help students integrate their positive identities into the mathematics classroom. To achieve this goal, it is important to enhance protective factors, such as having mentors and peers from similar backgrounds, and provide opportunities for developing and utilizing various coping methods, including instructional designs that adjust pacing, promote multi-channel communication, and structure equitable participation (Hwang et al., 2022; Rios, 2022, 2024).

Conclusions

This study analyzed the identity formation of three multilingual women in graduate mathematics by integrating intersectionality and PVEST. The findings traced three distinct pathways: the carry-over of past hostility (Jihyun), the navigation of a split ecology across social and academic contexts (Helena), and the consolidation of identity through a protective transition (Maria). Theoretically, the study extends PVEST's application to Asian and Latin women in mathematics education, specifies the dual-function nature of coping mechanisms, and highlights the role of ecological transitions in reinforcing identities.

As this narrative inquiry captures a snapshot of their lived experiences at the time of data collection, their identities are likely to have continued evolving in subsequent PVEST cycles. This temporal limitation, along with the researcher's own positionality as a Korean multilingual woman, shaped the scope and interpretation of the findings. Recognizing these aspects, future research should test the mechanisms identified here across multiple sites and over longer time scales.

Setting Up Group Tasks: Rights and Duties of Instructors and Students

Rebecca Butler
Virginia Commonwealth University

Nancy Kress
University of Colorado Boulder

Peter Karanevich
University of Colorado Boulder

Pablo Duran Oliva
Virginia Commonwealth University

In this contributed report, we share results from a study focused on the verbal communication acts of four undergraduate mathematics instructors while they are setting up group tasks. All four instructors teach at the same large eastern university and are experienced with active learning instructional practices. We found that two of the four instructors engaged in numerous verbal communication acts that assigned rights and duties to themselves as instructors and to their students. The other two instructors assigned only a few rights and duties to themselves or to students. We describe patterns in instructors' assignment of rights and duties, as well as how instructors' verbal communication acts shaped the classroom learning environment. Finally, we suggest how verbal communication acts focused on assigning rights and duties may relate to opportunities to learn and propose considerations for supporting students' participation in group work in active learning undergraduate mathematics classrooms.

Keywords: group work, opportunities to learn, positioning, participation, communication

Research on undergraduate mathematics classrooms has increasingly emphasized active learning and the use of group work to foster student engagement and deeper understanding. While numerous studies demonstrate that active and inquiry-based learning can improve learning outcomes (Laursen & Rasmussen, 2019; Freeman et al., 2014), the dynamics of how group work is set up by instructors remain underexplored. Work in this area is especially important since scholars note that group work does not automatically ensure a rich participation of all students in mathematical discussion; rather, instructor practices play a critical role in shaping the quality and distribution of learning opportunities (Cohen, 1994; Tanner, 2013).

To address this gap, we leverage positioning theory as an analytical tool, contextualized within Esmonde's (2009) theoretical framework for Opportunities to Learn (OtL). Esmonde's OtL framework identifies four interrelated dimensions of mathematics learning in groups: participation, social ecologies, communication, and identity development (detailed in the following section). In positioning theory, storylines, speech acts (or communication acts), and positioning (or rights and duties) form a triad in which the three constructs are mutually interdependent (Harré, 2012; Herbel-Eisenmann et al, 2016). This study is grounded in Esmonde's OtL framework and informed by positioning theory; we leverage two closely connected components of positioning theory to support our data analysis: communication acts, and rights and duties (Drageset & Ell, 2024). We identify instances of instructor communication acts, specifically verbal communication acts, in which they assign rights and duties either to themselves or to their students.

Recent scholarship has highlighted specific instructional practices related to each of the four dimensions of Esmonde's OtL framework that broaden access to OtL in group settings. Instructor facilitation practices such as assigning roles or explicitly inviting all members to contribute have been shown to promote more balanced participation (Webb et al., 2014). Related to social ecologies, patterns of social interaction combine with classroom layout, group size, and

the design of collaborative tasks to affect who has access to shared resources and whose ideas are visible (Horn, 2012). Regarding communication, researchers emphasize the importance of instructors explicitly framing discourse norms – for example, requiring explanation, justification, or collaborative sense-making rather than answer sharing (Yackel & Cobb, 1996; Yackel & Rasmussen, 2002). Finally, for identity development, instructor beliefs and positioning moves are critical: affirming students' competence, validating diverse approaches, and distributing authority have been linked to stronger identity alignment with mathematics (Hand, 2012; Nasir, 2002).

While this body of work demonstrates the importance of instructional practices, little research has examined how instructors set up group tasks in undergraduate mathematics classrooms – the period when expectations, norms, and participation structures are first introduced. Task setup is a critical moment when access to OtL can be expanded or constrained, yet it remains underexplored. In this report we share findings from our study investigating the verbal communication acts instructors use when setting up group work. Specifically, we ask the following research questions: (a) What rights and duties do undergraduate mathematics instructors assign to themselves and/or their students during verbal communication acts while setting up group tasks? And (b) What patterns are identifiable across instructors in their assignment of rights and duties during group work setup?

In our discussion section, we consider how instructors' verbal communication acts that assign rights and duties may shape students' opportunities to learn, and we suggest how this study contributes to a deeper understanding of how active learning environments are enacted. We also highlight practical considerations for supporting effective group work in undergraduate mathematics classrooms to increase students' participation in mathematical discussions.

Literature and Theoretical Framing

As mentioned above, Esmonde's (2009) Opportunities to Learn (OtL) framework identifies four interrelated dimensions that structure access to mathematics learning in groups. Participation concerns who is invited to engage and how access to problem-solving is organized. Social ecologies emphasize the role of cultural norms and patterns of social interaction along with physical arrangements, group composition, and resource distribution in how the group organizes their relationships. Communication captures the expectations and norms for mathematical discourse, such as justification, explanation, and turn-taking. And identity development attends to how learners are positioned – as capable contributors or marginalized participants – through instructor and peer interactions. Together, these four dimensions provide a framework for examining what students are asked to do, how they are enabled or constrained in doing so and ultimately, the opportunities available to students to take up more central roles or positions as doers of mathematics.

For this study, we employ positioning theory, which includes the interrelated constructs of storylines, rights and duties, and communication acts. Rights and duties refer to the positions individuals and groups perceive themselves and others to hold in interaction (Drageset & Ell, 2024). In relation to Esmonde's OtL framework, they are enacted and negotiated through communication, and they shape who speaks, who listens, and how contributions are taken up. These dynamics influence participation (the ways individuals are invited to or restricted from engaging), social ecologies (patterns of authority and interaction), and identity development (how competence is recognized or marginalized). Rights and duties are not fixed; they evolve as participants interact, challenge, or reinforce each other's positions. Rights and duties are deeply intertwined with the communicative processes that structure opportunities to learn.

Communication acts (including verbal and gestures), aligned with the communication construct of the OtL framework, work to uphold or shift storylines (described next) and confirm or introduce new rights and duties. We use the construct of communication acts in this study with a specific focus on verbal communication acts that serve to name rights and duties of instructors and students. The third component of positioning theory, storylines, are "the ongoing repertoires that are already shared culturally or they can be invented as participants interact" (Herbel-Eisenmann et al., 2016, p. 188). In relation to Esmonde's OtL framework, storylines contain aspects of participation (how people participate), social ecologies (patterns of social interaction) and identity development (who is seen as more or less competent). Participants may have different storylines, even within the same class or group, and storylines can evolve as participants see new ways to interact or engage with each other. Analyses focused on non-verbal communication acts and storylines, while potentially useful for future studies using this data, are beyond the scope of this report.

Methods

The data for this study was collected at a large, research-intensive, urban university in the eastern United States. We video recorded the first session of four classes in two different sequences of precalculus courses. Students in both courses are mainly freshman STEM students. The demographic makeup of these courses in terms of race/ethnicity and gender reflects the diversity of the campus (62% identified themselves as Female students, over 17% as Black/African American, 9% as Hispanic/Latinx, 13% as Asian, and 44% as White students, in a recent report). Between 10 to 15 instructors (mostly non-tenured) usually teach these courses, often in more than one section. The primary data for this study consists of four video-recorded episodes of four of these instructors introducing a group task in class. Each episode begins at the moment the instructor first references the task and ends when students transition into working together on the task. In addition to these video recordings, supporting data includes task artifacts (e.g., worksheets, slides, board captures) and contextual information (class size, course type, and institution). All instructors provided informed consent, and student images were blurred in all visual material.

We define the episode (the full instructor-led setup of the group activity) as our primary unit of analysis. Within each episode, we segment the interaction into verbal communication acts which are bounded events in which the instructor carried out a single type of action (e.g., framing the task, explaining roles, presenting norms for talk). Instructors' verbal communication acts serve as our coding unit. Most instructional moves during the setup of group work involved the instructor prompting tasks, encouraging students to do work, reflecting on their own learning, and justifying class structure and organization. We categorized these verbal communication acts in one of four categories: instructor's rights, instructor's duties, students' rights and students' duties. We defined rights as the entitlements of participants and duties as the obligations or tasks that are assigned to participants. Two coders initially coded select verbal communication acts together to develop a coding scheme and then coded the remaining data independently. Finally, the two coders came together to gain consensus on the codes, and to select representative quotes for sharing in the results.

Results

Our coding revealed numerous instances of instructors engaging in verbal communication acts in which they assigned rights and duties while setting up group tasks. Table 1 provides the number of times we coded each participating instructor's verbal communication acts as assigning

rights and duties. Note that all names used are pseudonyms. Table 2 provides examples of the types of verbal communication acts that were coded as teacher rights, teacher duties, student rights, and student duties. In the next section, we will present data analysis from quantitative and qualitative perspectives.

Table 1. Instances of instructor verbal communication acts in which they assign rights and duties.

Distribution of Assignment of Rights and Duties in Speech Acts				
Pseudonym	Teacher Duty	Teacher Right	Student Duty	Student Right
Barb	6	6	7	6
Celia	6	3	2	4
Harry	2	2	3	2
Donna	2	1	0	3

Table 2. Examples of the type of instructor communication acts in which they assign rights and duties.

Examples of Communication Acts that Assign Rights and Duties			
Teacher Duties	Teacher Rights	Student Duties	Student Rights
Facilitate student introductions	Assign students to groups	Be open to learning math in a new way	Have good mathematical learning experiences
Caring for the success and well-being of students	Select students to present work to the class	Communicate with group mates	Receive assistance with difficulties
Minimize lecture	Solicit knowledge from student groups	Join the group the instructor assigns them to	Be accepted into a community within the classroom

Analysis

The results presented in the previous section suggest that instructors' strategies for setting up group tasks vary widely. In this section, we present analyses from both quantitative and qualitative perspectives to more fully elaborate on these variations. First, we share two different perspectives for making sense of these results from a numerical perspective. We then provide descriptions of each of the four instructors' strategies for setting up group work to add context to the numerical findings.

Making Sense of the Data from a Numerical Perspective

These results reveal a variety of ways instructors set up group tasks, which can be understood through two different ways of viewing these numbers. First, instructors' use of verbal communication acts focused on assigning rights and duties differed in absolute quantity. While Barb and Celia assigned rights and duties relative to engaging in group work extensively,

Harry's and Donna's verbal communication acts while setting up group tasks included far fewer instances of assigning rights and duties.

Viewing these results from a different perspective reveals that instructors' verbal communication acts also varied in the relative number of instances of assigning rights and duties, as well as whether they assigned those rights or duties to themselves or their students. Barb and Harry assigned rights and duties to themselves as instructors, and to students, in ways that were roughly balanced across the two distinct roles (instructor vs student). In contrast, Celia and Donna assigned rights and duties in ways that were imbalanced. Celia and Donna both assigned more teacher duties and student rights, and fewer instances of instructor rights and student duties. We observed a balanced assignment of rights and duties in the verbal communication acts of one instructor who assigned numerous rights and duties (Barb), and a second instructor (Harry) who assigned relatively few rights and duties. Correspondingly, an imbalanced assignment of rights and duties occurred in the communication acts of one instructor, who assigned many rights and duties (Celia), and another instructor, who assigned relatively few rights and duties (Donna).

Making Sense of the Data From a Qualitative Perspective

Of the four teachers in this sample, Barb's verbal communication acts related to assigning rights and duties were the most numerous. Barb also provided the most explicit expectations for herself and her students in relation to group tasks. She positioned both herself and her students as a classroom community, providing explicit time for students to introduce themselves to others nearby and share contact information with each other, establishing chosen "math families" with whom they would work in class. She set specific duties for students with respect to these math families, saying that she "expect[s] that you guys are [talking] with the person next to you or some part of your math family multiple times in the class" and that students "don't always have to get it right…but you have to be doing as much as you can to learn from those around you." She sets herself as having the authority to monitor the status of group conversations, repeatedly commenting to specific students and the class that they should be communicating more (e.g., "this is awfully quiet for people who are working together" and "You have to talk with people. I'm sorry.") While she sets herself an authority to monitor and structure group conversations, she explains that this group format is motivated by students' right to have an engaging mathematical learning experience (e.g., "I don't want you guys to be working by yourself because it's so boring") and learn mathematics in an optimal manner, explaining that lecture is "not the best way to learn math, the best way to learn math is being interactive with it." Overall, Barb positions students as belonging to "math families," with certain rights and duties associated with belonging to such a group, and herself as a director and supporter of these groups.

Similar to Barb, Celia also engaged in numerous verbal communication acts focused on assigning rights and duties. And Celia also explicitly oriented her class around group work, explaining that she would occasionally provide "mini-lectures" to introduce concepts, but that the remainder of class time would be devoted to students "talking to each other, working on problems, and, of course, asking questions." During this work time, she stated her expectation that students should be "polite" to one another and that "if someone asks a question and you know the answer to it, it's good practice for you to explain it to somebody else." She also emphasizes her role in managing these group discussions, saying "I'll walk around and if I [think] someone's hanging back or not trying to engage, I'm going to try to encourage you to jump in and have that conversation." She encourages students to share their authentic thoughts about mathematics because "if I see a lot of people get it wrong, that's a nice clue to me that we

need to slow down and talk about something more." Thus, Celia positions those in her classroom similarly to those of Barb's but places a stronger emphasis on student questions.

Harry exhibited fewer instances of verbal communication acts focused on rights and duties but also structured his class around group work. Harry set less direct expectations for himself and students than Barb and Celia. Interestingly, he was the only instructor in our sample to assign students to groups, rather than letting students choose their own groups. He did this by handing each student a playing card as they walked in, then grouping based on kinds of cards (e.g., all four kings together, all four sixes together). While Barb and Celia repeatedly stated and reiterated specific expectations for the group work environment of their classrooms, Harry briefly explained to students that "you should first ask the other people in your group if they can help you out and if everybody's stuck, then just let me know and then I'll come by and help out." While this dynamic of consulting group members and the instructor about mathematical questions is similar to what Barb and Celia describe for their classrooms, Harry does not present a specific social framework around ideas of comfort or community.

Donna had the fewest instances of verbal communication acts focused on rights and duties, and, unlike the other instructors, Donna did not explicitly mention group work as a component of the course. However, she did position herself similarly to other instructors, describing students' right to ask questions and her duty to answer student questions. For example, she stated, "it's because you asked a question that all of a sudden things made sense. That's how this class works. All right, give me more questions." Notably, she emphasized that students in her classroom should be able to ask questions without shame, telling students that they shouldn't "be embarrassed about asking me questions" and that "you're going to make mistakes. Congratulations. You're human … So, I don't want you feeling bad if you made a mistake. I'm not going to think any worse of you." Thus, while Donna did not directly mention group work, she did express the value of asking questions, much like the other instructors.

It is also worth noting some general observations from across all four instructors' classrooms that may differ from active learning classrooms more generally. From a positioning standpoint (Herbel-Eisenmann et al., 2016), the students in these active learning classes mostly accepted the duties assigned to them. Barb sometimes pushed students to talk together to exchange emails/phone numbers, but otherwise, there were no instances of students resisting or speaking out against the active learning environment. And, while students have a right to learn, the instructors never suggested that students had a right to choose the learning environment. All of these courses are designed with active learning in mind, and students do not have another option. It is therefore an implied duty to adapt to the expectations of the classroom. Barb points out that high school classes might still have lecture models, and students will have to make the adjustment (a student duty) if that was their experience.

Discussion: Implications, Questions, and Future Work

In this study, we have examined several distinct ways in which mathematics instructors structure group work in pre-calculus courses. Notably, we found that, although all instructors involved in the study were experienced university mathematics teachers who self-identified as having strong commitments to implementing active learning practices, they varied in the extent to which they explicitly positioned themselves and students in group work settings. While some instructors (Barb and Celia) laid out specific ways in which students should interact with one another and the instructor, others (Harry and Donna) provided less direct guidelines for classroom interactions.

In active learning classrooms, communication and interaction are central and impactful aspects of students' learning experiences. Thus, it is crucial to have effective methods of revealing and understanding the vast differences in learning environments and experiences that result from different patterns of communication and interaction across active learning classrooms. Using communication acts, rights and duties provides one way of understanding important differences between classrooms that might otherwise seem quite similar.

As mentioned earlier, in the literature and theoretical framework section, rights and duties refer to the positions individuals and groups perceive themselves and others to hold in interaction (Drageset & Ell, 2024). They are enacted and negotiated through communication, and they shape who speaks, who listens, and how contributions are taken up. Rights and duties, as dynamic indicators of positionality, provide a way of understanding the OtL available to any individual student in classrooms that are all using active learning instructional practices, and that might seem similar in many ways. Leveraging positioning theory enables us to see differences in students' access to OtL, along with the degree to which students are more or less able to shift from marginalized or peripheral roles into more central roles of participation.

It is important to note that, while we have presented counts of rights and duties in this study separately for instructors and students, there may be a connection between instructor duties and student rights. If instructors have a duty to provide certain actions or resources to students, then correspondingly, students have a right to access those instructional actions or resources. There may also be a connection between instructor rights and student duties, as evidenced by some paired examples of the types of rights and duties instructors assigned. For example, if an instructor has a right to select students to present their work to the class, students may have a corresponding duty to present that work. Finally, there may be some rights and duties that exist independently. For example, a student duty that is not in direct relation to an instructor's right is the duty to help peers when they have questions. We aim to explore these connections in future work, especially in longitudinal data obtained from these courses.

Looking forward, we aim to further explicate the connection between these positioning acts and various aspects of the OtL framework. We are especially interested in questions such as: to what extent does the quantity or balance of verbal communication acts related to rights and duties correspond to OtL? How are these dimensions related and what are the implications? Additionally, we aim to incorporate student communication acts into our analysis and explore whether and how students take up, reject, or negotiate the positionings laid out by instructors in the initial class sessions, with particular attention toward how these roles influence students' access to mathematics content.

We conclude by highlighting the importance of instructors supporting effective group work in undergraduate mathematics classrooms by explicitly sharing or developing norms for participation, by naming rights and duties that position students as knowledgeable and capable doers of mathematics, and by opening the possibility for students to enact rights and duties in new and evolving ways that serve to increase their participation in mathematical discussions.

Experiences of Students with Dyslexia in Undergraduate Mathematics: Cognitive Challenges and Navigational Strategies

Brian Tyrrell-Nic Dhonncha
Queen's University Belfast

Vladislav Kokushkin
James Madison University

How do undergraduate students with reading difficulties engage in mathematics – a symbolically dense, text-heavy subject? This study analyzes reflections from seven undergraduate STEM students with dyslexia on their approaches to mathematical learning and problem-solving. Our findings indicate that students experienced multiple dyslexia-related cognitive challenges, including processing, organizing, and manipulating conceptual information. To combat these challenges, students reported strategies to structure information visually and minimize the cognitive burden of the tasks. These results offer an initial account of how students with dyslexia approach and experience undergraduate mathematics.

Keywords: dyslexia, working memory, cognition, visualization, student experiences

Dyslexia can be characterized by measurable difficulties with phonological processing, affecting reading and writing skills, and is often unexpected in comparison to other academic abilities (International Dyslexia Association, 2025; Lyon et al., 2003). Dyslexia is estimated to affect between three and seven percent of the population (Wagner et al., 2020), and comorbidity with other neurodevelopmental differences is high (Moll et al., 2020). In the past two decades, enrollment of post-secondary students with specific learning differences has increased dramatically, with dyslexic students constituting the largest subgroup (Richardson, 2021).

Despite this prevalence, little is known about how students with dyslexia understand, learn, and do undergraduate mathematics. Research on undergraduate students with dyslexia (USDs) tends to focus on study skills (e.g., Andreassen et al., 2017; Mortimore & Crozier, 2006), general academic challenges and strategies (e.g., Knight et al., 2024; MacCullagh et al., 2016; Richardson, 2021), or identity and perception (e.g., Griffin & Pollak, 2009; Pino & Mortari, 2014). Language-based difficulties (such as reading, memorization, note-taking, organizing work, and communication) and cognitive difficulties (such as concentration, executive functioning, retaining the meaning of texts, and processing sequential information) are also explored in the literature (Klein, 1993; Mortimore & Crozier, 2006; Riddick et al., 1997; Smith-Spark et al., 2016). These cognitive difficulties largely relate to working memory (WM) – a mental workspace of limited capacity for the temporary storage and manipulation of information (Baddeley, 2000; Baddeley & Hitch; 1974) – sometimes used as a framework for understanding specific learning differences (e.g., Jeffries & Everatt, 2004; Swanson, 2020; Swanson & Siegel, 2001).

For mathematics specifically, the discussion often focuses on foundational or lower-level mathematical issues faced by USDs, such as problems recognizing symbols, notation, or "following a sequence of steps or actions" (Searle & Sivalingam, 2004, p. 5). Developing learning support resources and recommendations for USDs has also been discussed extensively (Perkin & Croft, 2007; Trott, 2003a, 2003b). Our study highlights, in their own words, the cognitive challenges and navigational strategies USDs report when engaging in higher-level mathematical tasks (such as proof production and comprehension) and when reflecting on undergraduate mathematics learning. In doing so, we expand and develop the findings of Perkin's engineering case studies (Perkin, 2004). As Lambert and Harriss (2022) did for research

mathematicians with dyslexia, we aim to develop an emergent account of USDs' mathematical experiences from an 'insider perspective'. Our primary research questions are:

RQ1: *What cognitive challenges do USDs experience in mathematics courses?*

RQ2: *What strategies do they implement to navigate these cognitive challenges?*

Theoretical Framework

We frame our study within the theory of neurodiversity, which conceptualizes neurological differences (and dyslexia in particular) as natural and valuable variations in human cognition. Originally developed in the autistic community (Robertson & Ne'eman, 2008) and recently adopted in studies on dyslexia (e.g., Lambert & Harriss, 2022), neurodiversity posits that cognitive differences are a natural part of human diversity and can carry both affordances and challenges. This perspective stands in contrast to the traditional *medical model* (also called the *deficit model*) of disability, which depicts dyslexia primarily in terms of individual impairments.

Through this theoretical lens, we view challenges that USDs experience in undergraduate courses not as evidence of deficiency, but as reflections of how students with dyslexia interact with cognitively demanding mathematical tasks and learning environments, which oftentimes privilege particular forms of information processing. At the same time, this framework highlights the strategies that USDs develop to navigate these challenges as distinctive strengths they bring to undergraduate mathematics. We follow an insider perspective (Lambert & Harriss, 2022; Lambert et al., 2019) by studying USDs' own reflections on their perceived challenges and navigating strategies, positioning their voices as central to understanding both barriers and affordances in mathematical learning.

Methods

The data reported here are part of a larger study aimed at understanding how USDs use hand gestures during cognitively demanding mathematical tasks. We recruited seven participants who were professionally diagnosed with dyslexia, representing a range of STEM majors but all enrolled in undergraduate mathematics courses: Aoife, Aran, Caitlin, Eibhinn, Maeve, Sean, and Siobhan (all pseudonyms).

Each student completed an online survey, then participated in a task-based interview (Interview #1) and a stimulated recall interview (SRI; Interview #2). The survey asked participants to (1) describe their experiences learning mathematics at university, including classroom interactions and assessments, (2) explain how dyslexia had impacted their learning of mathematics across school and university contexts, and (3) identify strategies or coping mechanisms they use for managing mathematical tasks. These survey responses provided descriptive context for each participant and were used to facilitate discussion in Interview #2.

The task-based interview invited students to solve mathematical problems while verbalizing their reasoning, which provided insight into the cognitive and linguistic processes they engaged in while problem-solving. The tasks reported on in this study are summarized in Table 1, below. Because of the design of the larger study, participants were not given access to a pencil and paper while working on these tasks. The SRIs followed several days after Interview #1; During the SRIs, students viewed selected video clips of their own problem-solving and reflected on the challenges they faced and strategies they employed. Building on these reflections, the interviewer also asked participants about dyslexia-related difficulties they experienced when navigating undergraduate mathematics courses, drawing on their earlier survey responses.

Table 1. Summary of Interview #1 tasks.

Task name and source	Task description
Triangle Task (Nathan et al., 2014)	True or False? The sum of the lengths of two sides of a triangle is always greater than the length of the third side. Provide proof for your claim.
Gear Task (Nathan et al., 2014)	An unknown number of gears is connected in a chain. You know what direction the first gear turns, how could you figure out what direction the last gear turns? Provide a justification as to why your answer is true.
Two-Color Theorem (Kokushkin, 2024)	Read and understand the proof of the statement: "$n \geq 1$ circles are given in the plane. They divide the plane into regions. It is possible to color the plane using two colors, so that no two regions with a common boundary line are assigned the same color."

All interviews were audio-recorded and transcribed verbatim. Survey responses and interview transcripts were analyzed using the constant comparative method (Glaser & Strauss, 1967). We first coded our data to identify specific challenges and navigating strategies. These codes were further combined into categories, which served as the foundation for latent themes that captured shared experiences across participants (Braun & Clarke, 2006). To enhance trustworthiness, two researchers independently coded an initial subset of transcripts, resolved discrepancies through discussion, and applied the refined scheme to the full dataset. In the excerpts presented here, emphasis added by the authors is indicated through underlining.

Results

We report on four themes that provide insight into our research questions. We remind the reader that in our experimental setting, participants were required to complete all activities mentally. This experience was used to prompt students to reflect on their daily struggles processing (i.e., understanding, structuring, and manipulating) mathematical information. We do not claim these challenges and strategies are unique to USDs; however, we believe it is important to recognize how such challenges are encountered and addressed by these students.

Challenges

Many of the challenges our participants reported can be understood as a difficulty (A) with organizing and structuring written and verbal information, and (B) with holding and manipulating information in their WM.

Organizing and structuring information. Our participants reported persistent obstacles to engaging in undergraduate mathematics, centering on difficulties in internally (re)organizing written and verbal information. Describing the experiment conditions, Aran found it "hindering" not being able to write, as writing "helps [him] keep all [his] thoughts in place." Siobhan found it notably difficult to keep her train of thought organized and "in line" when answering mathematical questions. Similarly, Sean found it "much harder" to tackle the mathematical problems verbally, as "[his] ideas get jammed with one another, and [he] lose[s] [his] train of thought." He further elaborated: "When I'm thinking it in my head…it's all just black and white. So in other words, you know, it all just gets kind of mixed up within one another."

To articulate their difficulties in processing written and verbal content, participants often used the language of "visualization" – forming mental images to help recognize and structure relevant details into a coherent whole. Sean expressed a need to be provided "some sort of diagram or something that's not just fully word based" – because "if there's nothing to visualize, you have to be your own person to visualize it." Eibhinn found it challenging "trying to picture

the situation from what [she] was reading" while Caitlin similarly remarked: "It's very hard when I can't draw it out, because I feel like I'm a very visual…I need to see how it's actually happening." When asked "what was difficult about these tasks?", Siobhan indicated it was:

> "…hard to like, visualize and not being able to write anything down, it's just like coming up with what to say just off the tip of the tongue, usually I have to like, write down my thoughts, or, like, organize them in a way that's sometimes hard to do that on my head."

Along similar lines, participants sometimes expressed frustration or dissatisfaction when they were unable to clearly 'see' how information is assembled: Siobhan shared how "textbooks… sometimes give an image, but it's all combined. Or if they're, like, telling you to graph things, it's the whole graph at the very end" – not showing "the process being done" from the presented information. Likewise, Sean expressed dislike "when someone gives [him] just a big paragraph of an essay for a math problem, because [he] can't visualize that."

WM challenges. Participants also reported difficulties with activities that placed demands on their ability to simultaneously hold and manipulate information – highlighting WM as a potential source of struggle. For example, reviewing the gear task, Sean commented:

> "I couldn't really see how it would turn, because I could imagine, you know, the gears all lined up, right, but seeing them all go like, in motion with one another, that's a little too much that I can't think in my head."

While Maeve described visualization as "really easy" for her – even saying "I can take things in my mind and twist them around…like, on SolidWorks" – she struggled when trying to coordinate several objects simultaneously, an activity that places greater demands on her WM:

> "…I can never visualize that [interlocking gears turning], like, I can never figure out which way it's going…I always get mixed up with the way that the arrows are spinning… when [the gears], like, attach, in my mind, they're going the same direction, even though I know they're not."

In the context of the Two-Color theorem, Eibhinn struggled and ultimately failed to grasp the inductive step in the proof. In recounting her struggle, she distinguished between the "easy to picture" static arrangement of k colored circles (the inductive hypothesis), and the "hard to picture" inductive step, which involves adding one more circle and recoloring. Failing to mentally operate on her concept image in the inductive step suggests a difficulty in navigating the cognitive load for the task, and an overtaxing of her WM. On a more general level, Sean explained he keeps a mental "whiteboard" of task-relevant information, that he updates while working through a problem:

> "I would have, like a whiteboard of a thing in my mind, and I'm just drawing this out and just combining one with another and seeing where that goes…for me, I really just need to visualize it. And could be because I can't read well and…it takes me a longer time to comprehend the writing in general."

Sean is aware this strategy has its limitations, adding "the hard thing about it [is] that there's only so much room you could have on there, and when you start throwing at me more and more stuff, I might lose track of certain things." Our participants' reflections suggest that it was not only the conceptual content, but the cognitive load in simultaneously visualizing and manipulating task-relevant elements, which they felt posed a significant challenge to them.

Strategies

Participants conveyed a number of 'coping mechanisms' or 'strategies' to offset the impact of dyslexia on their mathematical learning. We report on these strategies below, organized to complement the challenges identified in the previous section.

Organizing and structuring information. A core tool for structuring thoughts and answers (mentioned by most of the participants) was writing. Aran explained that "writing all these things down, helps you remember them, and helps [him] keep all [his] thoughts in place." Similarly, Sean expressed his desire for "just a little piece of paper or something to write it all out, or, you know, put one idea with another" as this would have aided him to "answer the question more fluently." Writing also featured in the routine some students were taught to help them tackle problems: Maeve reported she systematically identifies her "given, assume, and find" in a question, to ensure she does not overlook important information.

The repetition of information through writing also gave students confidence they had correctly understood information from the presented text. Maeve, referencing exam questions, explained: "I'll write *m* is equal to one, even though it's in the question. Just having it out there, like is, like, just reassurance that I know *m* is equal to one." Echoing this, Aran described how writing gives him confidence, sharing: "I know I already got this in the problem. I trust myself. I wrote this things down [sic]." For Interview #1, he reported using his hands "as [his] pencil" to mentally underline text and highlight important information. Aran felt that "it's not permanent, but it would help [him] understand, at least at that point, what…[he's] trying to understand."

Students used their hands not only as tools to focus their attention, but also to organize abstract aspects of their mathematical work. While discussing the triangle task, Aran explained he gestured to give himself "an image of what [he] was trying to do" and to "visualize what's happening" – to understand the task and to marshal his approach to its solution. To keep her thoughts "in line", Siobhan pointed to parts of the table before her, left to right, as she solved the gear task. She clarified she was "categorizing" her thoughts, and giving herself a visual representation of spatially organized "thought process[es]" to structure her verbal answer. Eibhinn and Maeve also used gestures to facilitate communication with the Interviewer, with Maeve clarifying "[she] was trying to draw with [her] hands that time, not for [her] sake, but to convey what was happening in [her] brain."

All of our participants identified visualization as a key strategy for attempting the mathematics tasks – with Sean stating "visualizing it has always been [his] best friend in trying to do any math problem". In her SRI, Aoife suggested that, to her, the underlying meaning of mathematical information is expressed visually, and not symbolically:

> "I think it just makes a lot more sense that way, as an image. Like, in my mind, I can kind of think about it that way a lot better than like the numbers or like the math or equation type thing like that…I can solve it, but it doesn't really mean that much to me. But I think I like images and pictures, I think that's how I think."

Navigating cognitive load. Our participants described a range of strategies to help them retain and manipulate information in their WM. These included strategies of selective attention while encoding information, active rehearsal for retention, and mechanisms for offloading information. In what follows, we elaborate on these strategies for navigating cognitive load.

Given our participants' persistent challenge in processing written text, selective attention emerged as one of the key encoding strategies. Broadly, this strategy can be summarized as deliberate actions for reducing redundant processing by focusing on the most relevant or the most important pieces of information. Several participants described underlining key pieces of text in problem statements or coloring mathematical expressions to minimize overlooking critical details. Sean, for example, shared: "When I take down my notes, especially for math, I like to color things in…when I'm thinking it in my head…it's all just black and white."

Some students described strategies for reformatting written information in a more cognitively accessible way, which, as they reported, was especially helpful in mathematics. Maeve, for instance, sometimes replaced technical terminology with simpler terms: "By switching the element with an easier-to-read element, I'm able to focus more on the math than the reading of the problem, while still understanding the context." Similarly, Siobhan noted that symbolic expressions were easier to process when visually rearranged: "When you're doing a division problem, if it's like, *p* minus one divided by *n* minus one, I would understand it better if I just saw it written out vertically, not just horizontally on the page."

Another common strategy students described involved re-reading written text, or 'rehearsing' information. These practices were referenced as an efficient way to retain information, especially when writing is not available. Eibhinn reported using noise-dampening headphones during exams, as they allow her to "hear [herself] say the stuff a little bit more" clearly in her head. Aran shared he needed to re-read "[j]ust to get the information out" because he would "forget it…not understand it fully, or mess it up a little bit." Sean re-read text to help him connect information at the end of a paragraph to information he was given at the beginning, explaining:

> "I always try to relate this new information to what we talked about before, so that that original information I got in the beginning doesn't get lost. So I'm always trying to go back and just trying to fill in these gaps that the problem is slowly giving me."

Most participants described strategies for offloading encoded information to alleviate demands on WM. For example, Aran explained that when working on a mathematical problem, he typically writes down everything he considers "useful" before attempting a solution. In a similar vein, Aoife emphasized the importance of recording information, as "making it out of [her] head and on the page" prevents her from becoming overwhelmed and "mixed up." Several participants reflected on how gestures also supported their WM when writing was restricted. During his SRI, Aran explained that hand motions helped him to make progress on the gear task, as "moving [his] hands helps [him] actually move the gears in [his] head," and allows him to "remember, in a way, what's happening…keep [his] thoughts into [his] hands and [his] motions." To help her stay engaged and retain information, Caitlin noted:

> "A lot of times, I space out when someone's talking to me…I think drawing and hand movements really helped me stay engaged. If, like, I can move my hands or picture it a little bit, I can commit a little bit more to memory and then be able to see it."

Discussion and Conclusion

All of our participants identified challenges related to mathematical learning, commonly associated with dyslexia – including reading text, writing and understanding symbols, and taking notes in class (MacCullagh et al., 2016; Perkin, 2004; Searle & Sivalingam, 2004). Together, our findings suggest that a larger obstacle to undergraduate mathematics for these students may be in place before any reasoning or calculation is undertaken: A barrier in translating mathematical text to mathematical meaning, structure, and action.

Mathematical texts possess features that can prove challenging for students to navigate, such as complex sentence structures, precise definitions, specialized terminology and symbols, and a high density of concepts (Shepherd et al., 2009). For students with dyslexia, these features may compound existing difficulties with processing information from text (Perkin & Croft, 2007). Mortimore and Crozier (2006, p. 240) found that USDs disproportionately struggled with "organizing essays" compared to their non-dyslexic peers, suggesting that dyslexia exacerbates the challenge of organizational or language-heavy exercises for these students. Our findings suggest that these organizational difficulties extend to processing and structuring mathematical

information presented in text, and producing a linear, coherent narrative in the way of a solution to a problem. This complements the reported challenges of research mathematicians with dyslexia in "translating mathematical thinking into text" (Lambert & Harriss, 2022, p. 99), as well as those of one postgraduate engineering student with dyslexia, who encountered problems "structuring written work" and "deciding what to write" (Perkin, 2004, p. 7).

To combat their difficulties, many of our participants identified *writing* as a way of (visually) structuring their thoughts, giving them confidence and assurance in the information they had read. Students also used their hands to support problem-solving activities and to communicate their solutions, sometimes relying on their gestures to supplement key aspects of their answers. Reframing mathematics as a visual activity was standard across our participants, echoing Bacon and Handeley's remark that "a preference for reasoning strategies based on visual processes may be a robust feature of the dyslexic cognitive profile" (Bacon & Handeley, 2014, p. 337). An inclination for 'visual thinking' has been anecdotally noted by a number of authors (e.g., Griffin & Pollak, 2009; Lambert & Harriss, 2022; Perkin & Croft, 2007; Trott, 2003a, 2003b) and is repeatedly among the guidance given for supporting USDs (Trott, 2003a, 2003b). We found our participants identified strongly with this characterization, and often that mathematical meaning-making was synonymous with 'visualization' in their accounts.

Participants' accounts also indicated that the cognitive load in simultaneously remembering and manipulating task-relevant elements imposed a substantial challenge (cf. Sweller, 1988, 2010). Swanson and Siegel (2001) argue that specific learning differences – including dyslexia – reflect "deficits" in WM, related to the phonological loop and central executive of the Baddeley-Hitch model of WM (Baddeley, 2000; Baddeley & Hitch, 1974). Bacon and Handeley (2014, p. 341) refine this view, asserting that dyslexic students' reasoning is "disproportionately" negatively affected when they are required to remember visual patterns – proposing that the tasks of remembering and manipulating information are "competing for the same visual cognitive resource" and that disadvantage arises only under conditions of high WM load. To compensate, our participants described strategies such as minimizing cognitive demands (via selective attention or offloading) and rehearsing information to preserve it in WM. *Gesture* also appeared throughout the participants' recollections of undergraduate mathematics, serving as a means of visualization, communication, and offloading (Risko & Gilbert, 2016; Kokushkin, 2024). In the context of high school students, Hord and colleagues note visual representations (including gestures) "may provide scaffolds for students with learning disabilities related to difficulties with working memory...to facilitate concentration on processing, storing, and integrating information" (Hord et al., 2016, p. 190). Future work of the authors will focus on the role of gesture and embodiment in mathematics learning for USDs.

We caution against drawing broad conclusions on dyslexic undergraduate mathematics education, due to the small sample size of our study and its focus on personal experiences. We also do not claim these challenges and compensatory measures are unique to students with dyslexia, or any specific learning difference. Dyslexia, however, introduces its own layer of complexity, and thus may disproportionally disadvantage undergraduate students on certain tasks. We believe these experiences of USDs, reported in their own words, offer a unique, rich, and informative perspective on the strategies and challenges they face when engaging in undergraduate mathematics learning.

Association for Women in Mathematics as a Place for Reimagining Gender Dynamics in Graduate Mathematics

Talia LaTona-Tequida
Virginia Polytechnic Institute and State University

This study examines gender-inclusive practices within a graduate chapter of the Association for Women in Mathematics (AWM). Using an ethnographic approach, I explore how AWM navigated their inclusive practices. Results revealed that inclusion was viewed as both a logistical necessity and a strategic move toward equity, fostering community building and identifying male allies. Additionally, tensions such as maintaining women-centered spaces and replicating gendered labor divisions also arose. AWM's efforts reflect both an aspirational reimagining of gender dynamics and the persistent realities of societal gender inequities. These findings contribute to understanding how gender-inclusive social structures can both challenge and reproduce dominant gender norms.

Keywords: graduate mathematics education, gender, student organizations

Despite improved representation at the undergraduate level, women are still underrepresented in doctoral mathematics, with only 28% of doctoral degrees awarded to women in 2018 (National Science Foundation, 2021). Beyond graduate studies, the lack of representation for women extends to academic positions, with only 24% of women occupying tenure or tenure-track positions and 11% occupying full professor positions in mathematics (American Mathematical Society, 2019). Additionally, while women who have earned PhDs in mathematics in the US have slightly lower initial unemployment rates than men, their first post-PhD jobs are less likely than men's to be at top universities, and the percentage of new women PhDs who were employed at bachelor's-only departments is much higher than for men. This discrepancy occurs despite the prestige of their PhD-granting department (Vitulli, 2018).

In addition to the inherent inequity in the underrepresentation of women in advanced mathematics, underrepresentation has been shown to be detrimental to women's experiences at the postsecondary and graduate level. Women have experienced overt prejudice (Herzig, 2010), the impact of negative stereotypes (both gendered and racialized), and experiences of invisibility (Herzig, 2002b). Furthermore, women have suffered damaging impacts because of negative gender stereotypes (Good et al., 2012), experienced a lack of belonging, reported insufficient or negative advising experiences (Herzig, 2002a, 2002b, 2004), and had to adapt their identities to minimize their gender expressions (Herzig, 2010; Rodd & Bartholomew, 2006).

Although the experiential reality of being a woman in advanced mathematics includes negative factors, much of the research in this area has positioned them as outsiders or "'other' but with a right to be there" (Rodd & Bartholomew, p.42). This focus on women's negative experiences in doctoral mathematics, with little understanding of women's strengths and agency, perpetuates deficit narratives. Furthermore, some theoretical framings imply these deficits lie within the students themselves, overlooking sociopolitical themes in women's experiences (Damarin, 2008).

In addition to limited research examining the experiences of women pursuing doctoral degrees in mathematics through a critical lens, there is a dearth of literature that works to understand supports for women in advanced mathematics. Extending the research, through a critical lens, of women graduate students' experiences and their supports, this study examines the

social practices of a graduate chapter of the Association for Women in Mathematics (AWM). To investigate these areas, I answer the research question: *How does the discourse of inclusion mediate the social activity of AWM?*

Theoretical Framework

Theoretically much of the literature (e.g., Herzig 2002a, 2002b) has relied on assumptions that position women as needing to move toward an existing, static culture, framing their experiences in doctoral mathematics as an inability to integrate. To reframe women's experiences in a way that highlights their agency and impact on their local departmental culture, I leverage the figured worlds framework, with a particular emphasis on authoritative discourse (Holland et al., 1998) and refine this lens through the construct of prefiguration (Curnow, 2022).

Figured Worlds

Holland et al. (1998) define a figured world as "a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others" (p. 52). Many studies have leveraged figured worlds as contexts with their own histories and cultures that construct identities as individuals participate in them (e.g., Solomon et al., 2010; Voigt et al., 2020). However, Holland et al. (1998) emphasize that identities are co-developed *with* figured worlds. That is, identities are formed in the process of participating in the activities organized by figured worlds, *and* figured worlds are produced and reproduced through the work of participants. As such I leverage the figured worlds framework to understand how individuals, through their participation in AWM, contribute to their figured world of PhD mathematics.

Authoritative discourse. Holland et al. (1998) propose discourses as significant in mediating the construction of figured worlds. Discourses "capture the ways in which people recognize socially and historically significant identities…through well-integrated combinations of language, actions, interactions, objects, tools, technologies, beliefs, and values" (Gee, 2015, p. 1). Additionally, Holland et al. (1998) include the construct of *authoritative discourse* in their descriptions of figured worlds, which are discourses that are often accepted without question. Authoritative discourse "demands that we acknowledge it, that we make it our own" (Bakhtin, 1981, p. 342). Individuals may reject or attempt to modify an authoritative discourse, but they cannot simply ignore them. The authoritative discourse of *inclusion* has been identified as significant in education (Dune, 2009).

Inclusion "signifies a right to membership and participation, often viewed as a marker of political correctness and sensitivity…" and has been identified as an authoritative discourse in education (Dunne, 2009, p. 305). However, the unquestioned implementation of inclusive practices may lead to unintended consequences (Dunne, 2009). This includes limitations in discussing differences and relinquishment of responsibility for meaningful change by treating inclusion as a terminal act. As such, critics of unqualified inclusion encourage one to address the nuances of inclusion and answer the question "who is served by inclusion?"

While authoritative discourse via the figured worlds allows one to account for the impact of systemic and social power structures, there is a need to understand agency at the group level. One way to frame the activity of the AWM group that emphasizes their activity as one of empowerment and choice, is through the lens of *prefiguration*.

Prefiguration

Prefiguration refers to the idealized social practices of a group that reflect the aspirational or desired outcomes of the group in alignment with their political goals (Uttamchandani, 2020). Prefiguration as a theoretical lens affords the identification of "...the emergent, ongoing development of practices and philosophies of a collective…" (Curnow, 2022, p. 556). Because AWM is an inherently political organization, with the official goal of "promoting equitable opportunity and treatment of women and others of marginalized genders and gender identities across the mathematical sciences," prefiguration allows the politicized practices of the group to be foregrounded. Lastly, using a prefigurative lens gives prominence to the agency demonstrated by AWM, by highlighting their activity as an enactment of political resistance.

Methodology

The overall methodology in answering the research question - *How does the discourse of inclusion mediate the social activity of AWM?*- was an ethnographic approach. This approach includes identifying a culture-sharing group, selecting themes to study about the group, gathering information in the group context, generating an overall interpretation of the group, and presenting patterns of the group (Cresswell & Poth, 2016). A graduate chapter of AWM was selected as the culture-sharing group, allowing the investigation of the intersection of gender and mathematics.

Context and Participants

Southwest University (SU) is a large public university in the southwest United States and is classified as a very high research activity institution. The mathematics department at SU has approximately 200 students enrolled in their doctoral program, with about 15% of students identifying as women. There are approximately 60 faculty, a minority of which are women.

Participants included five women enrolled, or recently enrolled, in the doctoral mathematics program at SU. The women were selected using a stratified purposeful sampling (Patton, 1990) with respect to years' experience in the program. This included one woman enrolled in coursework, two women in early research, one woman in advanced research, and one woman taking a leave of absence after completing coursework. Additional sampling criteria included participation in the local graduate chapter of the AWM.

The SU graduate chapter of AWM was reestablished in Fall 2019, after a ten-year period of inactivity. At the time of the study, AWM was starting its fourth year after this period of dormancy. Since coming out of dormancy, the group had initiated a variety of activities including weekly social events known as 'Teas,' a mentorship program, a faculty interview series, and most recently an industry panel showcasing women working professionally in STEM.

Data Corpus

Participant data included a mathematics autobiography, one episodic narrative interview (Mueller, 2019), six weeks of diary entries (Cresswell & Poth, 2016), one future-focused diary entry, and one semi-structured interview per participant (Bernard, 1998). There was also one focus group interview with all five participants (Morgan, 1997).

Observation data included two quarters (16 weeks) of observations and field notes of the AWM activities. This primarily included weekly Teas and Executive Council meetings for a total of 24 observation hours. For each observation I gathered information about the space, purpose, people, and dialogue. Additionally, the observation data included one recorded conversation with

the current AWM president about her perspective, as a representative of the group, on the inclusion of men in their events.

Analysis

In conducting this ethnography, my goal was to understand the figured world of AWM at SU. In support of this goal, I refined the ethnographic approach through thematic analysis to capture more fine-grained themes (Braun & Clarke, 2006). Analysis included reduction of the participant data to those excerpts which directly addressed the inclusion of men in AWM activities. This was followed by open coding, capturing distinct ideas related to the research question. I also open coded the observation data and the conversation with the current AWM president. After open coding, I began to look for connections among the codes, grouping them into themes. During this time, I continuously refined codes, adding new excerpts and eliminating others as well as refining the code definitions to better represent the data.

The results of the analysis revealed how the discourse of inclusion mediated the largely gender-inclusive structure of AWM. In the following sections, I present findings from the thematic analysis that detail the AWM's reasons for inclusion, the reflective ways they navigated inclusion while still serving the interests of women and other nondominant genders, and the possible consequences of their choice to include men in their events.

Results

The themes that arose as a result of the thematic analysis – *reasons for inclusion*, *benefits of inclusion*, *challenges of inclusion*, *navigating inclusion*, and *replication of domestic labor inequities* – were consistently shared among at least four of the five participants and often identified across multiple data sources (i.e., individual interviews and focus group interview). Overwhelmingly the statements about the inclusive practices of AWM were in support and often with a sense of advocacy. I first detail the reasons for gender inclusivity at AWM events.

Reasons for Inclusion

Early in my observations of the AWM Teas I asked Mariam (year 4) about her perspective on the decision to include men at the events. Her response was reflective of the group's prefiguring of gender dynamics in their department and in mathematics in general. She shared:

> In an ideal world, we don't want to have an AWM because everybody's equally welcome and represented in their department. And if we want to reach that ideal state, we can't… these male colleagues are also in your program, and they're facing almost the same things, and there is a lot to gain by talking to them also. So, it's good to include them in events, I feel like, because in the future we want that. (Mariam, year 4, Interview 1)

Mariam shares her view that women and men have experiences in common in the PhD program and proposes the possibility that there is support to be gained through connections with men. Furthermore, Mariam's description of an ideal world includes equal representation and inclusion of women. Other AWM members viewed the inclusion of men as a logistic matter.

Both Ida and Lucy, the present and founding president of AWM, viewed the inclusion of men as necessary for the group to be operational due to there being few women in the PhD program. Ida discussed the need to have men initially serve as principal members because at the time AWM restarted there were not enough women to fill all the roles of the Executive Council. Ida reflected "…when we started the group, we didn't have enough women to run the group, so we needed men to volunteer to help run the group and do a lot of this important stuff" (Ida, year 6, Interview 1).

Although the principal members of the Executive Council were all women at the time of the study, the need to have men participate persisted. Lucy, the current AWM president, explained how the continued gender imbalance still necessitated the inclusion of men:

> But I think for the social events, it's tricky. I think AWM wants to be known and active in our department, and because there are fewer women, I feel like sometimes if we make our events smaller, then maybe we're not as well known in the department. You need a sort of a critical mass of just people to meet your goals. (Lucy, AWM president, private conversation)

Lucy's explanation reveals the strategy of including men for the greater good of the group and to reach their goals of being recognized in the department. As evidenced by Ida and Lucy's explanations, the gender makeup of the graduate students necessitated the inclusion of men in the AWM group. Participants also discussed the benefits and of including men in AWM activities.

Benefits of Inclusion

In asking the participants directly about their reasoning for including men, they responded that events structured by inclusion benefited the department community, prevented AWM from being isolated, and benefited women. During the focus group Cindy compared her experience in her undergraduate studies to her experience in AWM at SWU. She said:

> I think for AWM here, I don't know how it is at other schools, but I know, for, like in undergrad, women in STEM…there were no men involved whatsoever. And here there's like a lot of men who actively attend our events, or volunteer to help with stuff. And so, I think that overall helps contribute to a better environment in the department. (Cindy, year 2, Focus Group)

Cindy expresses the possibility of isolation in creating a group that is segregated and connects the value of community to AWM's practice of inclusion, explaining that the inclusion of men is beneficial to the department as a whole. In addition to the benefits to the department, inclusion was explicitly connected to benefiting women. For example, Ida shared:

> It doesn't seem to matter so much if there are more men than women, which will happen if you have 60 people in an event in our math department because you don't have 60 women. I think it just matters that there are a lot of women to talk to and that there's a space where the women feel comfortable to talk to people and ask questions. And they're a focus. (Ida, year 6, Interview 1)

It is here that AWM's practice of inviting men into their events is distinct from a version of inclusion in which women are invited into a space in which they are marginalized. If the women being included in another, dominant group, the scenario Ida describes would structure participation in a way where women were being integrated into the dominant culture. However, because it was AWM that included the men, the social interaction is happening outside (to an extent) of a context in which men are the default. Through a prefigurative and figured worlds lens, gender inclusivity at AWM Teas facilitated the enactment of a mathematical context where women's presence was normalized.

Another reported benefit of inclusion was the potential for men to become allies to AWM as a group and women as individuals. Cindy stated "I feel like it kind of builds allies and like, oh, well if this guy comes to AWM Tea, he is probably supportive of women in math. (Cindy, year 2, Interview 1). Bringing men into the advocacy goals of the group demonstrates a prefigurative vision in which men are personally invested in the success of women. In addition to the reasons in favor of gender inclusivity in AWM, there was also evidence that the group was reflective of the potential challenges of including men in most of their activities.

Challenges of Inclusion

AWM members discussed differences between gender-inclusive and women-only events, including the times when inclusive events recreated a mathematical contexts in which women were marginalized. Cindy spoke about the differences in the AWM that were not inclusive:

> So, I feel like sometimes when it's just women or gender minority focused, maybe you would say things you wouldn't say when it's just anyone's welcome. And I think that's also valuable to hear and maybe feel like you're not as alone in some experiences or also I remember I got some good advice there. (Cindy, year 2, Interview 1)

Cindy details the experience of being to share more openly struggles related to graduate school at women and gender minority events. She also describes support and camaraderie as advantages of being more vulnerable at events without men. In addition to the possible missed opportunities for support in inclusive events, Ida recalled a time when inclusion backfired and lessons the group learned from this misstep. She recalled:

> I think it's important to always have women only events as well as mixed events. And in the beginning, we had a real wake up moment with this when our events started getting completely overrun with men…the men were just coming and talking about all their issues. It was coded, it was supposed to be a female space, but things were done in a way that was way more open to everyone…I think we had to be a lot more heavy handed. (Ida, year 6, Interview 1)

Ida describes early attempts to be inclusive by "coding" events as women focused. At times this implicit messaging was not enough to create an inclusive space that still centered women. She was candidly reflective that there are consequences to inclusion "I told you the reasons why we made the choices, and now I'm telling you the reasons why those choices, the costs of those choices." (Ida, year 6, Interview 1). Acknowledgement of the sacrifices, and sometimes consequences, of inclusion implies the value AWM sees in opening their events to men. Balancing the benefits and challenges of including men was discussed by the current AWM president as she discussed the group's plans to navigate these tensions.

Navigating Inclusion

In speaking with Lucy, the current president, about the inclusive nature of the AWM events she discussed a careful balance in their decisions to host events that included men:

> So, I think that this is something maybe in our officer meetings we don't necessarily explicitly talk about a lot, but I think we all think about it a lot because it's tricky because their math being a male dominated academic field…We do make a lot of friends in our classes and things like that, especially if we're doing a more social geared event that's like, oh, well we're very close friends with a lot of the men in our department. Whereas…the industry panel that's an actual conversation that's probably going to be brought up in our meeting… are we going to restrict that to underrepresented genders because it's more of a recruiting or talking about your experiences as a woman. (Lucy, AWM president, private conversation Jan 24, 2024)

Lucy describes wanting to include men in events since due to the social relationships shared among the men and women, echoing earlier sentiments that inclusion connects women more extensively to the department. In contrast, Lucy appears more reluctant to assume the inclusion of men in the industry panel event where the focus is specific to issues relevant to women and other nondominant genders.

Replication of Domestic Labor Inequities

As I attended weekly Teas, I observed what I viewed as an inequitable division of labor. Men regularly attended the weekly Teas and often outnumbered the women. While this didn't appear to have significant impacts socially, it became apparent that women were responsible for setting up and breaking down the events. This observation was verified in a conversation with the current AWM president. Lucy explained:

> If a historical or traditional idea of things are that women's jobs would be cleaning or cooking or things like that and then we have an event and if the majority of the attendees are men, but the women are the ones who are staying after and cleaning up and it's like… well who are we putting on this event for? (Lucy, private conversation, Jan 24, 2024)

Lucy is reflective of the implications of the labor division at the AWM events. Importantly, she asks the question "who are we putting on this event for?" This indicates that although the group assumes many reasons why inclusion is beneficial to their goal of supporting women, they also attend to the potential impacts of those decisions. So, while the discourse of inclusion allows the group to enact an idealized future of gender equity, there is still a tether to the reality of inequitable domestic labor among men and women.

Conclusion

AWM at SU subscribed to inclusion as an authoritative discourse that informed the structure of many of their activities. However, they navigated the complexities of inclusion by incorporating men into their events while also striving to maintain a space that supports women and gender minorities in mathematics. As such, AWM's approach to inclusion reflects both adherence to and negotiation of this discourse, as the group actively questioned who is served by inclusion but did not challenge inclusion as an assumed value to the group.

The framework of figured worlds and prefiguration highlights how AWM created alternative gender dynamics within the male-dominated space of their department. By including men in their events, AWM modeled a more integrated and aspirational environment where women were more visible and less isolated. This approach allowed for informal mentorship, allyship, and increased presence within the department, reinforcing the idea that gender inclusivity at AWM events benefits not just women but the entire academic community.

In tandem with the reported benefits of inclusion, members acknowledged the need for women-only events, recognizing that some conversations and experiences would be more accessible in a space free from dominant-group influence. Additionally, while inclusion was intended to foster an environment where women were more integrated, there were instances existing gendered power dynamics were reproduced. In this way the prefigurative enactment of gender equity in mathematics was contradicted by societal influences outside of the department.

Previous research indicates that women may significantly resist integrating their gender and mathematical identities due to the underlying bias associated with being a woman in mathematics (LaTona-Tequida, 2025, Solomon et al., 2011). This resistance reflects the need for a cultural shift in mathematics that positions women as more fully legitimate. In response, the gender inclusive practices of AWM at SU point to potential mechanisms to initiate this cultural shift. Participants expressed that spaces exclusive to women were somewhat isolating and potentially worked against their goals of being more integrated into their departmental community. The AWM activity, mediated by the discourse of inclusion, appeared successful in creating a departmental atmosphere that was beneficial to the participants.

Expert Perspectives on the Set of Outcomes for a Non-Standard Presentation Counting Problem

Adaline De Chenne
New Mexico State University

The objective of a counting problem is to determine the cardinality of a set of outcomes, but there is never a singular, unique way to conceive of those outcomes. I report on data of combinatorics experts solving a counting problem whose numerical solution is 2^6, a standard expression to see in combinatorics, but whose set of outcomes is not standard. I demonstrate four distinct models that the participants used to conceive of the outcomes, and how each of those led to different ways of explaining the solution. I argue that these differences among experts reflect the challenging nature of articulating what the set of outcomes for a counting problem is, and how to approach a solution using this set. These data may inform how counting could be presented to learners when adopting a wide view on the multiple possible sets of outcomes for any given problem.

Keywords: combinatorics, mathematicians, expert reasoning

Consider the Roads Problem: How many ways are there to traverse the diagram from point A to point B in Figure 1, if no line segment can be repeated? This counting problem is notable because the outcomes being counted—paths along a particular diagram—are not immediately similar to common archetypal problems. It is possible to create a bijection between the outcomes and length-6 binary strings, which means that there are 2^6 total outcomes, and the Roads Problem can be considered to involve arrangement with repetition. However, as I elaborate later, it is also possible to conceive of the outcomes as involving subsets, or simply as path diagrams independent of auxiliary representations. There is no singular set that can be described uniquely as the set of outcomes, and the model of outcome used can impact how a solution is found, and the form it takes. If a set of outcomes is the foundation of a counting problem, what does it mean for combinatorics if there are multiple contenders for what that set is?

Figure 1. Diagram for the Roads Problem.

This paper reports on data of nine combinatorics experts solving the Roads Problem during task-based interviews. I draw on these data because four distinct models of the set of outcomes emerged from the participants, which demonstrates the multiple faces of a set of outcomes even among experts. These results can provide additional context when working with K-16 students, particularly when conventional solutions might depend on a specific way of conceptualizing or encoding the outcomes.

Literature Review and Theoretical Framework

Student difficulties in combinatorics have been well-documented, including the challenge of distinguishing between problem types. Batanero and colleagues (1997) found that students can have difficulty distinguishing between problem types, and Lockwood (2014) reported that students sometimes use their 'gut' when the problem statement does not specifically say order

matters. Literature has increasingly applied an approach that values how students create and justify solutions based on the outcomes being counted. For example, systematically listing sets of outcomes (English 1991, 1993; Montenegro et al., 2022), or even thinking about how to do so (Halani, 2012) has been shown to correlate with successful solutions even at the undergraduate level (Lockwood & Gibson, 2016). Some of this work reports on how students conceive of outcomes, and how those conceptions impact the way they find or justify solutions (e.g., Lockwood et al, 2018; Wasserman & Galarza, 2019), showing that certain (sometimes unfamiliar or unintuitive) ways of encoding outcomes are more likely to lead to successful solutions than others.

Lockwood (2014) has advocated for a set-oriented perspective on counting, where attending to the sets of outcomes is a fundamental aspect of a solution. This perspective draws from her (2013) model of student reasoning, which examines the interactivity between *sets of outcomes, formulas/expressions*, and *counting processes.* The set of outcomes for a counting problem is the set of elements being counted, the cardinality of which is the solution to the problem. Formulas and expressions refer to the mathematical formulas and expressions (such as $\binom{n}{k}$ or 2^6) used in the course of the solution, and what is typically used to write the answer. I refer to mathematical expressions that solve a counting problem as *counting expressions.* Counting processes refer to internal or external processes a counter engages with as they solve a problem (such as listing). Wasserman (2019) argued that counting expressions can also represent a particular enumerative strategy or counting process. For example, although $\binom{n}{k}k = n\binom{n-1}{k-1}$ both count headed size k committees chosen from n people, and are thus numerically equal, they represent two distinct ways of counting those committees. The left-hand side first selects the members of a committee before choosing the head, and the right-hand size chooses the heading before selecting the remaining members. I adopt Lockwood's model for student reasoning in this paper, and I discuss how the duality of counting expression can be observed when different conceptions of a set of outcomes are used to solve a counting problem.

Four Models of the Set of Outcomes in the Roads Problem

To illustrate how the duality of counting expressions might arise when solving the Roads Problem, I present four different ways to model the outcomes. These models are my own formalizations of the approaches I observed from experts, and which I expand on in the Results section.

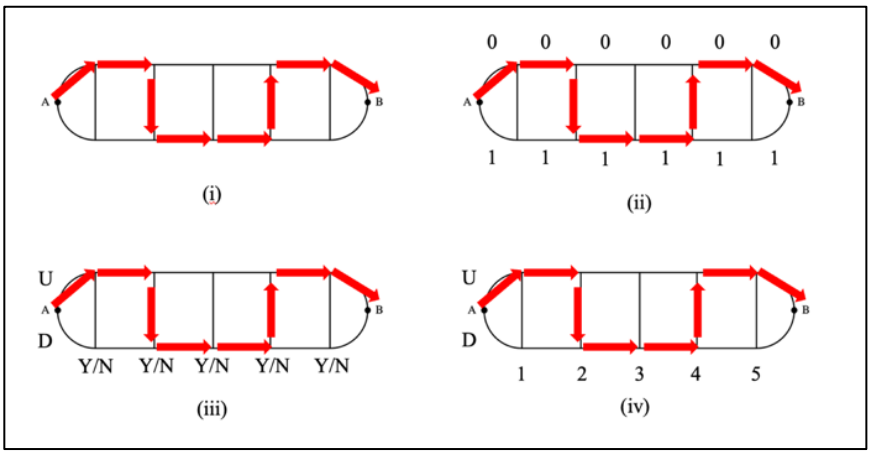

Figure 2. One path shown under four augmented diagrams.

Literal model. The literal model interprets outcomes as visual paths along the diagram. This model does not include an alternate way of encoding or otherwise representing an outcome. I refer to this model as literal because it most closely aligns with the outcomes as described in the problem statement.

Binary model. The binary model encodes paths as a six-character sequence of 0s and 1s, where each 0 or 1 refers to a path segment along the top or bottom of the diagram, respectively. This model does not directly encode vertical path segments, but rather those segments can be deduced from the encoded information. The path in Figure 2.ii represented in the binary model is 001100. This model creates a bijection between all possible paths and six-character binary sequences, and thus there are 2^6 possible outcomes.

Sequential model. The sequential model encodes paths as an initial decision to move up (U) or down (D) from point A, followed by a sequence of choices to cross (Y) or not cross (N) at each vertical path segment. The path in Figure 2.iii represented in the sequential model would be UNYNYN. There are two possibilities for the first decision (U or D), and two possibilities (Y or N) at each subsequent intersection, and so there are $2 \cdot 2^5$ possible outcomes. Note that I distinguish between $2 \cdot 2^5$ and 2^6 because the former illustrates how the first decision (U or D) is a distinct type of decision from the others.

Subset model. The subset model encodes paths as an initial decision to move up (U) or down (D) from point A, followed by a subset of $\{1, 2, 3, 4, 5\}$ to indicate which of the vertical segments occur in the route. The path in Figure 2.iv represented in the subset model would be U$\{2, 4\}$. There are two possibilities for the first decision (U or D), and 2^5 possible subsets of a 5-element set, so thus there are $2 \cdot 2^5$ possible outcomes. I have used 2^5 to represent the ways of counting subsets to reflect the reasoning of the experts reported on in this study, but another counter using the same model might have used a different expression to represent the subsets.

The binary, sequential, and subset models demonstrate distinct models of the outcomes, even if they are used to produce the same or similar mathematical expressions. It is not possible to exchange a representation in one model for a representation in another through a direct character exchange, and each model selects some but not all information about a path to create a representation. For example, despite both binary and sequential models using six-character sequences to encode routes, the outcome 001100 cannot be converted to UNYNUN by a simple exchange of 0s for N and 1s for Ys. Moreover, the binary model selects only information about horizontal segments, and the sequential model selects only information about the vertical segments. In terms of Wasserman's duality of mathematical expression, 2^6 and $2 \cdot 2^5$ represent distinct enumerative processes, and moreover the expression $2 \cdot 2^5$ can even take on more than one interpretation.

Methods

The data presented here were collected as part of a larger study that examined the role of representations in solutions to counting problems for both undergraduate students and combinatorics experts. Both populations were presented with a sequence of tasks meant to elicit the use of representations as part of the solution process. The task sequence for the expert population was comprised of eight problems, the first four of which were selected from the student sequence, and the second four of which were not given to students. I chose expert tasks from the student tasks because they were non-standard presentations of common problem types. Most experts participated in one 90-minute interview, and their work on the tasks comprised most of that interview. However, some experts participated in two shorter interviews due to

scheduling constraints, although they were given the same materials. Most of the experts only completed the tasks that were given to both populations, and only one expert completed all eight problems.

I focus here on expert solutions to the Roads Problem, which was the first task given to the experts. I present these data because prior analysis of student solutions on the problem revealed several approaches that reflected differences in how the outcomes were modeled, which seemed to impact how students approached a solution. While the comparison between the populations is not reported here, the expert solutions demonstrate similar impacts between model and solution approach. Moreover, several of the experts commented that the problem was not one they already knew how to solve, and none of them stated the answer prior to reasoning about the outcomes verbally. I thus argue that the work discussed here demonstrates how experts approach an unfamiliar problem that can be solved with their existing combinatorial tools, rather than how experts recall prior solutions.

The experts were recruited for the study because they were either combinatorialists or education researchers who had previously studied combinatorial reasoning. Six combinatorialists and three educators participated in the study. Their pseudonyms and areas of study are presented in Table 1. The research areas of the educators are only summarized to preserve anonymity. Seven of the participants were tenure-track, one was an instructor, and one was a postdoctoral scholar. Three participants had taught graduate-level combinatorics courses, and five had taught undergraduate-level combinatorics courses, or courses that included combinatorics.

Table 1. Participant demographic information.

Pseudonym	Expertise	
	Mathematician (M) or Educator (E)	Research Area
Austin	M	Algebraic and enumerative combinatorics
Craig	E	Student reasoning
David	E	Student reasoning
Erik	M	Algebraic and enumerative combinatorics
Leo	M	Graph theory and discrete geometry
Oscar	M	Logic, computability theory, and graph theory
Seamus	E	Student reasoning
Silvio	M	Group theory
Ted	M	Algebraic and geometric combinatorics

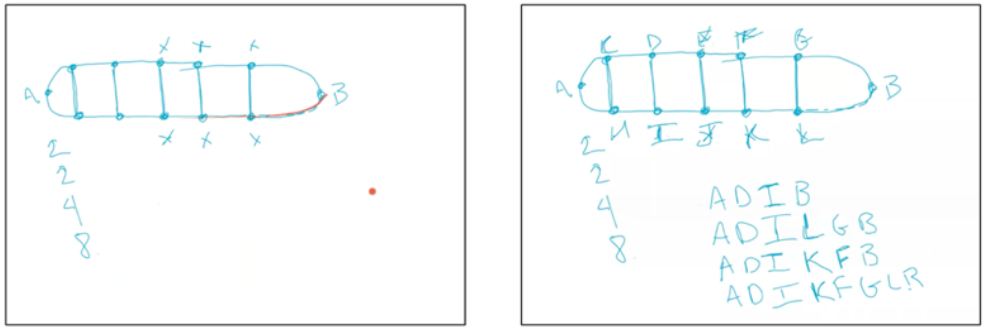
All interviews were conducted over Zoom, and both audio- and video-recordings of the interviews were collected. One participant solved tasks on a blackboard that was visible during the interview, but the remaining participants solved tasks on an electronic tablet whose screen was shared. I created enhanced transcripts of the interviews, where screenshots of the participants' work were used as references alongside the text of the interview. I performed thematic analysis (Braun & Clarke, 2022) on the transcripts to identify the different models of the set of outcomes, problem solving techniques, and how the participants leveraged their conceptualizations of the outcomes to identify a solution.

Results

I present the four models of outcomes I observed, and how these models impacted how the participants sought and justified their solutions. Present in many of these solutions, but not expounded on here, was reasoning about whether a path could move 'backward.' Some participants quickly reasoned that this could not occur, but for Austin this seemed to be the impetus that led to his model.

Literal Model

Craig was the only participant whose work primarily involved reasoning about the literal outcomes, and he spent approximately 37 minutes solving the problem. He began by tracing paths along the diagram with a stylus, which appeared as a red line on the screen that followed his stylus but was not permanent. He organized his tracing by categorizing the outcomes based on the first vertical segment to be part of the path. The first two paths he traced were those that went entirely on the top half or bottom half of the diagram, and the second two paths were those that went on the top or bottom half of the diagram until reaching the last vertical segment. Craig kept track of the number of paths he had traced mentally, and he would record the total number of paths in each category once he had traced all of them (see Figure 3.i). Although it seemed that Craig had developed an internalized way of keeping track of which paths he had or had not traced, he never verbalized it and the red line from his stylus did not appear on screen consistently enough to develop inferences. After tracing out the first four categories, he appeared to have difficulty keeping track of which paths he had already traced, and he labeled each vertex with a letter, as seen in Figure 3.ii. He then used the labels to record paths for a short time, but he commented "This also feels like it's a representational nightmare" before erasing them. It seemed that the primary use of the labeling was to keep track of which outcomes he had traced, and they did not seem to be directly relevant to reasoning about a mathematical expression.



(i) (ii)

Figure 3. Craig's sketching of the literal model, and his use of the model.

After observing that the first five categories included 2, 2, 4, 8, and 16 outcomes, Craig predicted that the last category would include 32 outcomes, and the total number of outcomes would be $2 + 2 + 4 + 8 + 16 + 32 = 64$. When I asked him to describe why there might be powers of two, he responded "Um, having to do with decisions […] each time you reach a point you have a decision. Um, the thing that I don't love about it is that I was trying to think about, uh, for a little bit why I got 2 and 2." By this, I infer that Craig connected the summand of 2^n with the last n vertical paths, but he could not justify why that pattern was inconsistent with the

number of paths that used zero vertical segments. I did not push Craig to further justify his solution. Craig appeared to have difficulty using the literal model, perhaps because they were distinct from archetypal outcomes for counting problems, and he had not developed techniques to identify structural patterns within the set.

Binary Model

Austin was the only participant to use the binary model of the outcomes, but he did so only at the end of his solution. The first part of his solution involved decreasing the number of vertical segments in the diagram, and then sketching each of the literal outcomes. By doing so, he observed that there were 2^{n+1} total paths for a diagram with n vertical segments, and he stated "So I'm envisioning a bijection between, um, paths and bit strings." This bijection is illustrated in Figure 4. Austin used this observation to claim that there were 2^6 paths around the original diagram because he knew that there are 2^6 six-character bit strings. This method uses prior knowledge about binary strings to create a solution, and Austin stated "it's unfamiliar […but…] it just absolutely gives up its secrets when you start doing small examples."

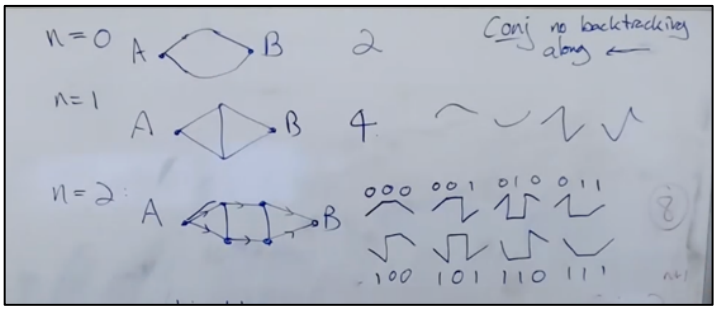


Figure 4. Austin's work using the binary model.

Sequential Model

David, Leo, Oscar, Seamus, and Silvio each used the sequential model. David characterized this method by "we could probably compute the, like, the total number of routes or paths in terms of the number of choices you have to make along the way," which draws an equivalence between a path and a process that would generate that path. Unlike the binary model, where each path was represented by an element of a well-understood set with a known cardinality, the sequential model counted the number of ways a process could be carried out by an agent that traversed the diagram. Similar to David, Oscar and Seamus used language like "if I go down I'd have to go to this point, and again I have two choices there," and "if we went on road two we'd have the same options but in… sort of reverse," indicating they imagined themselves or an agent traversing the diagram, and the path traced out by the agent depended on a sequence of decisions. To further distinguish this model from the binary model, the characterization of the path depended on which vertical components were taken, and each expert differentiated between the first decision (up or down from A) and the subsequent decisions, whereas the binary model depended on which horizontal components were taken and did not distinguish the first path segment from the others. Oscar summarized the method by stating "maybe the right way to think of it is… a route is 'do I take the bridge or not, yes or no?' And then also, but I, realizing that I have two choices initially." This statement seems to indicate that using a sequence of decisions was not merely a process used to count the literal model of outcomes, but instead a complementary way of conceiving of the outcomes themselves.

Subset Model

Erik and Ted used the subset model of the outcomes, which was like the sequential model but included a noticeable difference in terms of how the decisions related to time. Unlike the sequential model, where the experts seemed to think of a path as a sequence of decisions an agent would make while they traversed the diagram, the subset model seemed to make those decisions prior to an imagined traversal. For example, Ted stated "the idea I'm gonna do is say, like, which of these middle paths am I gonna cross?," which indicates selecting the paths prior to traversal, and Erik stated "So I think it really is just any collection of those five vertical roads tells me exactly what I'm going to do […] So, step one is do I go… Do I start up or down. Then, I pick any subset." Erik's statement indicates a distinction between the first decision and subsequent decisions, and both statements indicate choosing the paths prior to diagram traversal. This sentiment seems to be reflected in their final solutions, both of which counted subsets as a single object with cardinality of 2^5. By comparison, although 2^5 appeared in solutions using the sequential model, this expression seemed to indicate one unit repeated five times rather than a single unit. Ted's written work, shown in Figure 5, appears to reinforce that 2^5 stood for the single unit of subset rather than five distinct decisions.

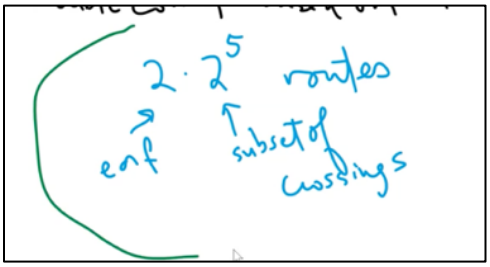

Figure 5. Ted's solution delimitating the first decision from the subset.

Discussion and Conclusion

The expert solutions discussed here shed some light on the nature of sets of outcomes in combinatorics problems. The literal outcomes as described in the statement of the Roads Problem—paths along a diagram—were used as the exclusive set of outcomes by only one participant. All other participants created alternative models of the paths (binary strings, sequences of decisions, and subsets) that seemed to inform how they found a solution and the form of the solution.

It did seem to be the case that the alternative models were strictly artifacts of counting processes the participants employed. The language used by the participants, such as when Oscar said "a route is 'do I take the bridge or not, yes or no?," shows that they were using the literal model to create a secondary model they could hold simultaneously. The second model also demonstrated beliefs about the outcomes that might provide insight on the relationship between outcomes and counters. For instance, the experts who used the sequential model used language that indicated the outcomes would be constructed as an agent traversed the diagram, while the experts who used the subset model used language that indicated the outcomes would be determined prior to an agent traversing the diagram. The binary, sequential, and subset model reflected different temporal relationships between the outcomes and the counter. Whereas the binary model did not include a temporal relationship, the sequential and subset models included language that referenced future or in-the-moment decisions, respectively. The models also showed a difference between counting static complete sets of outcomes (all binary strings), and processes that would generate a single outcome (sequential model).

Exploring Aspects of Student Facility With Taylor Series in the Context of the Electric Dipole

Cameron Flynn
University of Washington

Suzanne White Brahmia
University of Washington

Using a grounded theory approach, we investigate students' facility using Taylor series expansions in the context of the electric dipole. Eight students participated in one-on-one teaching-learning interviews, during which audio and video data were recorded while they completed a written activity. We show that while physics students at this level are very familiar with the procedural aspects of Taylor series expansions, they may not recognize several common cues to use them to simplify functions. We find that sketching out the exact function and an approximation of it can help students learn to associate these common cues with Taylor series. In addition, we probe students' conceptions of the meaning of the expansion point and find that one difficulty in choosing an expansion point in a physics context is associating that 'point' with a spatial location. We conclude with recommendations for physics and calculus instructors.

Keywords: Taylor Series, physics, applications

Introduction

In their studies, physics students must often approximate complicated functions that describe physical systems. While crude approximations—such as setting small parameters to zero—may be sufficient in early coursework, they lose pedagogical value as students advance. A more versatile and effective method involves using a small ratio of parameters to construct a Taylor series expansion, which serves as an approximation with adjustable accuracy. This use case of Taylor series, which Jones et al. (2019) refer to as an "extension of a linear approximation," is an indispensable mathematical technique in a physicist's toolkit and plays a pivotal role in connecting mathematical rigor with physical intuition.

Usually students first encounter Taylor series towards the end of their introductory calculus sequence, although they use results of Taylor series in physics courses earlier. One early use is the 'small angle approximation', that $sin\,\theta \approx \theta$ for $\theta \approx 0$. However, applications like these are often treated as facts to be memorized, justified only with plausibility arguments. In calculus courses, they are expected to remember the general formula for the Taylor series expansion of a function *f(x)* expanded about some expansion point *a* $f(x) = f(a) + \frac{\partial f}{\partial x}\Big|_a (x-a) + \frac{1}{2}\frac{\partial^2 f}{\partial x^2}\Big|_a (x-a)^2 + \cdots = \sum_{n=0}^{\infty} \frac{1}{n!}\frac{\partial^n f}{\partial x^n}\Big|_a (x-a)^n$ and be able to apply it to complicated functions that are already in terms of the expansion variable. However, in physics explicit prompting for Taylor series is rare: students are usually expected to pick up on contextual cues, such as one quantity being much smaller than another, or that an approximate expression is required (Wilcox et al., 2013). Physics courses expect students to understand when a Taylor series expansion is needed, to create their own small and dimensionless expansion variable, and only then to perform the expansion (Loverude & Li, 2013).

A common context for Taylor series expansions is to approximate the electric field at a distance *L* from an electric dipole, which consists of a pair of charged particles of equal magnitude and opposite sign, separated in space by a distance *s* (see Fig. 2). An expert would treat the variable *L* as a parameter that takes on values either much smaller or much larger than *s*, and would use the *parameter ratio* $\frac{s}{L}$ as the expansion variable for the Taylor series in order to

understand the field's behavior at relative extremes. The expansion point is the approximate value of the parameter ratio, and the zeroth-order term *f(a)* is often physically meaningful. Students may struggle with this even if they have mastered the computational techniques in a calculus course, as these contexts require sense-making with physical quantities.

In this paper we investigate problem-solving strategies of sophomore-level students when applying Taylor series to the electric dipole. We aim to identify specific student strengths and conceptual barriers—specifically those related to cue recognition and interpretation of the meaning of the expansion point—to better inform instructional scaffolding. Following a review of the literature on Taylor series in physics education, we outline our study design, present and discuss our findings, and conclude with instructional implications for both physics and calculus courses.

Our research questions are as follows:

1. Research Question 1 – Cuing with the Parameter Ratio: Do students in this population recognize that the request to find an approximate expression when the charge separation is much smaller than the observation distance—indicating a very small parameter ratio—serves as a cue to apply a Taylor series expansion, without explicit prompting? If not, what prompts allow students to come to the conclusion themselves that these phrases are cues to do so?
2. Research Question 2 – Conceptions of the Expansion Point: What are students' conceptions of the meaning of *a* (the expansion point) in a physics context?

Background

Knowing when and how to apply Taylor series in physics is often difficult, even for students who have attained procedural proficiency in their use from calculus courses (Smith et al., 2013; Wilcox et al., 2013; Loverude and Li, 2013). Some of this may be due to the increased number of steps required to use a Taylor series expansion in physics as compared to in calculus courses. One such step is determining the expansion point: Wilcox et al. (2013) and Smith et al. (2013) showed that students have difficulty when the expansion point is non-zero. Another step is to recognize the cues to use a Taylor series that experts recognize. Loverude (2025) observed that while students readily employ basic approximation methods when prompted, they may not yet intuitively select more sophisticated techniques that experts use to extract physical insights.

Common cues for students to use a Taylor expansion are outlined in the Wilcox et al. study. These cues are: explicitly asking for a Taylor series expansion, asking for an approximate expression for a complicated function, and the use of language or symbols implying that one parameter is much smaller than another. Their students were successful in picking up the cues, but their population was also from a course in which these cues would be taught. We sought to evaluate whether the second and third cues are sufficient for students—who had not had explicit instruction identifying these as indicators—to infer the appropriateness of a Taylor series expansion when given an intellectual need for such an expansion (Harel, 2008). We predicted, given the documented difficulties students have in transferring knowledge between courses (Loverude, 2017), that students would struggle to come to the conclusion that a Taylor series expansion is necessary. We wanted to explore their reasoning at this stage.

Methods

The student population sampled in this study consists of physics majors and minors at a large-enrollment R1 institution in the Pacific Northwest that graduates about 100 students annually. Approximately 15% of students self-identify as members of underrepresented minority

groups and about 27% identify as female. Math Methods I is a sophomore-level course, usually taught with minimal physics context and from the standard textbook (Boas, 2005). The course is typically taken after one year of introductory calculus and one year of introductory calculus-based physics. Similar to patterns across the U.S., the introductory physics sequence followed by most participants did not require students to solve problems using calculus (Loverude, 2025).

Eight students, all enrolled in Math Methods I, volunteered for this study in exchange for $200. All participants identified as female and used the self-selected pseudonyms Abby, Chad, Grace, Jake, Jenna, Priscilla, Summer, and Susan. While this sample was not representative of the course demographics, time constraints prevented further recruitment. Two participants, Jake and Summer, were non-traditional students who had transferred from community colleges; Jake had completed the same course in the prior quarter.

Participants engaged in one-on-one teaching-learning interviews (Nguyen & Rebello, 2011), completing a Taylor series-based activity with intermittent input from an interviewer. Previous studies on the use of Taylor series expansions in physics have asked students to complete the entire problem at once, with written responses analyzed afterwards (Loverude, 2025; Loverude & Li, 2013; Wilcox et al., 2013). Other studies have conducted teaching interviews in which students were explicitly prompted to use Taylor series (Smith et al., 2013). Teaching-learning interviews allow for deeper probing of student reasoning than analysis of written responses alone. Interviews were conducted in quiet rooms, lasted 1–2 hours, and were screen-recorded on an iPad. Audio was transcribed using AI software and manually corrected. Grace's audio was not recorded, so her data were only used when video and notes were sufficient.

Data processing followed the procedures outlined by Otero and Harlow (2009). After reviewing interview notes and recordings, the lead researcher identified sections of interest, usually where students struggled most. Content logs were written for about one-third of the activity questions; these logs helped us focus on three questions from the activity, reproduced at the end of this section. Student written data were integrated into the corrected transcripts.

Figure 1. Schematic of the data analysis process. We used grounded theory to generate codes which were grouped by theme (such as 'Expansion Point'), and report on patterns that emerged from within those themes (Attride-Stirling, 2001; Glaser & Strauss, 1967; O'Callaghan et al., 2024).

Our data were analyzed using thematic analysis informed by grounded theory (TAG) (Attride-Stirling, 2001; Creswell & Creswell, 2018; Glaser & Strauss, 1967; O'Callaghan et al., 2024). We used a grounded theory approach in generating a codebook from the raw data (Fig. 1, left). A primary focus of the analysis was on students' initial responses to the activity questions; codes for these were initially developed by the lead researcher during a review of the content logs and later validated through application. A second focus was on students' responses to interviewer prompts. Both the prompts and the corresponding responses were coded inductively. Both coding efforts contributed to the development of the final codebook. The lead researcher and two undergraduate research students applied the completed coding scheme on one interview before independently applying it to other interviews and reaching above 85% agreement.

We subsequently used our codebook to identify themes, which formed the basis of a thematic analysis (Fig. 1, center). Individual codes were grouped into broader themes (e.g., Expansion Point), and we describe several reasoning patterns that emerged as clusters of codes within each theme (Attride-Stirling, 2001; O'Callaghan et al., 2024). This analysis yielded the reasoning patterns which inform the discussion throughout this paper.

The activity used was adapted from the Tutorials in Mathematical Methods in Physics by Loverude, Thompson, and Christensen (Loverude et al., n.d.) to provide an intellectual need for a Taylor series expansion (Harel, 2008). The goal of the activity was to model the electric field produced by an electric dipole at an observation point P far away from the center of the dipole; that is, $L \gg s$ in the diagram.

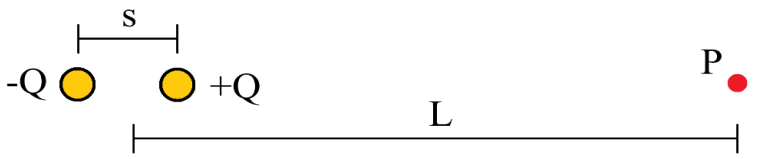

Figure 2. The figure given on the activity. The two circles ('+Q' and '-Q') are the equal magnitude, oppositely signed charges that constitute the dipole. L is distance from the dipole's midpoint to the observation point P and s is the distance between charges in the dipole. Students were to work in the regime where $L \gg s$.

In their study, Loverude and Li (2013) report that students have difficulty finding an appropriate expansion variable and getting their equations into a productive form for expanding in a Taylor series. Since we were unsure to what extent students would be cued to use a Taylor series—if at all—they were guided to write their exact expression in terms of the parameter ratio $u = \frac{s}{L}$ before expanding it as a Taylor series.

The relevant questions in the activity are listed below. Note that the 'expression in question 6' is the exact equation for the electric field as a function of u: $E = \frac{kQ}{L^2}\left[\frac{1}{\left(1-\frac{u}{2}\right)^2} - \frac{1}{\left(1+\frac{u}{2}\right)^2}\right]$.

10. Let's say instead that we want to know what the electric field is when u is very small, but not exactly zero. What could you do to your expression in question 6 to approximate the electric field for small values of u? (Answer: Expand it as a Taylor series and truncate.)
13. One of the most important Taylor series expansions to learn is the expansion for $(1 + x)^P$. Derive the Taylor series to three terms for this expression.
14. Look again at your expression in question 6. If we were to use the expansion that you just derived, what should p be equal to? What should x be equal to? *Asked verbally: What should a be equal to?* (Answers: p=*-2*, $x = \pm\frac{u}{2}$, and a=*0* since x is small.)

Findings and Discussion

RQ 1: Cuing with the Parameter Ratio

Findings. Our first research question is whether students would recognize that a very small parameter ratio and a request for an approximate expression are cues to use a Taylor series expansion, and if not, how they come to recognize this. Prior to Question 10, students were asked to describe the physical and mathematical results of setting the parameter s to zero and the

parameter L to infinity separately, and subsequently about the results of setting the quantity $u = \frac{s}{L}$ to zero.

To answer Question 10, Chad, Jake, Susan, and Summer initially suggested that (in Susan's words) they "do the limit as u approaches zero". Abby, previously informed by the interviewer that setting $u=0$ was not correct, settled on "a limit approaching one". Summer and Jenna suggested 'dropping' u, which appeared to mean setting it to zero rather than excluding the symbol. Priscilla only algebraically rearranged the symbols without altering the expression. After clarification that taking the limit as u approaches zero would yield the same result as setting $u=0$—which they had already done—Jake and Susan proposed plugging in a number close to zero (such as 0.001). No others had alternate ideas before discussing with the interviewer.

The interviewer then asked each student a variant of: "In introductory physics, you used the small angle approximation $\sin x \approx x$. Why is that valid?" Only Jake immediately related this to the Taylor series of sine. Four (Abby, Grace, Summer, and Susan) were asked to sketch graphs of $y = \sin x$ and $y=x$ overlaid and three of them eventually concluded that the approximation was due to a Taylor series. Among those who did not graph, none came to this conclusion. These results are shown in Table 1.

Table 1. Student reasoning in Question 10. Three of the four students who concluded that a Taylor series expansion was necessary drew the functions $y = \sin x$ and $y=x$ on the same axis. Three of the four who did not conclude such also did not draw any graphs.

	Concluded Taylor Series	
	Yes	No
Drawing	Abby, Grace, Susan	Summer
No Drawing	Jake	Chad, Jenna, Priscilla

Discussion. That five out of seven of our students initially suggested using a limit is not surprising, as prior questions likely primed them to think about limits. However, all of their initial suggestions would result in exact values for the electric field at various values of u, rather than in approximations valid over a range of values of u. These data agree with Loverude and Li (2013), who noted that students often interpreted $L \gg s$ as a reason to set $s=0$. Combined with the fact that their alternatives also give exact values rather than approximate expressions, this suggests that students at this level may struggle to conceptualize approximations of functions.

The graphing task proved useful in helping students connect mathematical tools to contextual use, though the interviewer's prompts also mattered. Before coming to the correct conclusion Abby and Susan were asked how to increase the domain of validity of the approximation, while Summer was asked how to improve its accuracy and did not conclude that the approximation was the result of a Taylor series. This suggests that prompting students to broaden the approximation's domain may be more effective, possibly because it avoids assumptions about the series' exactness; according to Martin et al. (2011), students commonly view truncated Taylor series expansions as being exact throughout the domain of validity.

These results show that the cues from Wilcox et al. (2013) may be valid if they are taught, but students who have not learned Taylor series in a physics context may not recognize them. While visualizations help, additional prompting about the nature of the graph may be necessary. This illustrates how effortful the transition from mathematical abstraction to physical application is for learners while also supporting the idea that students have emerging graphical-mathematical blended reasoning, which is present in experts (Zimmerman et al., 2023).

RQ 2: Conceptions of the Expansion Point

Findings. Before investigating students' conceptions of the expansion point, we first assessed their procedural facility with Taylor series. In Question 13 we asked students to find the Taylor series expansion of $(1+x)^p$ without giving them the general formula. Six of the seven immediately started taking derivatives to get the coefficients, while Jake attempted a summation expression. All of them ended up with the correct formula with minor errors. Most errors involved the expansion point a: three students dropped all powers of x-a, three omitted $-a$ from the powers of x (two—Jenna and Susan—did so intentionally, stating that $a=0$), and one had to be prompted to evaluate the derivatives at a.

In Question 14, students matched the result of their expansion to the exact expression of the electric field from earlier. Most incorrectly chose $p=2$ rather than the correct $p=-2$, which is consistent with Loverude and Li (2013). While most correctly or nearly correctly identified x, only Jake immediately concluded that $a=0$ without interviewer guidance.

When asked for the meaning of a, Jake paraphrased the interviewer's earlier explanation of a and concluded that $a=0$ since the expansion variable was close to zero. Priscilla offered that a is "something really close to the value of whatever x is" but needed prompting to identify its value. Chad also produced an acceptable definition of a without prior explanation by the interviewer but initially believed that 'point' referred to the spatial location point P, as did Abby. When told by the interviewer that $a=0$, Abby explained that zero makes sense because s and L are measured from the origin, another spatial location. Summer reported that a is "where we are basing the expansion", but then was unsure what it would represent, guessing the variable u, Coulomb's constant k, "the electric field", and $\frac{1}{2}$.

Table 2. Students' initial responses to Question 14. A question mark indicates that the student did not give a definite response without aid from the interviewer. Jenna and Susan had already chosen a=0 in Question 13, though with incorrect/no justification.

	p	x	a
Abby	2	±u/2	Point P
Chad	2	±u/2	Point P
Jake	2	±u/2	0
Priscilla	2	±u/2	?
Jenna	2	u	0*
Summer	2	Q or k/L^2	?
Susan	?	u	0*

Discussion. Students generally showed comfort deriving the Taylor series expansion for $(1+x)^p$. Errors in Question 13 mostly involved omitting or misplacing the expansion point a, suggesting that students are accustomed to dealing with expansions where $a=0$ (Martin, 2009; Habre, 2009) and have limited experience with making sense of a in physics contexts.

When applying the Taylor expansion to the physics context, identifying p and x became a straightforward extension of students' mathematics knowledge. Arriving at the conclusion that $a=0$ was more difficult. Though many students were able to offer workable definitions of a, this did not always translate into finding its value. Priscilla and Summer may also have resisted concluding that $a=0$ from a mental distinction between Taylor and Maclaurin series.

We did not expect to observe conflation of the expansion point with a spatial location. This issue likely arises from the diagrams used in physics problems: they are often spatial diagrams of the problem set-up and not graphs of the expression to be approximated, as are found in calculus.

While students demonstrated a good grasp of the procedural aspects of Taylor expansions, their difficulties identifying and interpreting *a* reveal that applying Taylor series in physics requires scaffolding extending beyond the procedural proficiency developed in calculus courses.

Conclusion

This study adds to evidence that while sophomore physics students are often procedurally fluent with Taylor series, they may not recognize when and how to apply them in physics contexts. Our findings focus on how students interpret common cues for approximation (Wilcox et al., 2013) and how they adapt the formula using physical parameters.

Consistent with Loverude (2025) and Loverude and Li (2013), no students identified the need for a Taylor expansion without prompting, often preferring to 'do the limit' instead. We found that graphing both exact and approximate expressions in the case of the small angle approximation helped students recognize that "find an approximate expression" is a cue to Taylor expand. We further conjecture that, for students who are not immediately helped by graphing, prompting them to consider how to extend the domain of validity of the approximation yields better results than prompting them to focus on increasing its accuracy within a fixed domain. We hypothesize that this is because the former avoids the conceptual challenge of reconciling the inexactness of a truncated Taylor series.

Choosing the expansion point was also challenging for students. Both Smith et al. (2013) and Wilcox et al. (2013) report on student difficulties with non-zero expansion points, but in neither study were students' conceptions of the meaning of the expansion point investigated. We show that even students who could self-generate reasonable definitions for *a* struggled to determine that *a=0* in this context. Some interpreted the expansion point as a spatial location, a confusion which is likely more prevalent in physics and engineering contexts than in mathematics because diagrams in these disciplines often depict spatial configurations rather than graphs of the function, so students cannot visually locate the expansion point.

Our evidence indicates that students need support in identifying when a Taylor series is an appropriate tool in physics contexts. To help them develop this sense, we recommend that math instructors use physical examples that are within students' zone of proximal development (Vygotsky, 1978) to illustrate the practical uses of Taylor series. For instance, the potential energy between two objects is $U = -\frac{GMm}{r}$, where *M* and *m* are the masses and *r* is the distance between the objects. The potential energy between the Earth (radius *R*) and an object at a height *h* above Earth's surface is $U = -GMm(R+h)^{-1}$. Using $x = \frac{h}{R}$ as the (very small) parameter ratio and expanding about *x=0*, this yields $U = -\frac{GMm}{R} + mgh$; the first-order term is the familiar expression for potential energy above the surface of the Earth. Examples like these give physical meaning to the parameter ratio and the expansion point while illustrating common cues to Taylor expand, like a small parameter ratio.

Lastly, we recommend that physics instructors be aware that even algorithmically proficient students may not understand or remember the mathematical properties of the tool they are using if those properties don't help them to perform the algorithm. In addition, math courses make definitional distinctions between similar concepts (like Maclaurin series, Taylor series, and Taylor polynomials) which students may retain in contexts where physics instructors are not.

Acknowledgments

The authors would like to thank Trevor Smith for his feedback on this manuscript, Evan Vellinga and Jace Baptista-Allan for their work in correcting sections of the audio transcripts and verifying the coding schemes, and Michael Loverude for feedback on the interview protocol, for the use of his teaching materials, and for helping to make sensible modifications to them. This work was funded by the National Science Foundation under grant DUE-2417104.

Exploring Sense of Belonging Among Black and Latina Students in College Algebra and Precalculus: Insights From a Mixed Methods Study at a Minority-Serving Institution

Sarah Hyonsuk Park
Georgia Gwinnett College

In this sequential explanatory mixed methods study, I examined Black and Latina female students' sense of belonging in gateway mathematics at a diverse, open-access minority-serving institution. Using frameworks of intersectionality, sense of belonging, and authorizing student perspectives, I explored how students' identities shaped their experiences in college algebra and precalculus. I surveyed 1,136 students (pre-survey) and 639 students (post-survey) using an adapted Math Sense of Belonging Scale and analyzed data using ANOVA and ANCOVA. Results showed that mathematics affinity and expected grades were stronger predictors of belonging than race or gender. From the qualitative data, I identified six positive and six negative factors influencing belonging, including professors' mathematical microaffirmations and microaggressions, perception of caring faculty, peer collaboration, peer connections, mathematics self-efficacy, and perceptions of class diversity. These findings highlight the importance of caring faculty, collaborative learning, and peer support in fostering belonging in racially diverse mathematics classrooms.

Keywords: Sense of Belonging, Intersectionality, Gateway Mathematics Classes, Minority-Serving Institutions, Authorizing Student Perspectives

Despite increasing diversity in higher education, Black and Latina women remain underrepresented in STEM and face persistent barriers in introductory mathematics courses (Ong et al., 2016; Hatfield et al., 2022). College Algebra and Precalculus at open-access institutions often serve as gatekeepers rather than gateways to STEM pathways, characterized by low pass rates and unwelcoming environments (Seymour & Hunter, 2019). These students navigate racialized and gendered challenges due to their intersecting identities (Leyva et al., 2020; McGee & Bentley, 2017). Moreover, minoritized female students are less likely to report feeling a sense of belonging in STEM although classroom-level belonging is critical to persistence and success (Wilson et al., 2015; Rainey et al., 2018). However, most studies overlook the intersection of race and gender and rarely focus on diverse, open-access minority-serving institutions.

In this study, I examined how Black and Latina female students' identities influence their sense of belonging in gateway mathematics classrooms at a racially and ethnically diverse open access minority-serving institution. The research questions are: (1) How do Black and Latina female students' sense of belonging in the college algebra and precalculus classrooms differ compared to students in other racial and gender groups? (2) How does Black and Latina female students' sense of belonging in college algebra and precalculus change from the beginning to the end of the semester? (3) How do Black and Latina female students describe their college algebra and precalculus learning environment, experiences, participation, persistence, support systems and challenges as it relates to their sense of belonging?

Theoretical Perspectives

To frame my study, I drew on three interconnected theoretical perspectives: college students' sense of belonging, intersectionality and authorizing student perspectives. Strayhorn (2019) argued that belonging is a fundamental human need that must be satisfied before students can

achieve higher-order outcomes such as confidence and creativity. Belonging is context-dependent and closely related to mattering, which is a feeling that one is valued by others. It influences academic behaviors and is associated with engagement, persistence, and achievement. Absence of belonging can lead to anxiety, low self-esteem, isolation, and poor performance.

Moreover, I used Collins and Bilge's (2020) framework of intersectionality, which explores how overlapping systems of power, such as race, gender, and class, mutually shape individual experiences. For Black and Latina women in mathematics, intersectionality reveals how marginalization occurs at the intersection of race and gender, often referred to as the "double bind" (Delgado & Stefancic, 2012). Finally, I use Cook Sather's (2006) concept of authorizing student perspectives to center students' voices and lived experiences. This framework positions students as experts in their own educational journeys and calls for creating spaces where their insights are valued and used to inform meaningful change in classroom practice.

Literature Review

Much of the extant research on sense of belonging focuses on minoritized students at the campus level, particularly within four-year PWIs or research universities (Hurtado et al., 2015; Zumbrunn et al., 2014). Belonging is positively associated with academic achievement, persistence, and mental health (Strayhorn, 2019), while its absence contributes to STEM attrition, especially among minoritized and female students. Although campus belonging is important, the classroom plays a central role in shaping students' daily experiences and decisions to persist in STEM (Wilson et al., 2015; Riegel-Crumb, 2019).

Recent studies have begun to examine belonging at the classroom-level in mathematics education. Griffin (2023), McGrane and Rasmussen (2023), and Lahdenpera and Nieminen (2020) found that interactive learning environments, mentorship, and instructor engagement significantly enhanced belonging. Griffin's study showed the majority of female calculus students identified group work or interactive lectures as key contributors. At Hispanic-Serving Institutions, McGrane and Rasmussen found calculus support courses improved belonging, while Cawley and Wilson (2024) documented that microaggressions undermined it. Urbieta (2022) highlighted how socioeconomic challenges, such as housing instability, lowered belonging among low-income students.

Su (2015) introduced the concept of mathematical microaggressions to describe subtle, often unintentional ways instructors signal that certain students do not belong in mathematics. These include dismissive phrases such as, "It's obvious" or "You should have learned this before," as well as behaviors such as ignoring questions or rushing through the material. On the other hand, mathematical microaffirmations, which are intentional, affirming practices that validate students' mathematical thinking help foster positive mathematics identities and reinforce belonging. As Cawley and Wilson (2024) observed, students often remember how they felt in mathematics class very vividly.

Classroom belonging is tied to motivation, engagement, and confidence (Freeman et al., 2007; Wilson et al., 2015). Students report stronger belonging when instructors are perceived as caring and when active learning is encouraged (Kirby & Thomas, 2022). Despite its importance, research on minoritized women's mathematics classroom belonging remains limited, underscoring the need for further study in diverse institutions.

Methods

I used a sequential explanatory mixed methods design, integrating both quantitative and qualitative data to examine Black and Latina female students' sense of belonging in college

algebra and precalculus classrooms. The quantitative phase was conducted first to identify patterns in belonging, followed by a qualitative phase to interpret and expand upon those findings (Creswell, 2015). The study site was an ethnically diverse, open-access, four-year public college near a major Southeastern city. Of its 11,000 students, 32% identified as Black, 27% Latinx, 24% White, and 12% Asian. Over half were eligible for Pell Grants and 40% were first-generation. The institution holds designations as both an Asian American Pacific Islander Serving Institution (AAPISI) and a Hispanic Serving Institution (HSI).

Quantitative Phase

Participants were enrolled in College Algebra and Precalculus during Fall 2023, in which semesters are 15 weeks long. I visited all sections to administer pre-surveys (weeks 1-3) and post-surveys (weeks 11-14). Surveys were distributed via Qualtrics using QR codes, and only students who completed both were included in the final analysis. The sample included seven sections of College Algebra with support, 37 of College Algebra, and 14 of Precalculus. Courses ranged from 25-30 students. A total of 1,136 students completed the pre-survey (31.0% Black, 30.3% Latinx, 20.7% White, 13.4% Asian, and 4.5% Other; 51.7% female and 48.3% male), and 639 students completed the post-survey (30.4% Latinx, 29.1% Black, 21.1% White, 14.2% Asian, and 5.2% Other; 50.4% female and 49.6% male). The faculty included 44 full-time instructors (47% White, 29% Asian, 18% Black, 4% Hispanic) and five part-time instructors.

Students completed a demographic questionnaire and an adapted Math Sense of Belonging Scale (Good et al., 2012) revised to reflect classroom context. The scale included 30 Likert items (1=Strongly Disagree to 6=Strongly Agree) and demonstrated high reliability (α=0.94). Composite scores were calculated for pre-, post-, and change in belonging. I analyzed the data using SPSS, using an alpha level of 0.05. Descriptive statistics and histograms were used to examine distributions. To address Research Question 1, I conducted a one-way ANOVA on pre-belonging scores across race-gender groups. For post-belonging scores, I used a multi-factor ANCOVA controlling for pre-scores, with race-gender, faculty, mathematics affinity, and expected grade as factors. To address Research Question 2, I conducted a multi-factor ANOVA on belonging change scores using the same variables.

Qualitative Phase

In the qualitative phase, I explored students' experiences to interpret and deepen understanding of the quantitative findings. This approach aligns with the study's theoretical perspectives, intersectionality and authorizing student perspectives, which center students' voices and experiences. I collected two types of qualitative data: mathematics autobiographies and individual interviews. Thirteen participants (five Black, six Latina, and two Black/Latina women) who completed both pre- and post-surveys were purposefully selected to represent a range of belonging scores. Eleven of these participants also submitted mathematical autobiographies reflecting on K-12 mathematics class experiences, which informed the interview protocols. Semi-structured interviews (average 59 minutes) were conducted in person or via Zoom at the end of the Fall 2023 semester. Interview prompts included questions such as, "In what ways did you feel that you belonged in your math classroom?" and "Can you think of a specific example of a time in this class when you felt like you didn't belong?" All interviews were professionally transcribed and I verified the transcripts for accuracy. I analyzed the data using Braun and Clarke's (2022) six-phase reflexive thematic analysis to identify patterns and themes related to students' sense of belonging.

Findings

Quantitative Results

Research Question 1: How do Black and Latina female students' sense of belonging in college algebra and precalculus classrooms differ compared to other racial and gender groups?

Quantitative analyses revealed that Black and Latina female students' mean belonging scores were comparable to other race-gender groups. At the beginning of the semester, only one statistically significant difference emerged: Latina female students reported lower pre-belonging scores than Black male students (p=0.026, Mean Difference=-0.24). Black female students' scores did not significantly differ from any other group. By the end of the semester, when controlling for pre-belonging scores, race-gender was not a significant predictor of post-belonging (p=0.740), indicating no meaningful differences between Black and Latina female students and their peers. Post-belonging mean score for Black female students was 4.5 and for Latina students was 4.4, while the overall mean score was 4.4.

Research Question 2: How does Black and Latina female students' sense of belonging change from the beginning to the end of the semester?

There were no significant differences in change scores based on race and gender (p=0.541). However, other factors were significantly associated with belonging change: faculty (p=0.034), mathematics affinity (p<0.001), and expected course grades (p=0.012). These findings suggest that students' perceptions of their instructors, enjoyment of mathematics, and confidence in their academic performance, played a more substantial role in shaping belonging than race and gender.

Overall, students maintained relatively stable and high belonging scores throughout the semester, with minimal average change. While race and gender did not significantly influence post-belonging or belonging change scores, mathematics affinity and expected grades were significant predictors of students' sense of belonging. Faculty did not significantly impact post-belonging scores, but did influence changes in belonging over time, highlighting the importance of instructors. These quantitative findings provided a foundation for the qualitative phase of the study, and in the next section, I expand on these results.

Qualitative Findings

Through thematic analysis of interviews and mathematics autobiographies, I identified six key factors that promote a sense of belonging in diverse introductory mathematics classrooms:

1. Professors' mathematical microaffirmations – Small validating interactions that affirm students' mathematical thinking and effort.
2. Perceptions of professors as caring, supportive and helpful – Students felt more connected when instructors were approachable and invested in their success.
3. Encouraged peer collaboration – Structured group work fostered academic and emotional support.
4. Peer connections – Positive interactions and relationships with classmates contributed to a sense of community and inclusion.
5. Positive mathematics self-efficacy – Confidence in math ability both supported and was reinforced by belonging.
6. Perception of classroom diversity – Seeing diversity in race and gender helped students feel represented and included.

These factors often worked together to enhance belonging. For example, students who received mathematical microaffirmations were more likely to perceive their professors as caring. Mathematics self-efficacy was both a contributor to and outcome of belonging, forming a positive loop. A conceptual model (Figure 1) illustrates these interconnections.

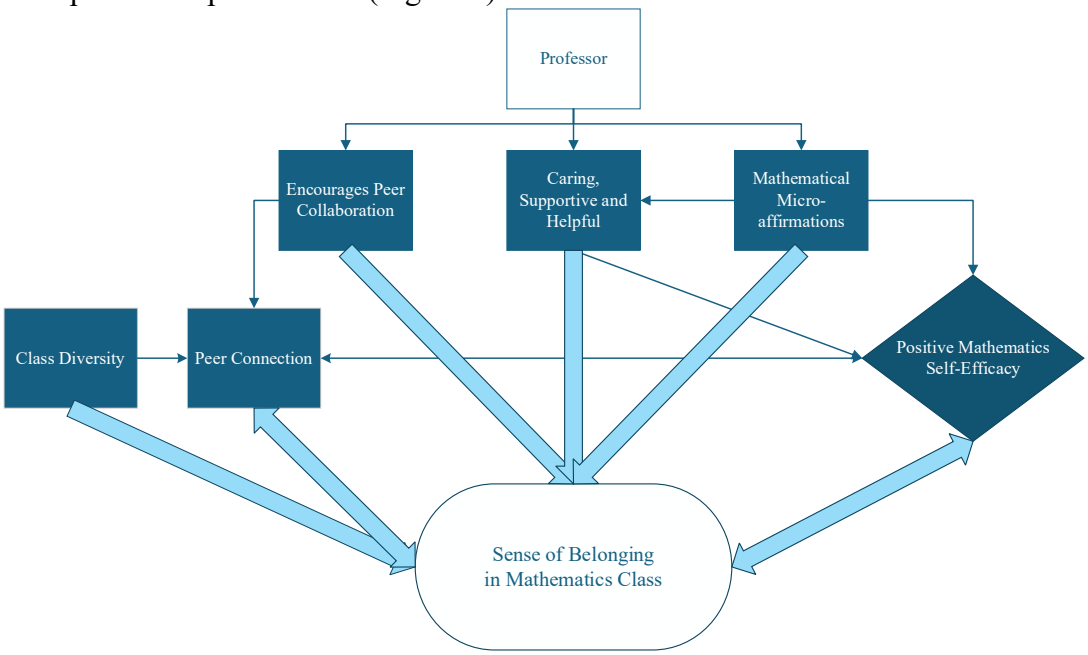

Figure 1. Six Factors that Promote Sense of Belonging in Mathematics Classrooms.

In contrast, students also described six factors that diminished their sense of belonging:

1. Professors' mathematical microaggressions – Subtle, dismissive comments that undermine students' mathematical confidence.
2. Perception of professors as uncaring or judgmental – Students avoided seeking help, fearing embarrassment or shame.
3. Limited peer collaboration – Lack of structured interaction hindered relationship-building.
4. Lack of peer connection – Isolation from classmates reduced feelings of inclusion.
5. Negative mathematics self-efficacy – Low confidence in mathematics ability weakened engagement with class activities and peers.
6. Past negative mathematics experiences – Previous struggles shaped current perceptions of belonging.

Students emphasized that when professors communicated, either explicitly or implicitly, that they were not valued, they became reluctant to be vulnerable about their mathematical challenges. This led to avoidance of interaction, increased frustration, and in some cases, disengagement. Similarly, lecture-only teaching approaches and lack of peer interaction reinforced feelings of isolation.

Notably, supportive professors and strong peer relationships served as protective factors, buffering students against negative experiences. Some students with low mathematics self-efficacy or prior negative mathematics experiences reported increased belonging when these support systems were present. As Britteny shared, "If you need help with something, [Dr. S.] is always there... [They were] easy to talk to so that made the course easier to get through because

when you're in a course for so long with a teacher, you have to get to know them, or it just has to be very easy to approach them. Like you bond over math."

Importantly, the qualitative findings reveal that students' sense of belonging is shaped more by relational dynamics, such as faculty support and peer interaction, than by the perceived difficulty of mathematics itself. Past negative experiences do not necessarily determine future belonging. When professors foster inclusive, affirming environments, students can develop a strong sense of belonging regardless of background or prior mathematics self-efficacy.

Discussion of the Integration of Quantitative and Qualitative Findings

The integration of quantitative and qualitative findings deepens our understanding of how a diverse institutional context influences Black and Latina female students' sense of belonging in mathematics classrooms. While the quantitative data showed no significant differences in belonging scores across race and gender groups, the qualitative findings revealed that diversity alone is not sufficient to foster strong belonging. As Hurtado and Guillermo-Wann (2013) suggested, representation matters, but it must be accompanied by relational and structural support. Students appreciated seeing peers who shared their racial or ethnic identity, but the ability to form supportive peer groups based on shared experiences played a more critical role in fostering belonging.

Racial and gender identity were not salient factors in shaping belonging for most participants in this diverse setting. Participants reported no experiences of racial or gender microaggressions, contrasting with studies at less diverse institutions. However, racial representation still mattered, and students valued being in classrooms where they felt seen and saw others who looked like them. The lack of significant differences in belonging scores across race and gender groups suggests that other factors, such as peer relationships and classroom dynamics, may be more influential in diverse classrooms.

Moreover, students' confidence in their mathematical abilities, shaped by prior educational experiences, influenced their engagement and sense of belonging. Students with negative K-12 mathematics experiences often started college with low mathematics self-efficacy, which impacted their classroom participation. However, when these students encountered supportive professors and collaborative environments, their sense of belonging improved. This suggests that mathematics self-efficacy may be more salient than racial or gender identity in shaping belonging, especially in diverse classrooms where students see others who look like them. It is important to note, that while race and gender did not directly affect belonging scores, students' past educational experiences are often shaped by systemic inequities, which are a direct influence of intersectional identity. This underscores the need to consider how historical and structural factors influence students' current sense of belonging.

Finally, while faculty was not a significant predictor of post-belonging scores, it was a significant factor in belonging change. Supportive faculty behaviors fostered belonging, while mathematical microaggressions and lack of support diminished it. Students did not explicitly connect these experiences to race or gender reinforcing the idea that relational dynamics were more salient in this context.

The integration of findings reveals that belonging is a complex, multifaceted construct shaped by students' prior experiences, classroom relationships, and institutional context. While diversity provides a necessary foundation, intentional pedagogical practices and relational support are essential for fostering belonging among minoritized students in mathematics classrooms.

Practical Implications for Gateway Mathematics Faculty

Creating a classroom where students feel they belong requires intentional, sustained effort throughout the semester. As Strayhorn (2019) emphasized, belonging must be actively nurtured and neglecting this need can contribute to students' academic and emotional struggles.

A strong link emerged between mathematics self-efficacy and students' sense of belonging. Faculty should adopt practices that build students' mathematical confidence, such as normalizing struggle, sharing personal educational experiences and journeys, and offering low-stakes assessments with revision opportunities. Creative assignments such as discussions, presentations and projects can also increase engagement and self-efficacy. Individualized support, especially early in the semester, is crucial for students with low-mathematics self-efficacy.

In addition, students shared that mathematical microaffirmations enhanced their sense of belonging, while mathematical microaggressions hurt it. Faculty development should include training on recognizing and using microaffirmations intentionally, while avoiding harmful language. Faculty peer observation groups can help instructors reflect on classroom communication patterns.

Moreover, clear and accessible office hours, both in person and virtual options, should be consistently communicated, especially to first-year students. Structured peer collaboration, with class norms co-constructed with students, and diverse groupings, can foster meaningful connections. Digital tools such as group chats may further support academic and emotional peer engagement.

Directions for Future Research

Future research should explore which faculty practices most effectively foster belonging by examining instructors whose students show significant changes in belonging over time. Classroom observations and interviews with faculty could reveal how instructor beliefs and behaviors shape belonging, especially through classroom norms. Additionally, studies should investigate the experiences of students who withdraw from or stop coming to mathematics classes, centering their perspectives to better understand attrition. Finally, expanding research to include students with disabilities, LGBTQ+ students, and varied learning environments (e.g., online, hybrid, elementary mathematics education and advanced courses) would offer a more comprehensive understanding of belonging in mathematics education).

Conclusion

This mixed methods study examined the sense of belonging among Black and Latina female students in gateway mathematics courses at a diverse, minority-serving institution. I identified that mathematics self-efficacy, faculty-student interactions, and peer relationships were more influential than race or gender in shaping students' sense of belonging in diverse mathematics classrooms. Faculty practices, such as using mathematical microaffirmations, demonstrating care, and fostering peer connections, played a critical role. Students also actively built peer relationships, even in classrooms lacking collaborative structures.

The study highlights the importance of centering student voices and identifying both positive and negative factors that shape belonging. Importantly, it shows that intentional faculty practices can buffer against negative mathematics experiences and foster inclusive learning environments. As Alexa shared about her belonging experiences, "You're not in it by yourself. You're going to have someone else to help you along the way… not just being there because you have to but being there because you feel like you're needed here." Mathematics classrooms can and should become spaces of belonging for all students.

Undergraduate Students Metacognition While Constructing Mathematical Proofs

Sarah Sparks
University of Northern Colorado

This phenomenological case study examines evidence of undergraduate students' metacognitive reasoning while completing proof construction tasks. Two pairs of undergraduate mathematics majors participated in task-based video recorded interviews where they were presented with contextual scenarios and asked to prove or disprove a related mathematical statement using think-aloud protocols. Participants then took part in stimulated recall interviews where they were shown video clips from their task completion and asked to reflect on their thought processes. This contributed report explores each student's access of metacognitive knowledge and the subsequent actions they took during these proof tasks.

Keywords: Metacognition, Problem Solving, Proof

Mathematical proofs and their underlying logical structures are foundational to the development of mathematical knowledge (Hanna & Barbeau, 2008). The common vocabulary, deductive reasoning, and formatting used to develop and write these proofs are used to communicate new mathematical knowledge (Ernest et al., 2016). Undergraduate mathematics proof-based courses aim to imbue the necessary mathematical knowledge, writing and reasoning skills in students for them to be able to read, construct, and analyze mathematical proofs. The development of these skills is not confined to individual courses, but it is declared to be one of the overarching goals of an undergraduate mathematics program (Committee on the Undergraduate Programs in Mathematics [CUPM], 2015). Although research has explored the cognitive processes related specifically to the proof construction process (e.g., Hanna, 2020; Inglis & Alcock, 2012; Moore, 1994; Tall, 1998), considering that research recognizes metacognition's impact on student success with other mathematical tasks (e.g., Mamona-Downs, 2002), investigating metacognitive aspects of proof construction explicitly may inform how metacognition impacts proof construction and how to leverage this knowledge to improve teaching of proof construction.

For the purposes of this research, I utilize the definition of *metacognition* as "any knowledge or cognitive activity that takes as its' object, or monitors, or regulates any aspect of cognitive activity; that is, knowledge about, and thinking about, one's own thinking" (Lerman, 2020, p. 608). Metacognitive processes of *monitoring* and *control* describe the interaction between the *meta-level* (internal metacognitive knowledge and related models of the object-level) and the *object-level* (external to the meta-level, anything external to the individual and their metacognitive knowledge). *Monitoring* is the process where the "meta-level is informed by the object-level" (Nelson & Narens, 1994, p. 11) such that the information taken in during the monitoring process can change the models at the meta-level. *Control* is the process where the "meta-level modifies the object level" (Nelson & Narens, 1994, p. 11). Knowledge at the meta-level can cause action at the object-level, either through starting or ceasing an action. The choice not to take a certain action is part of the control process. In the case of an individual working on constructing a mathematical proof, the theorem statement, their written work, any other related cognitive processes, would all be at the object-level. The meta-level would encompass the individual's judgements about their proof construction process (e.g., how they perceive their own success) and any knowledge of strategies useful to this particular type of proof.

Metacognitive knowledge is partitioned into *declarative*, *procedural*, and *conditional* metacognitive knowledge (Schneider & Artelt, 2010; Shraw & Dennison, 1994). *Declarative* metacognitive knowledge encompasses knowledge a person has about themselves, their cognitive knowledge and abilities. *Procedural* knowledge describes individuals' knowledge of relevant strategies, heuristics, and other tools. (Schneider & Artelt, 2010). *Conditional* metacognitive knowledge is the knowledge of when and why specific cognitive tools and strategies are useful in a given context (Lerman, 2020).

Due to the focus on students' metacognitive processes rather than the validity or rigor of their resulting proof product, I utilize a broad definition of *proof construction* as the process of using a series of logical assertions deduced from a set of premises and previous assertions, and/or a set of instructions that when followed are representative of these deductions, where this collection of assertions and instructions results in an argument that "justifies a claim to oneself and others" (Blanton et al., 2003, p. 113). *Proof* is then defined to be this resulting collection of assertions.

The purpose of this phenomenological case study is to contribute to the field of metacognition research in mathematics education by examining the experiences of undergraduate mathematics students' metacognitive processes during proof construction. Specifically, this research aims to address the questions: What declarative, procedural, and conditional metacognitive knowledge do undergraduate mathematics students demonstrate or claim to have and use during construction of a mathematical proof? What metacognitive processes do undergraduate mathematics students engage in during construction of a mathematical proof? In particular, what monitoring and control processes do undergraduate mathematics students engage in during construction of mathematical proofs? And, in what ways do the cognitive and metacognitive processes of undergraduate students inform each other during construction of mathematical proofs?

Theoretical Perspective and Methodology

Entering this research from a social constructivism theoretical perspective, I considered individual's constructed conceptions, acknowledging that these conceptions are inextricable from the social contexts in which they were constructed (Patton, 2002). Vygotsky claimed the process of learning to include the appropriation and use of tools and signs (Grossman, 1999) that occurs during social interaction. Vygotsky not only considered social interaction with others but interaction within the self, intramental thinking (Ernest, 2010). This sort of internal interaction with the self is enmeshed with metacognition, the individuals reasoning about their own cognition. I specifically considered intramental and intermental thinking, (i.e., the internal and external respectively) (Ernest, 2010). Restructuring one's own conceptions through the process of metacognitive monitoring is analogous to the restructuring of conceptions that occurs with the appropriation of tools and signs inside of social settings. The metacognitive process of control therefore is enmeshed with the appropriation and use of tools and signs itself, as the metacognitive level impacts the individuals' external responses.

This study explores the phenomenon of individual's cognitive and metacognitive processes during the proof construction process. To examine this phenomenon, I conducted a qualitative study with four undergraduate mathematics majors as they completed paired proof-based tasks in an interview setting. Utilizing the participants' verbalizations during the tasks and their self-described experiences and reflections in follow-up interviews, I investigated indications of metacognitive processes for each student and the subsequent actions the students took in their proof construction process. The four undergraduate student participants were from proof-based undergraduate courses at a mid-size university in the United States. Prior to interviews, students

were paired based on similar mathematical backgrounds and experience working on mathematics collaboratively together.

Data Collection

The four participants in this study were mathematics majors at a mid-size university in the United States. They each had previously completed several proof-based courses and were currently enrolled in an abstract algebra course designed to specifically focus on proof writing. To address that individuals' conceptions are "formed through their interactions with each other as well as by their individual processes" (Ernest, 2010).

Each pair of participants were given two tasks, and were audio and video recorded and monitored remotely via Zoom© while Livescribe© pens recorded written data. Two to three days after a task, each individual completed a stimulated recall interview, watching selected video clips from their task completion, and asked to reflect on their experience and thinking during those clips. For each task, one pair was given a true claim (Version A), and one pair was given a false claim (Version B) and asked to prove or disprove the given claim. For the second task, each pair was given a different version of the task from the one they were given for the first task. Both tasks are given below

Task 1 Version A prompt. [Adapted from Gilbert and Larson (2012)] A gamekeeper gives player A a positive integer. The players then take turns changing the integer they are given to a smaller integer and then pass that smaller integer back to their opponent, player B. If the integer you received and are changing is even, the two legal moves are: subtracting 1 from the integer *or* dividing the integer by 2. If the integer you received and are changing is odd, the two legal moves are: subtracting 1 from the integer *or* subtracting 1 from the integer, then dividing this result by 2. The game ends when the integer reaches 0, and the player who makes the last move (changing an integer to zero) wins the game.

Prove or Disprove the Claim: Assume the starting integer is given to player A. Any starting integer that when factored is written as $2^k * l$ where k is an even integer and l is an odd integer, will guarantee that player A wins the game.

Task 2 Version A prompt. On a rectangular $n \times m$ grid, there are candies on each square of the grid. The bottom left corner square in the grid contains a bitter candy, all other candies are sweet. The two players take turns picking squares. When a player picks a square, they must eat every candy that is on the square they picked, or on any remaining squares of the grid above and to the right of the square they chose. The players take turns doing this until one of them eats the bitter candy (on the red square). Whichever player eats the bitter candy loses the game. Suppose there are two players, Player 1 and Player 2, where Player 1 makes the first move.

Prove or Disprove the Claim: For a game played on any $n \times m$ rectangular grid, where n and m are both positive integers, Player 1 will always have a winning strategy. (Excluding the trivial case of a 1×1 rectangle)

Data Analysis

Task interview data and stimulated recall interview data were transcribed. All utterances were coded, first deductively to distinguish verbalizations describing internal reasoning versus verbalizations describing something external. The Model of Sign Appropriation and Use (Ernest, 2010, p. 44) was referenced during this deductive coding to help make these distinctions, and code internal reasoning as intramental.

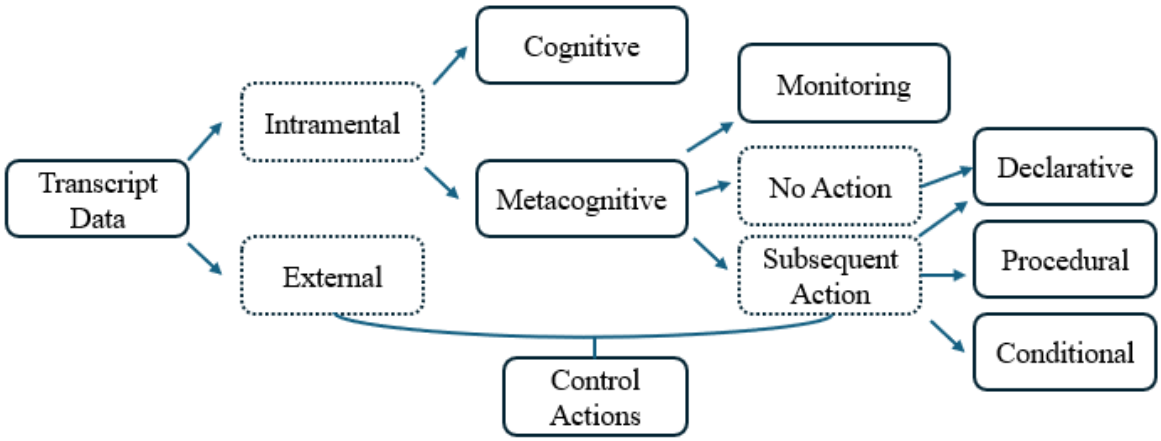

Figure 1. A Flow Chart of the Data Analysis Process

Once verbalizations regarding internal reasoning had been identified, the subject of these utterances was determined. If the subject was something external, that data was coded as cognitive. If the subject of the verbalization was other internal reasoning of the individual, the data was coded as metacognitive.

Data coded as metacognitive was then coded into three categories. Any metacognitive data that was immediately followed by the participant taking an action (or stated intentional inaction) was coded as having a subsequent action. These codes were paired with external coded actions to identify indicated metacognitive control. Metacognitive data where participants stated some intentional reflection about something external was coded as indicating potential metacognitive monitoring. Statements that were declarations of some metacognitive knowledge were coded as stated knowledge, and then deductively coded as declarative. All metacognitive data was deductively coded as indicating declarative, procedural, or conditional metacognitive knowledge. Any data that was coded as metacognitive control, was then connected with external actions and control actions were inductively coded into types of actions.

Consider this example quote from Harper, "I don't know if this general tree thing is ever going to end…Any pattern…has probably already showed up and we just didn't notice it. Let's go back to actual numbers." This excerpt is related to Harper's internal reasoning and therefore was coded as intramental. Then, because the subject of these statements is Harper's own thinking and reflecting on that reasoning and the success of her strategy, this was coded as metacognitive. Harpers initial statement was followed by an action coded as evaluating strategy, and her eventual action was coded as trying examples, as indicated directly in the quote. The relevant metacognitive knowledge was coded as procedural, related to the use of strategies and heuristics.

Results

The control actions, actions participants took immediately following the access of their metacognitive knowledge, included the following: Re-reading the prompt, Reading Aloud, Trying Examples, Conjecturing, Evaluating Argument, Evaluating Strategy, Intentional Inaction, Taking Notes, Math Drawing, Using a Tangible Object, Generalizing, Checking Work, Re-working examples, Organizing Proof, Writing Proof, and Re-reading Proof. Each of the participants engaged in most of these control actions at some point over the course of both tasks. Table 1 offers examples of data for a few of the control action codes, the quoted data, and descriptions of the example control actions.

Table 1. A table of a few demonstrated control actions participants took (Sparks, 2025).

Metacognitive Control Process Actions During Proof Construction		
Control Actions	Description	Example Transcript Data
Re-Working	Re-visiting examples for understanding (not for verification)	"wanting to go back and run through the logic again, remembering what I was trying to prove"
Evaluate Strategy	Actively considering the value or effectiveness of their current approach	"I don't know if this general tree thing is ever going to end…Any pattern…has probably already showed up and we just didn't notice it. Let's go back to actual numbers."
Organizing Proof	Determining what will be included in the proof or the order	"I don't know, the most efficient way to write this? Let's hit let's write out the tree and then. Yeah, so B can give two…"
Writing Proof	Deciding to move from "scratch work" to writing down a proof or part of a proof	"…I write chaos all over the place on a page just to give myself a sense of what's going on…then I…write it out using more formal language and a series of steps that you can follow…"

Each of the participants had their differences in what types of metacognitive knowledge or processes they demonstrated. Lola often accessed declarative metacognitive knowledge about herself and her proof skills. She also was frequently able to access conditional metacognitive knowledge regarding when and why certain strategy uses might be beneficial in the proof process. Lola also regularly demonstrated evidence of monitoring, reflecting on external outcomes and using that information to inform strategy use or control actions. Harper consistently accessed procedural metacognitive knowledge, using knowledge of strategies and heuristics to initiate control actions.

Riley primarily indicated procedural and conditional metacognitive knowledge and consistently initiated the control actions of evaluating strategies and re-working examples. Spencer indicated declarative metacognitive knowledge, referencing his own perception of his strengths, weaknesses, or affect related to the task completion.

Discussion

There were several noteworthy results that came up during this data analysis. Because mathematical proofs constitute their own genre of writing (Selden & Selden, 2013) one of the insights this research provides is the connection between the access of metacognitive knowledge and the subsequent control actions regarding writing specific components of the proof construction process. The initiation of formal proof writing and the organization of proof structures both were impacted by students' metacognitive knowledge. In particular, in the majority of instances of these proof writing related control actions, students accessed procedural

metacognitive knowledge prior to taking these actions. Participants also made declarative metacognitive knowledge statements that also preceded writing proof and organizing proof related actions, often related to knowing at what point in their proof process they feel has worked well for them to start these components of a task.

In addition to the writing specific aspects of proof construction, another significant result is the control action of re-working examples. Students often accessed metacognitive knowledge before choosing to re-do examples. In this case, not re-doing examples to check for error, but instead to identify reasoning and patterns useful for translating to a more general argument. This is an aspect of these participants' proving process that did does not necessarily make an appearance in other forms of problem solving. While understanding or explaining reasoning is a common aspect of problem solving, the need to structure a generalized argument is not necessarily an expectation or necessity of other forms of problem solving. This data indicates that students are accessing and utilizing metacognitive knowledge to inform the decision to rework examples for this purpose. As this research continues, the types of metacognitive knowledge accessed before, during, and after re-working examples should be explored further.

Theoretical Reports

A Conceptual Framework of Emergent Utility of Advanced Mathematics for Inservice Teachers

Zachary Bettersworth, Western Kentucky University
Sarah Hartman, Middle Tennessee State University
Nicholas Fortune, Western Kentucky University

In this theoretical report, we present a conceptual framework that details inservice teachers' emergent utility perspectives towards advanced mathematics and their advanced mathematics coursework. We leverage a river journey metaphor to help illustrate aspects of our conceptual framework. Along the river are utility points that refer to opportunities for teachers to reflect on the usefulness and relevance of advanced mathematics content in relation to its impact on their teaching. Then, we provide examples of both preservice and inservice teachers from extant literature and an initial study conducted in a real analysis course to highlight the four main components of the conceptual framework. We end with implications for designers aligned with the instructional design theory of Realistic Mathematics Education for creating courses for secondary mathematics teachers.

Keywords: Emergent Utility, Inservice Teachers, Emergent Modeling, Teacher Education

Although inservice and preservice teachers have questioned the usefulness or relevance of upper division or advanced mathematics courses for their professional teaching (e.g., Cofer, 2015; Wasserman, 2017; Zazkis & Leikin, 2010), there is growing research that demonstrates how mathematics teacher educators may structure these courses to support teachers in seeing the utility of these courses for their own learning and teaching (e.g., Cruz et al., 2024; Goodchild et al., 2021; Qiu et al., 2025; Wasserman et al., 2023). For example, one common direction is the inclusion of direct content connections between advanced content and content relevant to secondary mathematics. A real analysis connection (Wasserman et al., 2019) could be the concept of continuity as seen in secondary school and a differential equations connection (Apkarian et al., 2023) could be the concept of function. Additionally, there are non-content connections that can be made such as relating experiences in mathematical practices between secondary and university mathematics (Cruz et al., 2024). Collectively, this body of research aims to address the double discontinuity first introduced by Klein (1932, 2016). Our work builds alongside this work, yet, what motivated us is slightly different. Inservice teachers take advanced mathematics courses to pursue graduate degrees, which means they bring experience and knowledge of secondary school mathematics and students to their own graduate learning. More specifically, drawing on Klein, inservice teachers may experience this double discontinuity anew.

The purpose of this theoretical contribution is to call attention to the differences between how inservice and preservice teachers view the relevance of advanced mathematics courses. We propose a conceptual framework that has potential applications for design aligned with Realistic Mathematics Education (RME; Freudenthal, 1973) as an instructional design theory and the concept of emergent modeling. This conceptual framework describes how inservice or preservice teachers (IPSTs) may progress towards seeing how their advanced coursework could have an impact on their teaching practice (i.e., the utility of their courses for their teaching). While both inservice and preservice teachers are important for the conceptual framework, and as such will be discussed, our contribution focuses on inservice teachers. At first, we consider IPSTs together as one entity, because both inservice and preservice teachers have preconceived notions about advanced mathematics. However, the experiences that inservice and preservice teachers bring to

their advanced mathematics courses may create fundamental differences in how they engage with the coursework. Thus, we distinguish between each population by discussing both existing literature regarding the support of preservice teachers in making connections and using our preliminary data from inservice teachers.

To illustrate our emergent utility conceptual framework, we draw on the river journey metaphor from Rasmussen & Keene (2019) on waypoints in one's mathematical learning. Rasmussen and Keene (2019) think of waypoints as opportunities for students to engage and connect various ways of reasoning with mathematical concepts (p. 2). These waypoints are content based. We, however, take a different perspective on waypoints. We refer to utility points as opportunities to reflect on the utility of content in relation to its impact on one's teaching. That impact may be different for inservice and preservice teachers. To describe our emergent utility conceptual framework in detail we first situate ourselves in our larger theoretical lens. We then describe the framework using the river journey metaphor and provide examples using an example from existing literature and from empirical data we have collected.

Theoretical Background

We adopt the Emergent Perspective as an interpretive framework to make sense of both students' conceptions of individuals' mathematics ideas and socially embedded classroom practices (Cobb & Yackel, 1996). By adopting the Emergent Perspective, we conceptualize learning as a coordination between students' cognitive development and engagement in mathematical activity. Inservice teachers enrolled in advanced mathematics coursework bring their beliefs about themselves as an instructor, their students, the mathematics they teach, and previously used pedagogical practices. Inservice teachers' previous pedagogical experiences must be considered as a lens through which they consider the relevance of advanced mathematics coursework. Though this framework describes inservice teachers' perspectives on the utility of advanced mathematics coursework, we conjecture it is still viable as a design framework for recommendations about designing courses for preservice teachers. Although preservice teachers may not have experience teaching in a classroom, their perspectives about advanced mathematics coursework might be informed by their beliefs and opinions about their future students (Scherer & Bertram, 2024) or their perception of their mathematical ability (Beisly et al., 2024).

To describe our conceptual framework, we use the instructional design theory of Realistic Mathematics Education (RME; Freudenthal, 1973). In RME, mathematics is a human activity. Then, the design heuristics of RME support instructors in developing materials that guide students in engaging in mathematical activity. This initial activity can be connected, with help from the instructor as a brokering agent, to formal mathematical logical structures as they are realized by the extant community of mathematicians (Rasmussen et al., 2005). This transition from informal to formal reasoning is directly related to the RME design heuristic of emergent modeling. We leverage this heuristic in our proposed framework. Providing IPSTs with opportunities to develop more formal ways of reasoning may guide them in making instructional moves that will help connect their own students' informal ways of reasoning towards the more formal. From the lens of RME, designers create mathematical tasks intended to elicit students' informal activities. These initial ideas might include sketches, graphs, input-output tables, etc. Students' initial activity forms the foundation for generating ideas and can be folded into classroom discussion by the instructor to become a model of more formal mathematics. As students gain experience working in this experientially real setting, their attention may begin to shift away from the experientially real setting towards mathematical patterns and relationships. Once these mathematical relationships enter the classroom discourse, they can be used by the

instructor to connect to the more formal mathematical ideas that they have in mind. Once the students' model(s) become a way to reason about mathematical relationships, as opposed to a way to represent the applied problem, the student uses it as a model for more formal mathematics (Rasmussen et al., 2005; Zandieh & Rasmussen, 2010).

In the next section, we introduce the notions of an IPST's utility of and utility for, advanced mathematics content and later provide examples of the four emergent utility perspectives of our conceptual framework. It should be noted that we view teachers' emergent utility as inextricably linked to the emergent modeling heuristic. As inservice teachers develop new ways of reasoning about advanced mathematics content, it is likely that the ways they perceive the relevance of this content are informed by the lens of their own teaching experiences.

Emergent Utility Conceptual Framework

To help illustrate our framework, we rely on the river journey metaphor (Rasmussen & Keene, 2019). The river metaphor is intended to convey students' non-linear progression through mathematical ideas that may require more or less time based on their previous instructional experiences and current mathematical reasoning. The journey is non-linear in the sense that some students might return to prior waypoints, spend more time in certain areas of the river, or branch off to explore aspects of the river they find interesting. More specifically, we conceptualize the specific ways in which teachers reason about the utility they continue along the river journey as key utility points. We do not comment on the exact nature of the content waypoints, as they are intended to be left general for the sake of encompassing any advanced mathematics course in which IPSTs might enroll. We also want to mention that the amount of time one spends in the river investigating each utility point will vary for each individual and might be impacted by external factors (e.g., shift in the river's features representing a change in the course structure).

When they first enter the river, IPSTs may have preconceived notions about whether or not the course will be helpful for their teaching, as indicated by the starting point in Figure 1. This could be based on the IPST's perception of students' mathematical ability, or their general impression of the advanced mathematics content. At first, IPSTs might perceive the utility of the advanced mathematics coursework as developing their understanding of related course content, but ultimately view the course content as irrelevant for their teaching. Thus, they may choose not to spend as much time at the content waypoint or utility points because they do not view the concepts as relevant for their teaching. Such an IPST develops a utility of a model of perspective towards the advanced mathematics content, as pictured by the top, blue, dotted line in Figure 1.

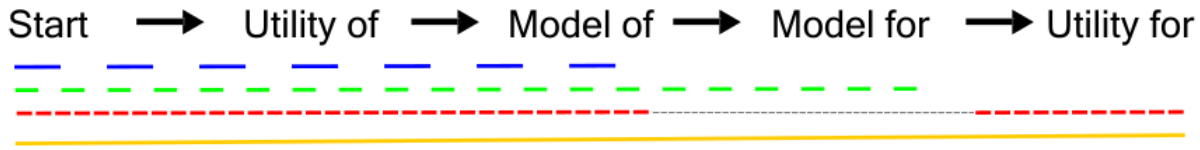

Figure 1. The Emergent Utility Conceptual Framework.

We view advanced mathematics courses as a river filled with opportunities, that some students may perceive as hurdles (e.g., rapids or rocks), to engage in iterative emergent modeling processes where one can spend more or less time building models for the relevant content waypoints and utility points. As IPSTs continue to build models of and for advanced mathematics content, they require opportunities to reflect on their learning in terms of its

relevance to teaching secondary mathematics, that is, time to spend at each utility point. Some IPSTs may come to develop models for a majority of the course content, but decide that the time they themselves spent exploring the river would take too long, or be too challenging for their own students. Such a teacher has developed a utility of a model for perspective, as pictured by the second, green, dotted line in Figure 1.

As the IPSTs begin to spend more time at each utility point, they begin to reason about the broader mathematical context and how the content they teach is situated within it. Here, inservice and preservice teachers likely have different knowledge around 'the content they teach' - an inservice teacher is returning to the river and their journey is now informed by previous experiences as a teacher. In other words, they themselves have guided students down a river. It may take more or less time for each individual teacher to reflect on the relevance of the course content to their teacher to the point they are willing to make shifts in their teaching. Eventually, with enough time at each waypoint, the IPST might come to envision changes in their pedagogical decisions about content they will, or have previously taught, that they now realize is directly related to the advanced mathematics content they are learning about. Such an IPST has begun to perceive the utility for advanced mathematics content to impact their teaching practice. In other words, IPSTs are developing an emergent model of/for their own teaching, as it is informed by their new models for advanced mathematics content. In this way, IPSTs are making connections between their formal ways of reasoning about course content and using these connections as a new pedagogical lens to make decisions about their own instruction. However, some IPSTs may not have enough time to spend traversing the river and discovering or reinventing all of the content waypoints but still believe that the course is relevant for their teaching. These IPSTs develop a model of the utility for advanced mathematics content, as pictured by the third, red, dotted line in Figure 1. Such IPSTs may struggle to provide explicit examples of which advanced mathematics content will shift their teaching in specific ways. Despite this, such IPSTs still indicate the impact of the course content on them as educators, which is why the red dotted line is broken by the smaller gray portion in Figure 1.

The IPSTs who develop a model for the utility for advanced mathematics have a new, or renewed, vision of how their formal ways of reasoning about advanced mathematics content will shift their teaching and can provide explicit examples. Such IPSTs have spent enough time at each content waypoint and utility point to reflect on the relationship between their formal ways of reasoning about the advanced mathematics content to determine ways in which this reasoning will shift their teaching practices. This is pictured below in Figure 1 by the unbroken, bottom yellow line. More specifically, an IPST who develops a model for the utility for advanced mathematics content is making new, or different, decisions about course content, pedagogical moves, and curricular innovations in their secondary mathematics classroom.

It should be noted that, for preservice teachers, this may be their first journey down a specific river. For inservice teachers, this may be their second, third, or fourth journey down a specific river. Revisiting the content waypoints additional times, visiting utility points with more teaching experiences, and coordinating this time down additional river journeys may impact the amount of time a specific teacher spends before developing an emergent utility perspective.

Examples of Emergent Utility Perspectives From Literature on Preservice Teachers

First, we consider the results of Liang et al. (2023). The three preservice teachers (William, Maria, and Sterling) were each interviewed twice about their transition to university math positioned as students (first interview) and future teaching practices, using inverse functions as the example topic (second interview). We begin with William because while he had a very

positive view about his experiences in advanced tertiary mathematics courses, he continually referred to secondary mathematics as "copycat" math. This was because, according to William, secondary students tend to mimic what the teacher does to solve math problems. This, from William's point of view, is not sufficient when it comes to the learning of mathematical proof at university. William's overall view of tertiary mathematics was that it was fun and interesting for him, but was reserved for individuals who developed a "shield" to survive a transition to proof course to get to the more interesting coursework. This belief about his potential students presupposes an approach to his secondary teaching (forcing students to "use their brains"), but he also appeared to view inverse functions solely as applicable for solving equations. A preservice teacher like William would have a utility of a model for (green line) advanced proof-based content with teaching the concept of inverse functions to his future secondary students. This is because while he has some ideas about how his tertiary mathematics experiences will influence his teaching; he did not appear to leverage his experiences in determining concrete ways to shift his future teacher practice.

Because of her experiences in secondary instructional settings, Maria conceptualized secondary classrooms as competitive (p. 116). She felt pressure from her teachers and instructional settings such as standardized exams, and her impression was that she had to practice problems repeatedly without a strong conceptual understanding in order to perform well (e.g., receive a high grade). However, Maria summarized her experience in tertiary math classrooms as exciting, and recommended to others to "dig deep". Though Maria did not identify herself as a "successful" tertiary mathematics student, she valued the notion of introducing secondary students to proofs that extend beyond the typical geometrically focused examples. A preservice teacher like Maria would have a model of the utility for (red line) logical proof techniques in secondary mathematics classrooms. This is because though Maria was open to the idea of including her experiences in tertiary math classrooms in her secondary teaching, she appeared to require time to "dig deeper" in her math studies and required more opportunities to reflect on ways in which more formal ways of reasoning might shift her future secondary teaching.

When asked to reflect on his experience transitioning from secondary to tertiary mathematics courses, Sterling focused on if and only if, or bidirectional, proofs because he initially struggled to make sense of them. Sterling then provided an example to illustrate how he would support his future secondary students in making sense of these types of statements (p. 119). This example, which involved creating if-then statements about the solutions to the equation x^2=2, illustrates an instance when reversing a true statement does not always produce a new true statement. By providing a non-example of a bidirectional statement to his imagined future students, Sterling was supporting them in making connections he himself struggled with in the transition from secondary to tertiary mathematics. The fact that Sterling was able to reframe an example of a secondary mathematics concept through the lens of his learning in tertiary mathematics contexts, coupled with claims that Sterling possessed a strong background in mathematics at the tertiary level, indicate that Sterling had developed a model for the utility for (yellow line) proof-based content (specifically bidirectional proofs) with teaching the concept of inverse functions.

Examples of Emergent Utility Perspectives From Inservice Teachers

We continue to illustrate our framework by presenting four examples from a study conducted with 10 inservice teachers enrolled in a graduate real analysis course. The following quotes are responses from reflections about the Fundamental Theorem of Calculus (FTC) and continuity and differentiability, with emphasis added.

When responding to a reflection about understanding the fundamental theorem of calculus as related to the concepts of rate of change and accumulation, Demi stated the following:

> *Demi*: Referring to the FTC in this manner would be interesting to a certain level of student. However, to a run of the mill calculus student who is just trying to master the skill of taking the integral I believe would overwhelm them. I would not show this until they were comfortable with the skill or with great explanation beforehand.

This demonstrates that Demi views the relevance of this real analysis content through their own teaching experiences and beliefs about "a certain level" of student. Demi contends that the formal aspects of the FTC would be more difficult than needed in their own instructional context. Demi views the utility of this advanced mathematics through her own teaching experience and appears to believe that because the content was challenging, it means that it would "overwhelm" their students. Such a teacher would possess a utility of a model of (blue line) perspective as her beliefs about her students appeared to mediate her willingness to engage with content waypoints and utility points throughout the course.

When responding to a reflection about comparing the formal, epsilon-delta definition of continuity versus a more informal definition, Eloise stated the following:

> *Eloise*: Honestly, when first completing the homework, I was unsure I really liked/approved of the analysis definition of continuity. However, after doing more problems and reading more about it, it has started to make more sense to me. I find it very interesting since I have never seen continuity defined this way but am starting to appreciate it because I enjoy having a deeper understanding of calculus and it's cool to continue to expand that understanding more still. I will say however that I do not think I will actually change the definition I use to teach continuity … the analysis definition is harder to understand especially for a first-time calculus student.

As Eloise self-describes that she understands the formal analysis definition yet indicates a lack of usefulness in their own teaching due to curricular and testing tensions. Throughout the course, Eloise demonstrated reasoning about continuity that was highly interconnected with other course content but ultimately decided that the reasoning they developed was "harder to understand" for their students and therefore they would not "change the definition" they teach. Whereas Demi's own reasoning about the reciprocal process of differentiation and integration mediated their perception of the level of difficulty of the content and its relevance for their students, Eloise made connections between the course content and their prior teaching practices but still decided to not make changes to the way they teach the concept of continuous functions to secondary students. This teacher possesses a utility of model for (green line) perspective.

When discussing the possibility of teaching derivatives Hannah thought about it "in a variety of ways so the concept can be fully understood." In this way, Hannah appreciates a conceptually focused approach to introducing students to the notion of differentiability. However, Hannah also believes that it would be "less confusing if you did it by practicing finding and taking derivatives." It appears that even though Hannah is open to the impact that advanced mathematics courses could have on conceptual understanding, the connections they made between "finding and taking derivatives" as a process and the relationship between this process and the notion of differentiability are seemingly disparate. Because of this disconnect, such a teacher who is open to changing their teaching practice based on their renewed understanding of the content, but the ways in which these instructional changes can occur is mediated by their own reasoning, would possess a model of the utility for (red line) differentiability as it relates to teaching derivatives to secondary students.

In the same reflection assignment as Eloise, Jocelyn responded:

> *Jocelyn*: Prior to taking this class, I know that I took a Real Analysis class in my undergraduate mathematics classes, but I fell back into the thought that a continuous function is just when you can draw the graph of the function without picking up your pencil. This is the way I have taught my students up until this school year, which is, I believe, on the level of their understanding. But seeing how this idea is used for differentiability makes me understand that this surface level of understanding does not prepare students for what they will see in calculus. I am able to see the connection between continuity and differentiability, which helps me understand both concepts on a deeper level.

It should be noted that Jocelyn was one of the few teachers with calculus teaching experience. A teacher like Jocelyn, who uses formal ways of reasoning to make shifts in their teaching practices has constructed a model for the utility for (yellow line) continuity as it relates to teaching AP Calculus content.

Conclusion

The nature of the transitions between the previously discussed emergent utility perspectives requires further attention and will likely change depending on the individual IPST. However, the purpose of this paper is to set a theoretical basis to inform researcher-designers about the nature of teachers' emergent utility towards advanced mathematics coursework. Inservice and preservice teachers engage with utility points differently. Likely, preservice teachers simultaneously engage with the advanced mathematics content for the first time and have not yet had opportunities to engage with students as a teacher. Inservice teachers have an additional challenge. Their teaching experiences informs the lens through which they view the utility of advanced mathematics coursework, and it could be the case they have a harder time making shifts in their teaching based on formal ways of reasoning about advanced mathematics content.

The ways in which an IPST navigates the river will be dependent on their previous experiences and beliefs. An inservice teacher will likely view the relevance of advanced mathematics content through actual teaching experience (e.g., Demi and Jocelyn) and therefore envision changes to previously implemented curricular materials. A preservice teacher (like William, Maria, and Sterling) can provide imagined examples of activities to include, or problems to address, but these are not considered in light of other issues that emerge from the actual practice of teaching, course creation, implementation, and classroom management. Preservice teachers are leveraging their own formal ways of reasoning and making decisions about whether it applies to imagined students, whereas inservice teachers are levering experiences with actual students and determining whether their own formal ways of reasoning are approachable to their instructional context. Because inservice teachers are likely engaging with the advanced mathematics content in a graduate level course, their new river journey can now be viewed through the lens of both previous instructional experiences as well as their prior teaching. This is what we meant earlier when we said that inservice teachers may be able to spend more time or make it further along the river in their journey. As such, designers must keep this in mind when determining whether certain activities are appropriate for preservice teachers, inservice teachers, or both.

Conceptions of Derivatives in Calculus: Merging and Extending Earlier Frameworks

Saba Gerami
California Polytechnic State University - San Luis Obispo

Researchers studying derivative conceptions often use Zandieh's (2000) framework, which emphasizes graphical, symbolic, verbal, and physical representations within three process-object layers of ratio, limit, and function. While foundational and aligned with traditional calculus instruction, recent literature on derivative teaching reveals additional conceptions. I present the Conceptions of Derivative (CoD) framework, which expands Zandieh's work to offer a more comprehensive perspective on contextual and cognitive processes when thinking about derivatives. The framework provides researchers with a comprehensive lens, while offering instructors awareness and language for intentional targeting of derivative conceptions based on their students' conceptual needs.

Keywords: Derivatives, calculus, conceptions, representations

When considering various conceptions of derivative in calculus, many researchers rely on Zandieh's (2000) framework or its extended versions (e.g., Roundy et al., 2015). As a cognitive framework for learning derivatives, Zandieh's framework has also shaped the research on derivative teaching (e.g., Hitier & González-Martín, 2022) possibly due to its resonance with instructional and curricular approaches to derivatives (Jones & Watson, 2017).

However, in my research on eight experienced college calculus instructors' derivative tasks (Gerami, 2023, 2024), I encountered conceptions beyond those captured by Zandieh's (2000) framework. This motivated the development of an updated framework—*Conceptions of Derivative (CoD)*—to accommodate both my empirical findings and more recent theoretical perspectives on other approaches to thinking about derivatives. This report begins with reviewing Zandieh's (2000) framework and its extended versions, followed by a discussion of its limitations. I then present the extended CoD framework.

Zandieh's (2000) Framework and Its Extensions

In a foundational piece, Zandieh (2000) constructed a theoretical cognitive model for students' understanding of the concept of derivative. For Zandieh, an individual's understanding of derivative is defined "in terms of its overlap or lack of overlap with the mathematical community's notion of that concept" (Zandieh, 2000, p. 104). As shown in

Table 1, the framework is organized by four columns, called contexts/representations, and three rows, called process-object layers. Therefore, each cell in the framework refers to a conception of derivative within a representation or context, and a process-object layer.

Table 1. Zandieh's (2000) framework for the conceptions of derivative

		Representations/Contexts				
		Graphical (Slope)	Verbal (Rate)	Physical (Velocity)	Symbolic (Difference Quotient)	Other
Process-Object Layer	Ratio					
	Limit					
	Function					

Defining representation using the notion of a person's different images of the same concept (i.e., concept image; Tall & Vinner, 1981; Vinner & Dreyfus, 1989), she captured four mathematical representations for the concept of derivative: graphical (slope), physical (velocity), verbal (rate of change), and symbolic (difference quotient). Zandieh (2000) also included an "Other" column within the representations/contexts to capture representations that may appear different but are structurally similar. In an example, she noted that rate of change of temperature is another physical manifestation of derivative, like velocity, stating that "Many other physical examples are possible, and there are variations possible in the graphical, verbal, and symbolic descriptions" (p. 105). Nonetheless, for her, these *other* representations within the process-object framework still describe the similar "underlying structure" of the same concept of derivative.

For the rows, Zandieh (2000) used the term "process-object" from Sfard's (1991, 1992) work to capture the duality of some mathematical concepts: processes acting on previously defined objects, and objects as a result of other processes acting on them. To refer to different process-objects within the concept of derivatives in her framework, Zandieh introduced the term "layers" to capture the hierarchical structure of the three process-object rows, as each layer is found by using that layer as a process over the previous layer as an object. The three layers in the framework are ratio, limit, and function. The first layer, ratio, is the object of the average rate of change between two points, which can be represented graphically as a secant slope, average velocity between two times, or symbolically as $\frac{f(x_0+h)-f(x_0)}{h}$ or $\frac{f(x_2)-f(x_1)}{x_2-x_1}$. To find the next layer of derivative—the *limit* layer, we hold the ratio layer as an object and use the *limit* layer as a process on it to decrease h as the horizontal distance between the two points. This gives us the limit of the ratio layer as an object: $\lim_{h\to 0}\frac{f(x_0+h)-f(x_0)}{h}$, referred to as $f'(x_0)$ or the derivative of the function at a point. Finally, at the final layer and via the functioning process, we find the instantaneous rates of change at every possible point on the function. This results in the derivative as a function: $f'(x) = \lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$.

Facing challenges to capture all the ways that university students made use of their understanding of the derivative to solve derivative problems, Likwambe and Christiansen (2008) added the *instrumental* representation to capture the "only learning exhibited" by most of their university student interviewees (p. 24). To define this new representation, Likwambe and Christiansen relied on Skemp's (1978) and Lithner's (2003) notion of instrumental understanding as the ability to use a rule or procedure, while specifying it for finding derivatives using *derivative rules*. Likwambe and Christiansen further argued that the instrumental representation is its own category because it does not have any layers (i.e., it does not 'live' in any one specific layer of Zandieh's [2000] framework).

Later, Roundy and colleagues (2015) built on Likwambe and Christiansen's work to further extend Zandieh's (2000) framework by: 1) changing velocity—the physical representation's example—to *measurement* to allow for changes in quantities other than time; 2) adding the *numerical* representation, as calculated values for ratio of changes at the ratio layer and limit layer (for small Δx values), and sequence of numerical ratios of differences at the function layer; and 3) categorizing instrumental representation outside of the rest of the framework as a symbolic representation within the function layer, because using "rules for symbolic derivatives does not require a conceptual understanding of the derivative" (p. 923) and the derivative rules only exist at the function layer. Figure 1 shows this extended framework.

Process-object layer	Graphical	Verbal	Symbolic	Numerical	Physical
	Slope	Rate of Change	Difference Quotient	Ratio of Changes	Measurement
Ratio		"average rate of change"	$\frac{f(x+\Delta x)-f(x)}{\Delta x}$	$\frac{y_2-y_1}{x_2-x_1}$ numerically	Limit		"instantaneous ..."	$\lim_{\Delta x \to 0} \cdots$	...with Δx small	Function		"... at any point/time"	$f'(x) = \cdots$	... depends on x	tedious repetition

	Symbolic
	Instrumental Understanding
Function	*rules to "take a derivative"*

Figure 1. Roundy and colleagues' (2015) extended framework.

Limitations and Resolutions

While applying Zandieh's (2000) framework to analyze eight experienced college calculus instructors' derivative tasks (Gerami, 2023, 2024), several limitations emerged that motivated the development of an extended framework.

Limitation 1: Placing Non-Limit Approaches

Some instructors in my study conceptualized tangent lines through approaches fundamentally different from the traditional limit-based method. Rather than finding tangents by pushing two points together via limits, they used infinitesimal reasoning—zooming in on a function until it appears flat. This approach represents a distinct epistemological perspective rooted in infinitesimal and differential calculus (Ely, 2021; Keisler, 2011; Samuels, 2017), not merely a different graphical representation of limits.

Similarly, while Roundy et al. (2015) appropriately included instrumental understanding (derivative rules) in their framework, as many students use them to think about derivatives, they positioned it within the limit-based structure. However, students using derivative rules do not conceptualize the rules through process-object layers from ratio to function; it is my understanding as a calculus instructor and mathematics education researcher that they bypass this conceptual development entirely. This suggests instrumental approaches should be placed in a separate epistemological category. Moreover, while Roundy et al. added instrumental understanding within the function layer, I also knew that one could use derivative rules to also find derivative at a point as well as "average derivative" or average rate of change between two points.

These observations revealed three distinct *Conceptual Epistemologies* for understanding derivatives: limit-based, infinitesimal/differential-based, and instrumental/rule-based. Each represents a fundamentally different way of conceptualizing how they are derived.

Limitation 2: Conflating Context and Representation

I also had difficulty with the representation columns *Physical* and *Verbal*. It seemed to me that the physical representation conflates mathematical representation with contextual application. Physics problems are not a way of representing derivatives mathematically; they are contexts where derivatives can be applied. Similarly, while Roundy et al.'s (2015) change to *measurement* addressed some concerns, the distinction between their measurement and numerical columns remained unclear. Moreover, one could use derivatives on problems regarding change within other fields, such as physics, biology, chemistry, and economics.

To resolve this issue, I separated contextual applications into a distinct component called *Contextual Framing*—the context in which derivatives are used. This resolution would also recognize that any epistemological approach can be applied across various contexts.

Limitation 3: Verbal "Representation" as Conceptual Signals

Lastly, my research (Gerami, 2024) suggested that the verbal representations directed instructors toward other derivative conceptions. Rather than being representations themselves, these verbal descriptions serve as signals to other ways for conceptualizing derivatives, which can be different for different people. To address this limitation, I drew on semiotics (de Saussure, 1959) to distinguish between the *signified*, or the mathematical representation itself, and the *signifier*, or the verbal label often used to reference it. This separation clarifies how language can guide conceptual understanding while maintaining mathematical representation as the focus.

The Conceptions of Derivative (CoD) Framework

The Conceptions of Derivative (CoD) framework addresses the limitations discussed above by reorganizing how we conceptualize derivatives using four distinct but interconnected components that capture the multifaceted nature of derivatives (Figure 2).

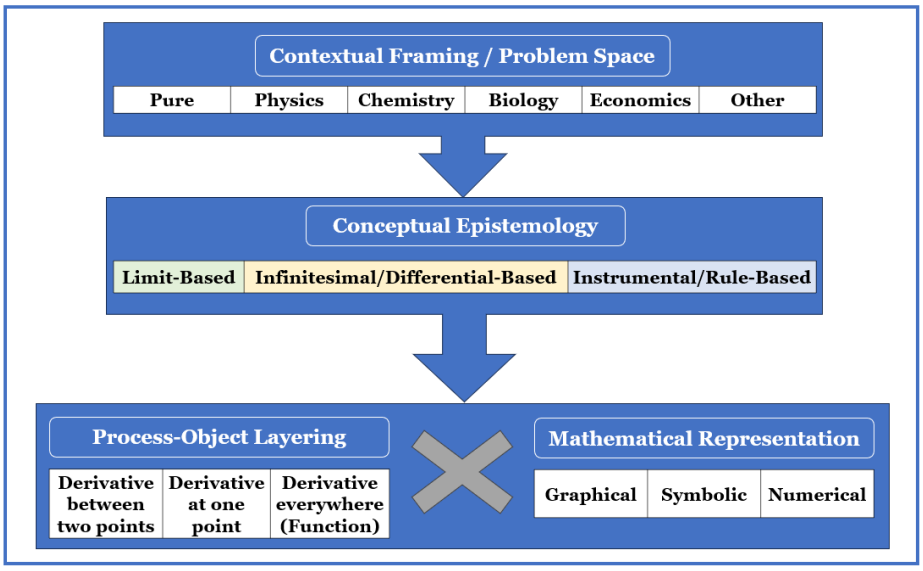

Figure 2. The four main components of the Conceptions of Derivative (CoD) framework

Contextual Framing is the context through which we frame or interpret derivative problems. Common contexts in calculus are pure mathematics, physics, chemistry, biology, and economics.

Conceptual Epistemology captures fundamentally different approaches to understanding what derivatives are and how they are derived. The framework identifies three distinct epistemologies:

limit-based (traditional approach using limits of difference quotients), infinitesimal/differential-based (using infinitesimal quantities or differential reasoning), and instrumental/rule-based (procedural approach using derivative rules).

Mathematical Representations encompass the three primary ways derivatives can be expressed mathematically: graphical (visual representations), symbolic (algebraic expressions), and numerical (calculated values). Following semiotic principles, each representation is understood through both its *signified* (the mathematical object) and *signifier* (the verbal label used to reference it).

Process-Object Layering maintains the hierarchical structure of derivatives from Zandieh's (2000) framework but adapts it to work across different epistemologies: 1) between two points (average derivative/rate of change), 2) at a point (instantaneous derivative), and 3) everywhere (derivative function). Unlike Zandieh's framework where layers are tied to limit processes, these layers can be conceptualized through any of the three epistemological approaches.

The comprehensive framework is shown in Figure 3. As the arrows show, the framework suggests that one encounters a derivative problem within a particular contextual framing. They then approach the derivatives via a specific conceptual epistemology. Within that epistemology, they can work across three layers using various mathematical representations, with verbal signifiers guiding their selection and interpretation of representations. I next explain the layers and representations within each conceptual epistemology.

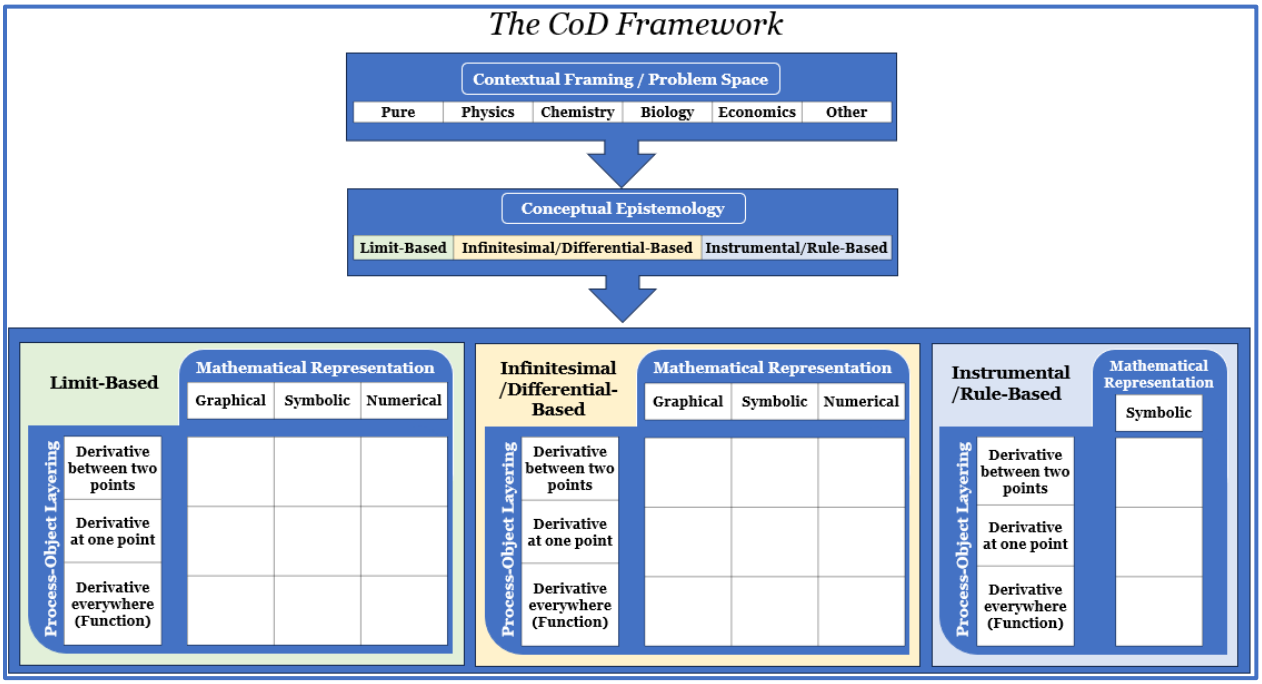

Figure 3. Conceptions of Derivative (CoD) framework

The limit-based conceptions in Figure 4 closely follow Zandieh's (2000) framework, where derivatives emerge through limiting processes. As I have reviewed these above, I do not repeat the details here. Signifiers like *secant/tangent slopes*, *difference quotient*, and *rate of change* are often used to direct attention to specific representations within each layer.

Limit-Based

Process-Object Layers	Representations: Graphical – Signified	Graphical – Signifier	Symbolic – Signified	Symbolic – Signifier	Numerical – Signified	Numerical – Signifier
Ratio		Slope of secant line	$\frac{f(x_0+h)-f(x_0)}{h}$, $\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x}$, or $\frac{f(a)-f(b)}{a-b}$	Difference quotient	Secant slope as a number	Slope value
Limit		Slope of Tangent line	$\lim_{h\to 0}\frac{f(x_0+h)-f(x_0)}{h}$, $\lim_{x\to x_0}\frac{f(x)-f(x_0)}{x-x_0}$, or $\lim_{\Delta x\to 0}\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x}$	Limit of the difference quotient	Tangent slope as a number	Table of tangent slope values
Function		Graph of the derivative function	$\lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$, or $\lim_{\Delta x\to 0}\frac{f(x+\Delta x)-f(x)}{\Delta x}$	Derivative as a limit	Tangent slopes as numbers	A list of slopes for "all" points

Figure 4. The limit-based conceptions of CoD

Infinitesimal/Differential-Based

Process-Object Layers	Representations: Graphical – Signified	Graphical – Signifier	Symbolic Infinitesimal – Signified	Symbolic Infinitesimal – Signifier	Symbolic Differential – Signified	Symbolic Differential – Signifier	Numerical – Signified	Numerical – Signifier
Ratio		Slope of a line through two points	$\frac{\Delta y}{\Delta x}$	Slope on a line through two points or "real rate"	$\frac{\Delta y}{\Delta x}$	Slope on a line through two points	Slope as a number	Slope value
Zoom		Local slope	$st(\frac{f(x_0+\Delta x)-f(x_0)}{\Delta x})$ The real number infinitely close to the answer for every non-zero infinitesimal Δx	Infinitesimal rate	$\frac{dy}{dx}$ *at* x_0 *Or* $\frac{f(x_0+dx)-f(x_0)}{dx}$	A quotient or a differential equation $dy=[\blacksquare]dx$ *at* x_0	Local slope as a number	Local slope value
Function		All local slopes	$st(\frac{f(x+\Delta x)-f(x)}{\Delta x})$ for every x and every non-zero infinitesimal Δx	The derivative function	dy/dx *Or* $\frac{f(x+dx)-f(x)}{dx}$	The derivative f' or a quotient or a differential equation $dy=[\blacksquare]dx$	Local slopes as numbers	A list of local slopes for "all" points

Figure 5. The infinitesimal/differential-based conceptions of CoD

The process for the infinitesimal- or differential-based conceptions in Figure 5 is 'zooming in.' At the ratio layer, derivatives are real rates of change between two points ($\frac{\Delta y}{\Delta x}$). At the "Zoom" or derivative at a point layer, the rate becomes infinitesimal ($\frac{dy}{dx}$); graphically, this involves zooming in until the function appears linear and one can find the slope. While I cannot provide details here due to space constraints, the infinitesimal approach uses the standard portion

of hyperreal numbers, whereas the differential approach uses first-order approximations, so they differ symbolically (see Ely, 2021; Keisler, 2011). The function or everywhere layer extends zooming process across the function's domain. Signifiers like *infinitesimal change* and *differential* are often used to target these conceptions.

Instrumental- or rule-based conceptions in Figure 6 focus on procedural ways of deriving derivatives. Unlike other epistemologies, this approach can be used bottom-up. The everywhere or function layer is found when rules are used to generate derivative functions. The derivative at a point layer can be found by evaluating derivative by 'plugging in' a specific x-value into the derivative function. Although not commonly used, the derivative between two points layer can be found by finding the average of two derivatives from the at a point layer. The symbolic representation and signifiers like *taking derivative* or *using derivative rules* (e.g., power, quotient) are often used for this epistemology.

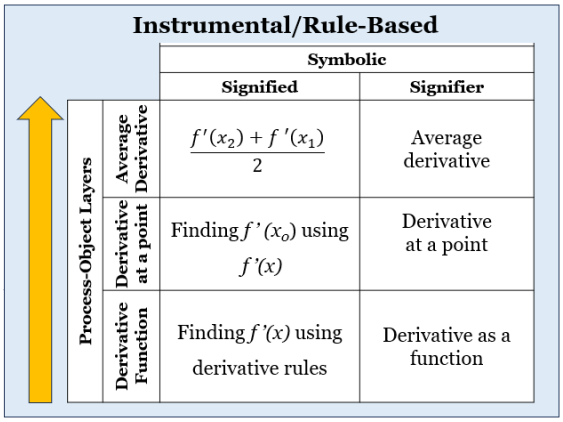

Figure 6. The instrumental/rule-based conceptions of CoD

Conclusion

The Conceptions of Derivative (CoD) framework addresses critical gaps in existing theoretical process-object models by recognizing that derivative understanding encompasses multiple epistemological approaches, not just limit-based reasoning. Rather than privileging a single epistemological perspective, the framework recognizes three distinct conceptual epistemologies—limit-based, infinitesimal/differential-based, and instrumental/rule-based—that can be used within various contextual framings. This offers researchers language to discuss derivative conceptions beyond those in traditional frameworks. Future research can use this framework to investigate how contextual framing influences epistemological choices, how instructors target various conceptions, and how students navigate between different conceptions. Different epistemologies appear to privilege different areas of study. Given that calculus courses are increasingly targeted for specific student audience like biology and business majors, the framework allows instructors and curriculum designers to choose which derivative understanding to emphasize and how.

If (Critical) Love is an Answer, What is the (Research) Question?

Kairi Black
Duke University

Research in math education calls upon "love" more and more, but rarely with careful theoretical development. Hence we offer a theory of "critical love" here, drawing upon pedagogy scholarship, activist writing, and queer theory. Critical love calls us beyond a superficiality of knowing in our minds to a deeper knowing in our beings and actions. We elucidate the theory by identifying its essential components, organized along four horizontal frames: change, power, connection, and practice. We conclude with implications of critical love as an orientation in mathematics classrooms, teacher professional development, and pedagogy research.

Keywords: love, critical, embodiment, transformation, queer

In this report we develop a theory of critical love, which we offer as a theoretical framework for our community's exploration of new ways of being as mathematics teachers, researchers, and learners. Critical love calls us beyond a superficiality of knowing in our minds to a deeper knowing in our beings and actions. Indeed, we affirm that "knowing differently reaches its deepest and most meaningful level when we are able to use this knowledge in service of living differently" (Ahluwalia, 2022, p. 313). We offer critical love as a conceptual resource for guiding transformation of knowledge into action. In this way, we endeavor partial work toward Green & Lopez's (2025) recent call for the development of "love as a grounding for STEM education" (p. 2) and Clingan's (2015) older call for us to "consider what might be possible if love were intentionally and specifically identified as a methodology, pedagogical practice, and value in… education" (p. 1). After a review of additional literature, we highlight sources of theoretical motivation – especially queer theory and the *Revolutionary Love Project* – before then moving into the 3 + 1 + 3 + 2 = 9 components of our conceptualization of critical love. We conclude with some implications for practice and potential uses of the theory.

Literature Review

Our suggestion of love as a potentially powerful force in pedagogy is not a new one (Freire, 1970; hooks, 1994; Anderson, 2002). However, in a mathematics culture which values logic and precision (Ernest, 2016), many folks shy away from the term for its perceived emotionality and imprecision. We acknowledge a key peril in the use of ambiguous and weighted terms like love: the potential harm of dual meanings. Johnson et al. (2018) highlight this risk of misnaming, saying that "when teachers embody fake love, it produces this bogus relationship… [that is] pretentious and masquerading" (p. 54). For example, in a study of STEM preservice teachers Green & Lopez (2025) note that "[the preservice teachers] rehearsed the dominant discourses in the United States which work to reproduce social injustice… while [also] giving strong commitments to social justice in terms of radical love" (p. 22). Rather, Johnson et al. (2018) call for a "practice of humanizing love… that is bounded in action" (p.48), a call echoed by social justice educator Brooks (2017) who states that "a critical theory of love… reunite[s] and rehumanize[s]" (p. 108). Tran and Pierre (2025) argue likewise, drawing upon hooks (2000) to state "when love is oriented purposefully, it becomes an anchor that empowers us to humanize each other" (p. 5). Thus, to love critically must be an act of humanization.

We therefore find resonance between the fact that a growing body of scholarship calls for (re)humanization of mathematics (Rosa & Orey, 2016; Ormseth et al., 2017; Gutiérrez, 2018; Simic-Muller, 2023; Kalinec-Craig, 2025; MacArthur et al., 2025), just as more and more math pedagogy literature calls upon love. In their development of a framework of ethnic studies for mathematics education, for example, Yeh et al. (2021) ground in an "orientation to [radical] love… drawn from activist and critical scholarship" (p. 73). However, they do not develop a deeper formulation of what they mean by "radical love" except to say that it is "interdependent, collective, healing, and nurturing" (p. 73). Likewise, in their "loving critique" of asset-based mathematics pedagogy, Paris & Alim (2014) avoid a theoretical framing of love and only remark that "love" refers to their "position of deep respect" (p. 1). Basile & Azevedo (2022), drawing upon Paris & Alim, also engage in a "loving (self-)critique" of their work as STEM educators, but offer only that their use of "love" reflects a "willingness and courage to deeply interrogate" (p. 1087) and their "patience and forgiveness" (p. 1095) in the process. My colleagues and I likewise engage in loving self-critique of our work in the ACT UP Math project on critical transformation in math education (Black et al., this issue). As such, even as mathematics educators call upon love, they do so without a robust theoretical development. Hence we offer a theory of "critical love" here, drawing upon and synthesizing the wisdom of pedagogy scholarship, activist writing, and queer theory.

Theoretical Framing

Queer theory provides a theoretical framing that: embraces fluidity of selves and identities (Morris, 2000); questions everything, especially things thought of as normal (Rands, 2019); embraces uncertainty (Shlasko, 2005); deconstructs binaries (Fifield &Letts, 2013); holds criticality of power relationships (Mayo & Rodriguez, 2019); and interrogates categorization (Brim & Ghaziani, 2016). For additional discussion, we refer the reader also to Chapters 2 and 3 of Hall's (2003) *Queer Theories*, and Chapter 1 of Browne and Nash's (2010) *Queer Methodologies*. We reference the preceding literature throughout our discussion of critical love. In particular, the *simultaneous holding of countless complexities* binds critical love together (see Table 1), aligned with queer theory's call to "engage with multiple [potentially contradictory] understandings" at once (Shlasko, 2005, p. 129).

We also draw inspiration from the *Revolutionary Love Project* (RLP), led by activist, documentary filmmaker, and faith leader Valerie Kaur. The RLP conceptualizes love as having three orientations: "love for others, love for opponents, and love for self", and teaches this practice of love "backed by research and infused with ancestral wisdom". While we draw upon the literature of the RLP – especially their *Educator's Guide* (2020), prepared by the project's Director of Education, Dr. Melissa Canlas – we organize critical love without reference to the recipient (e.g. self, others) of love. Instead, we focus on love as a force of individual and systemic transformation, which requires action and labor. Indeed, "love is a form of sweet labor" (Canlas, 2020, p. 17) and "love is an action, a participatory emotion" (hooks, 2000, p. 135).

A Theory of Critical Love

We elucidate our theory of critical love by identifying its essential components, organized in Table 1. We tabulate the elements of critical love to offer some conceptual structure and to facilitate the reader's remembering. However, queer theory calls us to hold caution around rigid categorization and hierarchy among the components. Throughout our discussion, therefore, we endeavor to explicate some of the ways that the components are inextricably interwoven.

Table 1. The essential components of critical love, tabulated in relation to one another.

	Individual	link	Systems
Change	Courage	*simultaneous holding of countless complexities*	Envisioning
Power	Humility		Criticality of Power
Connection	Curiosity		Interdependence
Practice	Embodiment Discernment		

Conceptual Core of Critical Love

First, critical love requires ***courage***. Courage empowers us to try, "fail", change, and try again, a cycle necessary for our individual and collective growth. Freire (1998) named the necessity of this cycle in teaching: "It is impossible to teach… without the courage to try a thousand times before giving in" (p. 3). Likewise, the RLP conceptualizes "transition" – or change – as a key practice of love, which they define as " the fiery process that is required to move from one reality into another" (2020, p. 118). Critical love calls us to willingly engage in this "fiery process", which places us in a state of vulnerability and thereby requires courage. As education researcher Ohito wonders, in conversation with colleagues Lyiscott et al. (2021): "Can we be courageous enough to *name* exactly who and what we fear? If we were to unstick from our fear and unfurl our tongues, then what would we feel free/d to say?" (p. 5). We invite the reader to consider what they fear – and why – as they consider the other components of critical love.

Humility forms another essential element of critical love. Again, we draw upon Freire (1985), who wrote "many things that today still appear to me valid… could be outgrown tomorrow, not just by me, but by others as well" (p. 11). Humility requires critical acknowledgement of where we are now, and loving imagination of where we might grow. One perspective might position humility as an antithesis to ego; aligned with queer theory's rejection of binaries, critical love takes a different stance. "The Hebrew word *anavah*… means 'to take up your God-given space in the world.'... [and] is translated into the English word *humility*... [to] take up space and just honor the full vision of who we are" (Lyiscott et al., 2023, p. 262). Critical love, through humility, calls us to continually grow in order to honor the "full vision" of ourselves. Not because we are "not enough", but rather because we each have a deep potential for fullness and the power to influence our world through our beings. Thinking of the classroom, Darder (2017) explicates that "knowledge production is lived out by the teacher through humility and openness… [and] this shift necessitates… the willingness of teachers to take responsibility for what they know" (p. 101). Thus, humility calls us to not only name what we do not know, but also take responsibility for what we do know, ever-aware of continual transformation at the fuzzy and amorphous interface of "known" and "unknown".

Along that interface, critical love calls us to ***curiosity and wonder***. The RLP encourages us to regard persons (including, at times, ourselves) with the mantra "you are a part of me I do not yet know" (Canlas, 2020, p. 25; compare to the Mayan concept of In Lak'ech as applied to math education in Gutiérrez, 2017). The phrase "I do not yet know" evokes a perpetual sense of curiosity and a readiness to construct new knowledge. "To wonder is to cultivate a sense of awe and openness to others' thoughts and experiences... wonder is the wellspring of love" (Canlas, 2020, p. 25). Through wonder we broaden our perspectives and learn from one another; in particular, we learn from our students just as they learn from us. We therefore offer critical love as a partial answer to Britzman's questions "How does one take joy in having ideas, in changing

one's mind, in encountering the work of learning?" and "What sort of relations [exist] between learning to love and loving learning?" (Britzman, 2000, p. 44). In a state of curiosity and wonder, we both learn to love and love to learn – an ontology aligned with queer theory's insatiable "interrogatory edge" (Rands, 2019). That said, we find an even deeper call in the seeing of others as "parts of us that we do not yet know": the practice pushes us to perpetually see the complexity of other persons and to feel that complexity reflected in ourselves. "Wonder is an orientation to humility [in recognition that] others are as complex and infinite to themselves as we are to ourselves" (Canlas, 2020, p. 25). We arrive therefore at critical love's conceptualization of the link between the self and systems outside of the self.

The ***simultaneous holding of countless complexities*** of personhoods presents a profound challenge. We again seek theoretical guidance in queer theory which "hopes to overwhelm our capacity to 'get it,' to bring us to a point where we… [have] neither knowledge nor resistance to knowledge… lacking answers, we are able to embrace questions, engage with multiple understandings, and imagine new possibilities" (Shlasko, 2005, p. 129). Curiosity and wonder help us "embrace questions" while courage and humility help us "imagine new possibilities". Here we elucidate critical love's holding of complexity, which requires that we can "engage with multiple [potentially contradictory] understandings" at once. In this way, critical love holds wariness around the idea of accessing an objective understanding and invites us to proactively recognize – and even celebrate – our subjectivities.

Recognition of our subjectives reminds us of the ever-presence of our history and position (Milner, 2007; Aguirre et al., 2017), and thereby leaves space for holding multiple understandings at once. Indeed, "queer theory attempts to understand the world (as do all theories) but makes this attempt while simultaneously recognizing the impossibility of ever developing a complete or unbiased explanation" (Shlasko, 2005, p. 125). Deeper still, critical love celebrates our subjectivities as reflective of our (individual and collective) capacity for transformation: "Queer thinking argues subjects and subjectivities are fluid, unstable, and perpetually becoming" (Browne & Nash, 2010, p. 1). In this way, critical love frees us from the chase of the unknowable and illusory capital 'T' 'Truth'. "The point of queering is not to fit the 'all' into one or more norms, but to mark, deconstruct, and pass beyond the regulatory impulse to fit being(s) into finite categories" (Fifield & Letts, 2014, p. 398). Rather, no one person or group of persons holds 'the' truth and critical love calls us to not just continually learn from one another, but also recognize (even celebrate) our dependence on one another for that learning. In an interview with Davis and Sarlin (2008), Michael Hardt describes love "as a social muscle" that has to involve "a kind of training… in cooperation with many". Likewise, Lanas and Zembylas (2015) write, drawing upon Nancy (2003), that "the transformational power of love arises precisely from the fact that it breaks the I" (p. 38).

We use ***interdependence*** to refer to this reciprocal dependence on one another for mutual knowledge production. For Darder (2017), in the classroom that reciprocity occurs through dialogue: "dialogue cultivates and nurtures students' curiosity and imagination toward a greater critical capacity to confront dialectically the content of their study and the task of constructing new knowledge" (p. 91). While critical love views dialogue as a manifestation of interdependence, there lies a deeper orientation at work. The RLP challenges us to "see no stranger" and critical love embraces the challenge as an invitation to depend on one another for our perpetual transformation. As Coles welcomes in conversation with colleagues Lyiscott et al. (2021), "I invite you to be transformed by my being, a being often falsely constructed as needing to be transformed by dominant power structures." (p. 3). Critical love calls us to transform one

another not just through dialogue, but also through relationships and curiosity – even in the face of ever-present pressure by the dominant systems of our context.

In this mutual transformation lies a deep sense of needing one another: I come to know myself and our world more deeply only in relation with others, whom I recognize as parts of myself I had not yet known. Implicit in this conceptualization of interdependence lies a perpetual expansion of each individual's meaning of "we". Critical love pushes back on worldviews built on "us" and "them", aligned once again with queer theory's rejection of binaries (Fifield & Letts, 2013). Traditional academic structures in mathematics, in contrast, overemphasize the transformation of students by instructors – which some authors describe as mathematical enculturation (Bishop, 1991; Perrenet and Taconis, 2008) – and thereby position students as a "them" separate from an "us" of instructors. Such a division limits the reciprocity of mutual transformation, and critical love views hierarchy as an obstacle here.

As such, critical love ***interrogates power relations***. Like Lanas and Zembylas (2015), we view love as "always connected to power" (p. 38) and as a powerful force for "the long-term process of transforming power in our institutions and everyday lives" (p. 40). Drawing upon prior conceptualizations of Nepantla – a liminal space at the in-between of two worlds (Anzaldúa, 2002; Gutiérrez, 2012) – and tension (Gutiérrez, 2015; Myers et al. 2023), Hagman et al. (2024) highlighted the tension between "power over" and "power with" in transformation efforts in pedagogy. Critical love likewise embraces this idea of Nepantla, and reaffirms the deep value of students as partners in recognition of students' "unique perspectives and contributions" (Green & Lopez, 2015, p. 19; also see Matthews et al., 2018; Cook-Sather et al., 2018; Bolick et al., 2024). At the same time, critical love holds wariness around the implicit binary that positions "power over" as a sort of opposite to "power with" or "shared power" (Brooks, 2017, p. 107). A binary framing might (subconsciously) celebrate "students as partners" as an "opposite" to more traditional "power over" models.

Instead, critical love asks: what could a non-binary conceptualization of power look like? Critical love calls for us to consider the varied forces of power in our lives – interpersonal and systemic – and not only seek out "power with" others, but also exercise deep trust and vulnerability by welcoming others to have certain "power over" us. As Darder (2017) writes, "teachers must recognize that there exist no human relationships, let alone educational practices, without the explicit or implicit existence of authority… [and] authority expresses itself in a multitude of ways" (p. 100). We must consider the systems and relations which give us power over others and give others power over us, and be critical of that power with a blend of courage, humility, and interdependence. Drawing upon Lewis's theorization of 'presence' (2022), Ahluwalia (2022) calls us to open up a "'third space' for more complicated, relational analyses of power" (p. 315). Critical love lives inside this "third space".

Critical love therefore requires that we ***envision*** alternative – or "third" – spaces of research, education, and relationship. Indeed, critical love knows us to be capable of, as Ohito envisions, "a future pluriverse expansive enough for myriads of humans to coexist in and cohabit peacefully" (Lyiscott et al., 2021, p. 5). Likewise, in their pedagogical guidance on culturally-relevant STEM education, Tran and Pierre (2025) describe love as "visionary" in its movement "toward justice", and that "love emphasizes the relationality of shared humanity, a type of love that is deeply personal, political, and collective" (p. 5). In pursuit of such a vision, the RLP grounds in the concept of reimagining: "to reimagine is to explore a vision of a relationship, community, and world where we all flourish" (2020, p. 80). We note not only a growing body of literature on (re)humanization of mathematics, but also a growing body of literature on

flourishing in and through mathematics (Su, 2017; Tunstall and Ferkany, 2017; Hill et al., 2021; Khan et al., 2021; Su, 2024). In cultivating a vision for the world in which we all flourish, we not only push back against injustice, but also ground in a vision of collective liberation. Such envisioning requires immense courage: "Dare to reimagine an outcome, a solution, a relationship, a future that does not leave anyone behind… imagine cultures, contexts, and institutions that run on love instead of fear" (Revolutionary Love Project, n.d., p. 2).

Foundational Elements of Critical Love

The prior seven components form the core of critical love. We turn to two foundational elements, which support the translation of more abstract notions into action. As the RLP reminds us, "theory can guide us but [it] must also be activated through action" (Canlas, 2020, p. 11).

The practice of critical love requires ***embodiment***. As a social justice educator, Brooks (2017) argues that "love must be embodied" (p. 111) for knowing "intellectually" is "insufficient to bring about justice" (p. 109). Here we arrive at a pivotal departure in our conceptualization of critical love from the "epistemic love" conceptualized by STEM educators Tran and Pierre (2025), which they describe as having four typologies: tangibility, emotionality, intellectuality, and audacity. We see in these an overemphasis on the role of the mind, for love also lives in the body and it is through the body that we find deeper transformation in our ways of being. As Ahluwalia (2022) notes, "the body knows" and it is through attunement with the body that we can "understand what is being stirred up in [us] as [we] try to do this work" (p. 311). We must practice awareness of the sensations that arise in our bodies, and exercise loving wonder of their meaning. Indeed, the RLP grounds in the metaphor of cyclical "breathing" and "pushing", for love is a perpetual "choice to labor and take action" (2020, p. 12). Without breath, we burnout; without push, we get stuck.

Critical love affirms that we are so much more than fragmentary minds elevated by elaborate flesh vessels. We are whole human beings, "not mathematical machines. We live, we breathe, we feel, we bleed." (Su, 2017). Likewise for the people all around us. In the classroom, for example, Darder (2017) affirms that the "perception of our students as embodied human beings" is fundamental to "a liberatory classroom practice", for "a student enters the classroom as a whole person and should be respected and treated as such" (p. 87). Embodiment calls us to ground in a perception of others as embodied human beings. Through such a grounding, we engage in a continual practice that teaches our bodies new ways of moving and being.

Finally, critical love calls us to ***discernment***. At the tension point of "simultaneously holding countless complexities" lies a fiercely tangled struggle of determining when and how to love in each moment. We note a possible orientation which resonates for us: the idea of "returning to our name(s)", employed by Lyiscott et al. when they first elucidate (2021) and later reflect (2023) on their editorial vision for *Equity and Excellence in Education*. Through the lens of "naming", discernment calls us to thoughtful consideration of what constitutes our names, and how we might return home to them "in loving accountability" (2023, p. 259). With courage, can we discern "who and what we fear" (2021, p. 5) and how fear pushes us from our names? With humility, can we discern our fullness of self and when we stray from it? With curiosity, can we discern "who should do the listening in a given moment" (Canlas, 2020, p. 69)? Can we discern with whom we might grow our interdependence? Can we discern which systems give us power over others and how to hold it, if we even should? Can we discern when we avoid others having power over us, and why? Can we listen to our bodies when they communicate, and discern the message?

Implications for Practice

As Johnson et al. (2018) wonder, couldn't "a pedagogy of love" serve "as an embodied practice that influences holistic teaching?" (p. 47). We affirm a resounding yes, and highlight some implications of critical love's *embodiment* on how we regard our students. We chose embodiment for this short paper as it deeply challenges our orientation to the teaching of mathematics, a discipline often positioned as disembodied and outside of human activity (de Freitas & Sinclair, 2013; Gutiérrez, 2017; Battey & Marshall, 2024; McNeill et al., this issue). We recognize the field of embodied cognition in mathematics education as a partial implication (cf. Edwards et al., 2014; Abrahamson, 2020; Khatin-Zadeh, 2022; Soto, 2024; also see MacArthur et al., 2025, p. 24-25 on "body and emotions" in the math classroom). However, we argue that critical love maintains an even deeper call. Darder (2017) cautions against "standards [in the classroom] of disembodied expectations removed from the organic responses of student bodies" where "teachers conduct themselves 'professionally' in ways that distance them from the possibility of expressing authentic human love" (Darder, 2017, p. 83). Critical love calls us to remember the body as an indivisible unit, not merely a vehicle for "cognition".

A simple practice might invite students to attune to their breath in the math classroom (cf Peper et al., 2016; Walkins, 2021). For another practice, I reflect on my first TA assignment in a calculus class of 200 students: for all exams, the instructor – in an act of critical love – would bring in a small "test box" of extra snacks, water, and personal hygiene supplies to support students in caring for their bodies. Indeed, some neuroscientific research has considered the impact of nutrition on brain function (Gómez-Pinilla, 2008), while numerous pedagogical studies have considered the impact of snacks (Kanarek & Swinney, 1990; Burrows et al., 2017) and hydration (Beezhold et al., 2018; Pawson et al., 2013) on university students' success.

Critical love also carries potential for teacher professional development. In our literature review, we highlighted Green & Lopez's (2025) recent study on training of STEM preservice teachers, in which they found that teachers "rehearsed dominant discourses" while also giving "strong commitments to social justice in terms of radical love" (p. 22). Rather than avoid the term "love" in training – and have it called upon anyway – we wonder about the incorporation of thoughtful dialogue on critical love as "an anchor that empowers us to humanize each other" (Tran & Pierre, 2025, p. 5). Hauk et al. (2014) draw upon Bennett's (2004) model of intercultural sensitivity to foster an "intercultural orientation" for post-secondary math instructors. We offer critical love as a potentially fruitful framing, for we find alignment between critical love and Bennett's "stages" of ethnorelativism (acceptance, adaptation, and integration). Moreover, we argue that the linearity and strong hierarchy of Bennett's model limit its application, while critical love actively avoids such structures via queer theory. Indeed, Lanas (2017) calls for "intercultural education in teacher education" that moves away from "seeing the relationships between teacher and learners as static" and is "connected more explicitly to a theoretical conceptualisation of love" (p. 1). As Green & Lopez (2025) put it, "further research could explore how love, serving as a foundation for STEM education, can prompt teachers to reevaluate… notions of individualism [and] competition" (p. 25), notions the prevailing culture of mathematics channels into broader STEM (Battey & Marshall, 2024).

Lastly, we offer critical love as an orientation in our research work. In our literature review, we highlighted various STEM and mathematics education research which call upon love without a deeper theoretical framing (Yeh et al., 2021; Paris & Alim, 2014; Basile & Azevedo, 2022; Black et al., this issue). With an orientation of critical love, we can expand our openness to new research perspectives and engage in generative loving (self-)critique.

Acknowledgements

I hold immense gratitude for the ACT UP Math project, through which I have found a welcoming community of mentors and scholars, especially Jess Hagman and Kaylee Fantin-Hardesty who supported my idea to write this article. Also, thank you to Kelly MacArthur for all that I learned as your TA years ago, and to Kristen Gerondelis, Shira Viel, Suzanne Crifo, Jack Bookman, Tori Akin, and Rann Baron for supporting my growth as an instructor since then.

Two Approaches to Rates and Foundations for Derivatives

Andrew Izsák
Tufts University

Sybilla Beckmann
University of Georgia

We distinguish 2 approaches to coordinating quantitative meanings for rates, proportional relationships, and variation. The first approach—based on coordinating unit rates, multiple batches, and chunky variation—has dominated existing research on rates and rates of change. The second approach—based on coordinating measurement rates, variable parts, and smooth variation—has not been recognized as distinct from the first. We examine affordances of each approach for reasoning about 2 aspects of rates essential for instantaneous rates of change and derivatives: They are single measures that remain approximately constant as changes in 2 variables tend to 0. We argue that the second approach complements the first in important ways and conclude that it should be recognized as an important focus in future empirical research.

Keywords: Rates, Derivatives, Calculus

Past research has recognized that the origins of students' and teachers' challenges with derivatives can often be found in their reasoning about quantities in combination with multiplication and division, variables, rates, and functions (e.g., Boyce et al., 2021; Byerley, 2019; Larsen et al., 2017; Thompson & Harel, 2021). One common challenge is that students and teachers often focus on rates as pairs of amounts rather than as single measures (e.g., Byerley & Thompson, 2017; Frank & Thompson, 2021; Johnson, 2015b; Yu, 2021). In calculus, a view of rates or slopes as pairs of amounts is problematic for developing an understanding of instantaneous rate of change and the derivative of a function. In particular, students who view rates and slopes as pairs of amounts will not be able to coordinate average or instantaneous rates of change of a function with changes in the input variable (e.g., Carlson et al., 2002; Yu, 2024).

In this theoretical report, we distinguish two approaches to mature meanings for rates that we term *unit rate* and *measurement rate*. Although mathematics education research has rarely articulated the distinction between these two meanings, we argue that the distinction matters because each presents different affordances for supporting two aspects essential for understanding how local, linear approximations lead to derivatives. First, a (constant) rate, rate of change[1], or slope is a *single quantity* that measures a quality such as steepness or speed by coordinating changes in two quantities multiplicatively. Second, understanding that m is the instantaneous rate of change of a function at a point relies, in turn, on the idea that *rates can remain constant or approximately constant as* Δx *and* Δy *tend smoothly and continuously to zero*. Our contribution rests on critical examination of ways that past theoretical research on quantitative reasoning has treated multiplication and measurement.

Unit Rates and Measurement Rates

Our delineation of two approaches to rates begins with the distinction between multiplicands and multipliers (e.g., Greer, 1992). If one invokes multiplication when considering a situation where three children each have four cookies, the number of cookies one child has is the multiplicand and the number of children is the multiplier. Sharing or partitive division results

[1] We view rate of change as an application of rate and therefore we use the term rate to include rate of change in the remainder of the article.

from dividing the product by the multiplier to determine the multiplicand. An example would be: "If 12 cookies are distributed evenly among three children, how many cookies does each child get?" Measurement or quotitive division results from dividing the product by the multiplicand to determine the multiplier. An example would be: "If there are 12 cookies, how many children can each get four cookies?"

Given the close connections among division, ratios, and rates, that there are two distinct quantitative meanings for division suggests, in turn, that there should be two distinct quantitative meanings for rates. We introduce these two meanings using red and blue paint mixed in a 4-to-3 ratio. When reasoning with *unit rates*, we consider an initial batch containing 4 gallons of red paint and 3 gallons of blue paint. We imagine variation occurring through partitioning and iterating this initial batch, and we use division based on equal sharing to determine that 4/3 gallons of red paint correspond to each 1 gallon of blue paint. If n is a natural number, then for n gallons of blue paint there will $n \bullet 4/3$ gallons of red paint. More generally, if r and s are natural numbers, then for r/s gallons of blue paint there will be $r/s \bullet 4/3$ gallons of red paint. Here, n and r/s function as *multipliers* acting in parallel on two fixed multiplicands, 4/3 gallons of red paint and 1 gallon of blue paint. A similar argument explains a second unit rate, 3/4 blue gallons for every 1 gallon of red paint. Beckmann and Izsák (e.g., Beckmann & Izsák, 2015; Izsák & Beckmann, 2019) have referred to such reasoning as the *multiple-batches* perspective on proportional relationships. The unit rate meaning and multiple-batches perspective have dominated past research on rates (e.g., Lobato & Ellis, 2010; Tallman et al., 2024; Thompson, 1994; Thompson & Thompson, 1994).

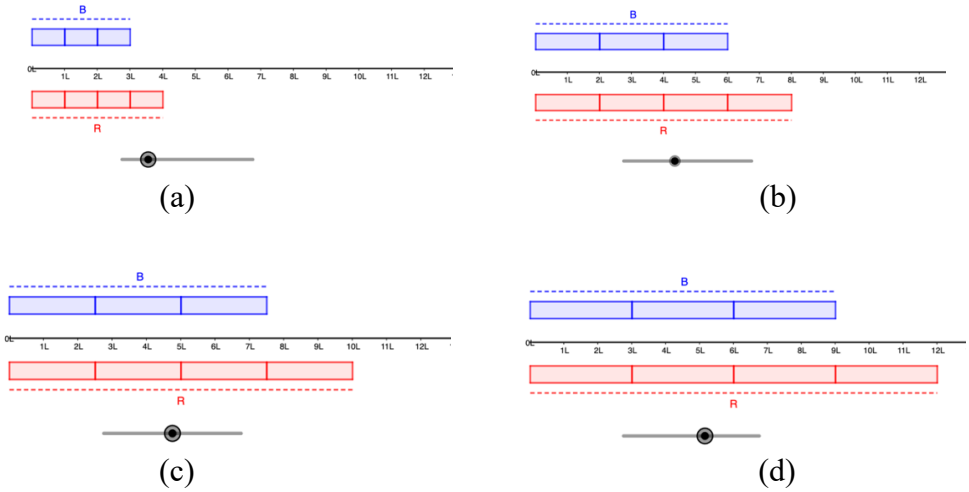

Figure 1. Covarying volumes of paint. All seven parts contain (a) 1 liter. (b) 2 liters. (c) 2.5 liters. (d) 3 liters.

In contrast, when reasoning with *measurement rates*, we organize the same mixture into 4 parts of red paint and 3 parts of blue paint. We imagine variation occurring through increasing or decreasing the volume of each part in such a way that any one part still has the same volume as all remaining six parts. Figure 1 shows screen shots from a dynamic illustration of covarying volumes in which each of seven equal-sized parts increases and decreases in parallel. In contrast to reasoning with unit rates, here we focus on measurement division and ask how much of the blue paint makes the same volume as the red paint. Because the number of parts of blue and red paint are fixed, and because all seven parts contain the same volume, it always takes 4/3 of the blue paint to make the same volume as the red paint, and it always takes 3/4 of the red paint to make the same volume as the blue paint. Notice that if B is any volume of blue paint, the

corresponding volume of red paint is 4/3 • B; and, if R is any volume of red paint, the corresponding volume of blue paint is ¾ • R. The measures, 4/3 and ¾, are the two measurement rates in this situation. In contrast with unit rates, with measurement rates variation is accomplished by varying a *multiplicand*, B or R, while the corresponding multiplier, 4/3 or ¾, remains fixed. Beckmann and Izsák (e.g., Beckmann & Izsák, 2015; Izsák & Beckmann, 2019) have referred to such reasoning as the *variable-parts* perspective on proportional relationships. The measurement rate meaning and variable-parts perspective has not been recognized in past research on instantaneous rates of change and derivatives as a second, distinct approach.

Research on Rates Grounded in Quantitative Reasoning and Covariation

Research on rates has often been grounded in Thompson's (1994) account of quantitative reasoning. The two features of his account on which we focus are (a) characterizing numerical operations and quantitative operations as two distinct categories of mental operations and (b) characterizing rates as reflectively abstracted constant ratios, or multiplicative comparisons of two quantities varying in constant ratio (pp. 190–192).

Thompson and colleagues discuss multiplication as operating on quantities sometimes and on numbers other times. Thompson and Saldanha (2003) characterized "conceptualized multiplication" as one-to-many relationships: "Envisioning the result of having multiplied is to anticipate a multiplicity" (p. 103). This perspective is consistent with thinking of ratio comparisons where one amount is so many times as, or as much as, another amount. Thompson and Saldanha then discussed multiple proportions that lead to "numerical multiplication." To illustrate, they gave the following analysis for the area of a rectangle that has dimensions 12 inches and 2 centimeters. One side is 12 times as long as 1 inch, one side is 2 times as long as 1 centimeter, and the area is 24 times the area of a rectangle of dimensions 1 inch by 1 centimeter (p. 103). This analysis treats 2 • 12 as a numerical operation and foregrounds three separate one-to-many relationships where the measures associated with each factor play symmetric roles. Such symmetry contrasts with the conceptually distinct roles played by multipliers and multiplicands discussed above, making it harder to recognize the distinction between unit rates and measurement rates.

How one conceptualizes rates interacts not only with one's conception of multiplicative comparisons but also with one's conception of covariation between two quantities. Existing research has emphasized partitioning and iterating two quantities in parallel (e.g., Lobato & Ellis, 2010; Tallman et al., 2024; Thompson & Thompson, 1994). Thompson and Thompson (1994) provided a particularly succinct statement using speed as the example: "If you go m distance units in s time units at a constant speed, then at this speed you will go (a/b) • m distance units in (a/b) • s time units" (p. 283). This coordination can be envisioned as partitioning both m distance units and s time units into b equal-sized parts and taking a copies of the result. Here multiplication is operating on two quantities, distance and time, in parallel. Other researchers have also examined partitioning and iterating in parallel as a starting point for mature conceptions of rates—for instance, Lobato and colleagues discussed composed units (e.g., Lobato & Ellis, 2010), and Peck (2020) described a "unit rate strategy" as a main outcome in a learning trajectory for slope. Appeals to reflective abstraction have left in a black box how partitioning and iterating two quantities in *parallel* leads to perceiving a fixed multiplicative comparison *between* amounts of each (e.g., between distances and durations of time).

More recently, researchers have examined connections between chunky and smooth variation (e.g., Castillo-Garsow, 2012; Castillo-Garsow et al., 2013) and students' conceptions of ratios and rates (e.g., Johnson, 2015a; Tallman et al., 2024; Yu, 2023, 2024). Castillo-Garsow et al.

explained that a chunky conception of variation focuses on concatenated intervals and endpoints of those intervals. Such reasoning applied in parallel to two quantities is consistent with Thompson and Thompson's (1994) description of constant speed (quoted above) and with Lobato and Ellis' (2010) discussion of composed units. Castillo-Garsow et al. explained further that a smooth image of change focuses on continuous progression through the flow of time. Researchers have recognized that smooth covariational reasoning is critical for building calculus from quantitative and covariational reasoning (e.g., Thompson & Carlson, 2017, pp. 442–443). Still missing from these more recent studies are explanations for how operating on two quantities in *parallel* through partitioning and iterating leads to fix multiplicative relationships *between* the two quantities.

Measurement and Variation

In this section, we connect conceptions of quantity, measurement, variation, and the asymmetric roles of multiplicands and multipliers. Mathematics education research has maintained a distinction between conceiving of a quantity and measuring that quantity. As one example, Thompson (1993) explained: "A person constitutes a quantity by conceiving of a quality of an object in such a way that he or she understands the possibility of measuring it" (p. 165). Interestingly, work in mathematics has given a rigorous treatment of such measurement.

1901 Otto Hölder formulated seven axioms for quantity that did *not* include measurement (Michell & Ernst, 1996) but from which he derived measurement. To begin, Hölder's axioms allow one to describe whole and rational number multiples of a quantity: Given any specific quantity Q and any natural number n, Q can be iterated n times to form a quantity $n \bullet Q$ and can be partitioned into n equal-sized parts to form a quantity $(1/n) \bullet Q$ (Michell & Ernst, 1996, sections 3 and 7). It follows that for any positive rational number m/n, where m and n are natural numbers, there is a quantity $(m/n) \bullet Q$, defined as $m \bullet ((1/n) \bullet Q)$, which can be formed by partitioning Q and iterating the result. Note that m/n is a multiplier acting on a multiplicand, Q, and that this action creates chunks. Following Hölder (Michell & Ernst, 1996, sections 10, 11, and 15), one can use completeness of the real numbers to show that for any positive real number t there is a well-defined quantity $t \bullet Q$ whose measure with respect to Q is t. Here, one views the measure, t, as the multiplier that varies as it acts on Q, a fixed multiplicand. We refer to such reasoning as *variation of measure*. The reliance on chunks—in the case of rational multiples—and on completeness—when t varies through irrational numbers—implies that reasoning rigorously about smooth variation in combination with measured quantities is non-trivial.

In contrast, it is also possible to view variation where a quantity increases and decreases without attention to a measure. For example, if a volume of water is poured continuously into a vase, then there is a specific volume in the vase at any given time even if we do not know its measure with respect to any particular unit of volume. This conception of variation aligns with smooth variation. As explained within the paint example, when one applies this perspective to covariation of two quantities, variation occurs in the multiplicand while the multiplier remains fixed. This perspective also resembles that used by Newton: In his history of calculus, Edwards (1979) stated that Newton regarded the speed of a point moving along a straight line as intuitively apparent on physical grounds (p. 192) and took smooth, continuous variation of quantities as given by nature, viewing time as flowing continuously and other quantities as increasing continually in time (pp. 210, 271). We refer to such reasoning as *unmeasured variation*.

Rates, Variation of Quantities, and Derivatives

As stated in the introduction, a quantitative notion of instantaneous rate of change rests on two ideas: Rates or slopes are single quantities and rates of change can remain constant or approximately constant as Δx and Δy tend smoothly and continuously to zero. We agree with Thompson and Carlson (2017) that smooth continuous variation is foundational for building calculus from quantitative and covariational reasoning (pp. 442–443). Below we articulate two approaches to coordinating rates, proportional relationships, and quantitative variation.

Unit rates, multiple batches, and chunky variation

Here we summarize an approach to mature reasoning starting with unit rates. Much of the research on rates has relied proportional covariation in which two quantities are of different types, such as distance and time or height and volume. Such approaches rely on the multiple-batches perspective and on *variation of measure*, at least initially. This follows because, if D and T are two unlike specific quantities such as a distance and a duration of time, then one cannot measure the other directly. The only way to determine new pairs in the same linear relationship is by letting D and T each function as a measurement unit for its own type of quantity (e.g., D measures distances and T measures durations of time). Thus, to explain multiplication as an operation on quantities varying at the same rate, D and T must be iterated and partitioned in parallel, where variation occurs by varying the multiplier, as in varying r/s in $(r/s) \bullet D$ and $(r/s) \bullet T$. As explained above, such variation involves chunks and extension to irrational multiples relies on completeness of the real numbers.

Measurement Rates, Variable Parts, and Unmeasured Variation

Here we summarize an approach to mature reasoning starting with measurement rates. Measurement rates fit most naturally in situations where the two covarying quantities are of the same type—for instance, two lengths or two volumes. In such situations, reasoning about proportional covariation can rely on the variable-parts perspective, *unmeasured variation*, and multiplication as a quantitative operation *between* two quantities. The numbers of same-sized parts are not limited to whole numbers: They can also be positive rational or irrational numbers. For example, if the number of parts is 2.3, then there are 2 whole parts and 3 mini-parts, each 1/10 the size of the whole parts. Covariation occurs by changing the size of one part, and therefore the size of each part or portions of whole parts. Moreover, variation occurs by varying the multiplicand, as in varying B and $4/3 \bullet B$ in the paint example. The parts are free to vary smoothly and continuously.

Entry Points into Derivatives

In this section, we examine the affordances and constraints of unit rates and measurement rates for developing instantaneous rates of change and the derivative. Approaching instantaneous rates of change through unit rates and variation of measure has several advantages. First, considering time as an independent variable may appear self-evident and natural to students—for instance, when thinking about the relationship between speed, distance, and time. Second, a wide range of further applications involve variation of unlike quantities. Examples include the relationships among current, time, and charge; among density, volume, and mass; and among pressure, surface area, and force. Third, past research (e.g., Lobato et al., 2013; Lobato & Siebert, 2002; Tallman et al., 2024; Thompson, 1994) has reported that students of various ages can spontaneously generate sound reasoning in which they partition and iterate in parallel. These results suggest that unit rates and variation of measure provide an accessible entry point for

initial reasoning about covariation and proportions in a range of situations where derivatives can be applied. At the same time, our discussion to this point leads to the conclusion that the current practice of engaging students primarily with speed and further situations that use pairs of dissimilar quantities poses an impediment to developing instantaneous rates of change and the derivative because it is difficult to relate unlike quantities through multiplication directly.

Approaching instantaneous rates of change through measurement rates and unmeasured variation of the same type of quantity has a contrasting profile of advantages. Here, it makes sense to interpret the difference quotient $\Delta y/\Delta x$ as a measure that is the result of measurement division: How many or much of Δx it takes to make Δy. This approach makes direct use of the connection between division and measurement, presents rates of change as single numbers that relate Δy and Δx directly, and affords reasoning about smooth and continuous variation.

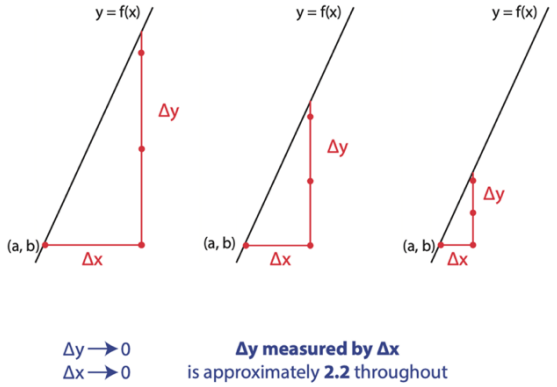

Figure 2. Difference quotient as measure: As Δx tends to zero, the measure $\Delta y/\Delta x$ remains close to 2.2.

To further illustrate a measurement rate interpretation of instantaneous rate of change in the non-linear case, we consider two points on the *x*- and *y*-axes that correspond to the *x*- and *y*-coordinates of a point moving smoothly and continuously in the coordinate plane. We use the variables *x* and *y* for the distances of these two points from the origin. We can regard the distances *x* and *y* as unmeasured covarying quantities and the curve that the object travels along as the graph of their relationship. In this situation, if Δx is small enough, the horizontal and vertical distances will change approximately uniformly relative to each other over the interval. Therefore, the measure of Δy in terms of Δx will remain approximately constant. Figure 2 is zoomed in on a small portion of a graph that shows snapshots of Δx (and Δy) decreasing toward zero from a point (*a*, *b*) on the graph. On this zoomed-in portion of the graph, the situation is similar to a linear situation, where $\Delta y/\Delta x$ would remain a constant measurement rate, regardless of the size of Δx (and Δy). Because of this approximate linearity, $\Delta y/\Delta x$ tends to a limit as Δx (and Δy) goes to zero, and this value is the instantaneous rate of change of the relationship at the given point, the derivative of *y* with respect to *x*. It indicates how *y*, the vertical distance of the moving object, is changing with respect to changes in *x*, the horizontal distance, at the given point. In Figure 2, assume that the derivative at the point (*a*, *b*) is 2.2. Then, at that point, the change in the vertical distance of the object is 2.2 times as much as the change in its horizontal distance. Therefore, the vertical speed of the point is 2.2 times its horizontal speed at that instant. When the point's horizontal distance changes by a sufficiently small amount from *a*, its vertical change in distance from *b* is approximately 2.2 times as much. So, for all changes Δx that are sufficiently small, when the horizontal distance of the object is $a + \Delta x$, the vertical distance of the object is approximately $b + 2.2 \bullet \Delta x$.

Discussion

Our delineation of two distinct approaches to coordinating quantitative meanings for rates, proportional relationships, and variation has implications for both research and instruction. With respect to the research, current quantitative approaches to rates have sought to combine reasoning with unit rates and multiple batches with smooth covariation. As one example, Tallman et al. (2024) reported a teaching experiment with one preservice teacher, Samantha, using a series of constant speed tasks involving a character named Clara. A main goal of the teaching experiment was for Samantha to develop an understanding of constant speed where she would anticipate that "any accumulated distance is some multiple k (where $k \in R+$) of the distance Clara travels in one unit of time, and that it therefore takes Clara that same multiple of one time unit to travel that distance" (p. 12). Samantha was able to solve the tasks appropriately by partitioning distances and times in parallel using chunky reasoning. At the same time, the authors argued that Samantha's reliance on chunky variation constrained her reasoning, and they hypothesized that smooth covariational reasoning is essential for constructing rates as reflectively abstracted constant ratios (p. 22). From our point of view, the constraints in Samantha's reasoning may have been an artifact of researchers presenting situations for which it was appropriate to partition and iterate two quantities in *parallel* with an expectation that such reasoning would support a different multiplicative relationship *between* those quantities. We understand this design to be based on a mix of the two approaches to rates and covariation that we have identified and explicated.

With respect to instruction, our analysis suggests that students might benefit from reasoning about rates with pairs of like quantities. We introduced measurement rates using volumes of paint. Further examples in the literature suggest students may be able to generate measurement rates reasoning spontaneously. As one example, Moore (2014) reported a teaching experiment during which Zac developed a preference for using the radius of a circle as a unit of measure and came to reason productively about multiplicative relationships between the length of the radius and arc lengths and sides of right triangles. Moore did not highlight distinct meanings for rates; but, from our point of view, Zac reasoned about measurement rates within a variable-parts perspective. As a second example, Yu (2023) reported a short intervention on linear motion designed "to move students from interpreting a speed of 1.7 m/s as 'for every additional second the person moves an additional 1.7m' into a meaning as 'for any amount of time that passes, x, the person moves 1.7x cm'" (p. 966). During the unit, college calculus students worked with a dynamic computer environment that allowed them to change horizontal and vertical lengths smoothly and to consider "how many times as large the change in the output is (the length of the vertical segment) with respect to the change in the input (length of the horizontal red segment)" (p. 972). Thus, from our perspective, Yu combined measurement rates with smooth covariation.

We hope to inspire further consideration of new possibilities for coordinating quantitative understandings of rates, proportional relationships, and covariation. Past research has focused on unit rates, multiple batches, and variation of measure, but measurement rates, variable parts, and unmeasured variation have characteristics that scholars have repeatedly described as important for calculus, including derivatives. Thus, we see further investigation into students' reasoning with measurement rates as an important direction for future research.

Research on students' and teachers' quantitative reasoning continues to underscore its importance for their learning and development. This importance requires that researchers continue to make strides in identifying salient and important ways of reasoning quantitatively. In this paper, we delineate four forms of quantitative reasoning to characterize both students' images of situations and their graphing meanings related to those images. Specifically, we differentiate between students conceiving quantities' changes via states reasoning, transformational reasoning, and gross or quantified covariational reasoning. We connect these forms of reasoning to their meanings for graphs when attempting to represent those quantities.

Keywords: Covariational Reasoning, Quantitative Reasoning, Graphing, Cognition

Quantitative reasoning involves conceiving a situation so that it entails measurable attributes (i.e., quantities) and relationships between them (i.e., quantitative relationships; (Smith III & Thompson, 2007; Thompson, 2011). *Covariational reasoning* involves conceiving the ways in which quantities vary in tandem (i.e., covary; Saldanha and Thompson (1998), Carlson et al. (2002), and Confrey and Smith (1995)). Together, quantitative and covariational reasoning (QCR) form a critical foundation for student development and teacher actions at all grade levels (e.g., Ellis, 2011; Johnson, 2015; Steffe & Olive, 2010; Tallman & Frank, 2020; Thompson, 1994). Over the past two decades, we have engaged in research to build models of students' and teachers' reasoning about experiential contexts in association with their QCR and graphing relationships in coordinate systems. In this report, we describe QCR forms that have emerged during this work: state, transformational, gross, and quantified. State and transformational reasoning entail thinking about quantities at distinct states. Gross and quantified reasoning additionally include images of covariation. We illustrate each form in the context of conceiving of a situation and constructing a graph to re-present quantitative relationships.

Covariation and Re-presentation

Carlson et al.'s (2002) and Thompson and Carlson's (2017) frameworks are two of the most used in the field, both because of the authors' prominence as QCR researchers and the generalized nature of the frameworks. We have drawn significantly on Carlson and Thompson's frameworks, with Carlson et al.'s (2002) attention to direction and amounts of change being a bedrock for our work in understanding students' graphing meanings (e.g., Liang & Moore, 2021; Moore, 2014; Paoletti et al., 2024). Thompson and Carlson's (2017) levels have aided us in describing student meanings for linear/non-linear relationships (Paoletti & Vishnubhotla, 2022).

A popular context-specific area for QCR research is students' coordinate-system and graphing meanings. Specific to our focus, coordinate systems provide a representational context for students to re-present quantitative relationships they have constructed in experiential contexts (e.g., taking a road trip or building a fenced pen). Lee et al. (2020) called this a *quantitative coordinate system*. Moore and Thompson (2015) termed such reasoning *emergent (graphical)*

shape thinking (*EGST*) if such actions involve covariation. In our use of covariation frameworks to describe participants' EGST and quantitative coordinate systems, we experienced the need to clarify or reframe aspects of them. These needs included incorporating a more intentional focus on magnitude reasoning, non-variational forms of reasoning that maintain the spirit of EGST, and the extent to which amounts of change are coordinated and compared.

Four Forms of Reasoning: States, Transformations, and Gross/Quantified Covariation

In Table 1, we delineate four forms of reasoning to discuss QCR and EGST: (1) state reasoning; (2) transformational reasoning; (3) gross (covariational) reasoning; and (4) quantified (covariational) reasoning. Each form is quantitative; each involves two quantities existing in a paired, possibly deterministic relationship. Each involves understanding that each quantity can take on a multitude of magnitudes, and that changing the magnitude of one quantity might involve changing the magnitude of the other.

Table 1. Four Forms of Reasoning about Two (or more) Quantities

Reasoning	Description
State	Quantities' paired magnitudes are only dependent on the state under consideration. Changing from one pair to another involves imagining a different instantiation of the situation.
Transformational	Quantities' paired magnitudes are only dependent on the state under consideration. Changing from one pair to another involves transforming between instantiations and reconstructing the magnitudes.
Gross (Covariational)	Quantities' paired magnitudes are dependent on the state under consideration. Also, one pair can be changed to another by imagining a quantity's magnitude increasing/decreasing with increases/decreases in the other quantity's magnitude.
Quantified (Covariational)	Quantities' paired magnitudes are dependent on the state under consideration. Also, one pair can be changed to another by constraining gross covariation by an invariant property of their simultaneous changes.

A person engaged in *state reasoning* conceives the relevant quantities as occurring in distinct instantiations called states. The quantities' magnitudes can change in the sense that there can be different magnitudes at distinct states. The magnitudes at a state exist independent from those at other states. In the context of imagining a road trip, any moment in the trip is a state. At every state, there exists some distance from the start and some distance from the destination. Because each moment exists independent of another, conceiving another state involves switching attention from one state to the next state *and then* constructing and determining anew the two distance magnitudes (Figure 1a; the red magnitude represents the distance from the start and the blue magnitude represents distance from the destination). The shift in states produces distinct distance magnitudes, which may or may not have different sizes from other states. For example, a person engaged in state reasoning might focus on the halfway point in their journey and identify that the two distances are equal. They might then shift their focus to a rest stop and, with their attention shifted, conceive how far the stop is from the start and end. An individual engaged in state reasoning understands that the path constrains possible states. They also might determine the two distances sum to a constant magnitude at every moment in the trip, conceiving this as an invariant property defining the quantities' deterministic relationship at any state.

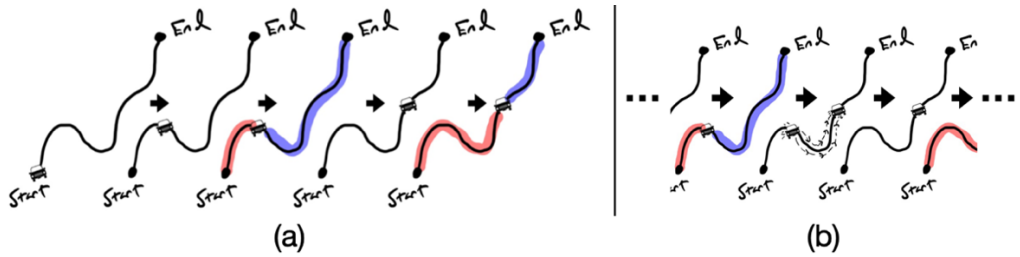

Figure 1. (a) State and (b) transformational reasoning about a road trip and distances.

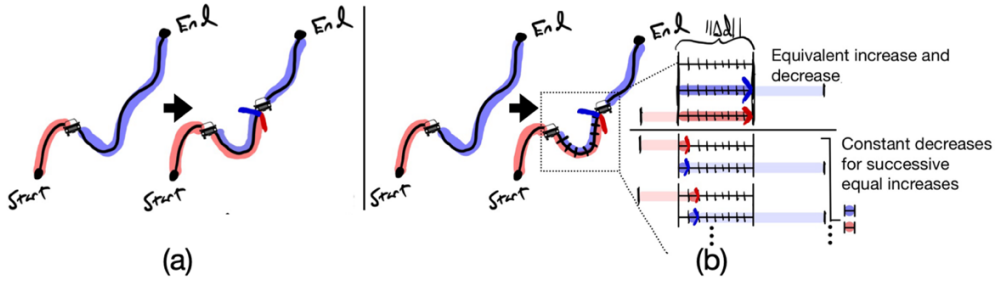

Figure 2. (a) Gross and (b) quantified reasoning about a road trip and two distances.

Transformational reasoning is equivalent to state reasoning, but the person imagines transforming the context from one state to produce another state. With a road trip, this involves imagining the car traveling along the road from one state to another, whether smoothly or in chunks (see Figure 1b, which is Figure 1a with the additional conception of the car traveling from one state to another). Like state reasoning, an image of the quantities' magnitudes must be constructed anew at the ending state due to the magnitudes not being sustained when conceiving the transformation. The states are no longer independent of each other, but the quantities' magnitudes constituting each state remain independent from those at other states. Both state and transformational reasoning allow for the quantities' magnitudes to change via being different sizes at different states. Each includes understanding the car's physical position can change, but neither includes images of the (co)variation of two quantities magnitudes.

A person engaged in *gross (covariational) reasoning* also understands quantities occur in distinct states and conceives states with respect to each other; any state is a *snapshot* occurring within the transformational image. Gross covariation additionally involves the quantities' magnitudes being sustained during a transformation. A person conceives one state of the quantities' magnitudes as dependent on the other state through a process of covariation; the ending state can be produced through a process of covariation emanating from the beginning state. In the case of the road trip, this might involve an individual reasoning that as they proceed from an early rest stop to some state later in the trip, their distance from the start increases and the distance they have remaining decreases (Figure 2a, indicated by the lengthening red magnitude and the shortening blue magnitude). They could conceive this as a loose process of simultaneous increase and decrease, or they could conceive the simultaneous increase and decrease in terms of the specific magnitude each quantity changes in total (e.g., explicitly identifying the magnitude increase in red and the magnitude decrease in blue). They might hold in mind that at any state during that covariation the two distances sum to a constant magnitude.

The aforementioned three forms of reasoning can entail holding in mind an invariant property defining the quantities' overall magnitudes at each state (e.g., they sum to a constant magnitude). A person engaged in *quantified (covariational) reasoning* also constructs a relationship in the *variations of each quantity* so that an invariant property *constrains their*

covariation when transforming from one state to another. Gross reasoning dealt with general intervals of increase and decrease and possibly considering specified total change. Quantified reasoning involves more precisely comparing the quantities' variations. In the case of the road trip, this could involve a person reasoning that as they change states, *any increase in the distance* from the start necessitates a decrease of *equal magnitude* in remaining distance (Figure 2b). Or a person might reason that as the distance from the start increases by *successive and equal magnitudes*, the distance remaining decreases by *a constant magnitude* (Figure 2b). In the former, the person quantified the gross covariation by comparing and generalizing one distance's variation relative to the other (i.e., each quantity changes by the same magnitude). In the latter, the person quantified the gross covariation by comparing one quantity's variation across fixed variations in the other (e.g., one quantity's magnitude changes constantly for constant magnitude changes in the other). In each, the quantities' covariation, whether chunky or smooth, was refined through constructing and quantifying amounts of change. Reiterating a point made above, quantified reasoning need not entail reasoning about specified values; in the road trip situation an individual can coordinate the two distance magnitudes without determining specific values in a unit (Figure 2b). As with the previous three forms of reasoning, the person might also understand that the total distances sum to a constant magnitude at each state. They might also consider how the additional invariant property of covariation maintains the invariant sum property.

Four Forms of Reasoning: EGST

To illustrate these forms of reasoning in an additional context and in relation to EGST, we use a fencing task adapted by authors of this paper to generate models of students' thinking: *Imagine constructing a rectangular playpen out of 20 feet of fencing. Construct a graph representing all possible width and length combinations for the playpen.* The task prompts re-presenting the relationship between the dimensions as they occur in the playpen context.

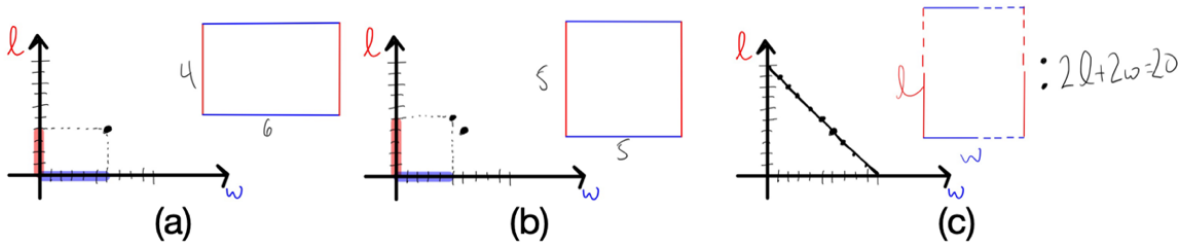

Figure 3. (a-b) Re-presenting paired magnitude states and (c) a sketched graph.

State reasoning involves understanding that each paired dimension is specific to a distinct, constructed playpen. The width and length magnitudes can change because of constructing a different playpen, with each state of paired dimensions being strictly dependent on the playpen one imagines constructing. The student might also understand the sum of playpen sides is 20 (e.g., $2w + 2l = 20$) at each state, and they might use this to determine dimensions at a state (e.g., choose $l = 5$ and determine w). Because the paired quantities are understood as dependent on a specific playpen, a student reasoning in this way produces a collection of points to capture each distinct playpen. They understand that each point captures a distinct playpen's paired magnitudes through the uniting of the axes-magnitudes re-presenting those quantities' magnitudes or values (Figure 3a-b). Having produced numerous points, they might also sketch a graph that captures a perceived visual pattern so that the graph captures every possible playpen (Figure 3c).

In the case of transformational reasoning, the person imagines transforming the pen from one state to the other; they have constructed a collection of playpens so that a playpen can be

produced by modifying another. The potential transformations a student might imagine are numerous, creative, and unpredictable. One involves imagining squeezing the pen in one direction while stretching it in another. An explicit image of length and width magnitudes are not sustained during such a transformation. Re-presenting such a relationship graphically is equivalent to that of state reasoning, except the person might imagine how the point may move for each transformation of the pen. A drawn graph conveys the appropriate path for that movement. Stopping the movement along a drawn graph creates a state in which they can determine the width and length pairs for that playpen. An image of the quantities' magnitudes and their covariation is not sustained during the movement.

Moore and Thompson (2015) introduced EGST with an eye toward graphs as emerging through quantitative schemes constrained by an invariant property in the quantities' covariation. EGST is not immediately relevant to state or transformational reasoning due to an absence of images of (co)variation. We perceive both forms to be compatible with Moore and Thompson's more general purpose of articulating EGST as a quantitative meaning (Moore, 2021; Moore et al., 2022; Moore et al., 2024; Thompson, 2011, 2012, 2013). The collection of points emerges from an individual's reasoning about paired quantities' magnitudes, their re-presentation, and (potentially) an invariant property constraining the pairs (e.g., constant perimeter). We thus characterize such actions as *non-variational quantitative meanings* for graphing.

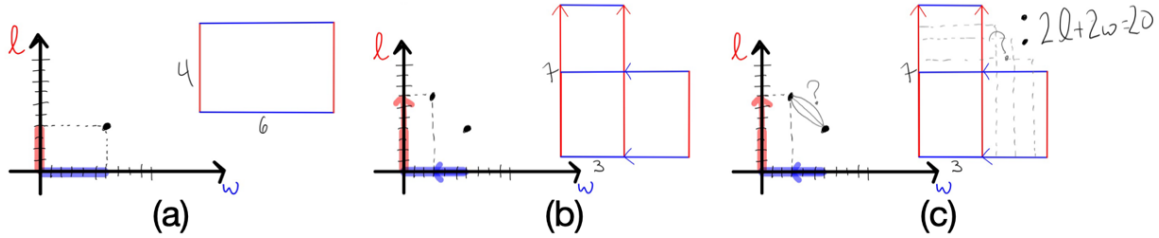

Figure 4. Re-presenting (a-b) paired magnitude states, (b-c) gross covariation, and (c) sketched graphs satisfying that gross covariation.

Gross (covariational) reasoning entails not only understanding that each pair of values corresponds to a constructed pen, but also that one pen can be conceived as a transformation from another pen through variations in the pen's length and width. Like above, a student reasoning in this way produces a collection of points to capture each state and they understand each point is a re-presentation of the state's paired quantities' magnitudes (Figure 4a-b). Differing from state or transformational reasoning, they also anticipate transforming from one point to the other via the quantities' covariation. For instance, they could reason about intervals of increase and decrease for the quantities that achieve the desired total variation amounts (Figure 4b-c). They could imagine these increases and decreases smoothly, and they might anticipate throughout the covariation that the quantities' total magnitudes at each state maintain the invariant property of a 20-foot perimeter. Because the quantities' covariation does not entail a quantified invariant property beyond (potentially) their resulting states maintaining the overall perimeter, the individual sketches a graph that results in that overall covariation. In doing so, they may or may not anticipate that the graph's emergence can occur in multiple ways to re-present that amount of variation between states (e.g., three possible graphs are shown in Figure 4c). Furthermore, the individual may or may not anticipate that, for whichever graph is accurate, the pen will transform in whatever way produces that graph (see dotted lines in Figure 4c representing an anticipated pen transformation). As with the previous forms of reasoning, having produced numerous points, a student might anticipate the sketch of a graph that captures a perceived pattern, the gross covariation, and a point for every state.

Both gross and quantified (covariational) reasoning involve determining invariant properties of covariation that constrain the transformation of the pens. With gross reasoning, the quantities' covariation within the two states is only constrained by achieving a total amount of variation. With quantified reasoning, an invariant property between the quantities' covariation is constructed so that one state can be transformed to another state in a way that additionally satisfies some property further quantifying the directional covariation. A student reasoning in this way might first produce one point re-presenting the pen's dimensions at some chosen state (Figure 4a from above). Then, they might use gross covariation and a conceived invariant property of that covariation to capture additional points or sketch a graph via re-presenting that property. An example of this is reasoning that the width and height magnitudes must covary such that any increase or decrease in width requires an equivalent decrease or increase in length, respectively (Figure 5a). For example, a width increase of 1 requires a height decrease of 1. The person's graph would then emerge as a result of coordinating the quantities' covariation under the constraints of that invariant property (Figure 5b). As with the road trip situation, a person could also reason that for successive, equal decreases in height, the width increases by a constant amount. A graphing action reflecting this might be the student denoting equal decreases in the height-axis magnitude and pairing that with equal increases in the width-axis magnitude. In either case, the individual might also consider how the invariant property in the quantities' covariation results in states that satisfy the invariant property of a constant perimeter.

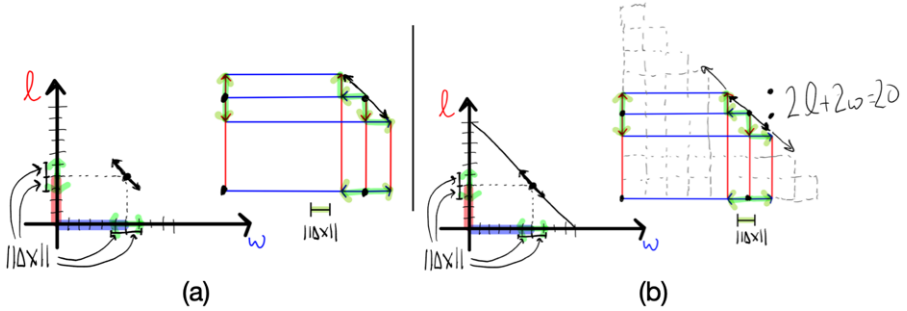

Figure 5. Re-presenting (a) quantified covariation and (b) a sketched graph constrained by that covariation.

All forms enable sketching a graph that captures states precisely. Using gross or quantified reasoning, an individual can construct a graph via EGST by first constructing points to capture snapshots and then sketching a graph that captures those states and invariant properties of covariation. Gross reasoning does not entail relative comparisons of variations, whereas quantified entails comparing variations between quantities (e.g., both quantities increase by the same amount) or within quantities (e.g., for equal increases in one quantity, the other quantity increases by decreasing amounts). With quantified reasoning, if the invariant property is quantified in terms of generalized properties (e.g., for a unit-magnitude change in quantity A, quantity B increases by 10% of its prior magnitude), then an individual can construct a graph via EGST strictly using one state and generating *all* other states using that invariant property.

A Brief Return to Informing Frameworks

We distinguish certain forms of non-variational reasoning from forms of QCR, and there are numerous connections to the frameworks within which we experienced the need to clarify these forms (Carlson et al., 2002; Thompson & Carlson, 2017). One need was introducing forms of reasoning that foreground magnitude reasoning. Whereas prior frameworks do not make magnitude reasoning explicit and often refer to or use numerical value, we describe our forms of reasoning with respect to magnitudes to be consistent with Thompson's (2014) emphasis on

magnitude-based QR. As a second need, we clarify distinctions between Carlson et al.'s (2002) directional and amounts of change reasoning. Gross reasoning can entail loose intervals of increase and decrease as well as identifying specified amounts of increase or decrease. The former is consistent with directional reasoning and the latter is consistent with amounts of change reasoning. Quantified reasoning is also consistent with amounts of change reasoning, but it makes explicit the coordinated comparison of amounts of change. To illustrate, gross reasoning includes understanding that as quantity A increases from 1 to 2 to 3, quantity B increases from 2 to 5 to 9. Quantified reasoning adds operations to compare these increases and conceive quantity B increasing by *increasing amounts* as quantity A increases by *successive constant amounts*. Thus, gross and quantified reasoning underscore important differences in how students can construct and reason about amounts of change. As a third motivating need for our forms of reasoning, Thompson and Carlson's (2017) framework foregrounds distinctions between images of variation, and specifically between chunky and smooth images (Castillo-Garsow, 2012; Castillo-Garsow et al., 2013). Our forms differentiate between reasoning that entails thinking of quantities as merely taking on different amounts (i.e., state and transformational reasoning) and that which entails explicit images of quantities' covariation (i.e., gross and quantified reasoning). Differences between smooth and chunky images are critical and relevant to each form of reasoning we identify, and we thus perceive our forms to complement those distinctions.

Closing

A question remains as to how an individual might conceive a drawn graph that connects the points they have produced through state or transformational reasoning. With both forms of reasoning, a student might conceive the drawn graph as capturing the infinite number of states that exist and maintain an invariant property among those states (e.g., constant fence amount and rectangular dimensions). In the case that a student has previously constructed and abstracted EGST meanings, the production of a graph via state reasoning can provide the source material for their constructing the quantities' covariation. For example, a phenomenon could be so physically and quantitatively complex that it is difficult for an individual to construct a covariational relationship within the phenomenon. They may instead determine paired values, construct an invariant property between the paired values or produce a substantial collection of them, and then sketch a graph. With the graph at hand, they could then engage in EGST to infer the covariational relationship between the quantities in the phenomenon. If compelled, they could then return to the phenomenon to judge the viability and further explore the relationship.

Having already constructed and abstracted EGST meanings, a student reasoning as above anticipates that in sketching their graph they are producing a trace constrained by covariational properties. What of a student who has not constructed and abstracted EGST meanings, but produces a drawn, continuous graph using state or transformational reasoning? Based on our work and the work of our colleagues (Byerley & Thompson, 2017; Moore, 2021; Moore et al., 2022; Moore, Silverman, et al., 2019; Moore, Stevens, et al., 2019; Thompson, 2013, 2016; Thompson et al., 2017), we are confident that without an explicit and persistent subsequent focus on quantities and their covariation, students are more likely to develop meanings rooted in indexical or declarative associations with mathematical facts (e.g., a line rising up-and-to-the-right means positive slope) than meanings stemming from QCR that can accommodate novel and unconventional situations. Without an explicit and persistent focus on quantities and their covariation, students are placed in a situation where they can associate the shape of a graph with capturing distinct paired values, invariant properties among those total values, and declarative facts, but the graph's emergence as an organic phenomenon between states is left unaddressed.

Toward a Framework of Caring Relations in Undergraduate Mathematics Education

Anne Cawley
Cal Poly Pomona

Megan Selbach-Allen
Harvard University

Introductory college mathematics courses remain significant barriers to persistence in STEM, especially for students from historically marginalized backgrounds. While recent reforms have emphasized pedagogical changes, relatively little attention has been paid to the social and emotional dynamics of these classrooms. Drawing on work from K-12 education, we argue that relational dimensions of teaching, such as care and cultural responsiveness, are essential for supporting equitable student success in undergraduate mathematics. This paper introduces a conceptual framework for understanding caring relations in college math instruction, using insights from research on warm demander pedagogy and sociocultural theories of learning. The framework centers on the instructor's dual role in challenging students intellectually while supporting them relationally. We offer this as a tool to guide research and professional development, aiming to expand how we define and study effective instruction in ways that humanize and affirm all students.

Keywords: Caring Relation, Mathematically Caring Relationship, Culturally Relevant Care

Despite many reform efforts, introductory college mathematics, especially developmental courses (e.g., intermediate algebra) and gateway courses (e.g., calculus), remain critical barriers for many students. These courses are characterized by high failure and withdrawal rates, and many students leave them with less confidence and a weakened sense of mathematics identity (Benken et al., 2015; Valentine, Konstantopoulos, & Goldrick-Rab, 2017). Developmental mathematics sequences, in particular, often derail students' academic trajectories, especially in community colleges, and disproportionately impact students from racially and socioeconomically minoritized backgrounds (Larnell, 2016; Mishra et al., 2025; Bailey, Jeong, & Cho, 2010). Research has also shown that subsequent courses for STEM majors (e.g., precalculus, calculus) continue to serve as barriers to progressing in their chosen field. Large national studies have shown that disproportionate numbers of students, especially women and underrepresented and minoritized students, leave STEM majors after struggling in calculus even with other indicators of adequate preparation (Bressoud et al., 2015; Ellis, Fosdick, & Rasmussen, 2016; Seymour & Hewitt, 1997).

Mathematics plays a unique role as a gatekeeper to STEM fields, which makes these patterns all the more concerning. Students who hope to pursue health sciences, engineering, or other quantitative fields are often stopped short, not because they lack interest or ability. They are hindered by confusing placement systems (Ngo, 2019; Park et al., 2021), an emphasis on procedural skills over conceptual understanding, or early classroom experiences that leave indelible marks on their mathematics identities. These hurdles disproportionately affect students who are marginalized in STEM, especially those who did not have access to high school calculus or who get misrouted by current systems (Sadler & Sonnert, 2018; Leyva et al., 2021a). These barriers are rarely just academic; they are relational and emotional too. Students who have long struggled in math often need to put in far more cognitive and emotional energy just to engage in the kinds of learning behaviors that support success.

Students' ability to engage in meaningful learning is tightly linked to their sense of belonging, prior experience, self-efficacy, and the ways in which they are invited into or pushed

out of mathematical communities. For students who have not historically felt affirmed in mathematics classrooms, engagement becomes even more difficult (Leyva et al., 2021a), and research has shown that providing caring and supportive relationships with students has had great impacts on their achievement (Battey et al., 2016). Without attending to how students feel, identify, and interact in these spaces, we may not be able to adequately support all students' successful mathematics learning (Boaler, 2022; Leyva et al., 2021b).

Affective and Relational Dimensions of Instruction

While reforms in undergraduate mathematics have focused heavily on pedagogy and cognitive engagement, recent work has begun to explore the affective and relational dynamics that shape student experience and success. A small but growing body of research suggests that instructor behaviors and classroom culture significantly influence students' sense of belonging, identity, and persistence, particularly for students from historically marginalized groups. Some studies have ventured to understanding how faculty relate to their students. In their study of a Real Analysis class, Bennett and colleagues (2025) examined how instructors viewed students and analyzed demographic disparities in course outcomes. They also included survey and interview data from students, who reported that their classroom experience was strongly shaped by how the instructor responded to their ideas and contributions. Selbach-Allen and Delaney (2025) presented a case study of a successful community college instructor who exemplified the traits of a warm demander (discussed in more detail later in this paper), a relational teaching model more commonly seen in K–12 education. They described how the instructor intentionally built personal relationships with students and engaged them in conversations beyond course content, demonstrating that he understood them as full people with goals and challenges beyond mathematics.

Students' experiences have also been analyzed in an attempt to understand what supports have been beneficial to them. Leyva and colleagues (2021a; 2021b) detailed racialized and gendered experiences of students in college math classrooms along with students' perceptions that these classes were intended to weed them out from STEM trajectories. Other work has shown that STEM mathematics students have indicated that mathematics professors and peers can impact sense of belonging to the classroom due to mathematical, racial, or gendered microaggressions (Cawley et al., 2023; Cawley & Wilson, 2024). Park (2025) explored female students' sense of belonging in college math classrooms, finding that small instructor actions, such as microaffirmations or microaggressions, had measurable impacts on students' perceptions of inclusion and emotional safety. In an analysis of student math autobiographies, Cawley and colleagues (2025), found that many upper-division students reported consistently positive math experiences, and those with more affirming experiences were more likely to reference instructors in their narratives, suggesting that supportive instructor-student relationships may play a defining role in how students perceive their mathematical journey. Stone-Johnstone (2025) studied a co-requisite support course for intermediate algebra and found that students described the class as warm, welcoming, and comfortable. They highlighted the instructor's responsiveness and demeanor as key to why they felt safe seeking help—often preferring her office hours to those of the primary course instructor.

While studies on belonging, identity, and student experience are increasingly visible, the field still lacks a cohesive framing of what instructors could and should be doing to improve students' social and emotional experiences in undergraduate mathematics classrooms. This gap between widespread attention to pedagogy and relative silence around relational dynamics points to a need for further development of theoretical tools that can help us name, study, and support

this work. The culture of a mathematics classroom is critically important—especially for students who are most vulnerable due to their demographic background or previous experiences with the subject. These students need environments where they feel supported, and instructors who can successfully encourage them, push them to work hard, set high expectations, and help them navigate the inevitable barriers that arise in the postsecondary learning process.

While at first glance an undergraduate mathematics instructor's job is simply to impart mathematical knowledge to students, the instructor also impacts the way a student engages with and sees themselves as part of the mathematics community. Also known as mathematics identity (Martin, 2012), the "dispositions and deeply held beliefs that individuals develop about their ability to participate and perform effectively in mathematical contexts" (p. 57) can impact a student's learning and engagement with mathematics. Research has identified that students' mathematics learning and identity has often been impacted by their previous experiences (Cawley et al., 2025), and that in many cases this is influenced by their instructors' beliefs, supports, and interactions (Andersson & Wagner, 2017). Mathematics trauma has also been identified to impact students resulting in a negative change in their disposition towards the subject, impacting their mathematical learning (Gunter & Gunter, 2023). General discourses around mathematics (e.g., "I'm not a math person", "mathematics is objective") can also impact a student's mathematics identity (Anderson, 2007). Instructors need to be aware of these possible experiences that are specific to mathematics and consider the power of their interactions with their students.

We argue that learning is a socio-cultural endeavor (Vygotsky, 1978), and that an instructor plays a large role in the way a student engages in their mathematics learning. That is, teaching mathematics content is not the only role that an instructor has—the instructor also nurtures and supports a student's mathematical development and sense of belonging. Evidence has shown that students need to be in an emotionally engaged state to be open to the processes in which we meaningfully learn (Immordino-Yang & Damasio, 2007). A student must feel enough trust in the learning environment to feel vulnerable enough to engage in deep learning (Delpit, 2013; Schonert-Reichl, 2017).

Notion of Care in Mathematics Education

We believe that undergraduate math instructors care about the work they do. We believe they care about their students and imparting mathematical skills to them. However, studies have shown that having high expectations about mathematical understanding alone is not sufficient to support students' mathematical learning and development (Lee et al., 1999). The notion of *care* has been discussed in relation to teaching and learning, and specifically in K-12 instructional spaces (Wentzel, 1997). Care is seen as a fundamental basis of humanity (Heidegger, 1927) and given the nature of teaching, Watson (2021) argues that teaching should be seen "as a caring profession…not only for nurturing intellectual subject-based development but also for the wellbeing of students" (p. 79). Care can be seen as both a virtue ("He is a caring person") or a relation (a relationship between two people; Noddings, 1999). Noddings (2002) contributed a theory of care in which both the teacher and the student participate, requiring reciprocity from both the teacher and the student. In her theory, a *caring relation* is one in which a teacher demonstrates care for a student(s), but one in which a student must show evidence that the care was received. The evidence by a student could be explicit (a smile or "thank you") or implicit (the student finishes a problem successfully or is eager to share a thought in their group; Noddings, 1999). This cyclical communication helps the instructor understand that care has been received, thus maintaining this relation. In this same way, it provides feedback to the instructor if

specific caring actions are not being received. Structuring *caring* as relational provides identities for both the cared-for and the carer.

Hackenburg (2010) extends Noddings' notion of a caring relation and defines a *mathematically caring relationship* "as a quality of interaction between a student and a teacher that conjoins affective and cognitive realms in the process of aiming for mathematical learning" (p. 237). Hackenburg (2005) argues that mathematics teachers may act as carers, but that they start "to act as mathematical carers when they work to harmonize themselves with and open new possibilities for students' mathematical thinking, while maintaining focus on students' feelings" (p. 47). This indicates that a mathematics instructor must have pedagogical content knowledge (Ball, Thames, & Phelps, 2008) to know and understand how to help students cognitively arrive at the learning outcome while also being aware of students' feelings. Finding that balance within each student (and a group of students) contributes to this caring relation in a mathematical way.

While Noddings and Hackenburg developed the ideas of care that can be envisioned within mathematics education, they do not attend to care in a critical way. In 1975, Kleinfeld attempted to address the issue of classroom instruction of Native Alaskan students who were placed with non-native teachers. In many cases, this pairing destroyed students' cultural identities in the name of "education". Kleinfeld did see examples, however, of teachers who were successful in building relationships with their students that utilized and respected cultural traditions, leading to successful learning outcomes. Based on her findings, Kleinfeld defined the notion of *warm demander*, which was a teacher who showed both personal warmth and also "active demandingess". That is, a warm demander shows care both in showing concern and attention to students in culturally relevant ways while also holding high academic expectations, demonstrating a belief that students can achieve such goals (Bondy et al., 2013).

In a different vein, Maloney and Matthews (2020) highlight two types of care in their work: transactional care and empathetic care. Transactional care is received by a student from an instructor who is a cheerleader, yet the instructor is not active with the student and waits for initiative from the student. Instructors who engage in transactional care may see students in a deficit mindset or as unmotivated if they do not initiate with the instructor. Instructors that exhibit transactional care demonstrate a care that is inert and a "one size fits all" care for all students, demonstrating that students are "cared about" but not necessarily cared for. The authors separate this from empathetic care, which is an active and constantly shifting care, in which the instructor sees students as complex beings and celebrates mathematical strengths while scaffolding mathematical weaknesses. Instructors who show empathetic care leave students feeling cared *for*, not just cared *about*. Maloney and Matthews found that students can sense the difference between these two types of care exhibited by their instructors, and that students who felt most connected to their math classroom were those with teachers showing empathetic care.

Considering the notion of warm demander and the value of empathetic care, we contend that a caring relation is also attuned to the identities of the student as well as the teacher, understanding that both identities can shape/influence that caring relation. In most considerations of care, "inadequate attention is given to issues of power" (Thompson, 1998), and therefore it is extremely important for an instructor to understand and develop awareness of their identity and inherent power as they demonstrate care for their students. *Culturally relevant care* is "characterized by a strong sense of community, rigorous demands, an integration of different cultures, and a general affirmation of one's humanity" (Watson, Sealy-Ruiz, & Jackson, 2016, p. 981). It extends beyond traditional care presented by Noddings (2002) in that instructors are "expected to recognize the inequities faced by students based on race [or other marginalizations]

and work to challenge them" (Watson et al., 2016, p. 985). Culturally relevant care requires an asset-based, justice-oriented perspective for students traditionally marginalized in the schooling system. Culturally relevant care "acknowledges the goal of justice to safeguard the rights of all students—to be respected and to be treated fairly" in which instructors need to have an understanding "of systemic, political, economic, and social structures that disproportionately appropriate opportunity according to race and a commitment to challenge and alter them" (Parsons, 2005, p. 26).

However, through the lens of culturally relevant care, what is seen as "caring" teacher behaviors can be easily misinterpreted as people show and interpret emotion, interest, respect, and body language differently in different cultures (Averill, 2012) and specific "caring" practices can be experienced differently by different students (Thompson, 1998). Cawley & Wilson (2023) describe mathematical microaffirmations as the subtle actions that can support students by affirming they belong in mathematics yet caution that some microaffirmations for students may be received as microaggressions due to these differences.

Because of this, we argue that the cyclical relationship in a caring relation is extremely important to consider. This feedback loop can help instructors to understand how their demonstration of care is being received and make subtle changes to ensure that students are receiving care in the way that supports them best. This means that an instructor needs to understand that caring relations with individual students will be uniquely different. It also implies that an instructor needs to be acutely aware of their identities (e.g., race, gender, language, educational background, etc.) and the way these impact the power dynamic within a caring relation. Being in touch with one's own identity can help bring perspective on the privileges and marginalizations that may exist within a caring relation.

Toward a Conceptual Framework of Care

This paper proposes a conceptual framework of a *caring relation* within the postsecondary mathematics classroom that attends to the theoretical perspectives above. Figure 1 shows a conceptual framework of care in an undergraduate mathematics classroom. A caring relation between an instructor and a student is cyclical and requires interactions from the instructor (the carer) and the acknowledgment of the caring actions by the student (the cared for), whether explicit or implicit. An instructor's interactions should be influenced by:

1) high mathematical expectations for the student which is informed by the instructor's pedagogical content knowledge (PCK) about the mathematics content being learned and for future mathematics content yet to be learned
2) reflection on their personal, cultural, and mathematical identities, bringing awareness to their privileges and marginalizations within the caring relation, acknowledging power dynamics as instructor
3) culturally relevant care in which the instructor learns about students' cultural and lived experiences and incorporates that into the classroom while also being apprised of current systemic, political, and social structures that may impact their students

In this conceptual framework, we see the instructor's caring interactions as malleable based on the three attributes above and that these attributes can be developed and refined both over time and on a student-by-student basis. While instructors cannot control how students respond or receive interactions, we believe that instructors can develop their interactions based on these attributes to shift and better attune care towards their student.

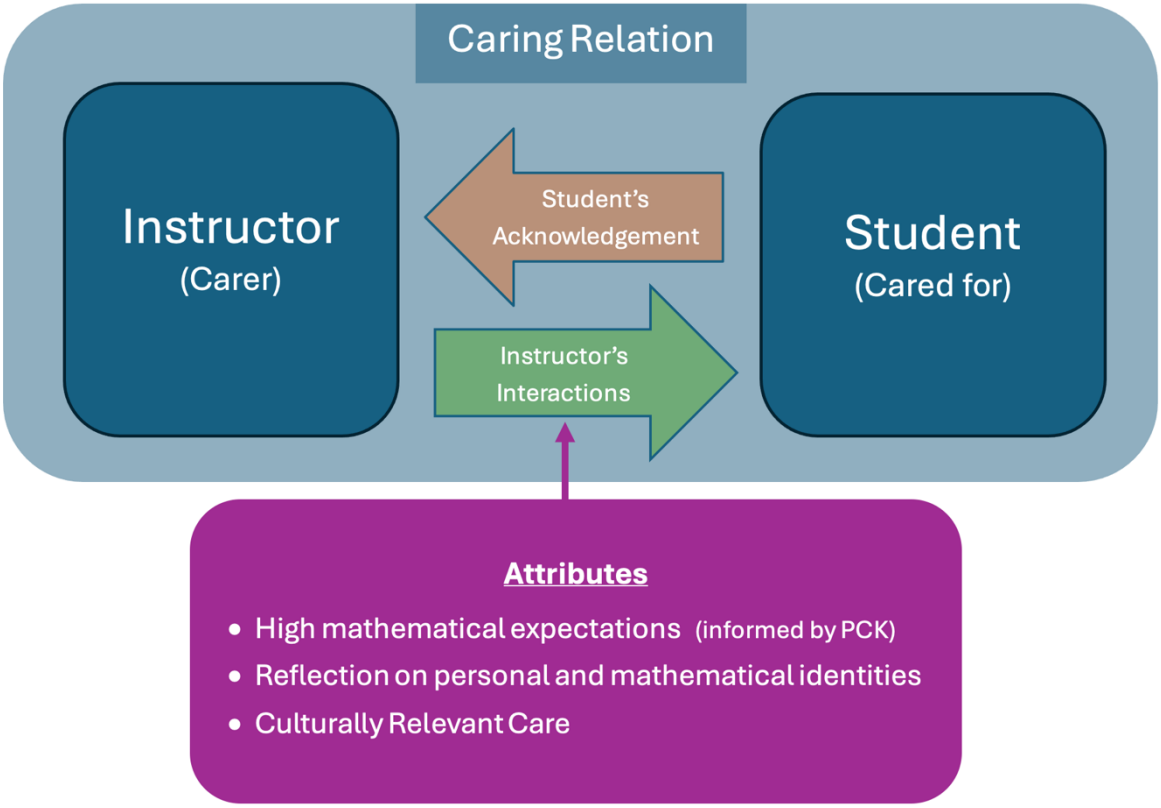

Figure 1. Conceptual Framework of Care in an Undergraduate Mathematics Classroom

So Why Does this Matter for College Mathematics?

We claim that colleges and universities are a unique environment in which to consider this work. College instructors often receive little or no pedagogical training when completing their graduate degrees (Robinson & Hope, 2013) and therefore may not have the skills and tools needed to engage with students. Providing a framework like this with attributes that can be considered in the effort to build a caring relation with students helps instructors to consider the different aspects needed to support a student. This is a unique setting also in that college students are generally adults who may hold different identities/obligations than the instructors. Instructors therefore are expected to enact care with fellow adults, which is seen as different than enacting care with children. College and university students usually hold more responsibility, life experience, and obligations than students in K-12 making it especially important to show sensitivity and culturally relevant care.

We posit that effectively communicating care and building caring relations with students is an important aspect of effective mathematics instruction at the undergraduate level. In a college setting students are transitioning to and expected to be independent learners. Their level of meta-skills to plan and attend to their own learning becomes increasingly important. These meta-skills are also often tied to affective factors that impact students' comfort with engaging with material or inclination to avoidance or procrastination. Higher education is also a choice – students make the choice to pursue college and so it is possible for students to drop out or stop out. Mathematics is well known to be a major reason why students either drop out, stop out, or change majors from STEM to non-STEM (Chen, 2013) and students sometimes struggle with the change from K-12 mathematics expectations to college-level expectations (Hernandez-Martinez,

2016). Students often carry mathematical experiences that impacted their sense of belonging in college mathematics, shaping their perspectives in mathematics and their ability to do mathematics (Cawley & Wilson, 2024). Therefore, mathematics instructors need to make concerted efforts to demonstrate care towards students.

We also have found in our experiences with professional development with community college and university mathematics faculty that the sense of care and concern shared in the aspect of instruction is most usually placed/emphasized on the *mathematical content*. This is often pushed by the urgent need to meet course outcomes and to prepare students with prerequisite material for the subsequent courses. Therefore, the attributes of care mainly focus on the mathematics content, and many times this can be done without pointed concern for the student or setting mathematical expectations that are both reasonably in a student's grasp. Our framework posits that it is simply not sufficient to care that a student "gets" the material (research has shown that students do not always carry forward prerequisite knowledge; Engelbrecht, Harding, & Du Preez, 2007) – students need to be seen and supported as who they are, and this requires more attention and intention. Some mathematics instructors teach with the hope that their students will see beauty in mathematics just like they do. However, it may take a long time for some students to warm up to mathematics as a field and feel confident and happy as a doer of mathematics. We believe that if a student has a caring professor who attends to these attributes in their interactions with students, students will be able to work on their dispositions towards mathematics. In fact, students tend to feel an obligation towards a teacher who acts as a warm demander even if they may not show interest in mathematics (Delpit, 2013). We see this as an intermediary step to bringing students into developing a better relationship with mathematics and shaping their mathematics identity to be one of confidence and positive disposition.

Conclusion

In this paper, we have argued that caring relations are an essential yet under-theorized component of effective undergraduate mathematics instruction. By synthesizing prior research on care, identity, and relational teaching models such as warm demander pedagogy, we proposed a conceptual framework that centers the instructor's role in building supportive and responsive environments for students. This framework underscores that care is not simply a personality trait or a passive orientation, but rather an active, culturally attuned, and pedagogically informed set of practices. We argue that such caring relations are especially important for students from historically marginalized backgrounds, for whom traditional mathematics instruction has often been alienating or exclusionary. Instructors who wish to support students' mathematical development must attend to their students' cognitive, emotional, and identity needs, not as separate concerns, but as deeply intertwined aspects of learning.

This framework offers a starting point for further research and dialogue. Empirical studies can explore how instructors enact care in varied postsecondary settings, how students perceive and respond to these actions, and what institutional structures best support this work. We also invite researchers and practitioners to consider how care interacts with issues of power, positionality, and discipline-specific expectations in college mathematics. By better understanding and enacting caring relations, we believe instructors can help more students persist, thrive, and reimagine their place in the mathematical community.

MATH-AI: An Integrated Conceptual Framework for Student-AI (LLM) Interactions

Katya Hernández Holliday
San Diego State University

With the rising popularity of generative artificial intelligence, particularly large language models (LLMs), it is imperative to understand how students are leveraging these rapidly evolving tools in their learning. Although researchers have begun to address issues of academic integrity, acceptance, and adoption, few conceptual frameworks exist for analyzing how students interact with LLMs in the context of mathematics problem solving. This paper introduces the MATH-AI framework, a synthesis of theories of metacognition, student agency, trust in automation, and human processing and regulation to examine how AI mediates math problem solving and potentially reconfigures the learning process. A case study of two students is provided to demonstrate the framework's application and illustrate distinct patterns of trust, processing, and self-regulation during AI-mediated mathematics problem solving. These cases highlight the potential risks and opportunities associated with LLM use and provide a foundation for future empirical studies and development of subject-specific AI guidelines.

Keywords: Undergraduate Mathematics, LLM, Artificial Intelligence, ChatGPT, Learning

Despite rapid adoption and integration of generative artificial intelligence (GenAI), especially large language models (LLMs), within higher education, little is known about how these tools shape cognitive processes during math problem solving. Influenced by institutional promotion and social normalization (Cialdini et al., 1991), many have come to view adoption of LLMs (e.g., ChatGPT, Google Gemini) as inevitable. Nonetheless, some worry about how prolonged use may interfere with skill development and learning (Nguyen et al., 2025).

While studies have addressed human-AI interactions within the university context, they often focus on issues of acceptance and adoption (Ivanov et al., 2024; Xu et al., 2025), academic integrity (Almisad & Aleidan, 2025), and perceptions among students and faculty (Tsiani et al., 2025). These studies provide useful insights about how individuals make decisions about how to use GenAI but do not address how such tools reconfigure student thinking and reasoning.

This paper proposes a framework for analyzing student-AI interactions with the aim of revealing conditions that support cognitive engagement and processes essential for learning math. While models of AI-human interaction typically center factors that influence adoption, perceived utility, or ethics, this framework highlights foundational academic practices such as studying, reasoning, and ultimately learning. We draw on frameworks from cognitive science (i.e., cognitive processing), educational psychology (i.e., self-efficacy, self-regulated learning), and human-computer dynamics (i.e., trust) to develop an interdisciplinary model for examining student-AI interactions during mathematics problem solving. By applying an interdisciplinary, empirically guided approach, this model serves as a conceptual tool for examining student-AI interactions and as a foundation for subject-specific, evidence-based AI use guidelines.

Theoretical Framework

Student Beliefs & Technology Adoption

Students who believe in their ability to learn often work harder, persist longer, and perform better academically (Bandura, 1997). At the same time, students hold different beliefs about their

abilities according to domain (e.g., math abilities vs. writing abilities). On a smaller scale, they gauge task-specific *self-efficacy*: whether they believe they can perform specific actions related to a task (Bandura, 1986; Pajares & Miller, 1995). Students with low *math* self-efficacy (Li et al., 2021) often exhibit higher levels of math anxiety, negatively impacting performance (Beilock & Maloney, 2015). In contrast, feelings of competence and autonomy have been linked to cognitive activation (e.g., attention, engagement, and thinking; Lu et al., 2022). Researchers have noted the important role teachers play in supporting students' task- and domain-specific self-efficacy by providing targeted feedback and guidance (Lu et al., 2022; Van der Beek et al., 2017). Open questions remain whether students prompt LLMs like ChatGPT in ways that result in such support, and whether they act on generated feedback during math problem solving.

Apart from beliefs about their own abilities, students' beliefs about chatbots' abilities may also influence use. Research on attitudes towards technology adoption suggests that positive attitudes often predict adoption and use (Ajzen, 1991). In the case of ChatGPT, students who hold positive attitudes extract more benefits by asking more detailed questions or experimenting with prompting strategies, leading to more productive uses than those who remain skeptical (Zhuang, 2025). However, students' trust in generated output can also enable overreliance. Theories of trust in automation describe over trust as a form of miscalibration whereby users rely on an agent to perform tasks beyond its capabilities. On the other hand, distrust often leads to underuse or disuse (Lee & See, 2004). Trust, therefore, guides reliance; a student who over trusts an LLM may override their own thinking/reasoning, uncritically adopting inaccurate output while students who avoid the tool may miss out on opportunities for support.

Cognitive Processing, Offloading, & Self-Regulation

Students' perceptions and beliefs manifest in how they engage both with concepts and tools during problem solving. Prompting LLMs may reduce memory demands by providing immediate information. Decreasing the working memory requirements of a task can reduce cognitive load (Paas et al., 2003), but the benefits of cognitive offloading (reducing cognitive demand by externalizing some part of a task) are contingent on whether offloaded demands are required to realize the learning goal (Risko & Gilbert, 2016). Offloading *mastered* procedures (e.g., arithmetic, symbol manipulation) may free cognitive capacity for conceptual reasoning, whereas offloading reasoning processes central to the learning goal may threaten learning.

To investigate when offloading supports or undermines learning, it is necessary to consider the types of cognitive processing students engage in during AI interactions. Craik and Lockhart (1972) differentiate shallow from deep processing where shallow processing consists of surface-level encoding (e.g., tending to appearance or sound), typically resulting only in short-term retention. In contrast, deep processing involves creating associations, facilitating long-term retention (McLeod, 2025). Between shallow and deep processing, the ongoing and sometimes incomplete process of self-explaining promotes integration of new information (Chi et al., 1994).

In addition to cognitive processing, students' capacity for self-regulation further shapes how they engage with LLMs. Self-regulated learning involves setting goals, monitoring one's own understanding, and adapting strategies in response to feedback (Zimmerman, 2000). However, unlike human instructors, LLMs do not provide formative feedback on students' progress toward conceptual understanding unless they are prompted to do so. Students must also monitor their progress while tending to the accuracy of output. Strong self-regulation skills can reduce uncritical acceptance of LLM output, while the lack of such skills may leave students vulnerable to over trusting tools and/or disengaging from problem solving altogether.

Practicing problem solving is a key aspect of studying mathematics. Studying, a key form of self-regulated learning, usually occurs without direct expert/teacher guidance, requiring students to rely on their own strategies or collaborate with peers. It often involves gathering and synthesizing information and usually results in the production of observable indicators of cognitive processing such as notes, annotations, or summaries (Winne & Hadwin, 1998). LLMs introduce a new dynamic; these tools can generate similar outputs, potentially reconfiguring how students approach studying. To understand this shift, it is important to examine the self-regulation strategies students employ when working with LLMs.

Potential Outcomes of AI Reliance During Math Problem Solving

Beliefs, patterns of use, and self-regulation determine the outcomes of students' interactions with LLMs. Depending on the quality of cognitive engagement, AI can support learning or pose significant risks including metacognitive miscalibration, changes in overall self-efficacy, and entrenchment of robust misconceptions. Recent reports (OpenAI, 2025) announce that ChatGPT has shown its strongest performance on academic tasks to date. As LLMs improve and grow in popularity, students may begin to treat them much like the internet, as general-purpose stores of knowledge. Studies have shown that internet searching can create the illusion of knowledge as individuals mistake access to information for a reflection of personal understanding, even in the absence of understanding (Fisher et al., 2015). These experiences may be further exacerbated by *metacognitive miscalibrations* where students overestimate their own knowledge (Lichtenstein & Fischhoff, 1977), and by new AI-specific challenges where students overestimate tool accuracy.

AI systems are designed to promote engagement, not challenge users (unless prompted to do so) and are more likely to reinforce assumptions embedded within prompts. Thus, an LLM is more likely to enable robust misconceptions if students interpret output as confirmation of understanding. Robust misconceptions are especially resistant to change and may become further entrenched rather than corrected in the absence of opposition (Smith et al., 1993).

Persistent reliance on LLMs may also influence math self-efficacy. If miscalibrations lead to overconfidence, lack of knowledge may be made apparent through formal assessments and academic performance. Furthermore, shallow forms of processing may become habitual through repetition. These risks can negatively affect students' learning outcomes and even their agency as they come to depend on LLM tools in ways that limit their abilities to regulate and sustain their own learning (Krook, 2025). Taken together, these constructs highlight the complex ways in which LLMs may interfere with cognitive processes and subsequent learning outcomes, providing a foundation to theorize student-AI interactions as part of the math learning process.

Conceptual Framework

As GenAI becomes increasingly present in educational contexts, we must clarify the cognitive and social processes students engage with when working with AI and identify frameworks that help math educators integrate these tools without undermining learning. Guided by these goals, the present framework emerged as a response to observations of students interacting with AI in ways that reflected less-than-optimal use. This framework is empirically informed by recurring patterns observed in interview data with undergraduates solving algebra problems with ChatGPT. Students in this study often operated in a space between having no strategy and having some relevant prior knowledge that *could* be activated. In these moments, ChatGPT enabled them to pursue solution pathways and eventually produce answers. However, interactions rarely resulted in advancements in conceptual understanding. Many students accepted output without fully integrating it with their own mathematical thinking. These

empirical insights illuminated the need for constructs that highlight levels of cognitive processing during AI interaction. They also underscored the need for interdisciplinary knowledge that captured students' self-perceptions, metacognitive monitoring, and sociocultural perspectives on tool use to describe the complex ways in which students navigate AI assistance/availability and their own cognitive faculties.

To capture the complex interplay between students' beliefs and perceptions, cognitive processes, and how these manifest in LLM use patterns, we propose the MATH-AI framework which encompasses five key dimensions: *metacognition*, *agency*, *trust*, *human processing/regulation*, and *AI mediation*. This framework integrates established constructs to address emerging challenges in mathematics education and offers a structure for educators and researchers to analyze use patterns and link them to potential benefits and risks. The five dimensions of MATH-AI are conceptualized as follows:

1. ***Metacognition*** refers to students' abilities to monitor and evaluate their own knowledge and performance. It captures how students assess their understanding during AI interaction, whether monitoring supports or undermines cognitive engagement.
2. ***Agency*** refers to students' sense of ownership/control over their learning. It is shaped by beliefs about their ability to learn and do math (self-efficacy) as well as their willingness and motivation to engage in the learning process. It captures students' orientations toward using AI (as a scaffold or a crutch). This is a dispositional construct that highlights whether students position themselves as active rather than passive in their engagement. Research has established connections between self-efficacy and motivation, yet little is known about how these are influenced by AI interaction. Early findings suggest a tendency of students to depend on AI, diminishing their agency (Darvishi et al., 2024).
3. ***Trust*** encompasses students' judgements about output reliability. Particularly, whether trust is appropriately calibrated to specific tasks or if it enables overreliance.
4. ***Human Processing & Regulation*** captures the cognitive/metacognitive moves students make during problem solving including the *depth* of cognitive engagement and the *regulatory* actions taken to monitor, evaluate, and adapt strategies (e.g., interrogating/verifying/seeking explanations). While agency reflects willingness and stance toward learning, processing and regulation describe enacted behaviors and strategies resulting from that stance. This construct draws attention to how students position AI in practice, as either a collaborator/scaffold or a shortcut to bypass deeper processing.
5. ***AI Mediation*** operates through all prior dimensions of the framework, highlighting the ways AI tools intervene in learning processes. For example, by offering scaffolds, feedback, or alternative representations or by encouraging reliance that diminishes agency and depth of processing.

These five dimensions are operationalized across three phases: input, interaction, and output. Inputs include students' preconceptions, beliefs and internalized views. Interactions encompass how students engage with ChatGPT, including prompting and verbalized processing. Outputs capture potential consequences of sustained patterns of use, including habitual cognitive processes, impacts on agency, and the risks/opportunities for learning. Each of the phases also incorporates a feedback mechanism consisting of students' reflections during and after AI use.

Students' self-efficacy (*input*) largely contributes to persistence, efforts to seek understanding, and the types of follow up questions they formulate. When working with AI, students with higher domain- and task-specific efficacy may be less likely to cede important

problem-solving actions to an LLM. Similarly, perceptions of tool efficacy influence attitudes, trust, and choices about whether and how to use such tools during math problem solving.

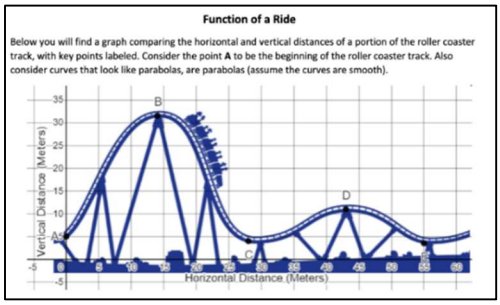
During AI *interaction*, students make decisions (perhaps subconsciously) about the depth of cognitive processing they engage in and their level of reliance. Importantly, a student may exhibit high levels of *productive* reliance. For example, using an LLM to generate practice problems, critique their reasoning, or explanations can promote self-regulation by helping students monitor their knowledge and discuss misconceptions. In contrast, reliance that offloads reasoning without verification may stall learning.

Sustained patterns of use may develop into habits that either support or threaten learning (*output* phase). Outcomes depend on prompting strategies and maintaining effort during problem solving. Over time, these outcomes can have lasting effects on students' broader sense of self-efficacy, metacognitive abilities, and ultimately student agency.

MATH-AI Framework Application

To illustrate application, we draw from a subset of data collected as part of a larger project investigating if/how students engage in productive struggle when working with ChatGPT. This subset includes undergraduates who completed an algebra task, Figure 1 during think-aloud interviews. Algebra was selected because it is a subject most undergraduates share prior knowledge/course experience in, unlike the other tasks involving statistics and calculus. During interviews, researchers encouraged students to share their thinking.

We present two contrasting cases not meant to represent generalizable findings but meant as illustrative applications of the framework and as a starting point for the development of subject-specific guidelines. Analyses are organized according to process order (input → interactions → outputs) to show how student beliefs may influence the ways they interact with ChatGPT and how these interactions can lead to specific outcomes.



(a)

1. What is the domain and range of the function?
2. Find the intervals where the function is decreasing and increasing. How did you know?
3. Where would you scream? Describe your ride as you travel the roller coaster. Include in your description your trip from point to point, whether you are moving up or down, and discuss what is happening to your speed.

(b)

Figure 1. Image Provided with the Roller Coaster Task (a) and the first 3 questions included in the task (b).

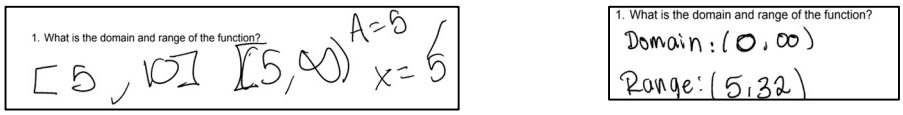
Case 1: High Trust, Shallow Processing

Despite expressing reservations, Participant 1 (P1), a food and nutrition major, described high behavioral reliance across coursework and a positive attitude toward ChatGPT for math problem solving: "I started using it because I saw how easy it was. You just put in the question …my friends were like, 'you don't use ChatGPT? Why?' I was just like, I don't know, I just don't like the cheating of it." P1's experiences are of particular interest because they show how LLM tools may be perceived as detrimental while simultaneously being promoted through social and institutional norms: "It made me lazy, I feel dumb. I don't feel like I'm learning…I don't think it's fair that [the institution] is pushing it on students…how do you expect students not to cheat if you're giving us ChatGPT?" P1's problem solving involved reading tasks, assessing their own knowledge, and prompting ChatGPT whenever they perceived a gap.

Inputs. P1 exhibited low self-efficacy both in general, as evidenced above, and across tasks: "I don't even know how to solve this…I haven't heard domain and range since high school so I'm asking ChatGPT to explain." Their positive attitude towards ChatGPT for math problem solving enabled a high level of trust, evidenced by unquestioned acceptance of generated outputs. When asked to explain their solution, they replied: "[ChatGPT] is giving me an example, the domain is -2 to 4 and it's saying that it goes upwards…so in this case it would be x = 5 because that's where it starts and then it ends at x = 4, in their case that's where it would end, and in my case I would say…x = 10 so I believe my domain would be that."

Interactions. Subsequently, P1 processed output only at a shallow level: "I'm just using their example to connect it to mine as much as I can." P1 did not monitor their own understanding or knowledge acquisition and ultimately did not identify and fix errors: "I honestly think it did a good job at [explaining domain and range] …I still don't fully understand…but it did help me understand just to solve the question." This reflection suggests that P1 did not actively participate in solving and instead ceded the process to ChatGPT. Poor performance coupled with high confidence in generated output resulted in miscalibration as P1 expressed high confidence in the solutions they provided, shown in Figure 2a, despite their inaccuracy.

Potential Outcomes. Sustained use of LLMs which follow this interaction pattern can lead to substantial detriment as users may repeatedly practice incorrect procedures that further entrench misconceptions and unproductive habits. In this case, shallow processing resulted in incorrect solutions and misconceptions without P1's awareness. More concerning than the incorrect answers, however, was the lack of evidence of developing conceptual understanding on topics the participant clearly expressed confusion about before interaction. P1 continued to struggle with domain and range after interacting with ChatGPT, despite having encountered these concepts in high school. This pattern illustrates how high trust combined with shallow processing can lead to miscalibration, potentially impeding the development of mathematical competence while also eroding students' broader sense of agency in their learning.



(a) (b)

Figure 2. Written Answer to Question 1 Provided by Participant 1 (a) and Participant 2 (b).

Case 2: High Trust, Deep Processing

Participant 2 (P2), a business management major, reflected on how ChatGPT has changed their approach to mathematics: "I remember, if I needed to do a math problem, looking it up on the internet and finding places where it didn't cost money…it would just be hard. I would always have to figure it out on my own." They also described how sustained AI reliance seemed to undermine their learning: "I'm not doing very well in the [math] class…at the beginning of the year, when I didn't understand stuff…I would just put it into ChatGPT…but now I'm trying a lot harder to do it on my own, so that I understand it for the final."

Inputs. P2 described low self-efficacy and high reliance. They also expressed efforts to shift away from dependence and toward building understanding. P2 described a high level of trust in ChatGPT, noting how easy it was to complete assignments by prompting the tool.

Interactions. P2 prompted ChatGPT for conceptual help, reflecting: "I always have to remember domain is this way [traces a horizontal plane] and range is this way [traces a vertical plane]," before prompting: "how to find domain and range." However, ChatGPT's lengthy,

decontextualized output caused frustration: "That makes no sense…I don't know how that helps me find the domain." Rather than abandoning the tool, P2 re-prompted with, "when looking at a graph with porabalas [sic]." P2 reflected on output: "this made me think about how to find it with numbers, so I said by actually looking at a graph" and exhibited deep processing, making connections both to real-world contexts and prior math knowledge:

> This [the right of the graph] has to connect with this [left end of the graph] eventually, right? It's not just going to be cut off…this has to come back to point A, which makes me feel like the domain is all real numbers…but a rollercoaster isn't infinite…obviously this is the end, so I feel like it has to stop here.

Potential Outcomes. P2 transitioned from frequent prompting to relying on their own thinking and integrated ChatGPT's examples with their own ideas: "If it's like the example, then the range is negative infinity to 32…but then there's the bottom of it [points to the bottom of the graph] …so I think it has to stop there." Although P2 struggled to interpret output, additional prompting enabled progress toward making sense of domain and range in the situated context of a rollercoaster. P2's written answer is shown in Figure 2b. Unlike P1, who relied on ChatGPT and shallow processing, P2 engaged critically with output. This pattern of use can support learning as students question their understanding and make connections to both prior knowledge and real-world contexts.

Discussion

The MATH-AI framework focuses on how meta/cognition, agency, trust, human processing, and AI interaction intersect to reconfigure the ways students approach common mathematics processes such as problem solving and studying. While this study was limited to two cases, it provides a foundation for empirical analyses to further extend and refine the framework, explore its applicability/comparisons across diverse student populations, and inform the design of interventions to guide students towards productive uses of LLMs for learning math. For example, a self-regulation framework informed by these analyses might prompt students to ask: Can I explain this concept without assistance? Can I solve a similar problem on my own?

To best support mathematics self-efficacy, self-regulation and cognitive processing, educators must intentionally promote productive uses of LLMs. Regardless of instructor views, AI is here to stay. The critical question now is how its mediation will shape students' dispositions and strategies for learning mathematics. As social-cognitive theories remind us, self-efficacy develops through mastery and regulation, while models of normative behavior suggest that students' beliefs about these tools may ultimately be overshadowed by widespread availability and adoption. At the same time, theories on cognition highlight the potential for LLM scaffolding and the risk of offloading essential cognitive processes. Together, these perspectives emphasize that the integration of AI in math education can lead to starkly different outcomes: either supporting learning or entrenching patterns of dependence that reduce students' opportunities for deep thinking and cognitive development. By applying the MATH-AI framework to research and teaching practice, educators can gain a deeper understanding of how to support mathematical thinking and learning in an AI-powered world.

Utah State University

In this theoretical paper, we build on prior frameworks on teacher knowledge and affect to propose a holistic framework for the competencies required for teaching modeling—a framework that integrates teacher competencies from both the cognitive and affective domains. We illustrate elements of the framework through the case of one secondary teacher's work from a modeling-focused professional development program. Finally, we describe the implications of our framework for researchers and educational stakeholders.

Keywords: mathematical modeling, teacher knowledge, affect, modeling competencies

Mathematical modeling (hereafter referred to as modeling) is the process of using mathematics to describe and make predictions about real-world situations. As modeling has increased in popularity across K-16 education, the modeling education field has developed numerous programs to help educators effectively teach modeling. For example, over the last two decades, research programs have designed modeling-focused professional development programs for teachers (e.g., Jung & Brady, 2016), investigated the competencies required to teach modeling (e.g., Borromeo Ferri, 2018; Greefrath et al., 2022; Wess et al., 2021), and introduced mathematical modeling in teacher-education programs (e.g., Anhalt et al., 2018). However, this research has predominantly focused on the knowledge required for teachers to teach modeling from a cognitive point of view and often emphasizes a pedagogical perspective (over a subject matter perspective). Yet, to develop a framework that provides a "complete picture" of the competencies required to teach modeling, there is a need to include both cognitive and affective perspectives (Thompson, 1992).

Chamberlin (2019) stated that modeling, cognition, and affect are intertwined with one another, and he proposed a theoretical framework that connects these three constructs. According to his framework, there is an interrelationship between cognition, affect, and modeling where each element influences one another and are in a continuous positive feedback loop with one another. That is, according to Chamberlin's (2019) framework, to successfully model, one needs to engage in successful cognitive and affective processes. Similarly, we contend that to *teach* modeling successfully, a teacher should acquire both cognitive competencies (i.e., knowledge for teaching) and positive affect (i.e., affective competencies required for teaching). In this theoretical paper, we propose a framework for the competencies needed for teaching modeling that combines both knowledge (cognition) and affective perspectives for *teaching* modeling. In light of this goal, we first provide the relevant background that supports the development of the framework. Next, we provide illustrative vignettes of the framework components using data from a secondary teacher, Olivia (pseudonym). Finally, we highlight the implications of our proposed framework for the modeling teacher education community.

Background

The Knowledge Domain

Several frameworks have long shaped research on teacher knowledge and competencies for teaching mathematics. For example, Shulman (1986) categorized teaching mathematics content knowledge into subject matter knowledge (SMK) and pedagogical content knowledge (PCK). Building on Shulman's (1986) work, Ball et al. (2008) presented a Mathematical Knowledge for Teaching (MKT) framework by unpacking SMK and PCK into more fine-grained domains. These include common content knowledge (CCK), specialized content knowledge (SCK), knowledge of content and students (KCS), horizon content knowledge (HCK), and knowledge of content and teaching (KCT). CCK refers to the general mathematical knowledge, not specialized or unique to teachers. SCK pertains to technical knowledge unique to teaching (e.g., looking for patterns in students' errors). KCS represents teachers' understanding of how students think and learn and the ability to anticipate what students find confusing or engaging. Teachers' awareness of how mathematical topics connect across the curriculum and discipline is associated with their HCK. Finally, KCT combines mathematical knowledge with teaching practices like sequencing content and identifying suitable instructional methods (Ball et al., pp. 399–403).

Although Ball et al.'s (2008) framework offers important foundations for mathematical teaching, few frameworks have described the additional demands required for teaching modeling. For example, Borromeo Ferri and Blum (2010) proposed a framework for the competencies required for teaching modeling. Their framework proposed that teachers of modeling should acquire skills along four dimensions: (i) theoretical (i.e., knowledge about modeling cycles, and modeling), (ii) task (i.e., knowledge about modeling tasks), (iii) instructional (i.e., knowledge about implementing modeling tasks), and (iv) diagnostic. Building on this framework, Wess et al. (2021) presented modeling-specific PCK by outlining four facets of knowledge: (i) knowledge interventions (i.e., ability to apply adaptive strategies and to assess their effect on learners' solution process), (ii) knowledge about modeling processes (i.e., competencies of diagnosing students' modeling phases), (iii) knowledge about modeling tasks (i.e., the skills in understanding modeling task characteristics and analyzing and developing them), and (iv) knowledge about modeling aims and perspectives (i.e., knowledge of modeling cycles and their suitability for various purposes in classrooms).

The Affect Domain

Although the interconnection between affect and cognition remains debated, affect is generally considered as consisting of the "non-cognitive aspects of human thought" (Hannula, 2012, p. 137). Research on mathematical affect takes various perspectives (Chamberlin, 2019), but the most prominent of these perspectives is McLeod's (1992) three-dimensional framework for affect. The framework comprises emotions, attitudes, and beliefs, with beliefs representing the most cognitive component and being less amenable to change (see Table 1 for the definitions). Di Martino and Zan (2011) proposed that attitudes function as a bridge between emotions and beliefs. Consistent with this view, DiMartino and Zan (2011) proposed a framework for attitude where emotional disposition, vision of mathematics, and perceived competence were included. In Di Martino's and Zan's (2011) framework, emotional disposition is defined as one's likes/dislikes towards mathematics, vision of mathematics is conceptualized as one's beliefs and values regarding mathematics, and finally perceived competence is conceptualized as "perception of being/not being able to succeed in mathematics (Di Martino & Zan, 2011, p.476).

Table 1. Definitions of emotions, attitudes, and beliefs, directly taken from Phillip (2007, p. 250).

Emotions	Feelings or states of consciousness, distinguished from cognition. Can be positive or negative.
Attitudes	Manners of acting, feeling, or thinking that shows one's disposition or opinion. Can be positive or negative.
Beliefs	Psychologically held understandings, premises, or propositions about the world that are thought to be true. Beliefs are more cognitive, are felt less intensively, and are harder to change than attitudes.

While students' mathematical affect has been studied through varied conceptualizations, research on teachers' mathematical affect is still emerging. Phillip (2007) notes that while beliefs are considered part of affect in research, they are treated as a distinct construct in studies on teacher affect. Research on teacher affect has documented that teachers' mathematical attitudes inform their mathematical beliefs and in turn instructional practices (Charalambous, 2015; Wilkins, 2008). At the same time, research has also documented that teachers' attitude towards mathematics plays a role in students' attitude towards mathematics (Mensah et al., 2013), and ultimately students' mathematical performance (Ma & Kishor, 1997). Thus, teachers' affective competence is an integral part of students' mathematical (modeling) learning. The takeaway is therefore two-fold: (1) teachers' positive affect correlates with positive teaching and learning outcomes, and (2) frameworks for modeling (and mathematical) knowledge required for teaching should consider both knowledge and affective domains to provide a holistic understanding of the competencies needed to teach modeling.

Conceptual Framework for the Competencies Required to Teach Modeling

We integrated theories (Prediger et al., 2008) of teacher knowledge (Ball et al., 2008; Borromeo Ferri & Blum, 2010; Wess et al., 2021) and affect (Di Martino & Zan, 2011; McLeod, 1992) to propose a framework for the competencies required for teaching modeling (Figure 1). The framework proposed in this paper consists of two major *domains*: knowledge and affect. At the core of this framework is the knowledge perspective. Surrounding the knowledge domain lies the affective domain (in green), which is influenced by the knowledge domain. The positions of the affect and knowledge domains were inspired by Mandler's (1989) work, highlighting that one's actions (based on their knowledge) result in affective responses.

The knowledge domain is further divided into *dimensions* (i.e., subject matter knowledge for modeling (SMK-M) and pedagogical content knowledge for modeling (PCK-M)) and *components* (theoretical knowledge, curricular knowledge, instructional knowledge, and assessment knowledge). This framework combines modeling knowledge for teaching with modeling specific perspectives of teacher expertise to teach modeling effectively. We adapted Ball et al.'s (2008) categorization of mathematical knowledge for teaching to modeling. SMK-M refers to the understanding of the modeling process and the mathematical content that teachers must possess to guide students through the modeling process. PCK-M refers to the knowledge required to effectively implement modeling in the classroom and diagnose students' modeling. Within SMK-M, we situate *theoretical knowledge*—knowledge about modeling cycles, modeling tasks and their suitability for various purposes. Both horizon modeling knowledge (HMK) and mathematical common content knowledge (CCK) impact teachers' knowledge of mathematics that then influences how they engage with and make sense of modeling, whether it involves applying basic mathematical fluency (CCK) or understanding broader mathematical connections across topics and levels (HMK).

We positioned *curricular knowledge* as the blending (Fauconnier & Turner, 2003) of SMK-M and PCK-M, as it draws on both concepts. It represents a bridge where teachers' knowledge of modeling intersects with their ability to transform that knowledge into meaningful learning experiences through modeling tasks. This overlap justifies its position in the framework. Knowledge about modeling task characteristics encompasses the theoretical perspectives underlying modeling task design. Similarly, *knowledge about content and curriculum* (KCC) and *specialized content knowledge for modeling* (SCK-M) are also situated within curricular knowledge as both require an understanding of mathematics and the ability to situate that in curricular structures. Teachers must know how modeling fits into the broader mathematical curriculum (SCK-M) and align with the content standards (KCC).

Instructional knowledge belongs in PCK-M because it is about transforming content knowledge about modeling into effective teaching practices. *Knowledge about intervention* requires pedagogical decisions on how to guide and support students during modeling tasks. On the other hand, *knowledge about modeling and teaching* focuses on teaching modeling in ways that foster mathematical understanding. Both components go beyond just knowing modeling to how to teach it, both as a vehicle and as content. Finally, the *assessment knowledge* in modeling refers to the teachers' knowledge of modeling, alongside their ability to anticipate and interpret the ways students are likely to approach modeling tasks. This knowledge enables teachers to better diagnose students' understanding of the modeling process as they go beyond grading answers to truly assess students' modeling competencies and learning of modeling.

To develop a framework for the affective competencies required for teaching modeling, we drew on McLeod's (1992) framework for affect. Specifically, we asked what are some qualities that are required for teachers to have a positive disposition towards teaching modeling (Jacobson & Kilpatrick, 2015)? We identified the following: (1) constructive emotional dispositions towards modeling, (2) constructive orientation (i.e., positive attitudes) towards teaching modeling, (3) positive perceived competence in modeling, and (4) optimistic vision (i.e., positive beliefs) towards modeling. Constructive emotional dispositions towards modeling refer to positive emotions and attitudes that teachers develop to meaningfully engage in the teaching of modeling. Constructive orientation towards teaching modeling refers to attitudes that promote modeling in the classroom environment. Positive perceived competence in modeling refers to teachers' confidence in tackling modeling tasks. Finally, an optimistic vision towards modeling is having a positive outlook on the broader impacts of modeling on the individual, community, and societal level.

Illustrative Vignettes from Olivia

To describe components of our framework, we drew from one secondary teacher's (Olivia) participation in a modeling focused professional development (PD) program. The overarching goal of the PD program was to develop teachers' proficiency in teaching modeling at the secondary level. A total of 24 secondary teachers (grades 6-12) participated in the PD program. As part of the PD program, Olivia engaged in seven modeling tasks (which consisted of solving and reporting the solution through formal and informal reports), submitted seven task reflections regarding her experiences working on the tasks, designed three modeling tasks, implemented one modeling task in her own classrooms (grade 9 and 10), and submitted a final report reflecting on her experience designing and implementing the task. These sources serve as illustrative vignettes for describing the functionality of our framework. Given space constraints, we present a selection of competencies and will elaborate on others in our talk.

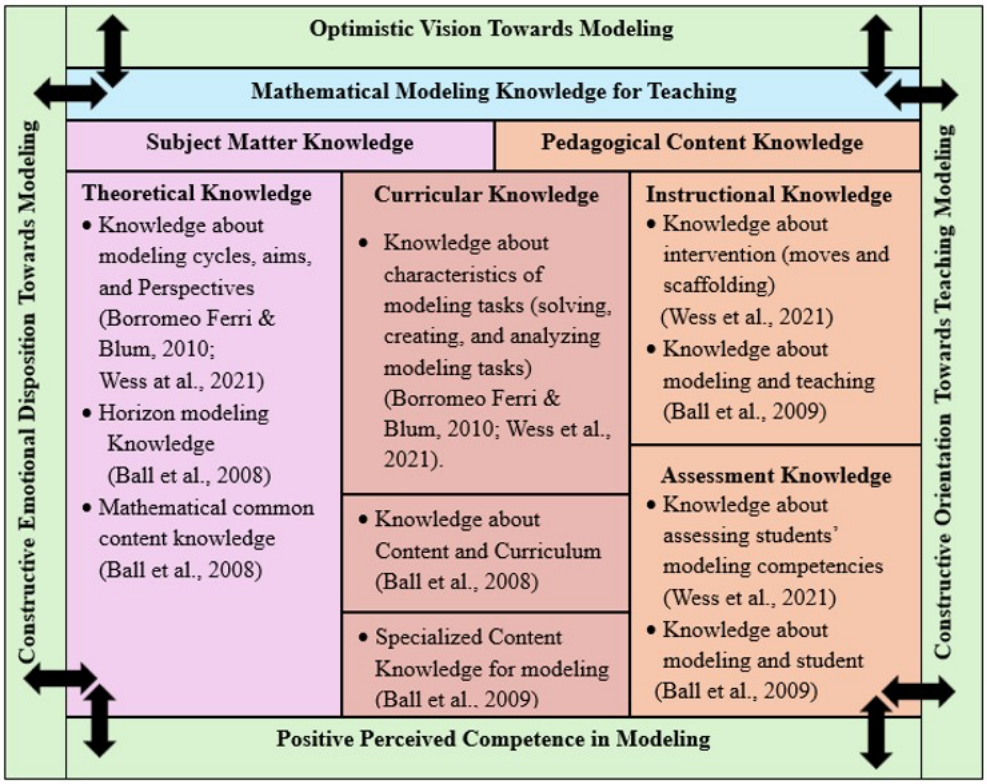

Figure 1. Competencies required for teaching modeling

Knowledge about Characteristics of Modeling Task

Olivia developed the *Eliminating Bottles* task (Table 2), which exhibited robust integration of both modeling task characteristics and socio-ecological awareness. The task exhibited the following task principles: (1) alignment with content standards, (2) learner-centered, (3) model development, (4) model documentation, and (5) reality principle (Aguirre et al., 2019; Galbraith, 2006; Jung et al., 2023; Lesh et al., 2000). First, the task was connected to the state's grades 9-10 content standards, such as surface area and volumes, ensuring that while students address broader social issues of plastic waste prevention, they would also meet formal curriculum standards. The task is learner-centered as the students were given the agency in making assumptions, creating a model, and interpreting the results in meaningful ways. Olivia's understanding of task characteristics also influenced her expectations for the task. For example, Olivia explicitly stated and collected students' poster reports that included the problem statement, assumptions, model formulation, validity, and improvements, addressing the model documentation principle. Finally, the task exhibited the reality principle through drawing on real-world issues of plastic waste that support students' socio-ecological awareness—a critical component of modeling tasks.

Table 2. Olivia's Eliminating Bottles task prompt

The Natural Resources Defense Council claims that 20 billion plastic bottles are thrown away each year. To reduce plastic waste, many public spaces are installing bottle filling stations to encourage the use of reusable water bottles. Develop a procedure to calculate the amount of plastic the [institution name] filling station has eliminated based on the reported number in the photo. Relate this measurement to something you are familiar with by describing how much space the plastic would cover (e.g., number of football fields, gym courts, etc.,).

Knowledge about Intervention

Olivia's knowledge about intervention was evident in her modeling task implementation report, where she documented her strategies to support students' understanding of the modeling process. For example, Olivia cited using several intervention strategies, including probing students' thinking when she felt that the students were stuck, incorporating contingent scaffolding or breaking tasks into smaller chunks for diverse learners, monitoring student work, facilitating small group interactions through the use of pocket questions (ready-to-use questions), creating groups based on her (Olivia's) knowledge of students, providing manipulatives for collecting data, and offering extension activities for those who finished early. These instructional approaches demonstrate Olivia's ability to design targeted interventions for implementing modeling tasks in her classroom.

Knowledge about Assessing Students' Modeling Competencies

Olivia assessed students' modeling competencies using an assessment rubric that evaluated specific stages of modeling cycles. The rubric reflected the modeling stages that Olivia prioritized and that she expected students to understand. These include making sense of the problem, assumptions and model creation, data collection, validating, and communicating the process clearly. She also added a quantifying description (Figure 2) to each modeling stage to communicate her expectations and provided fair feedback on students' work to support students' model development. Prior to students engaging in the task, Olivia shared the rubric and reviewed both the rubric and project expectations with the entire class, ensuring that the assessment process was open and transparent (Assessment Standards for School Mathematics, 1995). In addition, Olivia also diagnosed students' blockages informally as she walked around the class and listened to students' conversations, which supported Olivia's contingent interventions.

Modeling Task Rubric

	Excelling	**Progressing**	**Emerging**
Make Sense of Problem	Problem statement and conclusion are both made in context. Objective of the solution is identified. **30**	At least one, either the problem statement or conclusion, is made in context. The objective of the solution is not clearly identified. **20**	Problem statement and conclusion are identified but lack context. **10**
Assumptions and Model Creation	All assumptions listed are justified or based on background knowledge. All assumptions made are utilized in the model. **50**	One or more assumptions made lack justification. OR Not all assumptions made were necessary for the model. **40**	At least one assumption is listed but lacks justification. OR Model lacks evidence of use of assumptions. **30**

Figure 2. Excerpt of Modeling Task Rubric Developed by Olivia

Constructive Orientations Towards Teaching Modeling

Olivia demonstrated multiple constructive orientations towards teaching modeling in her task reflections and implementation reflections. For example, in her implementation reflection, she expressed that she wanted to challenge herself in implementing more modeling tasks in her classroom due to the overwhelming engagement she received from her students. She also expressed that implementing modeling tasks can be interdisciplinary. This idea is evident in her task reflection, where she reflected that if she were to implement modeling tasks with historical contexts, "[she] likes the idea that [she] could work with the history department and create a lesson that ties in with [the history department] and can integrate history into [her] classroom and mathematics into theirs." In other constructive orientations, Olivia provided guardrails for

students who may struggle with open-ended questions and designed modeling tasks that draw on students' personal interests, mathematical experiences, and local community-based knowledge to support mathematically rich discourse.

Positive Perceived Competence in Modeling

Through her engagement with the modeling tasks in the first part of the PD program, Olivia developed confidence in her modeling skills. For example, in her modeling task reflections, Oliva made statements such as "I think in the future I will be less afraid to create multiple models knowing that I will eventually adjust them to make them fit the task better," "I am gaining more confidence in my ability to attack these modeling tasks. I'm becoming more eager to attempt them, and I am realizing that I can be very creative in how I approach problems," and "I am impressed with my ability to clearly explain my processes and procedures in context and effectively discuss the applications my model has to the real world." These statements demonstrate her positive perception of her ability to model, which in turn has an impact on how she may teach modeling.

Discussion

The framework presented in this paper advances the holistic understanding of competencies required for teaching modeling by positioning cognition and affect as inseparable domains (Chamberlin, 2019). On the cognitive side, teachers require both SMK-M and PCK-M for teaching. On the affective side, teachers require positive emotions and attitudes, together with confidence in tackling and promoting modeling with an optimistic vision of its broader impact on learners and society. We argue that competencies along both domains must co-exist for teaching modeling successfully. This is because teachers with strong pedagogical content knowledge may avoid implementing modeling tasks if they lack self-efficacy in their own modeling competencies or in addressing students' difficulties during modeling. Conversely, teachers with positive affective orientation but with limited cognitive resources for modeling knowledge (Hammer, 2000) may struggle to design and implement modeling tasks effectively.

The integration of cognition and affect in our framework has several implications for teacher education in modeling. First, the design of PD programs can foster teachers' positive attitudes towards modeling and teaching modeling by incorporating tasks with various educational, cultural, and societal contexts that are equally challenging but also feasible at the same time. This PD environment will provide opportunities for teachers to (i) experience struggling in tasks in a productive manner and to (ii) appreciate the utility of modeling in describing and predicting real-world issues. PD programs can also consider incorporating book studies and journal reflections, where teachers are continuously encouraged to reflect on their learning both as a modeler and as an educator of modeling. Second, teachers' growth in modeling competencies for teaching should be assessed through both knowledge and affect domains. Evaluators can leverage tools such as longitudinal cross-sectional analysis of focus group interviews (Tuthill et al., 2020), and pre-post surveys of modeling specific attitudes (e.g., Asempapa & Brooks, 2022), to track changes in teachers' affective orientation towards teaching and learning of modeling. Finally, researchers may use the framework both to inform the design of modeling-specific PD programs and data collection, and to undertake empirical validation through its application to data. This work contributes to the fields of teacher education and modeling by challenging the prevailing emphasis on PCK for modeling. We argue that attention must also be given to *what* teachers need to know as *learners of modeling* and *how* teachers should *feel* towards the teaching and learning of modeling for its successful implementation in K-16 classrooms.

Interrogating Proof Norms: "It's kind of like telling me, 'Oh, act like a robot.'"

José Saúl Barbosa
Michigan State University

Kristen Vroom
Michigan State University

We draw on poststructuralism to interrogate assumptions of what counts as "normal" in proof. Guided by post-qualitative inquiry, we share moments from an unstructured interview with an undergraduate student, Sherine, alongside research literature to question two dominant proof norms: depersonalization and the absence of the problem-solving process. Our interrogations reveal how proof norms potentially reinforce messages that exclude relationality, storytelling, and emotional connection from the proof process, as well as newcomers to proof who benefit from seeing the nonlinear process of problem-solving. We argue for broadening what gets recognized as legitimate proof, where proofs can be both formal and personal, polished and messy, logical and human.

Keywords: Poststructuralism, Proof, Norms, Values

We invite you to read two proofs for the divisibility property: for all integers m and n, if $a \mid b$ and $a \mid c$, then $a \mid (mb + nc)$ (Figure 1). You, like others we have shared these with, might notice that the proof on the left feels like a "normal" proof[1] whereas the proof on the right feels unusual[2]. You might catch glimpses of my (the proof author - Saúl's) personality and uncertainties. I hope you feel a sense of connection between us- me and you (the reader).

By assumption, there exist integers k_1 and k_2 such that $b = k_1 a$ and $c = k_2 a$. For any integers m and n we have $mb + nc$ $= m(k_1 a)$ $+ n(k_2 a)$, by assumption, $= (mk_1 + nk_2)a$. Thus, $mb + nc$ is divisible by a.	My goal is to show that a divides $mb + nc$. To me, this means that I can write $mb + nc = ka$ where k is an integer. I'm really not sure how I will get there but I'll start with what I know. Since I know that a divides b, then I know that there must be an integer r so that I can write $b = ra$. Since I also know that a divides c, then I also know that there must be an integer s so that I can write $c = sa$. Hmm. It might sound a bit repetitive, but I like to keep track of where I have been to help me with where I'm going. Next, I will consider m and n to be integers. Since $b = ra$ and $c = sa$, I can substitute them in $mb + nc$ and write $mb + nc = m(ra) + n(sa) = mra + nsa$ Haha. N. S. A. Acronyms make me laugh for some reason. Anyway, I can see that I can factor out a from $mra + nsa$ so I can also write $mb + nc = (mr + ns)a$. It's not looking how I want yet but maybe I need to review my goal. My goal is to write $mb + nc = ka$ with k being an integer and that is not what I see. Wait! m, r, n, and s are all integers so $mr + ns$ is also an integer! I'm going to define k to be $mr + ns$ and say $k \coloneqq mr + ns$. Nice, nice, nice! I think I'm getting to where I want to be! Since $mr + ns$ is an integer, then k is also an integer because it is equal to $mr + ns$. Now I can write $mb + nc = ka$! I've reached my goal! This means that a divides $mb + nc$! #That'sShowbiz!

Figure 1. A "normal" proof, and a personalized proof

Entering this project, we (Saúl and Kristen) began feeling uncomfortable labeling the proof on the left "normal". Our experiences working with students and reading mathematics education literature suggested that what is typically considered "normal" in proof may not resonate with all learners, and that some students might find value in proofs that depart from these expectations.

[1] You can find this proof in Houston's (2009) textbook: *How to think like a mathematician: A companion to undergraduate mathematics*.
[2] I (Saúl), did in fact breach proof norms (Dawkins & Weber, 2017)!

For instance, Brown (2018) shared an example of a student who personalized a justification for the role of axioms in proof using culturally familiar language like "ese" and "holmes." Vroom and Alzaga Elizondo (2024) found that students appreciated existence proofs that included the author's problem-solving process, suggesting that such transparency offered a more relatable view of proving. Weber and Melhuish's (2022) observations further underscored our concerns: "The way to be 'good' at mathematics is, at least in part, to emulate the language, argumentation, and culture of mathematicians" and "deference to the discipline of mathematics (as conceived largely by a select few Western, white men) is likely to reinforce existing power differentials inherent in the system" (p. 307). In what ways, then, does this "normal" proof reinforce those dynamics? In this work, we draw on poststructuralism to interrogate taken-for-granted assumptions about what counts as a "normal" proof and whose ways of knowing it centers.

Poststructuralism: An Interrogation Lens

Rather than treating proof as universal and neutral, we understand it as embedded in particular institutional and cultural norms that govern who and what counts as mathematically legitimate. From a poststructuralist perspective, "truth" in mathematics is not fixed or discovered in isolation from people; instead, it is discursively created through language, practices, and social expectations for mathematical activity (Foucault, 1980).

Identifying mathematical proof discourses is no small task; discourses are so deeply embedded in practice that they often go unnamed. We appreciate Dawkins and Weber's (2017) work, which surfaced some taken-for-granted expectations through an extensive literature review where they identified different *norms*, or accepted expectations for practice, and *values,* or shared goals or orientations, in the context of proof. One such value, which we will continue to interrogate, is *independence from the author* – or that "mathematics knowledge and justification should be independent of (non-mathematical) contexts, including time and author" (p. 129). Two norms that uphold this value are the *depersonalization* norm – "mathematical proof is written without reference to author or reader's agency" (p. 129) and the *absence of problem-solving* norm – "a proof is an autonomous object, not a description of a problem-solving process" (p. 130). This means that a "normal" proof, for instance, avoids the pronoun "I", and authors' personas are concealed along with how they came to understand the argument.

Gee's (1989) framework on *primary* and *secondary discourses* helped us conceptualize how students might experience these norms. Primary discourses are developed in everyday settings through interactions with family, friends, and cultural communities, while secondary discourses are those required to engage in institutional spaces. Mathematical proof discourses (e.g., the norms and values of proof) are secondary discourses. Participating in proof may feel natural or comfortable for students whose primary discourses align with these academic expectations. But it might feel unnatural for others whose primary discourses do not align as much. This discomfort reflects a mismatch between proof discourse and the discursive practices students bring with them. This is *not* a deficit in the students, but a narrowness in the dominant norms.

Researchers studying the teaching and learning of undergraduate proof have largely engaged with the "predict" or "understand" paradigms of inquiry (Stinson & Walshaw, 2017), which are supportive to study the effects of teaching interventions or try to explain phenomena that are part of the teaching and learning of proof. For instance, such paradigms have been useful in investigating how students understand proof (e.g., Guajardo & Lew, 2024; Vroom & Alzaga Elizondo, 2024; Zazkis & Rouhani, 2024). We argue that there is more to learn from a "deconstruction" paradigm, such as the use of poststructuralism, which encourages scholars to continuously examine what is taken for granted and reveal what is unsaid when people settle into

norms (Lather, 2006; Stinson & Walshaw, 2017). While mathematics education researchers have drawn on poststructuralist theory in other contexts (e.g., Dubbs & Herbel-Eisenmann, 2021; Johnson et al., 2022; Stinson, 2008, 2013), this lens has not been widely applied to the study of proof in undergraduate mathematics. We believe that poststructuralism offers a powerful way to interrogate what is deemed as "normal" proofs, providing motivation to disrupt dominant discourses.

Our Positionalities

I (Saúl) was born and raised on the Texas border, surrounded by people who looked a lot like me. I've gone through different iterations of how I identify myself, not really knowing what to settle with (Hispanic, White, Latino?). As I write this, I identify as Latino/e. Despite taking mathematics courses at a Hispanic-Serving Institution, I struggled to see myself as a doer of mathematics until my enculturation into mathematics. While I enjoy research, I don't feel that I can *do* research. Like mathematics, it has always felt presented as a matter of fact. A long-term goal for my writing is to explicitly show the vulnerability of my work, along with how I, with the support of those around me, can do research. As Kristen and I attempt to make mathematics more inclusive, I also hope to do this for research.

I (Kristen) am a white woman who grew up in a deeply gendered space in the Appalachian Mountains. Much of my research has focused on students' *access* to mathematical norms (e.g., Vroom, 2022; Vroom & Ellis, 2024), but through ongoing collaborations, including with Saúl, I've started to think more critically; How can I support "changing the game" rather than just "playing the game" (Gutierrez, 2009, p. 6)? This shift, and especially our interrogation lens, is uncomfortable for me as someone who avoids rocking the boat. At the same time, it's important for me to help open up academic spaces, especially mathematics, to make room for more ways of being.

How We Interrogated the Norms

I (Saúl) engaged in an unstructured interview with an undergraduate student, Sherine. Sherine described herself as an Arab/Middle Eastern cisgender female person and used she/her pronouns. At the time of the interview (Fall 2024), she had recently completed an online Introduction to Proofs course over the summer. From the outset, I shared my purpose for the interview: to interrogate dominant norms in mathematical proof by learning from Sherine's experiences. In the first part of the interview, Sherine read a section from Dawkins and Weber (2017) titled "Value 2: mathematical knowledge and justification should be independent of (non-mathematical) contexts, including time and author." This approach was inspired by Stinson (2008, 2013), as we aimed to "[ascribe] more agency to the individuals in recreating or shifting meanings of the discourse" (Gutiérrez, 2013, p. 44). The second part involved her reading the full proofs shown in Figure 1. In both parts, I opened with the same prompt: *What do you think, wonder, and feel as you read or now that you have finished reading?* The interview was intentionally unstructured; we did not prepare follow-up questions in advance so I (Saúl) could be fully present with Sherine and let the data emerge organically rather than be shaped by prior categories. The interview lasted approximately 1.5 hours and was audio- and video-recorded.

Our interrogation process was non-linear and messy. We read and re-read, talked with Sherine, shared ideas with other researchers, re-listened to our conversations, and repeatedly revised through discussion and writing. This messy process was guided by post-qualitative inquiry (St. Pierre, 2024) and writing as a method of inquiry (Richardson & St. Pierre, 2005; St. Pierre, 2015). These invited us to release rigid structures in data collection and analysis,

embracing the uncertainty and creativity that arise when we allow something new to take shape (St. Pierre, 2015). We reemphasize that our goal was to interrogate the norms themselves, a theoretical endeavor, not to describe the entirety of our conversation with Sherine. Her conversation helped us, Saúl and Kristen, feel and notice our reactions to these norms. To do so, we often returned to the recording, at first to become familiar with the conversation, and then to notice connections and moments that pulled at us. We then paid attention to what seemed troubling about the norms. Alongside this, we regularly met to discuss, read, write, and reflect, allowing our engagement with the literature to shape our understanding and what we wrote. Our writing is personal, shaped by who we are, our interpretations, and our affective responses to the discourses.

We also want to emphasize that we view Sherine, as well as ourselves, as both shaping and reproducing mathematical proof discourses. In fact, Sherine indicated that she has reproduced some of the norms we are interrogating due to her teacher inexplicably reproducing them, even saying, "It never occurred to me if it makes sense." In our writing, we highlight moments where Sherine questions dominant discourses and also critique moments where she appears to reproduce them. We intend for you to read them *not* as a critique of *her*, but as a critique of the *discourse*. We also acknowledge that all of us act in ways that are sometimes inconsistent; we do not interpret her seemingly conflicting comments as evidence of confusion or deficiency. Rather, we use a "yes, and" approach to discourse: contradiction is not failure; it is part of being human within systems that are full of tension.

Interrogating Proof Norms

In what follows, we interrogate the two norms upholding the independence from the author value. We do so by drawing on the conversation with Sherine using research insights to argue how these norms can be exclusionary. We invite you to join our interrogation; ask yourself, how is this dominant way of doing proof messed up, and for whom?

Interrogating the Depersonalization Norm

Let us start with a quote cited by Dawkins and Weber (2017) in their discussion of this norm, where Davis and Hersh (1981) satirically describe "the ideal mathematician" as:

> [following] an unbreakable convention: to conceal any sign that the author or the reader is a human being. It gives the impression that, from the stated definitions, the desired result follows infallibly by a purely mechanical procedure. (p. 36)

Sherine questioned this "unbreakable convention," explaining:

> We know that they are human, so why would we conceal that fact? It's kind of like telling me, 'Oh, act like a robot.' [...] And it should be more like human, because you want people to be like, 'Whoa, oh my god, a person did that,' not think it's some robot. It is a huge achievement if it was really good, you know? [...] Humans are amazing, let them use their brains. So, like the idea that we're robots…I'm sorry, but we're better than robots, and robots aren't necessarily perfect.

Here, we see that the depersonalization norm sends troubling messages to students like Sherine to act in an unnatural way, "act like a robot," to suppress their humanness and ingenuity. Sherine expressed that proofs should be "more like human" to showcase the creativity of the person who authored the proof. We agree. Proofs should be allowed to reflect the identity of the author so that students can experience proof as a personal and creative practice.

When discussing an instance of a "more human" proof through the use of "I", Sherine explained, "Some people feel like they need to avoid using 'I,' so they would use the royal 'we'.

[…] ‘We’ is perceived better than ‘I’.” While Sherine acknowledged she has adopted this convention in her proof writing, she also explained, “if the proof is sound and looks good, then who cares if they used ‘I’?”. While scientific writing aims to view its subject matter as autonomous, authors are expected to avoid passive voice in writing. Burton and Morgan (2000) offer insight into why “we” might be perceived as better explaining that the royal “we” avoids passive voice while meeting the goal of making the subject matter independent of the author:

> The unwritten assumption here is that, in most cases, the author’s persona is not relevant. This assumption is consistent with the commonsensical belief that the subject matter is neutral and that the use of such impersonal language reflects this neutrality. (p. 437)

We want to highlight two points. First, the subject matter is *not* neutral (Bishop, 1990) and perpetuating that “truth” through the proof text reinforces that damaging narrative. Secondly, as Weber and Melhuish (2022) pointed out, avoiding personality to be more objective is not universal. This discourse is rooted in Western and masculine institutional traditions (Bishop, 1990; Hottinger, 2016; Leyva et al., 2021) and promotes generalization and colorblind practices (McNeill, 2025; McNeill et al., 2022).

While Sherine expressed a desire for proofs to be more transparent about the human author, she also gravitated towards the “normal” proof on the left in Figure 1, explaining,

> It’s cleaner. It does not have like extra words. Like, if I’m reading a proof, let’s be real, all mathematicians are kind of lazy. Like, nobody wants to read that whole script, right? We just want: proof, know what’s going on, and that’s it.[...] I wouldn’t say [the personalized components of the proof] adds anything. I don’t like it. It's just kind of there for no reason. Like, it’s not really helping me with understanding. Like, it’s not helping me with the proof and it’s not helping me with understanding. So, like, it’s not really useful.

What do *you* think? Does the personalized part add something? We believe it does. It adds a relational dimension between me (Saúl, the author) and you, the reader. I am being transparent about my persona, my humanness, and in doing so, I invite you to connect with me, to see yourself in the text, rather than encountering something sterile and robotic. And yet, the idea that my persona is irrelevant in proof writing is reproduced in the norms of mathematics; “good” provers (mathematicians) view relational elements as extraneous and undesirable: “Let’s be real, all mathematicians are kind of lazy. Like, nobody wants to read that whole script, right? We just want: proof, know what’s going on, and that’s it.”

The depersonalization norm conflicts with the epistemologies of students, particularly non-masculine and non-Western students, whose primary discourses value relationality and emotional connection (Bishop, 1990; Keith, 1988). Storytelling and other narrative-based ways of communicating have long played a central role in how many non-dominant communities teach, learn, and construct identity (Genz, 2011; Lauer & Aswani, 2009). These practices are not only valid forms of expressing knowledge, they are also more intimate. They stand in contrast to the depersonalized proof norm that prioritizes disembodied logic, objectivity, and detachment.

Our point is that the depersonalization norm implicitly sends messages that non-Western, non-masculine people cannot count as practicing mathematical proof unless they strip them of their history and culture. Proof can be exclusionary for those whose primary discourses involve personal and emotional connection, since it may invalidate how they engage with mathematical proof. How else do you see the depersonalization norm as messed up, and for whom?

Interrogating the Absence of the Problem-Solving Process Norm

Like the depersonalization norm, we see that the absence of the problem-solving process norm hides the humanity of the proof-author, and additionally, the proof-reader. Here, what gets hidden is not the *who* of the author, but the *how* they may have thought through the problem, struggled, and found a way through. When Sherine reflected on Dawkins and Weber's (2017) subsection about the absence of the problem-solving process, Sherine explained:

> I feel like describing the [problem-solving] process might be only for people who just started dealing with proofs instead of people who know how proof works.

Sherine's comment suggests that process, or the nonlinear, human work of figuring something out, is seen as something for newcomers. Then, after reading the personalized proof, she shared:

> It [the proof with the problem-solving process] makes sense, it's an explanation, but that's not what a proof *is*. Proofs do not explain stuff. Proofs show you why is something… Like proofs *prove* something.

Here, Sherine reproduces the view that proofs should not include the problem-solving process. To her, a defining characteristic of proof is that it only shows the validity of the claim, rather than it also explains why it's valid. Sherine did not dismiss the value of process. She saw it as helpful, just not something that belonged in a proof. She explained, "You should write the proof alone, and then maybe if you want to describe the process, that would be something not included in the proof" - a kind of footnote for beginners. We see that putting the process in the margins outside the "real" proof is narrowing for a couple of reasons. First, as with the depersonalization norm, this norm erases a relational dimension of mathematical work. Proofs are not simply abstract objects; they are human-made texts written for human readers. When the process is hidden, there is little sense that someone was here, thinking through this, maybe even thinking of you and your sensemaking as they wrote.

Second, the absence of the problem-solving process undermines support for newcomers and reinforces exclusionary norms about who belongs in mathematical spaces. Without an open discussion of how proofs are thought out and written, a curtain is maintained that separates those presumed to have an innate mathematical ability (people whose primary discourses are closely related to the secondary discourse for mathematical proof) and those who are not presumed to have it (people whose primary discourses are not closely related to this secondary discourse). Maintaining a norm that omits the process reinforces a kind of gatekeeping. Leyva et al. (2021) shared that instructional practices such as indicating to students that if they are not understanding course material soon enough, they should consider dropping the course, have been perceived by students as messages that they are not good enough to participate in any mathematical practice including those pursuing degrees such as Business since mathematics courses can be requisites for those majors. When proof-writing excludes process, a similar message may be conveyed: that unless you already understand how to read these polished arguments, you don't belong. This is particularly harmful for students whose primary discourses are not closely related to the secondary discourse necessary for mathematical proof.

In this way, the absence of the problem-solving process norm not only withholds intellectual support; it communicates a broader ideological stance about who is presumed to be a "real" mathematician and who must continually prove their right to participate. How else do you see the absence of the problem-solving process norm as messed up, and for whom?

An Argument to Interrogate Proof Norms

In this paper, we've argued that the depersonalization and absence of the problem-solving process norms are not neutral or purely mathematical. These norms are socially constructed and,

as we've shown, can function in exclusionary ways. By defining what counts as proof in such narrow terms, these norms obscure both the humanity of the author and reader. Secondary discourses are easier to acquire by those whose primary discourses are already similar to the secondary discourses (Gee, 1989). Therefore, these norms also privilege those whose prior experiences, discourses, and identities align with dominant mathematical values, values historically shaped by Western, masculine traditions, while invalidating relational, human, and process-oriented ways of engaging with proof.

Drawing on poststructuralism, we troubled what's been taken for granted. As Lather (1991), drawing on Caputo (1987), writes, the goal of this kind of deconstruction isn't to settle things once and for all, but "to keep things in process, to disrupt, to keep the system in play, to set up procedures to continuously demystify the realities we create, to fight the tendency for our categories to congeal" (p. 13). Through this lens, we questioned the binary between objective and personal proofs, pushing back on the idea that including the author's personality, thinking, or struggle somehow devalues a proof.

To be clear, we're not arguing that depersonalized proofs have no place. There are contexts where those norms may serve useful purposes (we suspect mathematics research journals). But that type of proof is only one representation, among many, that we should value and allow students to encounter. While we believe the implicit messaging alone justifies expanding these norms, there is also evidence that mathematicians themselves often adopt personalized styles and voice (Contreras et al., 2025). At the same time, some instructors may feel particularly compelled to emphasize precision and formality to their students - "sometimes to the point of being more pedantic than they might be with experienced mathematicians" (Rupnow & Randazzo, 2023, p. 305). We encourage broadening what gets recognized as legitimate proof, and inviting students into forms that are more relational, expressive, and reflective of the thinking behind the final product.

As an anecdote, when we wrote personalized proofs as we prepared for this project (and, frankly, this personalized conference paper), something opened up for us. It felt freeing. It felt vulnerable. It felt different from what math and academia usually allow. We think this is a promising direction for future research: What happens when students are invited to personalize proofs? How does it feel to write in ways that reflect your own thinking and voice? And just as importantly, how does it feel to read this kind of proof, or this kind of academic paper?

More broadly, we see this work as part of a growing movement in our field to reexamine and resist "normalities," such as those of you who are questioning "normal" curricula and teaching practices (e.g., Leyva et al., 2022; Osibodu, 2024). We invite you to join us in exploring poststructuralism, not only as a way to critique, but also to imagine differently. For some, deconstruction may offer a motivating approach that safeguards against dogmatism and reminds us that even cherished mathematical (educational) categories are not innocent. As Lather (1991) puts it, deconstruction continually demystifies the realities we create. It keeps the system in play. Let's keep the system in play, where proofs can be both formal and personal, polished and messy, logical and human. Where there's room for more kinds of knowing, more ways of belonging, and more stories of how we figured things out.

Defining a "Differentials-within-limits" Framework for First-year Calculus

Alex A. Swindler
Brigham Young University

Steven R. Jones
Brigham Young University

Work in first-year calculus has clearly shown the power that "differentials" afford for first-year calculus learning, but it also speaks of the need to build ideas of limits. While some researchers have loosely described informal differentials and limits within the same paradigm, their actual conceptual definitions and relationships have not always been explicitly constructed. Continued progress in this area could benefit from theoretical consideration of: (a) providing clearer intuitive definitions for differentials inside a limits-based approach to calculus, and (b) defining more exactly the relationships between differentials and limits. We provide here a theoretical framework for building a simultaneous differentials-and-limits approach to first-year calculus.

Keywords: calculus, differentials, limits, differentials-within-limits

There is a persistent theoretical issue facing the teaching and learning of first-year calculus. On the one hand, the research literature in recent years has painted a very clear picture of the need for first-year calculus to be heavily grounded in quantities and quantitative reasoning (Jones & Ely, 2023; Kertil & Gülbağcı Dede, 2022; Oehrtman & Simmons, 2023; Thompson & Dreyfus, 2016; Yu, 2024). These efforts are often centered on the need for *differentials* (e.g., *dx, dt*) to have quantitative meaning, which can then also interact with other quantities to, in turn, construct meanings for derivatives, *dy/dx*, and integrals, $\int_a^b f(x)dx$ (Hu & Rebello, 2013; López-Gay et al., 2015; Roundy, Dray, et al., 2015). Further, most STEM fields utilize free-standing differentials to capture quantitative relationships at small scales, such as $dI = r^2 dm$ or $dS = dQ/T$. Consequently, these paradigms have proven powerful for enabling students to develop deeper understandings of calculus and to become proficient users of calculus beyond the mathematics classroom (Amos & Heckler, 2018; Pina & Loverude, 2019; Roundy et al., 2014; Stevens & Jones, 2023; Von Korff & Rebello, 2012; Weber et al., 2012).

On the other hand, there has been a historical tension in the mathematics community between differentials and limits (Katz, 2009). The historical outcome was to discard differentials in favor of limits, leaving typical modern calculus based on limits exclusively, without differentials. It has taken considerable effort by researchers to redeem differentials to a "legitimate" status within teaching (Dray & Manogue, 2010; Ely, 2017; Martínez-Torregrosa et al., 2006; Rogers, 2005). In an interesting pendulum swing, however, some of these differentials-based reform efforts have now gone so far as to do away with limits, using (essentially) the hyperreal number system in their place. Because much of modern mathematics is based on the real numbers and on limits, this could create baggage for students in underdeveloping limits per se and in using a number system not generally accepted in the broader mathematical community.

What should calculus education do? Reasoning with differentials as quantitative objects is essential, but the limit is a necessary concept for the general mathematical community. The obvious answer seems to be to create instructional paradigms that coherently leverage *both* limits and differentials, yielding the benefits of each. In fact, some calculus education researchers have more-or-less done this, using approaches that in essence contain both differentials and limits (Jones, 2015; Oehrtman & Simmons, 2023; Weber et al., 2012). The problem is that some of this work has been done without careful attention to exactly *what* a differential is within a limit

structure, and what its *properties* and its *relationship* to a limit are. We admit that our own prior work falls into this category, and we are guilty of this same laxity. Additionally, other paradigms that have tried to define differentials more explicitly (Thompson et al., 2013; Thompson & Dreyfus, 2016) tend to not cohere very well with the growing body of work on differentials in math and STEM education. Similarly, paradigms that view differentials only as "linear approximation" tend to miss out on imbuing expressions like dy/dx with direct quantitative meaning – a major benefit of differentials. We find that continued progress could benefit from building clearer theoretical frameworks on a differentials-and-limits approach that is also built on and compatible with the body of work in this area. Thus, in this *theoretical* paper, we contribute by supplying one possible set of definitions and relationships. To be clear, our framework is focused on *intuitive, conceptual* definitions for use in first-year calculus, rather than on *formal mathematical* definitions used for proof in the mathematics community. We anticipate that one could disagree with our specific definitions and properties, and we welcome discourse in this area, and we welcome others providing alternate definitions or improving upon ours.

Background

While we aim to add theoretical clarity to the simultaneous use of differentials and limits, we most certainly want our framework to stay true to the important work that has been done on differentials so far. The major theme in the literature is that a differential is an informal construct, representing a "tiny bit" or an "infinitesimal bit" of a quantity (Amos & Heckler, 2018; Hu & Rebello, 2013; Jones & Ely, 2023; López-Gay et al., 2015; Von Korff & Rebello, 2012). In STEM education, dt might refer to a tiny bit of time or dA might refer to a tiny bit of area. Many STEM educators intentionally leave differentials as an intuitive idea, without providing any formal mathematical definition. For example, Von Korff and Rebello (2014) state that they use "d" to mean something "vanishingly small, without giving a mathematical definition of what it means to be… vanishingly small" (p. 698). The main reason for doing so is that a formal definitions from within non-standard analysis can be as problematic for first-year calculus as the formal ε-δ definition of the limit has been. Rather, it is the informal notion that affords so much reasoning power (Jones & Ely, 2023). Simply put, differentials for first-year calculus work best when kept *intuitive* and *informal*, and we adopt this stance for our framework.

Based on the power of differentials, a natural question is: Why not use only differentials and abandon limits altogether? Some have actually taken this approach, using what is essentially a less formal version of non-standard analysis and its hyperreal number system (Dray & Manogue, 2010; Ely, 2021; Keisler, 2011). In this camp, a differential is a literal "infinitesimal": a non-zero number smaller than all real numbers. While this approach certainly has solid mathematical footing thanks to the work of Abraham Robinson's group in the 1960s (Robinson, 1961), the issue for us with this approach is that non-standard analysis is not generally utilized in the mathematical community and most modern mathematics is founded on the real numbers instead. We are concerned with developing a number system in our students' minds that can, and probably will, clash with subsequent mathematics study. It also makes using differentials a much harder "sell" to the broader mathematical community, impeding progress toward adopting differentials in instruction. Thus, our framework does *not* use a hyperreal version of differentials. Rather, out intent is for differentials to be a construct that can readily cohere with limits.

Next, we note that the research literature on differentials describes two distinct possible conceptualizations of differentials. Von Korff and Rebello (2014) described that some differentials have a "change" nature, such as dt representing a tiny change in time. On the other hand, they also described that some differentials have an "amount" nature, such as ds

representing a tiny length on a curve. This distinction is important, because both types are used across STEM fields. Integrals such as $\int_R \rho\, dV$ and $\int_R r^2 dm$ make use of differentials that can be thought of as a tiny bit of volume (dV) and a tiny bit of mass (dm).

Finally, as quantitative objects, differentials can interact with other differentials or quantities to produce the key constructs of derivatives and integrals. A derivative can be seen as the ratio of tiny changes represented by two differentials, *dy* and *dx*, to produce *dy/dx* (Roundy, Dray, et al., 2015). An integral can be viewed as summing the products between a differential quantity and a "macroscopic" quantity, $f \cdot dx$, to produce $\int_a^b f(x)dx$ (Jones & Ely, 2023) – though other relationships beyond products are also possible (Ely, 2017; Simmons & Oehrtman, 2017).

Situating Our Theoretical Contribution

As mentioned, several researchers have already discussed approaches to calculus that essentially use both limits and differentials in the same paradigm (Jones, 2015; Oehrtman & Simmons, 2023; Weber et al., 2012). In these approaches, limits are examined in their own right, and derivatives and integrals are still defined as limits: $\lim_{\Delta x \to 0} \Delta y/\Delta x$ and $\lim_{\Delta x \to 0} \sum f(x_i)\Delta x$. But once the differential forms are provided, *dy/dx* and $\int_a^b f(x)dx$, the differentials are allowed to have meaning as tiny changes or amounts of a quantity. These approaches have proven powerful, yet the issue is that the co-existing nature of differentials and limits has not been carefully and explicitly articulated. On the other hand, when attempts have been made at articulating their interrelations (Thompson et al., 2013; Thompson & Dreyfus, 2016), the definitions have not been very compatible with the growing body of STEM research on differentials described in the previous section. Additionally, another attempt we have seen at describing the relationship was given as $dx = \lim_{\Delta x \to 0} \Delta x$, but such a definition has a major flaw. The value of that limit is unambiguously zero, meaning that all differentials would be size zero. Such thinking is akin to the problematic "collapse metaphor" described by (Oehrtman, 2009), wherein all differentials collapse to nothing and essentially disappear from the quantitative relationships altogether.

We wish to produce a framework for differentials and limits that (a) provides theoretical clarity, while (b) still aligning with and strengthening the important work done in this area in recent years. This theoretical paper contributes by describing one such possible theoretical framework to cohere differentials with limits. To be clear, we reiterate that our framework is meant to propose *intuitive, conceptual* definitions for first-year calculus education, and not *formal mathematical* definitions intended for proof.

The Basis of the Framework: Processes and Objects in the Limit Concept

Our theoretical framework for differentials and limits is based on Sfard's (1991, 1992) idea of processes and objects. Of course, many researchers have discussed processes and objects, including Arnon et al. (2014), Gray and Tall (1994), and others, but for our current purposes we only need the general idea of these processes and objects, as found in Sfard's work.

A *process* is defined as a dynamic action that can be imagined as happening. For example, one potential *process* for a limit, $\lim_{x \to a} f(x)$, is that of *x* sweeping through numbers as it moves closer and closer to *a* (Cornu, 1991; Fernández-Plaza et al., 2013; Oehrtman, 2009) (see Table 1). Yet, a different *process* that can be conceptualized for a limit is graphically zooming over and over toward a section in the neighborhood of $x = a$ (Ely & Ellis, 2018; Ely & Samuels, 2019) (see Table 1). Notice that these two intuitive processes are both, essentially, "never-ending" (Davis & Vinner, 1986), because one cannot literally enact *x* passing through infinite real

numbers on its way to a, nor can one zoom in a true infinite amount to a single point within the real numbers (see Table 1).

Next, a process can result in some kind of outcome that can be thought of as an entity in its own right. For limits, as x gets closer and closer to a, the function $f(x)$ might hone in on a single numeric value, L (or remain steady at L). This outcome can be conceptualized as its own entity, and when it is, it becomes an *object* existing in the person's mind (Sfard, 1991) (see Table 1). The entire symbolic expression $\lim_{x\to a} f(x)$ can now be seen as referring to this object, "L" (Gray & Tall, 1994). These objects can then be used in further processes, creating even more objects.

Table 1. Pre-existing definitions from the literature regarding limit processes and objects.

Idea	Definition
Limit Process, Approach	One type of limit process is dynamically *approaching*. For example, in $\lim_{x\to a} f(x)$ we can hold an image of x getting continuously closer to a.
Limit Process, Zoom	A distinct limit process is dynamically *zooming*. In $\lim_{x\to a} f(x)$, we can imagine of zooming forever into a portion of a graph around $x = a$.
Limit Process as Never-ending	There is never a moment at which the limit process "completes." While it results in an object, the process itself never attains a completed state.
Limit Object	The limit object is the outcome that results from the limit process. It is defined as the value we assign to the limit, as in $\lim_{x\to a} f(x) = L$.

Defining Differentials *Within* Limits

With these conceptual ideas for limits in place, we can now *conceptually* define a differential as a secondary object that also is produced from *within* the limit process. In other words, we do not simply see differentials *and* limits together, but we see differentials coming into existence *within* the limit process. Table 2 contains our definitions, which are intentionally kept informal for first-year calculus. They are not meant to be treated as formal mathematical definitions.

Table 2. Definitions of differentials as secondary objects from within the limit process..

Idea	Definition
Differential, based on approaching	Consider the approaching imagery for the limit process in $\lim_{x\to a} f(x) = L$. Once someone perceives that the input variable x has become incredibly close to its target a (even if never reaching it), they can "pause" the limit process at that moment and consider the remaining difference between x and a. In other words, the differential is the *object* produced by "pausing" the approaching process once x is extremely close to a, and by considering the remaining discrepancy.
Differential, based on zooming	Consider the zooming imagery for the limit process instead. As the zooming continues to tiny scales, one can again "pause" the limit process at some moment and consider the very tiny "amount" of a quantity remaining in the zooming window. Just as before, the differential is the *object* produced by "pausing" the zooming process once it has reached very small scales, and by considering the tiny bit in the zooming window.
Output Differential	One can also create a differential for the *output* variable. In $\lim_{x\to a} f(x) = L$, as x gets close to a, or as one zooms into a graph near $x = a$, one can also imagine a differential exiting for the output variable, *df* or *dy*.

Properties of Differentials in This Paradigm

Having provided our baseline conceptual definitions, we now provide specific properties that informal differentials have in our framework (Table 3).

Table 3. Properties of differentials in our framework.

Idea	Definition
Subjectivity of Closeness	What is "close enough" in the limit process for it to be paused, and for a differential to come into existence, is subjective both on context and the reasoner's perspective. In a scientific context, a differential often comes into existence once reaching the threshold of measurement tools, or when further measurement yields a "linear regime" (Roundy, Weber, et al., 2015). For math functions, a differential might exist once the error is in such remote decimal places that they contribute very little to the variable's value.
Lack of a Specific Size	As a direct consequence of the previous property, differentials do not have a single, specific size nor value. That is, the differential object is *not* defined by a numeric value, as opposed to the limit object. Rather, the differential object is defined by the conceptual idea of a tiny remaining change/amount.
Non-hyperreal	While a differential does not have an inherent size, it still resides in the realm of very small real numbers, and is *not* a non-standard hyperreal.
Contextual Assignment of Values	While differentials have no inherent size, for pragmatic reasons one can still assign a numeric value to a differential in a given situation, when context dictates, by "pausing" the limit process at a point deemed close enough or small enough. Upon pausing the process, one can imagine using that current state to assign a temporary value to a differential. This is actually a common and important practice in many STEM fields, which use measurements at small scales to produce contextual values for differentials (Roundy, Weber, et al., 2015). How small is small enough is context-dependent; in one situation a time interval of 0.01 seconds might be a "differential" amount of time based on that context, where in another situation a time interval of 0.01 seconds might be too big to be considered a "differential" amount of time.
Zero Value for Output Only	For $\lim_{x\to a} f(x) = L$, if $f(x)$ attains and remains at L at some point in the limit process, the differential *df* (or *dy*) is zero, a legitimate value for the *output* variable differential only. The *input* variable differential (*dx*) cannot be zero
Inheriting Quantitative Properties	Differentials automatically inherit all the quantitative properties of the quantity represented by that variable. For example, if *F* represents a force measured in Newtons, then the differential *dF* is automatically also a force, presumably also measured in Newtons (Hu & Rebello, 2013).

How is This Framework Different From Previous Work?

One could ask: Since this framework is also based on informal, conceptual ideas, does it add anything to what already exists in the literature? The main difference we see is that previous work tends to define differentials as "tiny bits" without giving much more theoretical clarity on how such tiny bits connects coherently to limits. Our framework clearly states one possibility where differentials come into existence as objects and what their relationship to limits is. By articulating them explicitly, we are better positioned to construct instructional activities to simultaneously build limits and differentials in the same calculus classroom.

Differentials-within-limits in Action: Differentials as "Models"

Our framework used the notions of limit processes and objects to provide a conceptual definition for differentials, and to lay out several conceptual properties of differentials. The next big question for our framework is what implications these definitions and properties have for first-year calculus teaching. These implications can be encapsulated through the idea of a mathematical *model*. In brief, a model is a mathematical description of an object or system, even if the model is not a perfect representation of the object or system being studied (for more on modeling, see Blum et al., 2007; Cai et al., 2014). We consider a "differential" to be precisely this – a *conceptual model* of what happens at small scales. To illustrate, imagine a string that produces a pitch when plucked, where a shorter length (*L*) corresponds to a higher pitch (*f*). Then consider the limit, $\lim_{L\to 0+} f$. In the limit process, we can think of the string becoming increasingly short and imagine "pausing" the process once we've reached some incredibly small length. This tiny remaining length is what we have defined to be a differential, *dL*, and it would correspond to a very high pitch. While we can never truly make the string be of length zero, because there would no longer be a string nor a pitch, we can model the phenomenon of the limit process by considering what happens as the string length becomes differential-sized. The *dL* is a *model* of an ever-shrinking string length, paused at a specific moment, and its relation to the output variable (*f*) can be examined within the differential model to generate expectations of what the limit value might be (i.e., ∞ or a finite value). The limit process can then be resumed and paused again, and the model *dL* can be reexamined.

Importantly, differentials are commonly used in this way across the sciences. Differentials such as *dm*, *dI*, *dF*, and *dU* are models of systems dealing with small masses or small energies, which can be given values through small-scale measurements (Roundy, Weber, et al., 2015).

Derivatives and Integrals as "Best Models" Within This Framework

Because derivatives and integrals are also defined as limits and use differential notation, our framework, including the idea of models, also extends to these concepts, though in a specific way. Derivatives and integrals are not only models, but are what we term *best models*.

To explain, in our definitions and properties for differentials, *dy/dx* would be a literal ratio of two tiny changes or amounts. But, there is a key theoretical issue to resolve. Take, for example, $y = x^2$. The derivative evaluated at $x = 3$ should be $dy/dx = \lim_{x\to 3}(x^2 - 3^2)/(x - 3) = 6$. The issue is that no matter where the limit process is paused, there is *no* specific point at which a literal ratio of tiny changes gives exactly "6." Even if the limit is paused when *x* is a distance of 0.0001 of 3, the tiny changes at that moment give 0.00060001/0.0001 = 6.0001, which is not exactly 6. How do we resolve this problem in our framework? First, differentials in our framework have no specific inherent size, and assigning a specific value like this would be done only for pragmatic, contextual reasons. Thus, we would not necessarily claim that *dy/dx* = 0.00060001/0.0001, unless the temporary assignment of those values is done for some practical reason, such as in experimental measurement. Even so, it is still a good model for what the derivative ultimately would be. Yet, there remains an uncomfortable mathematical issue in how we can state that *dy/dx* = 6, rather than *dy/dx* ≈ 6, when we define a differential through pausing the limit process. This is where the idea of a *best model* comes in.

The derivative is fundamentally meant to answer the question: "What is the *single* numeric value that best represents the idea of an instantaneous rate of change at a given point?" In other words, we want a *best model* for the tricky "instantaneous rate" question. The answer certainly isn't 6.0001, because if we un-pause the limit process and re-pause it later, we would have a

new, different discrepancy between x and a, and a different momentary ratio, say 6.0000001. Thus, none of these numbers functions as a single *best model* for the instantaneous rate, because unpausing the limit process will always refine our ratio past it. Since the differentials dy/dx are meant to *conceptually model* any arbitrary pause in the limit process, there is only one single number that encapsulates the whole set of ratios we could get by pausing at different moments – the value "6." That is, the limit object (the other object produced in the limit process) serves as this best model. Here is where the lack of inherent size for differentials is a benefit in our framework. We can say $dy/dx = 6$, because there are no specific values that dy and dx each have, and 6 represents the single *best model* we can construct for ratios of very tiny changes (i.e., an instantaneous rate). This also allows us to make statements such as $dy = 6dx$, because this statement is a *best model* for what to predict for an arbitrarily small change in x. If one imagined some miniscule change in x (dx) and tried to predict how much the output variable changed, then without specifying any particular size or value for dx, the single *best model* is that dy would be 6 times as large as dx (Yu, 2020).

Integrals function in a similar way. The definite integral fundamentally addresses the question: "How much of a quantity do we have, when variation in one of the quantity's constituents prevents using a simple relationship?" Take the example of water flowing through a pipe. If it had a constant rate, then given some elapse in time, we could calculate the amount that flowed through the pipe as $A = r \cdot t$. This is what Oehrtman and Simmons (2023) call a *basic model*. But, suppose the rate is not constant. We might then imagine the limit process of zooming into smaller and smaller time intervals, until the rate appears essentially constant. If we pause at that point, we create a differential time interval, dt, and a differential amount of water in that time interval, $dA = r \cdot dt$. Oehrtman and Simmons (2023) call this a *local model*. This local model is precisely the *best model* for how much water we have in that differential time segment. Of course, zooming can never reach a point where the variation in the rate is totally eliminated, but since differentials have no specific size, they are a *conceptual representation* of the best model for constructing a tiny bit of A in each piece. No other model functions better for capturing the amount of A. This is why we assign an equals sign for an integral value, $\int_a^b f(x)dx = I$, rather than $\int_a^b f(x)dx \approx I$, because no other number is a better model for what we should get for the total amount of the quantity over the given interval.

Conclusion

To recap, we had noticed that there was a need in calculus education research to construct an explicit framework for using informal differentials within a limits-based approach that coheres with the large body of work that is being done in differentials, integrals, and derivatives. In other words, we did not want a framework that would run counter to this important work. Using the literature as our launching point, we laid out both conceptual definitions and conceptual properties of differentials *within* the broader limit architecture. We then elaborated on the implications of this framework for instruction, based on the idea of *models* (for differentials, generally) and of *best model* (for derivatives and integrals, specifically). Of course, ours is one possible framework and we welcome discourse in this area. We believe that others' ideas could contribute to theoretically refining our framework, or creating alternate theoretical frameworks. Regardless, we believe that continued progress in calculus education research will benefit from having these explicit frameworks to work with. They can lead to instruction that better articulates for students what a differential is and how it fits within limits, so that students are able to learn *both* limits *and* differentials within a single course, leveraging the benefits of each.

An Argument for Teaching Logic With Euler Diagrams Instead of Truth Tables

Kyeong Hah Roh
Arizona State University

This theoretical report integrates insights from various lines of research to posit an argument that early logic instruction for proof-based mathematics should use set-based conditions for the truth of conditional statements rather than the widely used truth table definition. We claim the truth table definition poses unnecessary barriers for students, in part because it does not adequately express mathematical practice. In contrast, the set-based meaning seems highly productive and may better support students in reasoning about conditionals as objects, which our experiments suggest is a highly propitious development for learners.

Keywords: logic, conditionals, truth tables, Euler diagrams

It is standard practice in early proof courses to teach mathematical logic so that students can learn precise conditions for declaring mathematical statements true or false. This occurs especially often in transition to proof courses and discrete mathematics courses (David & Zazkis, 2020; Schumacher, Epp, & Solow, 2015). The most common approach to teaching the logic of statements uses truth tables (Alcock & Sa, 2025), which define the truth of compound statements – such as disjunctions, conjunctions, and conditionals – as a function of the truth of their component propositions. For instance, the conditional "if p, then q" is only false under the condition that p is true and q is false. Based on our joint experiences on two multi-year projects researching the teaching and learning of logic for mathematical proving, we have become convinced that this approach should be replaced with set-based definitions and Euler diagrams. In this theoretical paper, we set forth our arguments for this recommendation drawing on relevant literature from psychology, mathematics education, and our own research experiences. While many of these arguments have appeared in our prior work, we have not put them together in a unified argument meant to prompt a shift in teaching, as we intend for this argument to do.

To build this argument, we pursue a few lines of inquiry that challenge the preference for truth tables to help students understand mathematical language, specifically mathematical conditionals. The first principle we challenge is whether the truth table expresses a common-sense meaning of "if… then" statements from everyday language or how people reason about such statements. We share evidence from psychological research that the truth table definition of conditional truth (often called the "material conditional") fails as a descriptive account of everyday usage. Although this does not undermine the utility of this definition for mathematical usage, it points to the fact that it is a novelty being imposed upon student language use. Second, we challenge whether the material conditional adequately expresses what conditional claims mean in mathematics. We share some mathematics education research that challenges it as a descriptive model for how mathematicians reason. Further, we identify some counter-intuitive "facts" that arise when the truth table definition of "if p, then q" is taken to correspond to the mathematical notion that "p implies q."

The third component of our argument focuses on the adequacy of set-based truth conditions and Euler Diagrams to support student reasoning about conditionals in mathematics.

Specifically, a universally quantified conditional "For all $x \in S$, if $P(x)$, then $Q(x)$" is true whenever the truth set of P is a subset of the truth set of Q, which we shall refer to as the subset meaning (see also Dawkins, 2017; Dawkins, Roh, & Eckman, 2023). We offer three main points in favor of teaching with the subset meaning and Euler diagrams. First, we review some psychological research that suggests that Euler diagrams better facilitate novice learning, suggesting that there may be greater ease of use than has been found for truth tables (Hawthorne & Rasmussen, 2015). Second, our research suggests that some parts of the proof-based curriculum require that students learn to reason about conditionals as objects, meaning they conceptualize implication as a fixed relationship between two predicates. This kind of understanding is better facilitated by Euler diagrams than by truth tables. Third, we argue that set-based truth is a better descriptive account of how conditionals operate in mathematical language.

Point 1: The Truth Table Definition Fails as Descriptive Model for Everyday Conditionals

As Toulmin (1958) argued, scholars use the term *logic* to refer to at least four different kinds of endeavors. Two of them are descriptive, and two of them are prescriptive. In its descriptive mode, *logic* refers to either how individual people reason (Toulmin's *psychology*) or to how groups of people reason in some idealized or normative sense (Toulmin's *sociology*; note this second meaning blends in a prescriptive component). In its prescriptive mode, *logic* refers either to a means for building desirable arguments (Toulmin's *technology*) or to a formal system akin to mathematizing language (Toulmin's *science*). The descriptive sense of logic is at play when someone asks, "What is the logic in that?" while mathematical logic tends to focus on prescriptions that render language rule-based and consistent. Although the association of logic with processes of reasoning has been deeply criticized by some logicians (e.g., Frege and Husserl; see Schroyens, 2010, for helpful discussion), the potential association has led to two extensive lines of inquiry. Philosophers and logicians have pursued the question "can we build formal systems of logic that incorporate elements of everyday argumentation and language use?" This has led to novel logics such as fuzzy logic (in which claims can have truth values other than *true* or *false*) or modal logics that incorporate different senses in which a claim is true (e.g., *possibly true* in addition to *necessarily true*). Psychologists have pursued the converse question, "can we identify which formal system best describes how people interpret and reason about conditional claims?" It is this line of research that most directly informs our current argument.

One of the dominant means by which psychologists have studied how people interpret conditional claims has been the Wason (1966) card task. We will describe the task in its generalized form. Participants are asked to test a rule of the form "if p, then q" regarding four cards displayed. Each card has one side relevant to p and another side relevant to q. The four displayed cards show cases corresponding to p, not p, q, and not q. Participants must indicate which cards need to be turned to check whether the rule is followed/violated. It is far beyond the scope of this paper to review this vast literature (using variants of the Wason task and related study designs), but we shall recount a few key elements from the findings.

First, though the Wason card task seems a simple operationalization of the material conditional definition for conditional claims, the standard rate at which untrained undergraduates provide the normative answer is about 10% (Evans & Over, 2004). According to the material conditional definition that a conditional is false whenever p is true and q is not, the normative solution to the task is to turn the p and not q cards, since these are the two that might yield a counterexample to the rule. The most common answer provided by most undergraduates to many forms of the task are to turn the p and q cards, meaning they select an irrelevant card and omit a

relevant one. Second, performance on the task varies greatly depending upon the context for the rule. If the rule corresponds to a known social rule such as "if someone is drinking, then they must be at least 21 years old," then performance on the task greatly improves. This runs contrary to the underlying notion that logical reasoning pertains to the form of an argument, not to its content. These findings drive a wedge between the prescriptions of formal logic and empirical findings about human reasoning about statements in conditional form. For these and similar reasons, Schroyens (2010) claims that "Classical propositional calculus is vastly inadequate as a theory about how people reason. Whatever merits one (e.g., a logician) wants to attribute to the propositional calculus, one merit it cannot possess is being a descriptively adequate theory of human reasoning" (p. 71).

What role should a descriptive account of everyday reasoning hold for the teaching and learning of logic in mathematics? We see two main implications. First, instruction should not assume as intuitive any logical notions that do not have empirical support as being widely held apart from mathematics instruction. Second, instruction should privilege ways of teaching the logic of mathematical statements that do not needlessly introduce contrasts with everyday language use, all other things being equal. The descriptive account that has better empirical support relies heavily on probabilistic notions. According to the suppositional account, one's affirmation of "if p, then q" in the everyday is most closely linked with the conditional probability of q given p is true (see Evans & Over, 2004; Oaksford & Chater, 2020). This account helps explain why some human reasoning in experiments aligns to the *defective truth-table* for conditionals, which only includes the cases where p is true (Evans et al., 2007; Wason, 1966), as the meaning of "if p, then q" entails assuming p true. Cases in which p is false are taken as merely irrelevant to the conditional. Indeed, most anyone who has tried to teach the logic of conditionals using the standard truth table have found that convincing students that the conditional is true when p is false constitutes a steep uphill battle. The suppositional account justifies students in their resistance to this aspect of the material conditional.

We find these findings from non-mathematical settings insightful, and they help contextualize the rest of the paper. However, we should note that everyday meanings for conditionals need not restrain mathematical usage. There are fundamental distinctions. As Oaksford and Chater (2010) note, proponents of the suppositional account "argue that logical methods need to be supplemented with probabilistic notions not because classic logic is incorrect, but because they contend that outside mathematics, it rarely, if ever, applies to real human inferences and arguments" (p. 21). By contrast, mathematical inferences and arguments certainly align to logic in some manner (though it is worth considering the nature of this link carefully). Furthermore, we are concerned with student learning of technical meanings, rather than untrained usage of language (Alcock, 2025a). Next, we shall examine how the truth-table definition fails to express how mathematicians reason about conditionals, even in mathematics.

Point 2: The Truth Table Does Not Capture the Mathematical Meaning for Conditionals

As we noted in the introduction, the standard way of presenting the truth conditions for mathematical conditionals is the full truth-table. However, there are multiple reasons to question whether the material conditional truly aligns to mathematical usage. We will provide a few different strands of support for this claim.

Do Mathematicians Reason About Conditionals According to the Material Conditional?

First, if we assume mathematicians as paragons of logical reasoning, we may wonder how mathematicians respond to standard psychological tasks such as the Wason Card task. Inglis and

Simpson (2004) administered this task (with abstract content) to mathematicians and found that their answers differed from what is commonly observed among mathematics or history undergraduates, but still did not give the normative answer (conforming to the material conditional) more than half of the time. Mathematicians were more likely to avoid irrelevant cards (each irrelevant card was selected 19% of the time), but still only considered the not q card only 67% of the time.

In a more qualitative investigation of the process of reasoning, Inglis (2006) found that the best way to explain how mathematicians reasoned about mathematical conjectures (in conditional form) was the suppositional account. Specifically, he claims they assumed p true and then considered the probability that q was also. The distinction is that in the everyday, people will affirm a conditional even in the presence of counterexamples (instances of p and not q) while in mathematics, the observed reasoners sought to affirm that q was necessarily true without exception, ultimately by producing a proof. Excepting the affordance of various degrees of certainty in the truth of q, Inglis' account of the mathematicians' reasoning is compatible with the defective truth table account, which Hoyles and Kuchemann (2002) endorsed as adequate for usage in the mathematics classroom.

Attridge and Inglis (2013) provide a final piece of evidence supporting the link between mathematical conditionals and assuming p is true (consistent with the suppositional account or the defective truth table). In this study, the authors presented abstract reasoning tasks to students in mathematical and non-mathematical courses of study near the beginning and near the end of one year of secondary school studies. The goal was to compare the influence of mathematical study on abstract inference tasks with non-mathematics students as a comparison group. A year of studying mathematics (including no lessons on logic) decreased the rate of affirming the (invalid) converse inference, but also slightly depressed the rate of affirming the (valid) modus tollens inference from not q to not p. The authors explain this pattern as aligning to the defective truth table pattern of conditional inference.

Conditional Truth Versus Valid Inferences

Weber and Alcock (2005) asked mathematicians whether they affirmed the statement "if 7 is prime, then 1007 is prime," which everyone in the experiment took to be true according to the material conditional definition (1007 is non-obviously composite). Those authors found that mathematicians did not affirm this claim because 1007's primality does not follow from 7's primality (e.g., the inference "if x is prime, then $x + 1000$ is prime" is not valid). The authors concluded that the criterion by which these mathematicians evaluated the conditional was stronger than the truth table definition. Mathematicians required that q be a warranted inference from p. Along similar lines, Vargas (2020) notes, "This is the case for conditional statements which are not seen as formulas with truth values in themselves, but more as "licenses for inference" in logic programs" (p. 58). Janke and Wambach (2013, quoted in Vallejo-Vargas, 2023) add,

> a mathematical proof does not establish *facts*, but *implications*. A proof proves 'if-then-statements'. That means a mathematical theorem is not about a fact *B*, but about an implication 'If *A* then *B*'. Thus, the *absolute certainty* of mathematics does not reside in the fact, but in the *inferences*. (p. 471)

So, for teaching logic we should desire an account of conditionals that facilitates the important link between conditional statements and implications (Alcock & Sa, 2025).

It is precisely this intended link between conditional statements and implications that renders the material conditional an inadequate account of conditionals in mathematics. To see this

disconnect more vividly, consider that according to the material conditional, $(p \to q)\ or\ (q \to p)$ is a tautology. However, we would never want to affirm that for any claims p and q, one must imply the other. We raise this challenge because it allows us to endorse what we see as a more productive alternative to the material conditional. Most mathematical conditionals of interest are not conditionals involving propositions with a fixed truth-value, but rather universally quantified claims between predicates: "$\forall x \in S, P(x) \to Q(x)$." If we introduce this modification, the resulting expression $(\forall x \in S, P(x) \to Q(x))\ or\ (\forall x \in S, Q(x) \to P(x))$ is no longer a tautology. We will argue in the next section that an approach to conditional truth that builds upon universal quantification is more productive and instructionally adequate, namely the subset meaning represented using Euler diagrams.

Point 3: A Set-Based Definition for Conditionals is More Adequate for Teaching Logic

If we are to argue against the truth table definition of the truth of mathematical conditionals, we must offer a viable alternative. In our instructional design projects (NSF DUE #1954768, #1954613, and #2141626), we have explored such a viable alternative in the subset definition of conditionals. In this view, the conditional "$\forall x \in S, if\ P(x), then\ Q(x)$" is true whenever the truth set of P is a subset of the truth of Q. We encourage students to explore such relationships between truth sets using Euler diagrams. In this section, we provide three strands of support for the preferability of this approach.

Euler Diagrams Are Accessible for Novice Learners

One affordance of universally quantifying conditionals is that it brings them closer to the kinds of statements classically used in Aristotle's system of syllogisms. That system featured statements of the forms "All A are B," "Some B are C," and "No C are A." The development of this system preceded the development of modern logic by about 2000 years, which may speak to its relative intuitiveness, though this evidence is clearly only suggestive. Nevertheless, this allows us to draw upon research investigating how students reason about syllogisms in addition to the Wason Card tasks and inference tasks featured in the studies reviewed above.

Sato, Mineshima, and colleagues have conducted a series of experiments exploring how students solve syllogism tasks with relatively brief training (Mineshima et al., 2012, 2014; Sato & Mineshima, 2015; Sato et al., 2010, 2011). In many cases, they compare student success on syllogism tasks after one of three instructional treatments: brief training in Euler diagrams; brief training in Venn diagrams; and training only in sentential, non-diagrammatic approaches. Venn diagrams differ from Euler diagrams in that they always show the closed curves overlapping and use shading and *x*'s to indicate which regions are empty or occupied. Euler diagrams by contrast will show closed curves non-overlapping either to show one set is disjoint from another or is a subset of another (when one curve surrounds another). A brief summary of these studies' findings is that students perform better on syllogism tasks when using diagrams, and Euler diagrams support more accurate responses than Venn diagrams.

These authors claim that these findings demonstrate that such diagrams are highly accessible to novice learners. "The manipulation of diagrams in the inferential process is triggered without effort, if the spatial relations holding on external diagrams are governed by *natural* constraints" (p. 29, Mineshima et al., 2012). Although we do not echo their emphasis on the lack of effort involved for learners, we value their evidence that Euler diagrams are particularly helpful. "Our hypothesis is that Euler diagrams are *self-guiding* in the sense that the construction of diagrammatic proofs could be automatically triggered even for subjects without explicit prior knowledge of inferential strategies or rules, whereas Venn diagrams are not" (p. 7, Sato et al.,

2010). Their argument for this contrast, by which they explain their empirical findings, relates to the contrast between the underlying accounts of logic. Whereas the standard textbook treatment (based on truth tables) analyzes statements using quantification over individuals,

> in the field of natural language semantics, by contrast, quantifiers in natural language, such as *all*, *some* and *no*, are analyzed as denoting *relations* between sets… Thus, a sentence of the form *All A [are] B* is analyzed as $\boldsymbol{A} \subset \boldsymbol{B}$, rather than as the first-order representation $\forall x(Ax \rightarrow Bx)$. Similarly, *No A [are] B* can be analyzed as expressing $\boldsymbol{A} \cap \boldsymbol{B} = \emptyset$. (p. 2183, Sato et al., 2011)

They argue that Venn diagrams foster analysis by region of the diagram, while Euler diagrams foreground relations between the sets as units.

We argued in a previous section that findings about student thinking outside of mathematics inform logic instruction by helping us not place unnecessary barriers in students' ways. These studies of student performance on syllogism tasks suggest that Euler diagrams are particularly facilitating, likely because they foreground conditionals as relations between sets. The fundamental object relevant to truth-table analysis is the specific example object or a non-quantified statement about specific objects. Set-based truth conditions, especially as represented by Euler diagrams, support analyzing the truth of mathematical claims with the truth sets as objects. This means the truth of a conditional hinges on the relationship between two sets rather than a potentially infinite range of individual objects. Both views are ultimately useful in their way, but we contend that the view relating sets may be more facilitating for early logic learning. Insights from our studies in proof-based mathematics courses further support this claim.

Euler Diagrams May Support Students in Reasoning About Implications as Objects

In our investigations of student learning in introduction to proof courses, we have found that it is important for students to learn to reason about implications as objects, rather than actions or pseudo-objects (Norton et al., 2025). Building upon Sato et al.'s (2011) discussion, we can identify the distinction between noting a subset relationship between the sets $\boldsymbol{A}$ and $\boldsymbol{B}$ versus reasoning about the subset relationship as an object. As noted in Norton et al. (2025), this becomes particularly relevant when trying to act on a particular implication via operations such as composing implications ($p \rightarrow q$ and $q \rightarrow r$ yield $p \rightarrow r$), negating implications (which is distinct from negating either or both components), or transforming implications such as by inversion or conversion and reasoning about the properties of the transformed implication. We claim that set-based meanings for conditionals, especially when explored using Euler diagrams, may help foster understanding of implications as objects. While we acknowledge that this claim needs nuance in terms of how and how frequently this claim bears out in student learning, we also see evidence that truth tables are particularly unfit for fostering this kind of understanding.

Hawthorne and Rasmussen (2015) conducted one of the primary studies of how students reason about truth tables in learning logic in mathematics. One contrast they found was that the instructor conceived of the truth table as a unified definition of the truth of a statement while students often displayed a fragmentary understanding of the truth table. They understood each line as assigning truth values from the parts to the whole but did not reason about the truth table in a unified manner. We find it unsurprising that patterns of truth values do not support students in conceiving of a conditional statement as a fixed relationship between p and q, much less that it would support them to operate upon that object. Actions like composition, negation, and transformation can be carried out with truth tables by producing ever larger lists of T's and F's, but they do not provide a unified image of the meaning of the conditional to be acted upon.

By contrast, if students associate the conditional "if p, then q" with a subset relationship on their truth sets $\boldsymbol{A} \subset \boldsymbol{B}$, then we see easily how students could compose ($\boldsymbol{A} \subset \boldsymbol{B}$ and $\boldsymbol{B} \subset \boldsymbol{C}$ yields $\boldsymbol{A} \subset \boldsymbol{C}$), negate ($\boldsymbol{A} \not\subset \boldsymbol{B}$), and reason about transformations of this relationship (given $\boldsymbol{A} \subset \boldsymbol{B}$, what is known about $\boldsymbol{B} \subset \boldsymbol{A}$ or $\boldsymbol{A^c} \subset \boldsymbol{B^c}$?). We have explored some of these affordances in our teaching experiments (Dawkins et al., 2023; Hub & Dawkins, 2018). These experiments suggest these are viable learning pathways for at least some students, though further work is in order.

Another endorsement of the set-based meaning over the truth table definition comes from the literature we reviewed on the suppositional account and the defective truth table. As we noted before, students are most often troubled by the standard truth table because it claims conditionals are true when p is false. This whole question becomes a non-issue when analyzing conditionals using the set-based definition. Students are aware that to decide whether $\boldsymbol{A} \subset \boldsymbol{B}$ only objects in $\boldsymbol{A}$ are relevant and that objects outside of $\boldsymbol{A}$ certainly do not falsify the relation.

Subset Relations Capture Some Aspects of Mathematician Reasoning

In line with the potential compatibility between the subset meaning of conditionals and the suppositional account/ defective truth table, we think this could help explain some of the psychological findings about mathematician reasoning on the Wason Card task and abstract inference tasks. In particular, mathematical training particularly supports reasoners in avoiding fallacious inferences such as $q \to p$ and $\neg p \to \neg q$, but is less successful in promoting attention to the *modus tollens* inference $\neg q \to \neg p$. This seems reasonable given a strong association of a conditional with a subset relation, as subset relations are asymmetric (suppressing $q \to p$) and instances outside the subset are irrelevant (suppressing $\neg p \to \neg q$). It stands to reason that this same de-emphasis on cases where p is false would similarly suppress the *modus tollens* inference, as for a true conditional the truth sets of $\neg q$ and p are disjoint.

We will reference one final bit of evidence for the compatibility of mathematical practice and the subset condition. Alcock (2025b) investigated what diagrams mathematicians preferred for portraying conditional relationships. She found almost uniform preference for Euler diagrams over Venn diagrams. This means they chose representations that emphasize the truth conditions of a conditional, as Venn diagrams portray the region in which p is true and q is false, which may then be empty (the conditional being true) or non-empty (the conditional being false). While further work is needed to understand the nature of this preference, this supports our claim that the subset relation captures some aspects of how mathematicians reason about conditional statements in mathematics.

Conclusion

In this theoretical paper, we have drawn on a range of scholarship from different fields to build a case against the use of truth tables to teach logic for proof-based mathematics, which at present holds dominance in textbooks. We claim this approach puts unnecessary barriers between student reasoning from the everyday and mathematical practice, in part because the truth table definition does not adequately capture mathematical usage of conditionals. We offer the subset meaning as a viable alternative that avoids these challenges. Some studies we reviewed suggests that reasoning about conditionals in terms of set relationships is quite accessible, especially when explored using Euler diagrams. We do not mean to imply that there are not major challenges along that learning pathway, but we are convinced that this alternative approach has ample evidence to support a move away from the current status quo.

How and Why Mathematics Faculty Use Evidence-Based Instructional Practices: A Revised Model of Instructional Decision-Making in Undergraduate Mathematics Education

Mariah G. Moschetti
San Diego State University

Evidence-based instructional practices (EBIPs) are widely recognized as effective, yet their use in undergraduate mathematics remains sparse. While prior work has explained why faculty adopt EBIPs, less attention has been given to what happens after that decision – namely, how instructors implement these practices, why they use some approaches over others, and what shapes their persistence. In this theoretical report, I review literature on individual and contextual factors influencing EBIP use and identify limitations in existing models of instructional decision-making. I then propose a revised model that integrates Lattuca and Pollard's (2016) framework with Schoenfeld's (2010) resources-orientations-goals (ROG) theory. The model emphasizes the context-dependent nature of mathematics faculty's EBIP use and centers implementation as the site where persistence is shaped. Using data from one case study, I illustrate how the model can trace the full cycle of EBIP engagement from adoption, to enactment, to the experiences that influence continued use.

Keywords: Evidence-Based Instructional Practices, Active Learning, Undergraduate Mathematics Education, Faculty Decision-Making, Instructional Persistence

In undergraduate mathematics, traditional lecturing remains dominant across national and linguistic boundaries (Artemeva & Fox, 2011; Johnson et al., 2018; Stains et al., 2018), despite decades of research supporting evidence-based instructional practices (EBIPs), such as active learning. EBIPs promote student-centered instruction, foster higher-order thinking, and often involve collaboration, with evidence showing improved exam performance and reduced failure rates even in large classes (Freeman et al., 2014; Theobald et al., 2020). However, EBIPs encompasses a wide range of strategies, from minimal techniques like incorporating clicker questions to fully restructured formats such as inquiry-based mathematics education (Laursen & Rasmussen, 2019). This variation highlights that EBIP adoption is not a simple binary and that mathematics faculty may implement these practices in diverse ways (Johnson et al., 2018; Knowles et al., 2023).

Existing models of faculty instructional decision-making (e.g., Lattuca & Pollard, 2016; Sturtevant & Wheeler, 2019) explain why instructors might choose EBIPs but say little about what happens after that decision, such as how and why instructors implement these practices differently, and how these experiences shape their persistence using them. In this theoretical report, I highlight the need for research from this perspective and propose a substantial revision to an existing model of faculty decision making – one that better accounts for the iterative and context-dependent nature of EBIP engagement in undergraduate mathematics. This work aims to inform change initiatives that seek to expand EBIP use in undergraduate mathematics education.

Literature Review

This literature review has two parts. I first discuss the current body of literature on why mathematics faculty use EBIPs in their instruction. I then discuss limitations in what is known about why faculty use the specific EBIPs they do and how their implementation experiences are

connected with their persistence using these practices, underscoring the need for models that account for this.

The Use of EBIPs in Undergraduate Mathematics Education

The uptake of EBIPs among mathematics faculty appears to be sparse (Johnson et al., 2018), reflecting a broader trend in collegiate STEM education (Froyd et al., 2013; Henderson et al., 2012; Larsen et al., 2019; Stains et al., 2018). Consequently, much of the research on why faculty use EBIPs comes from STEM education more broadly. This body of research has identified two main categories of factors that influence faculty decisions to engage in EBIPs: individual factors and contextual factors.

Contextual factors influencing EBIP use. Contextual factors refer to external, institutional, and departmental influences (Sturtevant & Wheeler, 2019). These include physical resources such as class size and classroom space (e.g., Apkarian et al., 2021; Henderson et al., 2012); teaching evaluations and student buy-in (e.g., Deslauriers et al., 2019; Shadle et al., 2017); time constraints (e.g., Johnson et al., 2018, 2019; Turpen et al., 2016); and the level of support and incentives provided by institutions and departments (e.g., Lund & Stains, 2015; Sturtevant & Wheeler, 2019).

Large classes and fixed seating can limit the student collaboration many EBIPs require, while flexible learning spaces are associated with greater uptake (Foote et al., 2014; Knaub et al., 2016). Faculty concerns about student resistance, often tied to increased cognitive effort or unfamiliarity, may discourage adoption, especially when negative teaching evaluations are feared (Apkarian et al., 2021; Deslauriers et al., 2019; Owen et al., 2020). Time constraints are also a common barrier: faculty cite insufficient time to prepare EBIPs, learn them effectively, or cover content, with concerns in mathematics often linked to preparing students for later courses (Johnson et al., 2018, 2019; Woods & Weber, 2020). Without adequate institutional or departmental support, these challenges can be exacerbated, particularly in environments that prioritize research over teaching; conversely, departments with student-centered norms tend to foster EBIP adoption through professional development, mentoring, and ongoing teaching-focused dialogue (Andrews & Lemon, 2015; Lund & Stains, 2015; Shadle et al., 2017).

Altogether, this literature suggests that multiple contextual factors, such as physical space, student buy-in, time constraints, and institutional culture, shape faculty's use of EBIPs. These factors can discourage adoption by creating logistical or motivational barriers, particularly when institutions do not actively support or incentivize teaching innovation.

Individual factors influencing EBIP use. Unlike contextual factors, which depend on specific settings (e.g., a specific institution or class), individual factors refer to personal influences such as orientations (e.g., beliefs, values, dispositions) and goals (Schoenfeld, 2010), identity, and prior experiences (Sturtevant & Wheeler, 2019). These factors shape instructional practice and can, in some cases, outweigh contextual influences in determining whether faculty adopt EBIPs (Andrews & Lemons, 2015; Johnson et al., 2019). The most salient of these factors are faculty's prior experiences, particularly those shaping their satisfaction with EBIPs, and their orientations and goals.

Experiences and satisfaction. Faculty experiences – as both students and teachers – play a critical role in shaping instructional choices. In mathematics, most instructors experienced lecture-dominated classrooms as students, and many replicate these methods, particularly if they were personally successful in them (Lortie, 1975; Woods & Weber, 2020). Conversely, dissatisfaction with lecturing – such as perceiving it as less engaging or less effective – can prompt faculty to explore EBIPs (Andrews & Lemons, 2015; Johnson et al., 2019). Positive

experiences implementing EBIPs tend to encourage continued use (Andrews & Lemons, 2015; Sturtevant & Wheeler, 2019), whereas negative experiences – such as challenges in implementation, lack of preparation time, or unexpected student resistance – can lead to discontinuance (Hayward et al., 2016; Sturtevant & Wheeler, 2019). These findings suggest that satisfaction, whether with lecturing or with EBIPs themselves, is a pivotal motivator for instructional change.

Orientations and goals. Faculty orientations and goals – such as beliefs about student potential, views on where learning should occur, and perceptions of professional responsibilities – strongly influence teaching choices (Johnson et al., 2018, 2019; Shultz, 2022; Vishnubhotla et al., 2022). Instructors who believe all students can learn mathematics and value in-class engagement are more likely to adopt EBIPs, while those with lower expectations for student potential or a belief that learning occurs primarily outside of class (e.g., while studying) are more likely to lecture extensively (Johnson et al., 2019; Woods & Weber, 2020). Additionally, instructors who prioritize covering content with precision often view lecturing as the most efficient way to meet their goals (Woods & Weber, 2020; Shultz, 2022), whereas those who emphasize student sense making may view EBIPs as better aligned with their objectives (Dawkins et al., 2019; Johnson et al., 2013). Beliefs about student engagement also matter: some faculty see frequent questioning during lectures as sufficient active learning (Woods & Weber, 2020), in contrast to how active learning is usually conceptualized in the literature through higher-order thinking involving discussion, problem-solving, and collaboration (Chi et al., 1989, 1994; Hattie & Timperley, 2007; Banes et al., 2018, 2020; Callahan et al., 2021).

In short, faculty adoption and persistence with EBIPs is shaped by a combination of experiences, satisfaction, and deeply held orientations and goals. These individual factors can motivate faculty to innovate or reinforce their preference for traditional lecturing, and interact with contextual factors that either support or constrain their choice to use EBIPs.

The Need to Conceptualize How and Why EBIPs are Used by Mathematics Faculty

Active learning encompasses a wide range of instructional strategies that vary in intensity and impact. Some strategies, such as partial notes, clicker questions, think-pair-share, or small group problem solving, can be flexibly integrated into traditional lectures (Alcock, 2018; Braun et al., 2017; Dawkins & Weber, 2023), while others require substantial restructuring of the course, such as flipped classrooms (Milman, 2012), inquiry-based mathematics education (Laursen & Rasmussen, 2019), or the Extreme Apprenticeship method (Rämö et al., 2015). Research has shown that mathematics faculty use a variety of such EBIPs (e.g., Johnson et al., 2018). However, much of the literature examining these strategies in mathematics education is interventionist in nature, often situated within professional development programs or targeted course reforms (e.g., Hayward et al., 2016; Johnson et al., 2013; Laursen & Rasmussen, 2019). While these studies have been valuable for demonstrating the benefits of active learning, some research suggests that such intervention contexts (e.g., professional development) may influence the learning gains observed (Andrews et al., 2011) and the kinds of instructor experiences that shape persistence with EBIPs (Andrews & Lemons, 2015; Sturtevant & Wheeler, 2019).

Given this variation and the potential influence of intervention contexts, this highlights the need for theoretical perspectives that can account for both how mathematics faculty adopt and implement EBIPs in a range of settings, including the different ways they enact active learning in their classrooms. While many EBIPs have distinct names and program structures, they often share core practices such as facilitating student collaboration, eliciting student thinking, and structuring opportunities for sensemaking (Freeman et al., 2014; Theobald et al., 2020). Hence,

conceptualizing how mathematicians use these practices – including how contextual and individual factors influence which practices they choose and how their experiences shape their persistence – can complement intervention-based research and provide insight into the mechanisms that make active learning effective and sustainable. In total, this underscores the value of theory that can account for both how and why mathematics faculty use EBIPs.

A Model of Faculty's Use of EBIPs in Mathematics Education

In this theoretical report, I propose a model of faculty's use of EBIPs to investigate how and why mathematics faculty use these practices in undergraduate mathematics. I build on Lattuca and Pollard's (2016) model of faculty decision-making, as modified by Sturtevant and Wheeler (2019), and integrate Schoenfeld's (2010) resources–orientations–goals (ROG) theory. The ROG framework complements the decision-making model's structure and terminology while offering a lens for understanding how faculty decisions manifest in classroom practice and influence their experiences using EBIPs. I also incorporate refinements from my literature review.

Conceptualization of EBIPs

Implementing EBIPs with fidelity requires skills and knowledge that take time and effort to develop (Andrews-Larson et al., 2019; Archie et al., 2022; Fukawa-Connelly, 2016; Hayward et al., 2016; Johnson & Larsen, 2012). Some scholars therefore conceptualize EBIP use along a continuum rather than as a strict binary (Braun et al., 2017). Rather than urging all mathematics instructors to immediately abandon lecture, others emphasize ways to adapt lecture to be more student-centered and equitable (Alcock, 2018; Dawkins & Weber, 2023; Rasmussen & Johnson, 2023). Moreover, evidence of EBIP effectiveness (e.g., Freeman et al., 2014) often reflects a range of implementation levels, including courses with minimal active learning (Rasmussen & Johnson, 2023). I therefore define EBIPs broadly as instructional practices that actively engage students in learning mathematics, spanning both flexible and transformative strategies, from partial integration of active learning techniques to fully inquiry-based approaches.

An Existing Model of Faculty Decision-Making

Lattuca and Pollard's (2016) model of curricular change, as adapted by Sturtevant and Wheeler (2019) to focus on EBIPs, describes how extra-institutional, external, and internal influences shape faculty motivation to change instructional practices. Extra-institutional influences situate decisions within broader socio-cultural contexts, such as the COVID-19 pandemic or national calls to improve STEM education (Conference Board of the Mathematical Sciences, 2016; Saxe & Braddy, 2015). External influences include institutional and departmental culture, professional norms, and disciplinary orientations, while internal influences include beliefs, knowledge, professional identity, and prior experiences. These categories align closely with the individual and contextual factors described in my literature review.

The model posits that influences interact to shape motivation, which in turn drives adoption or rejection of EBIPs. Motivation may stem from perceived utility, personal interest, value alignment, or perceived costs (Lattuca & Pollard, 2016). Sturtevant and Wheeler (2019) extended the model to include dissatisfaction with current practice as a key motivator for EBIP adoption, and dissatisfaction with EBIPs as a driver of their discontinuance, aligning with literature on EBIP persistence (Froyd, 2013; Henderson et al., 2012). Overall, this model conceptualizes EBIP use as a motivated decision, which is constrained or facilitated by salient influences, and the decision to quit or persist with these practices is influenced by one's dissatisfaction using them.

Revisions to the Model

In this theoretical report, I propose revisions to Lattuca and Pollard's model. First, since many individual and contextual factors from my literature review align with the influences in the model, I adjusted it to use this terminology. Specifically, I expanded internal influences to include all individual factors and external influences to include all contextual factors, renaming them individual factors and contextual factors, respectively. I also embedded the model within the socio-cultural context to capture extra-institutional influences.

Next, I incorporated Schoenfeld's (2010) ROG theory into the model. While Lattuca and Pollard's model offers a framework for understanding faculty's decisions to engage in EBIPs, Schoenfeld's ROG framework provides a finer-grained lens for understanding how those decisions manifest in the classroom. Resources include both physical and knowledge-based assets, with knowledge being central. Orientations refer to the beliefs, values, and preferences that guide instructional choices. Goals are the intended outcomes, from long-term aims such as fostering mathematical engagement to immediate objectives like covering a topic. In familiar situations, decision-making is often automatic, but in unfamiliar ones, instructors' choices align with their orientations and goals, narrowing which approaches they consider

To integrate ROGs, I added an implementation phase to the model to address a limitation Sturtevant and Wheeler's (2019) adaptation; namely, the pathway from the decision to engage in EBIPs to the outcome of persistence or discontinuation is underdeveloped, leaving unexamined the experiences that shape instructors' satisfaction or dissatisfaction. In practice, these outcomes emerge through the implementation of EBIPs, where instructors encounter a range of both challenges and positive experiences. Including an "Implementation of EBIPs" phase makes visible how individual and contextual factors continue to influence instructional choices after the decision to use EBIPs is made. As others have argued, implementation experiences can influence whether faculty continue using EBIPs (e.g., Andrews & Lemons, 2015), highlighting the need to understand not just decisions to adopt, but the lived enactment of these practices in context. Hence, this addition enables researchers to examine not only whether mathematics faculty choose to use EBIPs, but also how they come to use them in specific ways, shedding light on both the substantial variation seen in EBIP implementation and the role of implementation experiences in shaping persistence.

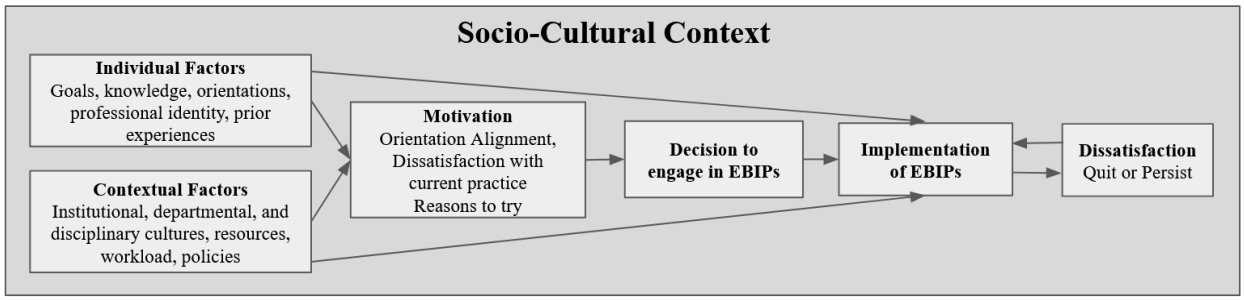

Figure 1. Visual Representation of the Revised Model. This revised framework models the influences that shape faculty engagement with EBIPs.

This model (Figure 1) provides a comprehensive cycle of EBIP use, not only looking at initial adoption but ongoing experiences. It distinguishes between individual and contextual factors, with contextual factors shaping individual ones. Individual factors include goals, knowledge, orientations, identity, and experiences. Contextual factors encompass institutional and departmental culture, resources (e.g., mentors, institutional support, classroom dynamics),

policies, and workloads. These factors, situated within a broader socio-cultural context, influence faculty motivation to engage in EBIPs and ultimately their decision to do so. Experiences implementing EBIPs, which are also shaped by individual and contextual factors, then influence whether faculty persist with or discontinue these practices continually (as indicated by bidirectional arrows in Figure 1).

An Example of the Model in Action

I draw from data from my dissertation to illustrate this cycle of EBIP use. Noah (pseudonym) is a tenured associate professor at a private research university in the western United States. He has several years of active-learning experience (including six years of flipped calculus) and, in Fall 2024, taught Discrete Mathematics using group worksheets and interactive lectures.

Motivation to Use EBIPs: The Decision to Engage in EBIPs

Noah's path to using EBIPs illustrates the influence of individual factors like goals, orientations, and prior experiences and contextual factors like departmental support. As a teaching assistant in an honors calculus course, he watched students "invent all these things for themselves," expanding his sense of what types of teaching were possible. Departmental culture later enabled him to use EBIPs, as he felt "more free to design courses" once in a department supportive of "teaching in different ways." Noah's prior experiences as a student and teacher also generated dissatisfaction with lecturing. While he "learned fine" from lecture plus homework, he recognized many of his students were "still learning…how to tell whether what they've done is correct," so they needed in-class opportunities for feedback, highlighting the need to bring active learning into his classrooms.

Implementing EBIPs: The Choice to Use Lecture and Group Work

Noah's resources, orientations, and goals explain how he implemented EBIPs: several days of interactive lectures followed by a class session devoted to small group problem solving. In discrete mathematics, his goal was for students to "learn how to read and write proofs." Firstly, Noah believed students needed initial exposure to content (orientation): "learning is also how the material is presented… they have to be exposed before they can sort of do [math]." While he preferred active learning, Noah described lecturing out of necessity, having abandoned a plan to flip his class due to limited time to prepare videos (time constraint): "I ended up lecturing content in class, and that's almost not as effective really." Still, he used active learning because "It's kind of basically kind of like getting everybody to come to office hours and work on homework…If I'm there in class when they're working on it, I can see what they're doing…" He described using group work specifically because "the process of explaining this to someone else" helps one identify "what you are stuck on," making group work better aligned with his goals and orientations than other options, such as individual problem solving in class. Hence, Noah was drawn to lectures followed by group work sessions since this let him cover content, while also providing opportunities for students to work together and receive feedback from him, while being less time intensive than flipping his class.

Dissatisfaction with EBIPs: The Choice to Persist

Lastly, an episode during the semester highlighted how Noah persisted past dissatisfaction stemming from student resistance to group work. When early group work fell flat during an initial observation, with limited interaction between students, he saw the problem not as a flaw in group work itself but as a mismatch between his orientation toward collaboration and his current

group work structure. In response, he moved from using unassigned groups to assigned pairs at shared whiteboards with a single marker to ensure collaboration. The next observation showed improved participation, including cross-interactions between pairs; Noah was "pretty happy with it" and reported using the structure again. This highlights Noah's adaptation as a persistence strategy: dissatisfaction during implementation triggered revision, not quitting, mediated by contextual factors and individual factors. In ROG terms, he mobilized resources (whiteboards), acted from orientations (collaboration) toward goals (improved proof writing).

Overall, Noah's case illustrates the revised model in action, highlighting how different factors influence one's initial motivation, EBIP implementation, and persistence. Moreover, this illustrates the potential affordances of research in undergraduate mathematics that conceptualizes the uptake and continued use of EBIPs in this way. Without this modification, the model would have had limited explanatory power beyond Noah's initial decision to engage with EBIPs. The modifications made it possible to analyze not only why Noah chose to use EBIPs, but also why he favors interactive lectures with small-group problem-solving (something the original model does not address), and how he persists despite dissatisfaction (with dissatisfaction accounted for in the original model but left vague). In particular, the model highlights how individual and contextual factors shaped both his use of EBIPs and his classroom experiences. These factors, in turn, gave rise to specific affordances and challenges, and revealed how Noah responded, both in the EBIPs he chose to adopt and in the ways he adapted them in order to persist.

Acknowledgments

I would like to thank Mary E. Pilgrim and Chris Rasmussen for their feedback on this manuscript and their ongoing mentorship and support.

Theorizing Anticolonial Praxis in Undergraduate Mathematics Education

Reagin Taylor McNeill
Michigan State University

Sabrina N. Zarza
Michigan State University

Jose Contreras
Michigan State University

Ayesha Maliwal Bundy
Michigan State University

Mathematics is frequently presented as a universal and objective discipline. Yet these claims of universality are culturally framed by whiteness and limit the possibilities for relational and ethics-driven approaches to mathematics that align with Indigenous knowledge systems. This theoretical report synthesizes insights from Indigenous perspectives, anticolonial theory, and critical mathematics education to critically examine the colonial underpinnings of mathematics. Leveraging these insights, we present a three-dimensional framework for anticolonial praxis addressing axiology, epistemology, and ontology, and seed an illustrative curricular possibility. We conclude with a call to action, urging instructors and researchers to negotiate the complexities of actualizing anticolonial praxis in institutions governed by colonial traditions.

Keywords: settler colonialism, indigeneity, curriculum, epistemology, ontology

Mathematics lags behind other disciplines in its readiness to radically reimagine the subject as just and liberatory (Gutiérrez, 2017a). At the undergraduate level, the lack of clarity about how mathematics may be reformed to advance equity can stifle broader institutional efforts. Consider Hispanic-Serving Institutions (HSIs) as an example. The rise of HSI designations has led to a wave of university efforts to decolonize curricula to provide course experiences that embrace Latin* ways of thinking, knowing, and being (e.g., Garcia, 2018). While equity-oriented research in mathematics education at HSIs has deepened our understanding of classroom social dynamics (e.g., Leyva et al., 2024), less attention has been given to how mathematical content itself is framed; HSI instructors continue to teach mathematics curricula that they believe to be culture-free (Shultz et al., 2024). In this way, the undertheorization of anticolonial approaches to mathematics may stand in the way of HSIs' progress towards truly serving Latin* students.

This theoretical report synthesizes anticolonial theory, critical mathematics education, and Indigenous perspectives to conceptualize anticolonial curricula and praxis in undergraduate mathematics. We open by challenging the myth that mathematics is universal, examining how its codification has been shaped by global power structures that reproduce white, imperial values (Bishop, 1990). Afterwards, we review relevant scholarship, emphasizing how more robust decolonial work in K–12 mathematics education and other postsecondary disciplines signals a pressing need for similar engagement in research in undergraduate mathematics education (RUME). Drawing on Indigenous and decolonial theories, we distinguish anticolonial praxis from common framings of decolonization and offer our conceptualization in the undergraduate mathematics context. We end with a call to action, urging mathematics educators to grapple with complexities of enacting anticolonial praxis within institutions rooted in colonial legacies.

The Colonial History of Mathematics

Mathematics is often viewed as neutral and objective (Bishop, 1990; Shahjahan et al., 2022). However, closer examination reveals cultural bias in narratives about mathematics. For example, mathematics curricula often highlight figures like Pythagoras in discussions of trigonometry,

while overlooking non-white contributors—such as the African architects of the Great Pyramids, whose achievements predate Pythagoras by millennia (McNeill & Gresalfi, in press; Raju, 2017). Such differences in recognition signify cultural power relations governing who controls the narrative of mathematics and, relatedly, which forms of mathematical knowledge are constructed as legitimate or worthy of preservation (Osibodu, 2024). These exclusions are not incidental; they function as mechanisms that uphold colonial and racialized hierarchies within the discipline.

The mathematics taught in Western education—which is governed by axiomatic logic and idealized notions of objectivity (Gutiérrez, 2017b)—is made possible only when a society has sufficient surplus to enable intellectual pursuits that serve no utilitarian or survival-based purpose (Zaslavsky, 1999). Exploitive labor structures and access to trade (Coates, 2011; Diamond, 1999) contributed to the development of such privileged forms of mathematics in Europe while mathematics in other areas of the globe remained deeply contextual and tied to social needs (Zaslavsky, 1999). These socially contextualized forms of mathematics were positioned as lesser by Europeans (Hottinger, 2016). European mathematics, along with the narrative that valuable mathematics is abstract, became globally dominant through settler colonialism (Bishop, 1990).

While the ontological distance between mathematics and social realities—a characteristic of European mathematics (Bishop, 1990)—is often cited as evidence that mathematics is neutral, it may actually enable mathematics to serve oppressive functions. Decontextualization allows mathematics to be engaged without ethical considerations and can operationalize imperialist values of commodification and control (Bishop, 1990; Ernest, 2018). Indeed, mathematics has played an important part in racial dehumanization (e.g., the three-fifths compromise; Ratliff, 2023), genocide (e.g., Israeli military strategy in the occupation of Palestine; the pseudo-science of the Holocaust; Alshwaikh, 2024; Ernest, 2018), capitalistic ecocide (Fúnez-Flores et al., 2024), and authoritarian governance (e.g., homeland security; Grewal, 2017).

Anticolonial Praxis as an Emerging Site of Inquiry in Undergraduate Mathematics

While decolonial and anticolonial scholarship has gained momentum across many educational fields, engagement with these conversations in RUME is nascent. For example, in a systematic review of 126 articles related to decolonization in higher education curriculum and pedagogy, Shahjahan and colleagues (2022) identified only one with a disciplinary focus in mathematics. Similarly, in reviewing engagements with decolonial theory in mathematics education Fúnez-Flores and colleagues (2024) identified only a single study from Bhattacharya and colleagues (2024) addressing postsecondary contexts. The study's project-based curriculum critiques dominant power structures and centers students' lived experiences, which the authors argue exemplify a decolonized curriculum. This curriculum engages Indigenous epistemology and ontology, which often proposes an environmental focus and relational ways of thinking (e.g., Kulago et al., 2021, Garcia-Olp et al., 2019). While this curriculum represents valuable progress, it does not match the depth of Indigenous engagement found in K-12 mathematics education.

This limited consideration of Indigeneity also appears in scholarship presented at the RUME conference—a venue that often reflects emerging priorities in the field. Within the last five years of RUME proceedings, we identified one theoretical report that engaged an Indigenous research paradigm and three other reports drawing on adjacent frameworks. Among these, it is notable that attention to instructional settings remains limited. For example, Hagman and colleagues (2024) use the Nahuatl term "Nepantla" to describe and theorize the tensions and instability inherent in equity-oriented departmental change efforts. The use of Nepantla to theorize such tensions in mathematics education research was first introduced by Gutiérrez (2008), drawing from Anzaldúa's (1999) original conceptualization of Nepantla as a liminal space of rupture and

transformation, where new forms of consciousness and resistance can emerge. Nepantla, as a space, disrupts Western dichotomies by embracing fluidity, multiplicity, and the coexistence of seemingly contradictory ways of being. Although Hagman and colleagues theorize with this Indigenous concept, its connection to instructional practice is remote and it is unclear whether the study's participants engaged this way of knowing. Similarly, Luecke's (2022) engagement with decolonial principles, though contextualized by a need to connect Western mathematics to Dakota/Lakota space, language, and culture at Tribal Colleges, focuses primarily on advancing an Indigenous research paradigm—a paradigm of "co-connecting knowledge" that is relational, reciprocal, and that decenters humans as the only source of knowledge. Although these inquiries importantly integrate Indigenous ways of being and knowing into scholarly conversations in RUME, they offer limited guidance to disrupt colonial paradigms in classrooms.

The ontological tensions Luecke (2022) identifies emerge within teaching inquiries in RUME, albeit in limited form. For example, critically examining the Western nature of mathematical representations as static and universal, Abreu (2022) proposes adopting mathematical drawing practices that are indeterminate and embodied. Similarly challenging the supposed universality that underpins undergraduate mathematics content, scholars also propose approaches that contextualize mathematical ideas or acknowledge the real-life limitations of mathematical abstraction. For example, although not published in RUME proceedings, Raju (2012) recognizes the physical impracticality of infinitesimals by advocating for grounding calculus curricula in Indigenous Indian approaches that achieve the major results of calculus without the use of limits. Abreu and Dickson (2024) propose instruction that invites stories that demonstrate isomorphisms and interrogates the topic's colonial underpinnings through questions such as, "Where does the persistent preoccupation for 'sameness in forms/structures' in dominant mathematics come from?" (p. 1315). Although these inquiries importantly integrate Indigenous ways of being and knowing into scholarly conversations within RUME, they offer incomplete models to guide anticolonial praxis.

The marginal theorization of anticolonial praxis in RUME exposes the field's complicity with colonial mathematical and instructional traditions (Gutiérrez, 2022; Raju, 2012), demanding reflection on what kinds of mathematical knowledge we validate and what educational possibilities we strive to create. Towards disrupting such complicity, we theorize anticolonial praxis in what follows.

Theorizing Anticolonial Praxis in Undergraduate Mathematics Education

Defining an Anticolonial Orientation

Efforts to critically address the legacy of settler colonialism have largely been framed as decolonization. However, the term decolonization has been co-opted in ways that retain limited connection to indigeneity and colonial violence, which can undermine its radical potential. Tuck and Yang (2012) caution against using decolonization as a metaphor, arguing that decolonization is a specific and material process grounded in the repatriation of Indigenous land and life. While we recognize the importance of preserving this meaning, we also recognize that higher education has been shaped by settler colonialism in ways that extend beyond land (Woldegiorgis, 2021). For example, while Latin* students at HSIs may lack Indigenous ties to the land on which the institution was built, these institutions are still structured by the colonial forces that may have dispossessed their ancestors in Latin America; dismantling those structures remains essential to actualizing justice (Garcia, 2018). Patel (2015) distinguishes between decolonial and anticolonial work noting that anticolonial more accurately reflects engagements that seek to understand and

counter colonial logics while acknowledging that such efforts, particularly within institutions of higher education, do not constitute decolonization. Adopting this perspective, we aim to theorize anticolonial praxis in undergraduate mathematics education as an orientation to curriculum and instruction that confront the epistemological and ontological hegemony that was mobilized through settler colonialism. We adopt an anticolonial perspective not to dilute the stakes of decolonial struggle, but to clarify the limits of our institutional locations and the transformative possibilities within them. We remain committed to disrupting the settler (mathematical) grammars that structure the very terms of legitimacy in education (Calderon, 2014).

A Framework for Anticolonial Praxis

Because mathematics is often perceived as socially neutral, many have not deeply considered how it could diverge from whiteness and colonial paradigms; this constrains radical reimagination of mathematics education as a site of liberation (Martin, 2019). Through a synthesis of decolonial theory, Indigenous epistemologies, and our own lived experiences with alternative pedagogies, we reimagine pedagogies of relationality, holism, and justice. Building on Gutierrez' (2022) theorization of Indigenous futurity, we propose a framework for anticolonial praxis consisting of three dimensions: axiology, epistemology, and ontology. Afterwards, we seed an illustrative curricular possibility to support the practical realization of this framework in undergraduate mathematics teaching.

Anticolonial axiology: centering political and spiritual desire. Axiology relates to ethics and value-driven action. Within anticolonial theory, axiology demands that we interrogate what is valued, who gets to define value, and how values are enacted in mathematics classrooms. We attend to political and spiritual dimensions of mathematics, restoring ethics in curriculum design.

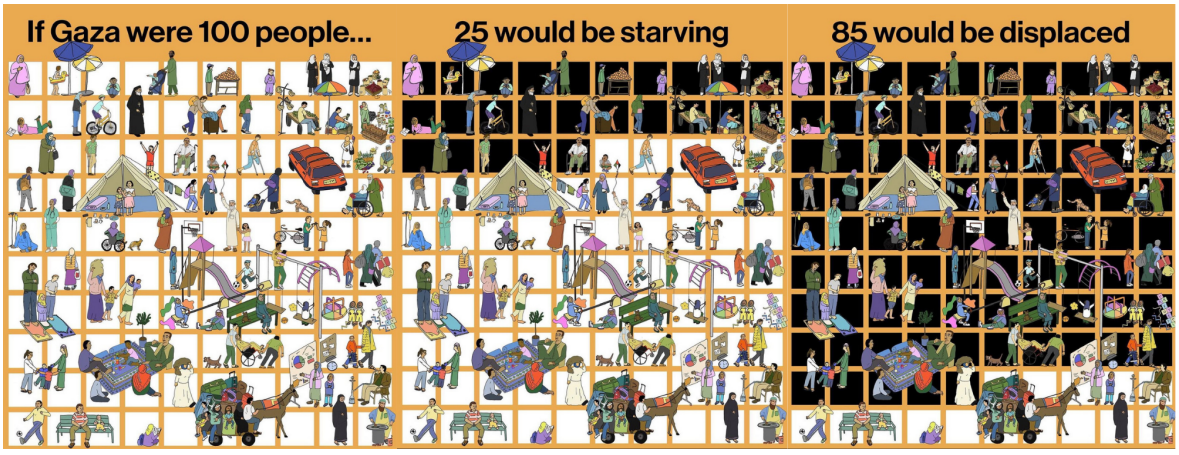

Figure 1. Chalabi's data visualization of genocide and displacement in Gaza

As Martinez et al. (2021) write, "an axiological departure of mathematics focuses on the shared experience lived while creating relationships with and across mathematics." When we are able to position the spiritual and mathematics as coexisting, "we can envision mathematics as alive, working with us as we engage in rich experiences. …[and] the experience of learning is no longer an individual task; it becomes a collective experience of knowledge construction" (p. 76). This view stands in opposition to dominant axiologies in mathematics education, where the value of mathematics is rooted in individual gain and the production of "rational and productive citizens" that would contribute to a nation's progress globally (Nikolakaki, 2016, p. 281). Such

framings are inextricably linked to capitalist ideologies, placing value on mathematics education as a tool for economic competitiveness rather than as a site for relational or spiritual engagement.

Embodying anticolonial axiology, Chalabi's (2024) data visualization (Figure 1) resists sanitized, apolitical norms, illuminating the discipline's potential to "live in harmony with values that protect life and enhance understanding" (Fasheh, 2012, p. 103). Visualizing the toll of the ongoing genocide and displacement in Gaza, Chalabi (2024) reveals embodied realities behind the numbers, rendering visible the lives and relationships erased by dominant data practices. In rehumanizing the data, Chalabi challenges capitalist and colonial tendency to quantify suffering for the purposes of policy, profit, or erasure, exemplifying anticolonial witnessing and solidarity.

Anticolonial praxis demands we reshape our views of what mathematics is for and integrate ethics as part of mathematical reasoning. Grounded in political and spiritual desire, anticolonial axiology values the potential for mathematics to foster connection and sustain collective life.

Anticolonial epistemology: honoring partiality and plurality in knowledge production. Epistemology relates to ways of thinking and constructing knowledge. Gutierrez (2017b) fosters epistemic plurality in her conceptualization of *mathematx*—a vision of mathematics where "multiple knowledges are valued and sought" (p.16) and such partialities are honored for their contributions to the whole. Mathematx calls on us to be epistemically disobedient—to refuse to recognize dominant forms of knowing as superior and to actively seek alternatives. This perspective intertwines with Anzaldúa's (1999) concept of Borderlands, which theorizes the space between categories, languages, cultures, lands, etc., as liminal, fluid, and inhabitable. The Borderlands are a third space, "greater than the sum of its severed parts," that allows for movement across and beyond imposed boundaries (p. 80). This perspective prompts mathematics educators to reimagine the field not as a bounded discipline, but as a site of possibility shaped by the cultural, historical, and experiential knowledge of those who engage with it.

Theorizing alongside Anzaldúa (e.g., 1999) and Gutiérrez (e.g., 2017b), Yeh and colleagues (2021) similarly call on mathematics educators to engage in acts of ontological and epistemological disobedience. They urge the field to interrogate long-standing borders that define what mathematics is, who it is for, and where it can be done. As an example in secondary mathematics, Yeh et al. (2021) assert that despite contemporary reforms emphasizing problem solving and reasoning "school mathematics is still typically defined as a discrete set of topics taught in a linear progression that ultimately leads to calculus" (p. 200). They ask, "If mathematics educators were no longer forced to guide students along a narrow path to calculus, what else could it mean?" (p. 200). They call for disobedience in the field, suggesting that as computers increasingly handle routine computations, mathematics education should focus on critical mathematical literacies—engaging with data and inquiry in ways that foster learners' community-based reasoning. This shift away from abstract mastery and towards the cultivation of relationally situated and multiple ways of knowing reflects epistemic plurality—one that moves fluidly across, within, and between boundaries.

Anticolonial ontology: mathematics as an interconnected way of being. Ontology relates to the nature of being. Kulago et al. (2021) emphasize how the dualism perpetuated by colonial knowledge systems severs connections between mind, body, spirit, and nature. In contrast, Indigenous epistemologies position knowledge as relational and dynamic—always in connection with others, land, ancestors, and the more-than-human world.

Anticolonial ontology resists the construction of the self as a disembodied knower, which Wynter (2003) names as a form of dehumanizing violence. Specifically, Wynter challenges the overrepresentation of "Man"—a specific, Western, bourgeois conceptualization of humans as

rational and detached from relational or spiritual ways of being. Through coloniality, this figure became the dominant standard through which humanity is defined, creating a *coloniality of being* that erases alternative ontologies. This framing aligns with dominant framing of mathematics as neutral, objective, and disembodied, which excludes ontologies rooted in relationality.

In contrast, an anticolonial ontology invites us to reimagine mathematics as a space of relational being, affirming our interdependence and entanglement with the world through land, community, and story. Rather than treating mathematics as a detached system of logic or symbols, this orientation considers mathematics as entangled with emotional and physical experience, lived histories, and collective futures. Martinez et al. (2021), for instance, describe a way of knowing and being that emerges through spirit, culture, and community. When learners engage mathematics in this way, they are not merely solving problems or mastering procedures. They are entering into a relationship with mathematics that is attentive to memory, land, family, and story. Through this lens, mathematics is part of becoming. This orientation does not seek to insert culture into mathematics as a contextual add-on. It requires a more fundamental shift in how mathematics is conceptualized. Instead of imagining mathematics as something to be applied to external realities, anticolonial ontology asks us to consider how mathematics already lives within those realities. Mathematics is world-making, shaped through embodied participation and connection.

A Curricular Seed: Integrating Light and Lifeworlds

I (the first author) choose to speak to you directly to ground our curricular seed in ontological intimacy, relationality, and ethics, thus embodying the principles of our theorization. Afterwards, I re-assume scholarly norms to analyze its constituent parts.

I credit Jake Morrow for this example—the farm manager at a school with a work program where I once taught. Jake came to me once with a calculus problem. He shared that for some crops, time to harvest depends not on the number of days that pass, but the cumulative amount of sunlight they receive. Locally, daylight hours varied significantly over the year. He wanted a mathematical model that could provide the date of the harvest given the date of planting.

I did not have the wherewithal to teach with this problem at the time, but now informed by Indigenous theories, here is how I envision it as anticolonial praxis. To begin, students would question what forms of mathematics would be needed; the answer is uncertain. It is unclear to me whether this problem might involve integrating a function whose inputs were calendar dates and outputs were the duration of daylight, or whether a more complex model is necessary. For example, could the higher light intensity near the summer solstice, when the sun is more directly overhead, influence growth in ways not explained by daylight hours alone? How do you account for days being discrete when a function for daylight over the year would likely be sinusoidal? These questions draw on our knowledge and experiences of the natural world as a guide.

We would have to try a variety of models. Given the local nature of the problem, we would draw on Jake's experience, or others who had a long history working with the land, to assess the utility of our models. In doing this, we would likely learn how harvests have been changing with the climate, and no longer follow their historical patterns. This would be an additional mathematical complexity to work into our model—one that might cause us to grapple with our fears and responsibilities related to an uncertain planetary future.

While this problem's original context was a school farm 1,000 miles away, it is also tied to injustices I witness locally and globally. I remembered this problem while creating a garden for my family. We are tired of eating food that supports corporate profits while degrading our health and we wish for less of our income to support forced labor (Bureau of International Labor

Affairs, 2025). However, we struggle to afford high-quality, ethically-sourced food. Of course, these are systemic challenges that affect many people more severely than they affect us, and inequities in land access make it difficult for some to grow food. I was pleased to learn our city has a number of community gardens that expand opportunities to work with the land, offering a potential site for service-learning if I were to teach around this issue. I am also reminded that our university, as a land-grant institution, was founded to develop agricultural knowledge for the region—knowledge that supplanted what was lost through the genocide and forced removal of Indigenous peoples (American Indian and Indigenous Studies, [masked] University, n.d.). I think of the educative possibilities of bringing this institutional history into a mathematics class, as we together consider what sophisticated forms of mathematics might have grown from that Indigenous knowledge. Perhaps this problem, and others, would have been solved long ago.

Situating the problem in our anticolonial praxis framework. Our curricular seed embodies our anticolonial praxis framework. Pertaining to axiology, our example holds meaning and embodies values of ecological justice and relationality. Students' mathematical engagement does not simply satisfy the requirements of schooling. Rather, it frames mathematics as intimately tied to the foods students grow and eat, food access inequities in their local community, and broader climate concerns. Epistemologically, the task of modeling has no clear "right answer." This invites multiplicity in interpretations and approaches, using lived experience and interconnected knowledge to explore models that are verified by their situated utility. Ontologically, mathematics becomes part of our constant quest to redefine who we are as people, and how we contribute to the world. Our experiences, embodiment, and intuition are inseparable from the mathematical endeavor, the outcomes of which have bearing on our ways of life.

Call to Action

The curricular possibility seeded here, and the larger anticolonial framework it represents, are not easily implemented in undergraduate mathematics classrooms as they currently stand. We teach and research within institutions that remain active sites of settler colonialism and are held accountable for reproducing colonial forms of knowledge therein. However, justice (in undergraduate mathematics education) cannot be achieved through incremental changes that do not fundamentally threaten these white paradigms (Martin, 2019; McNeill & Gresalfi, in press).

Our curricular possibility requires time investment in the relationships between ourselves, community members, and the ecosystem. Such reflective time is often limited when instructors are expected to cover the full range of computational and theoretical skills required for the next mathematics course; we anticipate instructors may feel concerned that their students would be "behind" in their mathematics learning as a result. We validate this concern. However, the first author is also reminded of their mathematics dissertation on symmetry groups of topological surfaces and of the limited hope they place in that work's capacity to yield spiritual, social, or planetary benefits. Indeed, it is difficult to imagine this would constitute the highest level of mathematics learning through Indigenous perspectives. When we consider how anticolonial praxis may impact students' preparation, we must ask what we hope to prepare students for. Are we preparing students to engage mathematics in supposedly ethics-free ways for advancement in a white supremacist, capitalist system, or to solve pressing social and global problems?

Informed by Gutiérrez' (2015) call for mathematics educators to nest in nepantla, we do not attempt to reconcile these conflicting instructional imperatives. An anticolonial vision cannot be squared with the status quo of postsecondary institutions. Still, in every lesson taught and every inquiry pursued lies the possibility of reimagining mathematics otherwise. We invite educators to embrace this possibility and carve pathways toward an ethical future (Gutiérrez, 2022).

Untangling Active Learning: A Framework of Dimensions, Strategies, and Outcomes

Ayesha Maliwal Bundy
Michigan State University

Active learning has become a widely cited cornerstone of undergraduate education reform; yet the construct remains conceptually ambiguous, leading to challenges in research synthesis, instructional implementation, and policy alignment. This paper synthesizes literature across mathematics and STEM education to trace this ambiguity to the conflation of three distinct but interconnected facets: dimensions of engagement, strategies for implementation, and outcomes of learning. To address this gap, I propose a theoretical framework that disentangles and defines these facets, providing analytic clarity for both researchers and practitioners. By situating this framework within ontological, epistemological, and axiological perspectives, the paper illuminates how differing research traditions conceptualize, investigate, and value active learning. This reframing enables systemic inquiry into how strategies activate specific engagement dimensions to produce desired outcomes in diverse contexts, informing instructional design. The framework thus offers researchers, practitioners, and policymakers a roadmap for advancing both scholarship and meaningful reform in undergraduate mathematics education.

Keywords: active learning, undergraduate mathematics education, student engagement, instructional strategies, learning outcomes

Calls for widespread adoption of active learning in undergraduate STEM education are ubiquitous (e.g., Conference Board of the Mathematical Sciences [CBMS], 2016; President's Council of Advisors on Science and Technology [PCAST], 2012). Meta-analyses and large-scale studies consistently report a positive impact of this pedagogical approach on student achievement and persistence (e.g., Freeman et al., 2014; Graham et al., 2013). Active learning has been credited with cementing the shift in focus to learner-centered environments, deepening learning "beyond surface-level knowledge acquisition", reducing achievement gaps for underrepresented students, and building student resilience (Duran et al., 2022; Kerrigan & Kwaig, 2024; PCAST, 2012; Theobald et al., 2020).

However, despite the theoretical arguments and mounting empirical evidence in favor of the construct, the adoption of active learning practices in undergraduate STEM has not kept pace (Børte et al., 2020; Nguyen et al., 2021). A significant barrier lies in the conceptual ambiguity surrounding the term itself: researchers and practitioners invoke "active learning" in divergent, sometimes conflicting ways—referencing engagement, strategies, outcomes, or a combination of them interchangeably. This definitional drift complicates efforts to synthesize the research and hinders its translation into effective, context-sensitive teaching practices. This ambiguity also weakens the influence of research on educational policy and large-scale reform initiatives.

The purpose of this paper is to bring conceptual clarity to the active learning construct by proposing and explicating a theoretical framework that distinguishes among three interrelated facets: dimensions of engagement, instructional strategies, and learning outcomes. This reframing of the construct seeks to clarify what characterizes active learning, how it can be effectively implemented, and what outcomes it produces. The framework paves a way for researchers, practitioners, and policymakers to interpret the active learning literature and make intentional decisions aligned with their goals.

Conceptual Ambiguity in Active Learning

Although "active learning" has become one of the most frequently invoked terms in undergraduate mathematics education reform, its meaning remains elusive.

Examining the Ambiguity

Often, active learning is thought of as the "antithesis of lecture" (Driessen et al., 2020). This broad conceptualization has created significant challenges in practice:

Multiple, sometimes conflicting interpretations. Bonwell and Eison's (1991) early definition of active learning as "activities involving students in doing things and thinking about what they are doing" highlights student engagement and reflective participation. Expanding on the idea of shifting students away from passively listening, Freeman et al. (2014) emphasize higher-order thinking and group work in their widely cited consensus definition of the construct. Laursen and Rasmussen (2019) stress the "inherently social nature" of active learning and emphasize equity in instructional design, "a characteristic that is notably absent in many scholarly definitions" (Williams et al., 2022). The use of broad descriptors—like "involving" and "doing"—leads to multiple, conflicting interpretations (Braun et al., 2017): Does active learning require group work? Are both conceptual and procedural tasks considered active learning? At what point does a traditional lecture, interspersed with some activities, qualify as active learning?

Variation in operationalization. Even when studies share a definition of active learning, they often operationalize it in very different ways. Some focus on a single technique (e.g., think-pair-share) while others examine whole-course transformations. Freeman et al.'s (2014) seminal meta-analysis on active learning included a wide range of courses, from lectures with "only 10-15% of the time devoted to clicker questions" to entirely "lecture-free 'studio' environments". These significant variations in intensity of practice limit comparability of research and risk rendering the construct too broad to be analytically useful (Lombardi et al., 2021).

Overlapping constructs. Active learning's porous boundaries with related approaches—such as inquiry-based, cooperative, and problem-based learning—have diluted the precision of the construct (Prince, 2004; Lombardi et al., 2021). Many studies treat these overlapping categories as interchangeable, making it difficult to isolate their individual impact. As a result, stakeholders often speak past one another while implicitly drawing on different conceptions of what *counts* as active learning.

Erasure of Context. Outcomes of active learning are not uniform and are moderated by context—class size, student identities, instructor beliefs and preparation, instructional choices, and institutional culture. However, active learning is often promoted as a "one-size-fits-all" solution for enhancing student learning and success. Ignoring the contexts in which it operates leads to a disconnect between conceptual understanding and practical application of the construct, widening the research-practice gap in mathematics education.

Consequences of Ambiguity

This conceptual murkiness has significant consequences. For researchers, the conflation of the characteristics, enactment, and outcomes of active learning complicates cumulative knowledge-building. Results are often aggregated over a wide range of interventions, which fails to provide a clear understanding of which strategies produce the desired outcomes under what conditions and why. For practitioners, this lack of clarity fosters misconceptions about active learning and hesitancy to adopt it. Thus, addressing this conceptual ambiguity and definitional drift is essential for advancing empirical research, supporting evidence-based teaching reforms, and enabling clearer dialogue within the mathematics education community.

A Framework for Active Learning

To address this ambiguity, this paper proposes a conceptual framework that unravels active learning into three interconnected but distinct facets: (1) dimensions of engagement, (2) strategies for implementation, and (3) outcomes of learning. These elements frequently overlap in the literature and are often used interchangeably, yet each plays a unique role in shaping how active learning is conceptualized, studied, and practiced.

Dimensions of Engagement

The first facet concerns the dimensions of engagement that characterize *how* students participate in active learning environments. Rather than treating engagement as a single construct, this framework recognizes multiple pathways through which learners can be actively involved in mathematical meaning-making. Synthesizing across scholarship (Edwards, 2015; Laursen & Rasmussen, 2019; Lombardi et al., 2021; Vale & Barbosa, 2023), five dimensions are identified. Table 1 outlines these dimensions with descriptions and illustrative examples.

Table 1. Dimensions of Engagement in Active Learning

Engagement	Description	Examples
Cognitive	Students' deep thinking about mathematical ideas	Higher-order thinking, purposeful meaning-making, self-regulation (planning, goal setting, adjusting approaches), metacognition
Social	Students' interaction with peers and instructors	Collaborative problem solving, co-construction of knowledge, mathematical communication
Behavioral	Students' observable participation and efforts	Use of movement and tools, task-focused persistence, resilience despite challenges
Emotional	Students' affective connection to learning	Curiosity, excitement, enjoyment, interest, sense of belonging
Agentic	Students' contributions to shaping the learning process	Initiating discussions, forming study groups, offering feedback to shape course design

Dimensions of engagement remain a relatively hidden paradigm of active learning research. This framework helps bring them to the forefront since they are essential to defining and understanding active learning. This multidimensional engagement model acknowledges that not every active learning technique will activate all dimensions uniformly, enabling researchers and practitioners to examine which aspects of engagement are activated by instructional choices.

Strategies for Implementation

The second facet centers on instructional strategies, the concrete practices and pedagogical approaches that operationalize active learning in classrooms. These strategies are the most visible aspect of the construct and range in complexity from brief, targeted activities (e.g., think-pair-share) to more comprehensive reforms (flipped classroom, using inquiry-based learning curriculum). Synthesizing the literature (Bonwell & Eison, 1991; Driessen et al., 2020; Freeman et al., 2014; Lombardi et al., 2021; Nguyen et al., 2021; Nardo et al., 2022; Martella & Schneider, 2024; Prince, 2004), the documented strategies can be condensed into three categories. Table 2 outlines these categories with descriptions and illustrative examples.

Table 2. Strategies for Implementation of Active Learning

Strategies	Description	Examples
Class Activities	Structured opportunities for student interaction, collaboration, and reflection	Think-pair-share, gallery walks, jigsaw, clicker questions
Assignments	Opportunities for scaffolding learning and extending engagement outside class	Pre-class work, formative checks for understanding, projects
Course Planning	Alignment of goals, materials, activities, and feedback processes for sustained participation	Backward course design, surveys, incorporating student input into curriculum and course design

By emphasizing the spectrum of strategies, this facet resists the tendency to flatten "active learning" as a single technique. For one, these strategies vary significantly in terms of intensity and design—for instance, a course that inserts occasional activities into the lecture bears little resemblance to a flipped classroom where all class time is dedicated to collaborative work—yet they are all labeled as active learning. Moreover, different strategies activate different forms of engagement. For example, clicker questions may primarily elicit cognitive and behavioral engagement, while group work may additionally support social, emotional, and agentic engagement. Thus, strategies need to be understood as means or *mechanisms* for activating specific dimensions of engagement, which in turn shape the learning results.

Learning Outcomes

The third facet addresses the learning outcomes associated with active learning. Outcomes are the most measurable aspect of this construct and encompass not only disciplinary knowledge but also developmental gains. This framework distills the outcomes reported in the literature (Bonwell & Eison, 1991; Freeman et al., 2014; Lugosi & Uribe, 2020; Theobald et al., 2020) into seven categories. Table 3 presents an overview of these, along with examples of impacts.

Table 3. Learning Outcomes of Active Learning

Outcomes	Examples of Impact
Cognitive	Increasing conceptual understanding, retention, problem-solving, metacognition
Academic	Improving exam performance, advancing toward credentials/ standards.
Relational	Enhancing collaboration, communication skills, interpersonal connections
Behavioral	Demonstrating greater task-focused effort, resilience, persistence
Affective	Experiencing greater motivation, confidence, sense of belonging
Agentic	Increasing ownership of and autonomy in learning, knowledge co-construction
Equity	Narrowing achievement gaps, providing equitable student support, fostering empathy and justice in learning spaces

This framework intentionally distinguishes academic from cognitive outcomes, recognizing that they may exist independently of each other (see Table 3). It also uses the term *relational* to emphasize the intimate, interpersonal connections often discussed in the literature under *social* outcomes. Importantly, outcomes mirror but are not identical to the engagement dimensions. For example, social engagement in class may foster collaboration (relational outcomes) while simultaneously influencing understanding (cognitive), belonging (affective), and co-construction

of knowledge (agentic) outcomes. By separating *process* (dimensions) and *results* (outcomes), this framework enables clearer theorizing about how strategies produce learning gains by activating specific dimensions of engagement.

Interrelations among the Facets

The dimensions of engagement characterize active learning (what it is), the instructional strategies highlight how active learning is enacted (how we come to know and observe it), and the outcomes capture why active learning matters (what values and purposes it advances). While conceptually distinguishable, these facets are dynamically interconnected: strategies are designed to activate specific dimensions of engagement, which in turn, produce context-situated learning outcomes. By making these relationships explicit, this multilateral model helps researchers and practitioners to navigate the complex landscape of active learning, enabling targeted research inquiry and better alignment of instructional choices with goals.

Note the connections of these facets, as described, to the ontology (what it is), epistemology (how we come to understand it), and axiology (what values shape its use) of active learning. In the next section, we will examine the philosophical underpinnings of the construct, both to strengthen the framework and to situate active learning within the broader traditions of mathematics education research.

Philosophical Grounding of the Framework

The ambiguity surrounding active learning is not merely a pedagogical challenge—it is deeply philosophical. Researchers (and practitioners) enter the conversation with different assumptions about what active learning is (ontology), how we can know it (epistemology), and why it matters (axiology). Making these philosophical perspectives explicit deepens theoretical rigor and enhances practical relevance.

Ontology: What Counts as Active Learning?

Ontology concerns the nature of the phenomenon. The lack of clarity surrounding the term "active learning", as described earlier, is fundamentally an ontological problem: Is active learning a set of instructional strategies, a mode of engagement, or a class of outcomes? Current literature often collapses these categories, producing competing ontologies. The framework addresses this tension by delineating three ontological layers—dimensions (process), strategies (practice), and outcomes (consequence)—and invites scholars to specify which aspect(s) their work investigates, thereby reducing ambiguity and supporting cumulative knowledge-building.

Epistemology: How Do We Know Active Learning?

Epistemology, here, examines the nature and origin of knowledge about active learning. Some studies on active learning employ positivist lenses, emphasizing empirical evidence and generalizability. These often examine outcomes of active learning (e.g., measuring exam achievement). On the other hand, studies focusing on dimensions and strategies (e.g., examining instructor beliefs, sense of belonging) often reflect interpretivist or social-constructivist paradigms. Distinguishing between dimensions, strategies, and outcomes helps researchers to align methodological choices with research questions.

Axiology: Why Does Active Learning Matter?

Axiology foregrounds the values and priorities that shape research and practice. Advocacy for active learning often rests on tacit or explicit value commitments: promoting equity, fostering

inclusion, nurturing belonging and agency, or advancing deeper understanding. By ensuring that values are centrally situated in how active learning is understood and discussed, this framework helps researchers and practitioners to align their values with their practice, inviting the field to more systematically investigate not just *what works* but also *what matters and for whom*.

Interplay of Ontology, Epistemology, and Axiology

Recognizing diverse ontological, epistemological, and axiological orientations clarifies why even a seemingly intuitive term like active learning can foster confusion. The proposed framework clarifies these orientations by making these philosophical underpinnings explicit: the dimensions of engagement that characterize active learning address the question, "What is active learning made of?" (ontology). Strategies enact active learning and shape the ways researchers and practitioners study it, answering the question, "How do we know active learning?" (epistemology). Finally, outcomes of learning reflect the values and intended purpose, answering the question, "Why does active learning matter?" (axiology). Rather than erasing differences among researchers, the framework offers a structure for explicitly naming them, enabling more transparent and productive inquiry and dialogue.

Implications

The framework presented here is not intended as an end to the ambiguities surrounding active learning but as an invitation—an invitation for researchers, practitioners, and policymakers to engage intentionally with the complexity of the construct. It provides a blueprint for engaging with existing literature and highlights where further research is urgently needed. The implications that follow articulate how this shift in perspective can strengthen both the research and practice of active learning, helping to realize its full promise.

Implications for Research

The framework calls for greater transparency in scholarship and highlights several areas where active learning research could be strengthened.

Attending to context. Research needs to move beyond dichotomous comparisons (e.g., "lecture vs. active learning") and investigate which strategies, activating which dimensions, in which context, produce which outcomes.

Clarifying ontologies. Researchers need to specify the aspect(s) of active learning they are studying. Is the focus on dimensions of engagement (what characterizes active learning), instructional strategies (how active learning is enacted), learning outcomes (why active learning matters), or a combination of them? This facilitates more productive synthesis and meta-analysis.

Aligning epistemologies with research goals. Selecting methodological approaches explicitly suited to the facet of active learning under study (e.g., dimensions may be better studied using qualitative approaches) and clarifying epistemological underpinnings will help researchers strengthen the validity of their work.

Integrating axiological commitments. By making explicit the values that motivate a study—such as equity, agency, performance, belonging—the framework encourages researchers to articulate their axiological commitments and critically examine whether the selected strategies and evaluated outcomes align with those commitments.

Methodological opportunities. This framework invites research that maps how strategies activate specific dimensions of engagement, how those dimensions shape outcomes, and the role of context in the process. Addressing this complex task invites methodological innovations that can generate roadmaps for both practitioners and researchers.

Implications for Practice

The framework also offers guidance for faculty, administrators, and institutions to implement active learning.

Context-sensitive implementation. Too often, research treats context as external to the learning model. This framework cautions against "one-size-fits-all" recommendations and highlights the need to adapt strategies to local conditions. For example, collaborative group work may foster social and agentic engagement in small classes. However, it requires adaptation in large lectures, such as the addition of teaching and learning assistants.

Roadmap for backward design. Practitioners often face the question, "How can I bring active learning practices into my classroom?" By distinguishing between strategies, dimensions, and outcomes, the framework provides a roadmap to backward design their choice. Instructors first identify the desired outcomes, then consider which dimensions of engagement are most likely to support those outcomes, and finally, select strategies that intentionally activate those dimensions given their specific context. For example, an instructor teaching a first-year calculus course at a public university may want to foster persistence and collaboration among students who often feel isolated in large lecture settings. To support these outcomes, the instructor would focus on social and behavioral engagement and might adopt strategies such as group problem-solving tasks facilitated by teaching assistants. By contrast, an instructor in a small seminar-style differential equations course might pursue the same outcomes through student-led discussions or peer-instruction activities. In both cases, reflecting on which engagement dimensions a strategy activates helps instructors design more balanced active learning experiences.

Fostering equity and belonging. By centering dimensions such as emotional and agentic engagement, as well as equity-based, relational outcomes, instructors can intentionally design learning experiences that not only boost achievement but also reduce opportunity gaps and support all students in the classroom, especially those historically marginalized.

Increased support for active learning. Clearer evidence-based research claims can strengthen institutional support (Børte et al., 2020), leading to better resource allocation and more targeted professional development opportunities.

Conclusion

Active learning has become both a rallying cry for reform in undergraduate mathematics education and a construct clouded by definitional ambiguity. As this paper has demonstrated, the conflation of engagement, strategies, and outcomes undermines research synthesis, yields generic policy recommendations, and leaves instructors uncertain about what active learning entails in their specific classrooms. By disentangling dimensions of engagement, instructional strategies, and learning outcomes, the proposed framework cuts through this persistent ambiguity by providing a robust lens for analyzing, comparing, and intentionally designing active learning experiences. For researchers, it provides sharper tools to frame and critique studies without flattening diverse practices to a single "active learning" variable. For practitioners, it serves as a reflective roadmap to design, select, and adapt strategies that align with their intended outcomes, context, and values—instead of reaching for one-size-fits-all solutions.

Most importantly, this clarity paves the way for real, equity-driven impact. When the links between strategies, engagement, and outcomes are made explicit, mathematics educators can design interventions that not only raise achievement but also build belonging, agency, and justice. Adopting this framework is therefore more than a conceptual exercise—it is a call to move beyond slogans and toward deliberate, value-based transformation in undergraduate mathematics education.

Acknowledgements

I thank Kenneth R. Bundy, Catherine Davis, and Dr. Sandra Crespo for their constructive feedback on earlier versions of this paper; Dr. Matthew Voigt and Dr. Beth Herbel-Eisenmann for their mentorship as I engaged with this topic; and Jose Contreras for guidance on navigating the submission and feedback process.

A Case for Applying Unit Transformation Graphs to Model Students' Solutions to Transformation Geometry Problems

Joseph Antonides
Colorado State University

Kyeong Hah Roh
Arizona State University

Eleanor Nelson
Colorado State University

In this theoretical report, we argue that unit transformation graphs are an appropriate and useful tool for modeling students' solutions to transformation geometry problems. Developed by mathematics education researchers working from a Piagetian theoretical perspective, unit transformation graphs explicate the mental actions that students use in solving problems, along with the objects (or units) on which they are acting. This theoretical report contributes to an understanding of how unit transformation graphs can be extended, beyond their current use, to model student reasoning in a new mathematical domain. We illustrate the potential efficacy of unit transformations in modeling students' solutions to transformation geometry problems with two researcher-generated solutions to a transformation geometry problem, and we call for future empirical research to model students' solutions to transformation problems with UTGs.

Keywords: Cognition, Learning Theory, Transformation Geometry, Second-Order Models

Transformation geometry—the study of geometry focusing on transformations (such as rigid motions and dilations) and properties that remain invariant under those transformations—is an important component of mathematics education at all levels. For nearly a century, mathematicians and mathematics educators have recommended that transformations play a greater part in geometry curricula (Betz, 1933; King, 2021; Usiskin & Coxford, 1972). The *Principles and Standards for School Mathematics* of the National Council of Teachers of Mathematics (NCTM, 2000) recommend that instructional programs from Grades PK-12 should "enable all students to…apply transformations and use symmetry to analyze mathematical situations" (p. 41). In the Common Core State Standards for Mathematics (CCSSM; Common Core State Standards Initiative, 2010), transformation geometry plays a broad role, elaborated below. At the postsecondary level, transformation geometry together with group theory can be used to classify Euclidean and non-Euclidean geometries—an idea introduced by Felix Klein in his 1872 address to the University of Erlangen, setting forth the influential Erlangen Program. Klein claimed, "The most important notion which is necessary in the following considerations is that of a group of spatial transformations" (cited in Herbst et al., 2017, p. 19).

Within the CCSSM, in Grade 8, students use hands-on activities to verify properties of rigid motions, describe the effects of rigid motions, and understand that two shapes are congruent if (and only if) one can be transformed into the other using a sequence of rigid motions. In high school geometry, students formalize notions of congruence and similarity in terms of transformations, leading to triangle congruence and similarity criteria (Wu, 2013). Transformations are also used in geometric proofs, such as proving that two shapes are congruent by describing a sequence of rigid motions that will map one onto the other. Consequently, middle and high school teachers need to be prepared to conceptualize and explain geometric transformations, including their use in proofs of similarity and congruence; evidence suggests this may pose a challenge (Hegg et al., 2018; Yanik & Flores, 2009).

Given the importance of transformations in students' geometry education, mathematics educators need to better understand how students conceptualize and reason about geometric transformations. From a constructivist perspective, understanding student reasoning in this way

involves engaging students in problem situations and, from observations of students' responses, posit answers to the question: "What mental operations must be carried out to see the presented situation in the way one is seeing it?" (von Glasersfeld, 1995, p. 78). Answering this question requires decentering from one's own mathematical knowledge and attuning to the mathematical knowledge of the student. In this sense, the researcher builds a *second-order model*, a model that can explain the researcher's observations of the student's mathematical reasoning (Steffe & Thompson, 2000).

Taking seriously the Piagetian position that students' mathematics is comprised of mental operations (i.e., mental actions), Norton et al. (2023) introduce *unit transformation graphs* (UTGs) as a tool for forefronting students' mental actions and illustrating their coordination in problem solving. UTGs are directed vertex-edge graphs, where vertices represent material being acted on (units) and edges represent mental operations (transformations applied to units). Although UTGs were originally used to model students' numerical reasoning, particularly about fraction multiplication (Norton et al., 2023), we hypothesize that UTGs can be extended beyond numerical contexts, modeling students' coordinations of mental actions generally.

In this theoretical article, we extend the scope of UTGs to the realm of transformation geometry. In doing so, we address the research question: *How, theoretically, can UTGs be used to build models of students' solutions to transformation geometry problems?*

Literature Review

We have research evidence that indicates students across Grades K-16 often experience challenges in making sense of and reasoning about geometric transformations. For example, middle school students, prior to instruction on transformations, may apply "holistic" strategies, rather than measurement-based analytic strategies, to solve transformation problems, with the latter being more likely to lead to correct solutions (Boulter & Kirby, 1994). Similarly, some undergraduate students may hold picture-based meanings of transformations without measurement-based or transformation-based meanings; students who hold either of the latter two meanings are more likely to successfully determine congruence and non-congruence of given shapes (Geotas et al., 2021).

Research has found specific transformations to present challenges for students. Dixon et al. (2022) found that, even after instruction (with traditional curricular materials), many middle school students struggle to solve problems involving rotations. Among 444 middle school students in their study, students answered an average of 59% of questions correctly, with only 46% of students correctly determining whether a given pre-image and image show a rotation and, if so, correctly locating the center of rotation. Hollebrands (2007) found that high school students may struggle to anticipate the results of transformations prior to carrying them out. Yao (2020) found similar results among preservice secondary teachers; moreover, they struggled to determine whether a composition of transformations can be performed as a single transformation. Frazee (2018) found that high school students may struggle to carry out reflections, especially over a slanted line, and to correctly locate a slanted line of reflection for a given pre-image and image, and they may struggle to carry out rotations and locate the center of rotation for a given pre-image and image. However, for both transformations, Frazee found significant conceptual progress after research-based instruction focusing on properties of transformations and developing students' mental processes for conceptualizing them. Research also indicates that preservice elementary school teachers, prior to research-based instruction, may struggle to identify examples from non-examples of reflections, rotations, and translations (Clayton, 2020) and to identify the correct center of rotation for a given pre-image and image

(Edwards & Zazkis, 1993). However, after research-based instruction (similar to that used by Frazee, 2018), Clayton (2020) found preservice teachers to make significant conceptual progress.

Secondary and postsecondary students may struggle to conceptualize transformations as not just motions, but as mappings (i.e., functions) from the plane onto the plane (Hollebrands, 2003; Yanik, 2011; Yanik & Flores, 2009). Hollebrands (2003) found that students' conceptions of domain were critical in understanding geometric transformations as functions. Yanik and Flores (2009) contributed a detailed account of one preservice teacher's trajectory toward developing a mapping-based meaning of translations, with vectors playing an especially important role. Although geometric transformations are formally defined as one-to-one and onto mappings on the plane (Martin, 1982), there are differing opinions about the nature, purpose, and productivity of thinking about transformations as motions versus as mappings (Edwards, 2003).

The challenges that K-16 students experience regarding geometric transformations underscore the importance of mathematics educators better understanding their conceptions and investigating ways in which they can be supported. We posit that to achieve such an understanding, mathematics educators need to better understand students' mental actions for carrying out, and anticipating the results of, reflections, rotations, and translations. This position is supported by research by Frazee (2018) and Clayton (2020), reviewed above, and by Johnson-Gentile et al. (1994), who found significant conceptual gains among middle school students who engaged in computer-based activities using Logo Geometry. They explained, "The need in Logo environments for more complete, precise, and abstract explication [of action commands given to the computer] may account for students' creation of conceptually richer concepts for motions" (p. 137). Although researchers have provided fine-grained analysis of student knowing and learning within transformation geometry contexts, including approaches using APOS theory (e.g., Hollebrands, 2003) and the Pirie-Kieren model (e.g., Yao, 2020), we argue that UTGs offer a uniquely fine-grained lens on students' mental actions that can provide important insight into students' conceptualizations.

Theoretical Framework

We frame our work in terms of Piaget's (1970) genetic epistemology; within this perspective, mathematics is constructed as a coordination of mental actions. A *mental action* is a transformation (a change in the state of some perceived/conceived entity) that may be carried out physically or entirely in one's mind. Within the realm of number, such mental actions include iterating, partitioning, and disembedding; these mental actions are applied to *numerical units*, which are entities conceptualized as 1 (Ulrich, 2015). For example, a student might iterate a unit of 1 to form a composite unit (e.g., 10), or partition a unit of 1 to form smaller equal-size parts (e.g., 1/2). They might disembed one of these parts (removing 1/2 from the whole), treating that part as a unit itself while keeping in mind its relationship to the original whole.

UTGs require researchers to identify the mental actions that students bring to problem situations and to model how they are coordinated. Consider the following example.

> *Cake Task*. Anita is having a birthday party. Her birthday cake is cut into 8 slices for Anita and her 7 friends. After the cake is cut, another friend arrives late to the party. Anita wants to share her slice of cake equally with the newcomer. What portion of the whole cake does Anita get? (adapted from Norton et al., 2023)

To solve this problem, a student might first take the whole cake as a unit. They could then *partition* the cake into eight equal-size pieces, then *disembed* one of those pieces to give to Anita. Then, when the newcomer arrives, this piece is further *partitioned* into two equal-size pieces, and one of them is *disembedded*. To relate the size of this piece to the whole cake, the

student might *iterate* it 16 times. Through this coordination of mental actions—partitioning, disembedding, partitioning again, disembedding again, and iterating—the student can conclude that Anita received 1/16 of the whole cake. This coordination of mental actions is illustrated by the UTG in Figure 1, where rectangular nodes represent units and arrows represent the student's mental actions on those units.

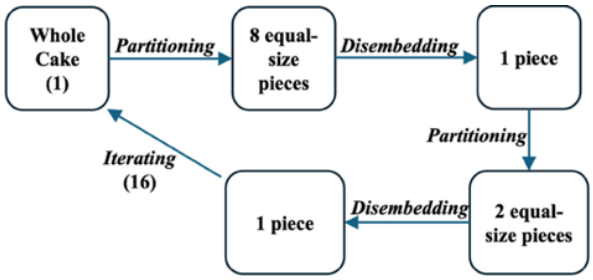

Figure 1. UTG illustrating a coordination of mental actions to solve the Cake Task

Spatial and geometric situations may involve a wide variety of units and mental actions performed on them. Following Antonides et al. (2025), we define a *spatial unit* as a perceived/conceived entity, such as a shape, that is spatially operable—that is, the entity is isolated as an object of attention and acted upon using spatial mental actions. Based on prior research on students' geometric reasoning, we generated a non-exhaustive list of mental actions that we hypothesized may be relevant in students' solutions to transformation geometry problems (see Table 1). We used prior research literature, where available, to suggest definitions of each mental action. We theorize definitions of mental actions not yet represented in the research literature. For example, a student might *unitize* a geometric shape and take it as material for spatial operation (Wheatley & Reynolds, 1996); they might *spatially disembed* part or parts of a geometric shape in problem solving (e.g., isolating one side of a square without losing track of the fact that the side is part of the square) (Barrett & Clements, 2003); or they might *spatially locate* an object in space (e.g., visualizing the location of a cube within a 3-D array, or a point in space corresponding to another point) (Battista, 2004). Understanding precisely how students temporally order mental actions on spatial units can reveal critical insights into their mathematical conceptualizations and reasoning (Antonides & Battista, 2022).

Table 1. Non-exhaustive list of mental actions hypothesized to be relevant in solving transformation geometry problems

Mental Action	Definition
Unitizing	Isolating perceived/conceived material as a distinguishable object through focused and unfocused attention (von Glasersfeld, 1981)
Spatial Disembedding	Isolating (unitizing) part of a spatial object, treating it as a separate spatial entity while maintaining its relationship to its original spatial whole (Barrett & Clements, 2003; Sarama et al., 2003)
Spatial Locating	Identifying the location of a point or other spatial object or region (Antonides et al., 2024; Battista, 2004)
Extending	Imagining a continuation of a spatial object such as a line segment

Directing	Establishing a spatially oriented relationship between two points
Reflecting	Flipping a spatial object, often (formally) over a line conceptualized as the line of reflection (or line of symmetry) (Clements et al., 2001; Edwards, 1991)
Rotating	Turning a spatial object in a particular direction (clockwise or counterclockwise), often (formally) in relation to a fixed point conceptualized as the center of rotation (Clements et al., 2001; Edwards, 1991)
Translating	Sliding a spatial object in a particular direction, often (formally) in relation to or described by a vector (Clements et al., 2001; Edwards, 1991)

Examples of UTGs in Transformation Geometry

To illustrate and support our theoretical argument, we provide two potential solutions (provided by the first two authors) to the K-Activity, described below, including mental actions used in these solutions (indicated by italics). We then illustrate how these two solutions can be modeled using UTGs.

K-Activity. There are two big K's, a black one of the top left, and a blue one on the bottom right [see Figure 2a]. Prove or disprove: The black K can be transformed to the blue K using a translation, a rotation, and a reflection, at most once each.

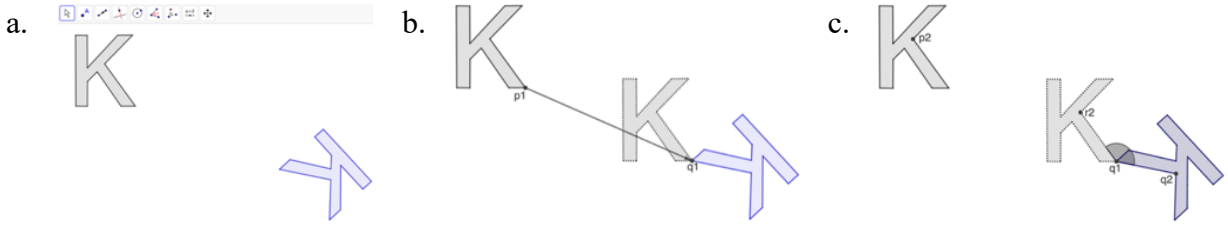

Figure 2. (a) Initial K-activity setup, and potential solution 1, involving (b) translation then (c) rotation

Potential Solution 1. In solving this task, a person might begin by *unitizing* the black K as an object of attention (a spatial unit) and isolating (*spatially disembedding*) a salient point p_1. By attending to the corresponding point q_1 on the blue K, the person *unitizes* the blue K as a spatial unit, then *spatially locates* and *disembeds* the corresponding point, establishing a relational anchor between the two K-shapes. Using these two disembedded points, they mentally construct a vector, $\overrightarrow{p_1q_1}$, by mentally imagining *directing* p_1 to q_1, and with this they mentally *translate* the black K toward the blue K, producing a new spatial unit (the translated K; see Figure 2b). Then, person may *spatially disembed* another point, p_2, on the black K, then *spatially locate* and *disembed* its translation, r_2, on the translated K, as well as the corresponding point, q_2, on the blue K (Figure 2c). The person may then *connect* points q_1 and r_2, forming a ray, and *connect* points q_1 and q_2, forming another ray; with these, they can imagine *turning* the former ray clockwise toward the latter, conceptualizing the angle $\angle r_1q_1q_2$. Then, with this angle, they can *rotate* the translated K, using q_1 as the center of rotation, in a clockwise direction. Through these coordinated mental actions, the person leverages fixed points and constructed angles as invariants to structure the sequence of transformations that map the black K to the blue K.

This person's solution can be modeled using the UTG shown in Figure 3. Rectangular nodes represent spatial units—material isolated as an object of attention and taken as input for spatial

mental actions (represented by arrows). The mental act of unitization is not represented by arrows, but rather by the creation of a rectangular node. Dark gray nodes represent the initial figurative material provided in the problem situation (taken by the problem solver as spatial units). Light gray nodes represent spatial units transformed in the process of accomplishing the translation of the black K. White nodes represent spatial units transformed in the process of accomplishing the rotation of the translated black K. The yellow node represents the final state of the black K.

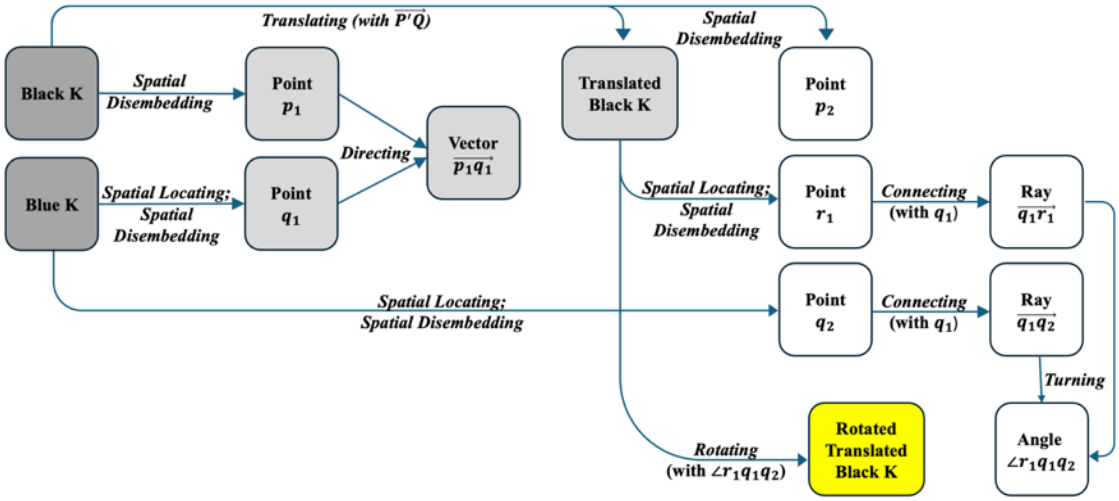

Figure 3. UTG illustrating the coordination of mental actions in Potential Solution 1

Potential Solution 2. As an alternative to the approach in Potential Solution 1, a person could first isolate the blue K as a spatial unit, via *unitization*, and from this *spatially disembed* its long flat side, then *extend* this side to form a line, L_1. They could repeat this process with the black K, *spatially disembedding* its long flat side and *extending* it to form line L_2. In doing so, the person can *spatially locate* a point, z, that they can use as the center to *rotate* the black K clockwise until its long flat side is visually aligned with L_1 (see Figure 4b). The rotated black K is *unitized* as a spatial unit that they will then translate. To carry out and describe this translation, the person could first *spatially disembed* a point p on the rotated black K, then *spatially located* and *disembed* the corresponding point, q, on the blue K. With these, they can conceptualize vector $\overrightarrow{pq}$ by mentally imagining *directing* p in the direction of q. Using this vector, they then *translate* the rotated black K (see Figure 4c), completing the transformation.

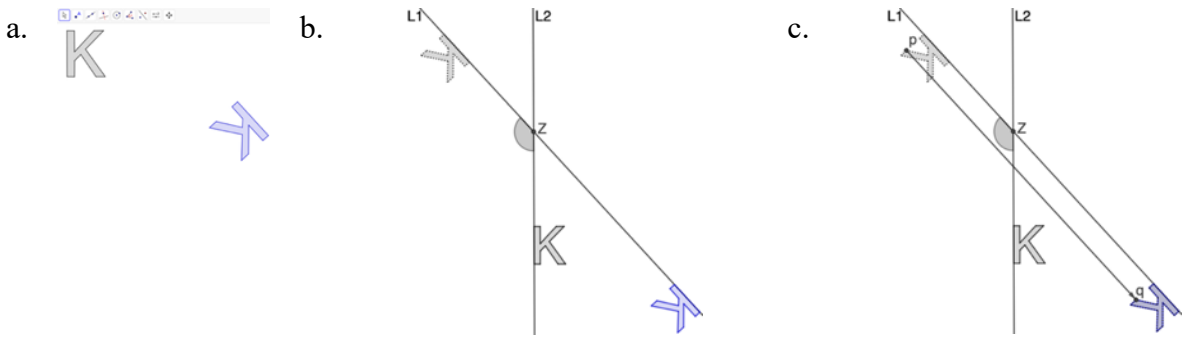

Figure 4. (a) Initial K-activity setup, and potential solution 2, involving (b) rotation then (c) translation

This person's solution can be modeled using the UTG shown in Figure 5. As with the previous UTG, rectangular nodes represent spatial units, and mental acts on those units are represented by arrows. Dark gray nodes represent the blue K and black K (the first two spatial units acted upon in the problem). Light gray nodes represent spatial units transformed in the process of rotating the black K. White nodes represent spatial units transformed in the process of translating the rotated black K. The yellow node represents the final state of the black K.

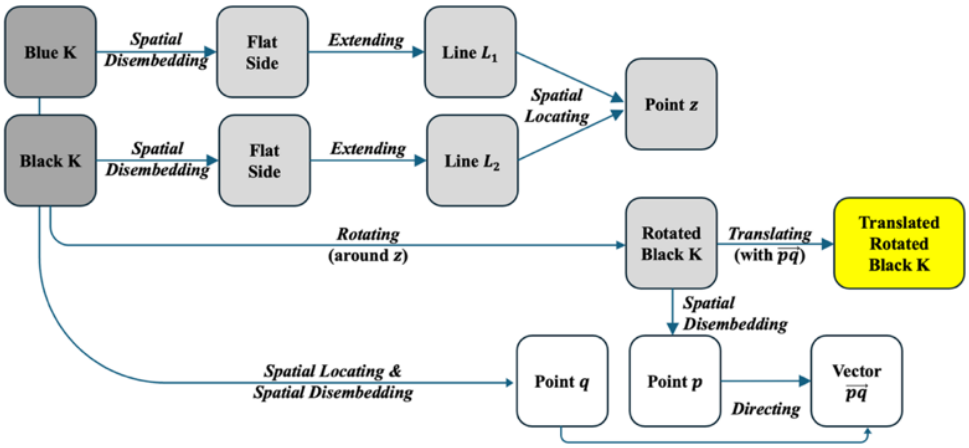

Figure 5. UTG illustrating the coordination of mental actions in Potential Solution 2

Concluding Remarks

UTGs contribute a more explicit lens on the units that students attend to and the mental actions that they coordinate on those units when solving transformation problems. Much prior work has documented the kinds of challenges students face, such as conceiving transformations as motions rather than functions (Hollebrand, 2003; Yanik, 2011), relying on picture-based rather than analytic strategies (Boulter & Kirby, 1994; Geotas et al., 2021), or struggling to anticipate composite transformations (Yao, 2020). UTGs offer a way to model not only the outcomes of these problem-solving attempts but also the evolving sequences of units and mental actions that students bring into coordination.

Additionally, our examples of the K-activity illustrate how different individuals may coordinate similar actions in different sequences: one beginning with translation then rotation, the other reversing that order. By modeling these variations, UTGs make explicit not only the actions themselves, such as unitizing, disembedding, locating, translating, and rotating, but also the ways these actions are sequenced and coordinated across units. This explicit attention to the interplay of units and mental actions offers insight into the diverse strategies students employ when reasoning about geometric transformations.

Finally, we suggest that UTGs can further illustrate the constructive ways that students coordinate units and mental actions, even when their solutions do or do not align with normative or textbook-like solutions. By making visible the variations in how students sequence mental actions, UTGs can reveal the resources that students bring to transformation problems, which in turn help researchers model student reasoning. With this in mind, we call for future research to engage students in solving transformation geometry problems and model their solutions with UTGs. These models can provide opportunities for researchers and teachers to support students in developing more productive strategies for solving transformation geometry problems while also highlighting how students' current reasoning can be a foundation for more productive ways of thinking in geometry contexts.

Conceptual Foundations for Connecting School and Abstract Algebra: A Historical Analysis

Erik Tillema
Indiana University

This paper uses a conceptual analysis of histories of algebra to identify a kind of reasoning, combinatorial reasoning, that was essential to the solution of polynomial equations. Historically, mathematicians' increased reliance on combinatorial reasoning in the solution of polynomial equations co-occurred with the rise of symbolic algebra. Algebraic symbols were often the context in, and on, which they engaged in combinatorial reasoning. Combinatorial reasoning, however, is often in the background of proofs or arguments—present but not framed as an essential kind of reasoning that could be developed to understand the proofs or arguments. The purpose of foregrounding this reasoning in this paper is to argue that it can serve as a conceptual foundation for designing coherent algebra curricula across grades 9-16—curricula that allow students and teachers to see deeper connections between school and abstract algebra.

Keywords: School Algebra, Abstract Algebra, Combinatorial Reasoning, History of Mathematics

Historically, mathematicians' work on the algebraic solution of the general polynomial equation[1] played an important role in the genesis of abstract algebra (Kleiner, 1986; Nový, 1973; Pesic, 2003; Stedall, 2012). However, one is hard pressed to see how the solution of polynomial equations, as presented in secondary curricula, is connected to ideas in abstract algebra, as presented in many modern-day textbooks. Secondary algebra curricula emphasize a range of techniques, often disconnected from one another, for finding the roots of polynomial equations (e.g., factoring, quadratic formula, rational root theorem, complex conjugate theorem) (Burch et al., 2021; Sangwin & Jones, 2017; Thompson, et al., 2012). Post-secondary abstract algebra curricula often begin with an abstract treatment of groups, making limited connections to the solution of polynomial equations in early parts of texts (e.g., Fraleigh, 2003; Herstein, 1997). This curricular structure can lead to a disconnect, particularly for future secondary teachers, between what they will teach to their future high school students, and what they are learning in their collegiate level abstract algebra courses (Wasserman, 2018).

For this reason, mathematics educators have recommended examining secondary curricula from an advanced perspective (Àlvarez & White, 2018; e.g., Lee & Heid, 2018; Serbin, et al., 2024), and using the history of algebra (Suoinmen, 2018; e.g., Barnett, 2017; Edwards, 1984; Blum-Smith & Coskey, 2017) to develop more coherent algebra curricula and experiences across grades 9-16. The purpose of this paper is to build on these recommendations. We do so by presenting a conceptual analysis (Thompson, 2008) that highlights how combinatorial reasoning with and on algebraic symbolism played a crucial role in advances in the algebraic solution of the general polynomial equation (Derbyshire, 2006; Stedall, 2012; Tignol, 1988/2016). Our examples start with Viète's formulas, and end with one of LaGrange's contributions to the solution of the quartic. These examples precede Ruffini's and Abel's work on the impossibility of the solution of the general polynomial equation of degree five (Ayoub, 1980; Pesic, 2003),

[1] Throughout, I focus on algebraic methods for solving polynomial equations and differentiate it from numerical methods (Rider Hamburg, 1976). Numerical methods are various approximation methods that give a numerical value for a root of a polynomial. Algebraic methods are ones that structurally relate the roots, factors, and coefficients of a polynomial to determine if the roots of the general polynomial equation can be expressed in terms of known coefficients.

and Galois's identification of general conditions for the solvability of polynomial equations (Edwards, 2012; Tignol, 1988/2016). We focus on this historical time-period (16th-18th century) because it laid the groundwork for the transition from viewing algebra as the solution of polynomial equations to viewing algebra as the study of structure. By identifying combinatorial reasoning as a foundational kind of reasoning during this period of time, we aim to make apparent a kind of reasoning that if emphasized in curriculum and instruction would allow students and teachers to experience a greater sense of connection between, and coherence across, secondary and post-secondary algebra experiences.

Background Literature: Context for Our Analysis

We use Kaput's (2008/2017) framework for algebraic reasoning as an organizational tool for discussing the algebra literature, which we use to motivate the reason for our analysis. Within Kaput's framework, secondary algebra research has tended to focus most heavily on strand 2, functions (Kieran, 2007; Warren et al., 2016), where mathematics education researchers have identified co-variational reasoning as a foundational kind of reasoning for this strand (e.g., Thompson & Carlson, 2017; Confrey & Smith, 1996). Less attention has been given to strand 1 at the secondary level (Kieran, 2007; Warren et al., 2016), a strand that includes the algebraic solution of polynomial equations. The studies that do attend to strand 1 often focus on students' development of structure sense as they engage in syntactically guided transformations on conventional symbol systems (core aspect B, Kaput's framework) (e.g., Hoch & Dreyfus, 2005).

Core Aspects and Strands
Two Core Aspects
(A) Algebra as systematically symbolizing generalizations of regularities and constraints. (B) Algebra as syntactically guided reasoning and actions on generalizations expressed in conventional symbolic systems.
Core Aspects A & B are Embodied in Three Strands
1. Algebra as the study of structures and systems abstracted from computations and relations, including those arising in arithmetic (algebra as generalized arithmetic) and in quantitative reasoning. 2. Algebra as the study of functions, relations, and joint variation. 3. Algebra as the application of a cluster of modeling languages both inside and outside of mathematics.

Figure 1. Kaput's (2008, p. 11) framework for algebraic reasoning

One common focus of this work has been to investigate the role computer algebra systems (CAS) can have in supporting students to develop structure sense, particularly in relation to expanding and factoring algebraic expressions and solving polynomial equations (e.g., Saldanha & Kieran, 2006). Early work in this area emphasized that a skilled teacher's use of CAS could support students to develop a better understanding of equivalence (Nicaud, et al., 2004; Kieran & Saldanha, 2005), and of the relationship between a polynomial and its factors (Artigue, 2002), including relationships that might otherwise be too complex for secondary students to handle outside of CAS (LaGrange, 2003). As CAS have become more widely used by teachers, and the tools more powerful, researchers have tended to present fewer positive results (Artigue, 2010). More recent findings, for example, include that CAS can support students to develop non-reversible equation solving techniques (Jankvist, et al., 2019), that CAS tasks in textbooks tend to involve low procedural complexity (Davis & Fonger, 2015), and tend not to foster opportunities for students to engage in proofs (Jankvist & Misfeldt, 2019).

At the post-secondary level, there have been recent studies with practicing or future secondary teachers that have focused on understanding relationships between a polynomial and its factors (e.g., Burch, 2023; Tillema & Burch, 2022). One focal point of these studies has been

to support secondary teachers to use concepts they are learning in abstract algebra to unify ideas related to factoring that they will teach at the secondary level (Serbin, et al., 2024). Often these studies, like the studies at the secondary level, have been framed around secondary teachers' development of structure sense (e.g., Lee & Heid, 2018; Novotná & Hoch, 2008). While many studies related to the algebraic solution of polynomials have been framed around structure sense, there has been less attention to foundational forms of reasoning that produce it (Linchevski & Linveh, 1999; Novotná & Hoch, 2008) as compared to the much more extensive literature on functions and co-variation. The primary purpose of this paper, then, is to explicitly name an important form of reasoning, combinatorial reasoning, from which students could develop their structure sense related to the solution of polynomial equations.

Conceptual Framework

Thompson (2008, p. 1-31) "propose[s] a method by which mathematics educators can make tacit meanings explicit and thereby address problems of instruction and curricula in a new light." The method he proposes is conceptual analysis. Conceptual analyses involve specifying the mental operations that a person must carry out to understand a situation in the way they are understanding it (Glasersfeld, 1995, p. 78). This definition of conceptual analysis makes historical sources of mathematics ripe for conceptual analyses for at least two reasons. First, historical sources often capture mathematical understandings as they emerged, developed, and changed over time. It is rare, for example, the way an understanding is initially expressed is the way that it is used or understood at later points in time. This evolutionary process allows one to analyze differences in understanding, along with what features of an understanding maybe advantageous to aim for in current curricula. Second, often features of an understanding are implicit or taken as shared at the time an understanding is expressed (i.e., in a particular historical time-period). These implicit understandings may support the development of new understandings where the new understandings may ultimately be what gets encoded in curricula, while the implicit understandings fall away. For example, many of the concepts related to group theory (e.g., a group, a normal subgroup, a conjugacy class, factor group, etc.) were initially intimately tied to the solution of polynomial equations (Cajori, 1912; Barnett, 2017; Dehn, 1930). However, over time this connection has become much more hidden in curricula (e.g., Fraleigh, 2003). The benefit, then, of examining historical sources is that one can make implicit understandings explicit, especially, if implicit understanding or reasoning that was important to the genesis of later understandings is lost.

Elsewhere, I have given accounts of the mental operations that are involved in combinatorial reasoning, and which produce combinatorial structure, along with the consequences this has for differences in secondary students' or teachers' understandings (e.g., Tillema, 2018; Tillema, 2020; Tillema et al., 2024; Tillema et al., 2025). I summarize that work here by saying that these operations (along with schemes, coordination among schemes, and abstraction) produce "psychological slots," and a structure on these slots. From this perspective, some of the main differences among reasoners has to do with the psychological slot structure that they use to interpret situations. For example, a reasoner might interpret a statement like, $(a+b)^2$, using a "psychological slot structure" that is represented as $(__+__)(__+__)$. This is a 2-slot structure where each slot contains two slots—the larger slots are structurally connected by multiplication and the smaller slots by addition. The structure implies a recursive embedding of slots where the additive slot structure is embedded in the multiplicative one. On the other hand, a student may interpret a statement like $(a+b)^2$ with the following psychological slot structure, $(__)(__)$. This is a 2-slot

structure where the slots are connected by multiplication only. This 2-slot structure yields non-normative interpretations of the expression, $(a + b)^2$. We provide this brief analysis to indicate what we mean by combinatorial reasoning and structure, but in our analysis below we do not map out in full detail the psychological slot structure that is implied by the analysis. We simply point out more informally where combinatorial reasoning can be inferred in the context of examining histories of algebra.

Examples from Histories of Algebra

The historical period between Cardano's (1545) *Ars Magna* and Lagrange's (1771) *Réflexions sur la résolution algébrique des équations* is often framed as a period of slow or no growth in histories of algebra (Stedall, 2012). This framing, in part, is because the discovery of methods for solving cubic and quartic equations, published by Cardano, occurred within a short timeframe. The short timeframe primed mathematicians to expect that the solution of higher degree equations might follow quickly (Bashmakova, 2000, van der Waerden, 1985). However, that did not happen; the discovery of whether and when higher degree equations could be solved had to await Ruffini (Ayoub, 1980), Abel (Pessic, 2003; Rosen, 1995), and Galois (Edwards, 1984, 2012) in the early 19th century. Thus, if growth is measured from the perspective of finding a solution to higher degree equations, then, indeed, little progress was made between Cardano and Lagrange.

However, Stedall (2012) convincingly argues that this time-period has both been neglected in histories of algebra, and that it was a period of *essential* growth (see also, Nový, 1973; Tignol, 1988/2016); essential in that the growth opened the way for the transformation that occurred to algebra in the 19th century (Kiernan, 1971). The developments in the 19th century changed the focus of algebra from the study of the solution of polynomial equations to the creation and study of structure more broadly (Derbyshire, 2006). The developments in algebra during the 16th to 18th century, then, should be of significant interest to mathematics educators who are aiming to design coherent algebra curricula across grades 9-16; that is, developments during the 16th to 18th century offer insight into the kinds of reasoning that supported the transformation of algebra in the 19th century. Moreover, the fact that historians of mathematics have given minimal attention to the 16th to 18th centuries means that studying it has the potential to provide new insight.[2]

One important transformation that occurred in the 16th to 18th century was mathematicians' perspective on equations and equation solving. At the beginning of the period, equations, including the solution of cubic and quartic equations, were solved within a mathematical framework of proportions. This perspective began to shift by the middle of the 17th century in the work of Girard, Descartes, and Harriot, all of whom began to treat polynomial equations as a product of factors (Funkhouser, 1930; Stedall, 2012, p. 50). This shift in perspective, coupled with mathematicians' growing use of symbolic algebra, supported mathematicians to make increasingly complex computations with symbols. As numerous mathematicians at the time commented, one impediment to progress on finding a general solution to higher order polynomials was the length and complexity of the symbolic computations (Stedall, 2012). Frequently, the structure that could be used to both simplify and organize this complexity was combinatorial structure (e.g., Cajori, 1912; St. George, 2003).

To illustrate this claim, I present three examples. The examples I provide are not intended to be a historical account of specific mathematicians' contributions to the development of algebra.

[2] Plenty has been written about Cardano's and Lagrange's contributions to algebra (e.g., Branson, 2013). It is largely the period between the two that is the focus of Stedall's (2012) book.

Rather, the purpose of the examples is to make explicit the forms of reasoning that emerged during this period, that, if developed with modern students, could serve as a basis for the design of more coherent algebra experiences across grades 9-16.

The first example is a combinatorial argument for Viète's formulas. A combinatorial argument relies on treating binomial factors as a choice between an indeterminant and parameter. So, for example, in the quartic case one can expand the binomials, $(x+a)(x+b)(x+c)(x+d)$, using the following reasoning. There is 1 way to choose the indeterminant from each binomial (blue, Figure 2), 4 ways to choose the indeterminant from three of the four binomials (grey, Figure 2), 6 ways to choose the indeterminant from two of the binomials (green, Figure 2), 4 ways to choose the indeterminant from one of the binomials (yellow, Figure 2), and 1 way to choose the indeterminant from none of the binomials (orange, Figure 2). Using this structure, the

Selection Process	Outcome of Selection Process	Selection Process	Outcome of Selection Process
$(x+a)(x+b)(x+c)(x+d)$	x^4	$(x+a)(x+b)(x+c)(x+d)$	bcx^2
$(x+a)(x+b)(x+c)(x+d)$	ax^3	$(x+a)(x+b)(x+c)(x+d)$	bdx^2
$(x+a)(x+b)(x+c)(x+d)$	bx^3	$(x+a)(x+b)(x+c)(x+d)$	cdx^2
$(x+a)(x+b)(x+c)(x+d)$	cx^3	$(x+a)(x+b)(x+c)(x+d)$	$abcx$
$(x+a)(x+b)(x+c)(x+d)$	dx^3	$(x+a)(x+b)(x+c)(x+d)$	$abdx$
$(x+a)(x+b)(x+c)(x+d)$	abx^2	$(x+a)(x+b)(x+c)(x+d)$	$acdx$
$(x+a)(x+b)(x+c)(x+d)$	acx^2	$(x+a)(x+b)(x+c)(x+d)$	$bcdx$
$(x+a)(x+b)(x+c)(x+d)$	adx^2	$(x+a)(x+b)(x+c)(x+d)$	$abcd$

Figure 2. Combinatorial expansion of four binomials

final polynomial can be written as: $(x+a)(x+b)(x+c)(x+d) = x^4 + (a+b+c+d)x^3 + (ab+ac+ad+bc+bd+dc)x^2 + (abc+abd+acd+bcd)x + abcd$. This combinatorial structure can, then, be used to link the roots and coefficients of a polynomial because $r_1 = -a$; $r_2 = -b$; $r_3 = -c$; $r_4 = -d$, which yields the following: $x^4 - (r_1+r_2+r_3+r_4)x^3 + (r_1r_2+r_1r_3+r_1r_4+r_2r_3+r_2r_4+r_3r_4)x^2 - (r_1r_2r_3+r_1r_2r_4+r_1r_3r_4+r_2r_3r_4)x + r_1r_2r_3r_4 = x^4 + Ax^3 + Bx^2 + Cx + D$. This yields that the negative sum of the roots is the coefficient of the cubic term (i.e., $A = -(r_1+r_2+r_3+r_4)$); the positive sum of all possible combinations of two of the roots is the coefficient of the quadratic term (i.e., $B = (r_1r_2+r_1r_3+r_1r_4+r_2r_3+r_2r_4+r_3r_4)$), etc.

One important observation about Viète's formulas is that the expressions in the roots that make up the coefficients (i.e., $-(r_1+r_2+r_3+r_4)$) are all symmetric where a symmetric expression is one whose value is invariant under all permutations of the roots. For example, swapping r_1 and r_3 so that $-(r_1+r_2+r_3+r_4)$ becomes $-(r_3+r_2+r_1+r_4)$ does not change the value of the expression. The expressions in Viète's formulas are called the elementary symmetric polynomials, when they are expressed in *n* indeterminants (Figure 3). During the 17th

$$\sum_{1\le i_1\le n} x_{i_1} = x_1 + x_2 + \cdots + x_n$$

$$\sum_{1\le i_1<i_2\le n} x_{i_1}x_{i_2} = x_1x_2 + x_1x_3 + \cdots + x_{n-1}x_n$$

$$\sum_{1\le i_1<i_2<i_3\le n} x_{i_1}x_{i_2}x_{i_3} = x_1x_2x_3 + x_1x_2x_4 + \cdots + x_{n-2}x_{n-1}x_n$$

$$\vdots$$

$$\sum_{1\le x_{i_1}<x_{i_2}\ldots\le x_{i_n}} x_1x_2\ldots x_n = x_1x_2\cdots x_n$$

Figure 3. The elementary symmetric polynomials

century, mathematicians worked on problems in which they generated other symmetric expressions, e.g., determining when two cubic equations shared a common root (St. George, 2003). Such problems led to the fundamental theorem of symmetric polynomials (FTSP) (Blum-

Smith & Coskey, 2017; Tignol, 1988/2016) and the Newton-Girard identities[3] (Cajori, 1912; Funkhouser, 1930). The FTSP states that any symmetric polynomial can be expressed as a polynomial in the elementary symmetric polynomials.

The second example I use to illustrate combinatorial structure is a case of the FTSP. This example continues with a quartic polynomial, $x^4 + Ax^3 + Bx^2 + Cx + D$. For convenience, I introduce the notation $\sum x_1^2 x_2 x_3$ to mean the sum of all possible combinations that take the form $x_1^2 x_2 x_3$ in four indeterminants (i.e., $(x_1^2 x_2 x_3 + x_1^2 x_2 x_4 + x_1^2 x_3 x_4 + \cdots + x_4^2 x_2 x_3)$). The FTSP states that it is possible to express this sum in terms of the elementary symmetric polynomials. Before accomplishing that goal, the sum itself can be understood through combinatorial structure; there are 4 choices for the indeterminant that will be squared, and $\binom{3}{2}$ choices for the remaining two indeterminants, which yields a total of $4 \cdot \binom{3}{2} = 12$ summands in $\sum x_1^2 x_2 x_3$.

Having identified a combinatorial structure of the sum, the goal is to find an expression in the elementary symmetric polynomials for the symmetric expression $\sum x_1^2 x_2 x_3$. We start with a product of elementary symmetric functions, $(x_1 + x_2 + x_3 + x_4)(x_1 x_2 x_3 + x_1 x_2 x_4 + x_1 x_3 x_4 + x_2 x_3 x_4)$, that produces partial products that take the appropriate form, $x_1^2 x_2 x_3$. Here again combinatorial structure can help to identify the number and form of the partial products. There are 4 summands in each of two polynomials so the product of the two polynomials will have $4^2 = 16$ partial products. Moreover, there are, for example, 3 expressions in the second polynomial that contain the indeterminate, x_1, and 1 expression that does not contain, x_1. Therefore, when we multiply the second polynomial by the indeterminate x_1 we will get these 3 expressions, $x_1^2 x_2 x_3 + x_1^2 x_2 x_3 + x_1^2 x_2 x_3$, and this 1 expression $x_1 x_2 x_3 x_4$, a structure that will be repeated for each of the four indeterminants, giving the 12 summands of the form, $x_1^2 x_2 x_3$ and 4 summands of the form, $x_1 x_2 x_3 x_4$. Thus, we can write $\sum x_1^2 x_2 x_3 = (x_1 + x_2 + x_3 + x_4)(x_1 x_2 x_3 + x_1 x_2 x_4 + x_1 x_3 x_4 + x_2 x_3 x_4) - 4(x_1 x_2 x_3 x_4) = \sum x_1 \cdot \sum x_1 x_2 x_3 - 4 \sum x_1 x_2 x_3 x_4$. This example illustrates multiple ways that combinatorial structure is useful to reasoning about a case of the FTSP.

Lagrange put the FTSP to work in his *Réflexions* where he provided an analysis of known methods for the solution of cubic and quartic equations (Barnett, 2017; Stedall, 2012). All of the methods he analyzed relied on using a resolvent equation, a secondary equation that allowed for resolution of the first (e.g., Cardano's method relied on a sextic equation that was quadratic in the indeterminant). Lagrange's central insight in this process was to determine the relationship between the roots of the resolvent equation and the roots of the primary equation to be solved (Edwards, 1984). From this analysis, he showed that the solution of a quartic equation could be reduced to the solution of a cubic equation precisely because there was an expression in the roots of the quartic equation that took on *three* values (Tignol, 1988/2016, p. 127-128). One way to understand this observation is that any expression in the roots of a quartic equation that takes on three values under all permutations of the expression can be used to reduce a quartic equation to a cubic equation.[4] As part of this reduction the FTSP must be used to write the coefficients of the cubic equation in terms of the quartic equation.

[3] The Newton-Girard identities are recursive formulas that can be used to express the sum of powers of roots/indeterminates (e.g., $r_1^2 + r_2^2 + r_3^2 = (r_1 + r_2 + r_3)^2 - 2(r_1 r_2 + r_1 r_3 + r_2 r_3)$). Practically, one use for these identities is that it is possible to express the sum of powers of the roots in terms of known coefficients without having to find the roots.

[4] Ruffini seems to have taken this observation as a starting point for his proofs of the insolvability of the quintic. With this as a starting point, he was able to show that no function in 5 indeterminants could take on 3 or 4 values

The third example, then, that I use to illustrate the role of combinatorial structure is the reduction of a quartic to a cubic equation, using the expression, $x_1x_2 + x_3x_4$, where the four indeterminants are assumed to be the roots of the quartic equation, $x^4 + Ax^3 + Bx^2 + Cx + D = 0$ (Cajori, 1912, p. 90-91). The expression $x_1x_2 + x_3x_4$ can take on the following three values under permutation of the indeterminants, $t_1 = x_1x_2 + x_3x_4$; $t_2 = x_1x_3 + x_2x_4$; $t_3 = x_1x_4 + x_2x_3$, an observation that we consider to be a form of combinatorial structure. It is, then, possible to write the following cubic equation, $(x - t_1)(x - t_2)(x - t_3) = x^3 - (t_1 + t_2 + t_3)x^2 + (t_1t_2 + t_1t_3 + t_2t_3)x - t_1t_2t_3$. Doing so uses a similar combinatorial structure to the first example. The expressions in the t_i are now symmetric, which means the expressions in the x_i are symmetric as well, a conclusion that involves a recursion of combinatorial structure. Figure 4 shows the relationship between the t_i and x_i. The second example we provided demonstrated how the FTSP could be used to express $t_1t_2 + t_1t_3 + t_2t_3 = \sum x_1^2x_2x_3$ in terms of the elementary symmetric polynomials. The FTSP can be used to derive the other two relationships shown in Figure 4, and doing so entails using combinatorial structure. Once each of the elementary symmetric expressions in the t_i are written as symmetric expressions in the x_i the following cubic equation can be written in terms of the coefficients of the quartic equation, $x^3 - Bx^2 + (AC - 4D)x - (A^2D + C^2 - 4BD) = 0$. The solvability of the original quartic equation, then, can be reduced to the solvability of the cubic equation with the addition of a fourth equation, namely that $D = x_1x_2x_3x_4$ because that yields a system of four equations in four unknowns.

$$t_1 + t_2 + t_3 = \sum x_1x_2$$
$$t_1t_2 + t_1t_3 + t_2t_3 = \sum x_1^2x_2x_3$$
$$t_1t_2t_3 = \sum x_1^3x_2x_3x_4 + \sum x_1^2x_2^2x_3^2$$

Figure 4. The relationship between the t_i and x_i

Discussion, Contribution, and Conclusion

In Lagrange's *Reflexions*, he commented that the FTSP was "self-evident," and provided no proof of it (translated in Tignol, 1988/2016, p. 95; Lagrange, 1770, 1771, Art. 98, p. 372). Tignol interprets this statement in two ways—both that the proof is not difficult and that among 18th century mathematicians the FTSP was commonly used in the solution of a range of problems. The latter interpretation is of importance to the argument in this paper; namely, that combinatorial reasoning with algebraic symbols was a foundational form of reasoning, even if taken for granted, that became commonplace during the 16th to 18th century as mathematicians sought the solution of higher degree polynomial equations. Moreover, an analysis of historical sources shows that this kind of reasoning was much broader than its use in Viéte's formulas, and the FTSP (e.g., Derbyshire, 2006; Stedall, 2012; Tignol, 1988/2016). This foundational form of reasoning contributed to the more obvious developments that occurred in 19th century algebra. Therefore, I position it as one form of connective tissue between "algebra" as the search for a general solution to polynomial equations, and "modern algebra," as the study of structure. It defines a *kind of reasoning and corresponding structure* that could be emphasized much more intentionally in modern secondary and post-secondary textbooks. Such an emphasis has the potential to lend coherence across students' algebra experiences.

(Ayoub, 1980; Bewersdorf, 2006). This starting point was one of the flaws with his proof—taking it as a starting point assumes the roots have a certain form without proving that they must be of this form. Abel's proof of the insolvability of the quintic addresses this flaw (Pesic, 2003).

Extending the Theoretical Boundaries of MKT to Mathematics Instruction in Service Courses for STEM Disciplines

Kristen Amman
University of Nebraska-Lincoln

Allan Donsig
University of Nebraska-Lincoln

Yvonne Lai
University of Nebraska-Lincoln

In this theoretical report, we argue for a need to extend the theoretical boundaries of Mathematical Knowledge for Teaching (MKT) beyond its historical applications. Our motivation is the longstanding concern regarding the ability of Calculus as a service course to effectively scaffold non-math-major students' ways of knowing mathematics to support them in transitioning to their primary discipline, particularly in Engineering. We extend the theoretical boundaries of MKT to encompass the knowledge needed to connect Calculus to its ways of use within Engineering in a way that is perceptible and comprehensible to students. Finally, we distinguish this form of MKT from existing work in MKT, and we demonstrate its utility in advancing our understanding of the knowledge required to improving Calculus instruction.

Keywords: calculus, mathematical knowledge for teaching, instruction, engineering

In many U.S. colleges and universities, introductory differential and integral Calculus courses serve students majoring in STEM client disciplines such as engineering, biology, and chemistry, rather than primarily mathematics (Bressoud et al., 2013; Rasmussen et al., 2014). These courses play two roles in tension: "filter" and "scaffold" (Biza et al., 2022). Performance in Calculus acts as a filter as it is a prerequisite to various courses (Bressoud, 2021; Törner et al., 2014) and is associated with retention (or the lack thereof) within STEM majors (Ellis et al., 2016; Rasmussen & Ellis, 2013; MAA, 2015; PCAST, 2012). At the same time, Calculus can support students by scaffolding their transition from high school to college as well as in their transition to the advanced coursework involving mathematics that is required by their major (Biza et al., 2022; Corriveau & Bednarz, 2017).

However, the STEM education community has come to question the efficacy of college Calculus in fulfilling its role as a scaffold. For instance, professionals in mathematically intensive STEM careers such as engineering have reported viewing their undergraduate mathematics experiences as irrelevant to their current work (Quéré, 2017; Härterich et al., 2012; Pearson, 1991). Likewise, student engineers have been reported to find university mathematics in conflict with mathematics use in engineering (Alpers, 2017; Bingolbali et al., 2007; Britton et al., 2005; Gainsburg, 2007; Jablonka & Bergsten, 2022; Wood et al., 2008). One hypothesis regarding the cause of this phenomenon is that Calculus courses, like other mathematics courses, are typically taught from a purely mathematical perspective. Applications to other fields often appear as optional examples that only come after relevant mathematics has been addressed (Kent & Noss, 2002) and serve to ultimately reinforce the mathematical perspective (deemed "applicationism" by Barquero et al., 2013). These concerns were one of the core motivations with the MAA's (2004) CRAFTY initiative which urged mathematics faculty to provide opportunities for students to "see mathematics in context" and to explain "the hows and whys" (pp. 3-4) in solutions over 20 years ago.

We offer a second hypothesis that builds on the first: that our current conceptualization of the *mathematical understanding* required for *mathematical knowledge for teaching* Calculus (Ball, Thames & Phelps, 2008) is premised almost exclusively on ways of knowing mathematics within

its own discipline. This is an issue for students, given that many essential concepts in the Calculus sequence are framed and understood differently by engineering faculty (Willcox & Bounova, 2004; Flegg et al., 2012). In this way, mathematical understanding for teaching students of client disciplines is related to but qualitatively distinct from disciplinary mathematics (e.g., Alpers, 2010; Diaz Eaton & Highlander, 2017). For Calculus courses to be a scaffold for engineering students, we must first understand the mathematical knowledge required for instructors to teach Calculus so that it connects naturally to STEM coursework in client disciplines.

In this theoretical report, we address the question: How does one define *the kind of mathematical knowledge needed by Calculus instructors* to support students in connecting mathematics to client disciplines? Similarly to Biza et al. (2022), we center our illustrative examples and literature review within this report on the client discipline of Engineering due to the relative wealth of research in this area regarding associations between student retention and mathematics. However, our intention is for our treatment of this conceptualization to serve as a model for those interested in examining mathematical knowledge for teaching Calculus to students in any client discipline.

Conceptual Framework

Here we conceptualize the key construct of this report: the kind of mathematical knowledge needed by Calculus instructors to support students in connecting mathematics to client disciplines. To do so, we first delineate this domain from three related domains: (1) mathematics as its own discipline; (2) mathematical knowledge for teaching (MKT) as it has been typically represented; and (3) mathematics as it is used in and for engineering (MEng). We then show how each of these three are conceptually related to the key construct, which we will refer to as MKT×MEng -- a notation that shows the intertwining of mathematical knowledge for the purposes of teaching in and for engineering.

Mathematics as its own Discipline

Mathematics can be pursued for its own sake, and the work of professional mathematicians entails its own language, reasoning, questioning, and practices (Kitcher, 1984). Mathematicians' practices often involve developing strategies for generalizing and specializing patterns and structures (Pólya, 1990), potentially to give insight into new ways of thinking (Weber, 2010). Most college Calculus instructors are enculturated to this discipline through their graduate studies, either completed or in progress.

Mathematical Knowledge in and for Teaching (MKT)

Teaching mathematics differs from *doing* mathematics for its own sake as well as doing mathematics in other mathematically intensive professions (Ball et al., 2008). We define *mathematical knowledge in and for teaching (MKT)* as the mathematical skills, dispositions, and reasoning entailed in and developed through the recurrent work of teaching (Ball et al., 2008; Rowland & Ruthven, 2011; Thompson & Thompson, 1996). MKT is a practice-oriented domain (Biehler et al., 2022; Ball & Bass, 2003; Kent & Noss, 2002). As situated knowledge (Lave, 1988), mathematical meanings may be constituted in terms of workplace concerns and interactions. In teaching, these include unpacking student thinking and constructing explanations that render content comprehensible to learners.

MKT is premised in part on the norms and expectations of mathematical practice; teaching mathematics is often conceived as teaching students to learn content in ways aligned with

mathematics as its own discipline (e.g., Stein et al., 1996; Greeno & Middle School Mathematics Through Applications Project, 1997; National Research Council, 2001). For instance, studies of instructors' knowledge in Calculus and Pre-calculus focus on mathematical constructs, and applications serve an ultimate purpose of creating mathematical meanings (for reviews, see Bressoud et al., 2016 and Thompson & Harel, 2021). Some exceptions include recent literature in mathematical modeling, but even this scholarship frames results in terms of enhancing teachers' and students' practices for mathematics as its own discipline (e.g., Anhalt & Cortez, 2016; Wickstrom & Jung, 2024). *Due to this inherent theoretical tie to the discipline of mathematics, we propose extending the theoretical boundaries of MKT to align with the norms and expectations of other STEM disciplines. This extending may allow us to better understand the kinds of mathematical knowledge required to teach Calculus effectively in service courses.*

By "kinds of mathematical knowledge" we include specialized content knowledge (SCK) and pedagogical content knowledge (PCK). SCK is defined as ways of knowing mathematics unique to teaching. In elementary mathematics, SCK includes understanding and connecting different fraction representations and the definition of fraction. In a Calculus course whose goal is only to enculturate students to the norms and expectations of math as its own discipline, it may include ways of explaining the concepts of limit, rates of change, and derivative. PCK includes familiarity with student conceptions as well as how students may need content in future courses. *As we will argue, it is reasonable to believe that SCK and PCK must be conceived differently when instruction is predicated on a domain other than pure mathematics.*

Mathematics in and for Engineering (MEng)

We use the term *mathematics in and for engineering (MEng)* to mean the mathematics entailed in recurrent work of engineering. Although this construct has been studied by a variety of researchers (see Alpers (2010) for a review), there was no common term that we found in the literature; researchers variously described "mathematical expertise of mechanical engineers" (Alpers, 2010), "mathematical dispositions of structural engineers" (Gainsburg, 2007), or "mathematical components of engineering expertise" (Kent & Noss, 2002). We use the term "mathematics *in and for* engineering" to acknowledge its practice-oriented nature.

The subject of Calculus provides several core ideas critical to solving problems in a variety of engineering domains such as continuity of functions, derivatives, and polynomial basis functions (Alpers, 2010), as well as minimizing surface area, finite element analysis, and Navier-Stokes Equations (Cardella, 2006).

However, ways of knowing Calculus that are relevant to MEng are distinct from those that would be relevant to mathematics as its own discipline; MEng is constrained and motivated by specific problems encountered by engineers (Alpers, 2010; Gainsburg, 2007; Kent & Noss, 2002). Throughout deployment of MEng, engineers using mathematical ideas may think primarily in terms of engineering objects and tools, and preference industry needs and practicality when evaluating which inputs, outputs, and options are relevant in given scenarios (Alpers, 2010; Gainsberg, 2007; Kent & Noss, 2002). MEng may differ from mathematics as a discipline in part because of the role of generalization. To illustrate, we use this excerpt from Gainsburg's (2007) ethnographic study of two engineering firms:

> The problem-solving conditions for these engineers engendered mathematical practices that often diverged from those in traditional and reform mathematics classes. Popular in reform instruction is the practice of generalizing (Radford, 2000; Schoenfeld, 1994), that is, detecting patterns in data and expressing them as mathematical rules or formulas...Generally, the engineers were expected to adhere to the rules of the industry,

> not invent their own. When invention did become necessary...no data existed from which to generalize a rule anyway. Further, the rare method or representation form that the engineers improvised was so situation-specific that it would have had no life beyond the task for which it had been developed (p. 485).

MKT×MEng: Mathematical Knowledge Needed to Support Students in Connecting Mathematics to Engineering

We now introduce the central construct of this paper: mathematical knowledge needed to support students in connecting mathematics to engineering. We use MKT×MEng to refer to this domain, as it is a form of mathematical knowledge for teaching, intertwined with the purpose of fostering learners' understanding of mathematics in and for engineering. *We define MKT×MEng as the MKT needed to connect course content to MEng in a way that is perceptible and comprehensible to students.*

MKT×MEng is distinct from mathematics as its own discipline, from MKT as it has been typically represented and examined, and from MEng. The purpose of MKT×MEng is pedagogical, which separates it conceptually from both mathematics as its own discipline and MEng. It is also different from MKT as often conceived, because the practices that it aims to ultimately support are mathematical practices within MEng. We see MKT×MEng as part of MKT, because it deals wholly with mathematical issues; but we also see it as strongly connected to knowledge outside MKT, because it is motivated by engineering contexts and concerns that are outside mathematics as its own discipline. To demonstrate one way that MKT×MEng is related to but conceptually distinct from MKT, we provide an illustration of how SCK as it is typically conceptualized within MKT does not meet the needs of MKT×MEng. A similar discussion of PCK is possible but is not provided here for brevity.

SCK within MKT includes mathematical knowledge for evaluating the viability of students' alternative algorithms for solving problems, with attention to whether proposed solution strategies are generalizable to other mathematical problems and contexts (Ball et al., 2008). Given the prior characterization of MEng, it seems unlikely that SCK in the domain of MKT×MEng would emphasize the notion of mathematical generalization. Instead, SCK in the domain of MKT×MEng may include an understanding of the contextual factors that determine the viability of various solutions strategies in different applications. For example, in the areas of statics and circuits, continuity is not treated as a property to be evaluated within a given function. Instead, emphasis is placed on how one manages discontinuity within an existing system (Faulkner et al., 2020) so that parameters can be chosen that satisfy the necessary constraints while being viable in the engineering context. In this way, many traditional assignments in single-variable Calculus that ask students to redefine functions at key points or intervals to make them continuous may unintendedly contribute to subsequent confusion for engineering students. SCK in the domain of MKT×MEng may therefore involve instructor knowledge regarding the context-dependent nature of the existence of discontinuities within a handful of real-world systems. Such knowledge could enable an instructor to do more than simply point out an application of the notion of continuity in another field; it could allow them to support and respond to student thinking on Calculus assignments that intentionally interrogate various interpretations of discontinuities and their context-dependent meanings.

We close this section on MKT×MEng with three questions we have encountered about the scope of MKT×MEng and a clarification of our views. (1) Is a focus on MKT×MEng meant to supplant any intention to teach mathematics as its own discipline? (2) Wouldn't MKT×MEng require an engineering degree? (3) Isn't MKT×MEng already encoded in curricular materials that

connect mathematics and engineering, and is therefore unnecessary to study? Our view on (1) is that there is active and robust literature on teaching Calculus (and other fields of mathematics) to represent disciplinary mathematics practices. More can be done to close gaps between research and practice, and we support the perspective that one aim of Calculus is to convey mathematics as a discipline. But in this paper, we draw attention to a domain of professional teaching knowledge that has not been extensively studied and whose examination may address the inefficacy of Calculus courses being a scaffold to disciplines outside of mathematics.

With respect to (2), we are not asserting that all Calculus instructors must be fluent in all aspects of MEng. Just as an elementary teacher does not need to know all of mathematics to develop robust MKT, we suggest that a Calculus instructor does not need to know all of engineering to develop the MKT×MEng needed to support freshmen and sophomores who are only beginning their engineering trajectories. The degree of fluency with respect to MEng that is required for such support remains an open question-one whose empirical investigation we intend to support by providing this framework.

Finally, in response to (3), MKT×MEng is *knowledge* and it is distinct from curricular *materials* that connect mathematics and engineering. We develop this argument in the next section.

How Attending to MKT×MEng Advances Existing Work

Here we review literature describing interventions in college mathematics classrooms that are meant to support student understanding of MEng. We have two purposes. First, we underscore the lack of conceptualization on the *knowledge for teaching* required to facilitate such interventions successfully, which we suggest is MKT×MEng. Second, we argue that a theoretical underpinning of MKT×MEng would provide affordances to work that seeks to improve college mathematics outcomes.

Interventions may be organized according to the depth of resources (class time, preparation, etc.) required to facilitate them. On one end lies successful resource-intensive approaches, such as those reported by Johnson et al. (2024) who increased student retention by revamping differential and integral Calculus courses to center ways of knowing Calculus that would better prepare students in client disciplines. For instance, they emphasized R to gain intuition about Calculus concepts and de-emphasized concepts viewed as necessary only to mathematics as its own discipline (e.g. l'Hopital's Rule). Similar resource-intensive approaches include team teaching between mathematicians and instructors from other STEM fields (e.g., Quintanilla et al., 2007), coordinated mathematics and engineering courses (e.g., Laoulache et al., 2001; Lowery et al., 2010; Schroeder & Carpenter, 1999), and specialized sections of Calculus courses for engineering majors (e.g., Horwitz & Ebrahimpour, 2002; Sathianathan et al., 1999).

These efforts require significant coordination and knowledge-sharing between mathematics and engineering departments. However, literature reporting on such interventions has tended to focus on the materials themselves rather than the MKT×MEng acquired by the mathematicians to decide how to sequence course topics, frame mathematical ideas, and interpret and respond to student thinking. For instance, in the area of pedagogy, Johnson et al. (2024) only report that their revamped Calculus course involves student board work with instructor feedback. One wonders, then: in what ways did mathematics faculty need to know Calculus differently to effectively respond to student board work and support connections to their client disciplines? Similarly, Horwitz and Ebrahimpour (2002) describe a variety of projects created for engineering-intensive sections of a differential Calculus and integral Calculus courses and provide more than enough information regarding the knowledge that *students* needed to know to

complete the projects. Almost no information is provided regarding the mathematical knowledge required of the Calculus instructor to support students in their investigations. Some projects required students to assess the extent to which experimental data can be approximated by mathematical formulae. The mathematical knowledge required to make such an assessment is not part of the standard Calculus curriculum and thus must have been modeled by the mathematics instructor. However, the following remains unknown: what knowledge of Calculus as it is applied in experimental fields was required for that instructor to effectively *teach* this to students? Questions such as these concerning MKT×MEng are critical to consider when thinking about how one might translate these successful interventions to other institutions.

Moderate resource-intensive approaches focus on in-depth assignments, rather than a total course overhaul. Perhaps the most notable example is the work of Schmidt and Winsløw (2021) who, over two decades, created in-depth assignments for service mathematics courses in contexts such as Halbach magnet arrays and red blood cells. In all tasks, the "central challenge" was mathematical, and context and discourse were true to engineering (p. 270). Their views are representative of other assignments with in-depth applications of mathematics to engineering (e.g., Anderson & Nguyen, 2024; Anderson & McCusker, 2019; Barquero et al., 2013; Härterich et al., 2012; Lowery et al., 2010; Peters, 2023; Rønning, 2023; Neubert et al., 2014). Given their more specific nature, literature regarding these assignments typically has the space to describe the MEng required for an individual to complete the task successfully. For instance, Anderson and Nguyen (2024) provide a rigorous, step-by-step overview to support the reader in "mastering the mathematical foundations of the linear algebraic" tool (p. 809) that underlies their in-class intervention. This information is necessary to understand the intervention, but it may be sufficient for supporting instructors in responding to the demands of teaching it. We propose that an investigation of the MKT×MEng employed by instructors, including in facilitating such projects, would provide theoretical support for implementation in other contexts.

Finally, low resource-intensive approaches focus on shorter examples infused into existing Calculus content throughout a term. For instance, Kerrigan and Prendergast (2021) solicited examples from engineering faculty for a flipped Precalculus course. Burrill et al. (2023) reported a similar effort to redesign linear algebra, with the effect that the "students appreciated the content much more and enrollment ... grew vigorously while that of the analogous class from the school of engineering dropped precipitously" (p. 800). Although these examples take up little class time, their effective facilitation may still require a particular type of mathematical knowledge to situate the examples. The relationship between resource intensity of an instructional intervention and degree of MKT×MEng required for effective facilitation remains an open and important question for future research.

Implications for Further Research

In summary, we propose a theoretical construct -- MKT×MEng -- that builds on existing work in MKT and whose further development will respond to ongoing calls for Calculus to fulfill its promise as a scaffold for STEM client disciplines. While mathematics education literature abounds with various examples, activities, and projects for use in courses such as Calculus, we are lacking in systematic studies of the mathematical knowledge required to teach with such materials in mathematics courses.

In broaching and delimiting the construct of MKT×MEng, we support researchers in undergraduate Calculus education in investigating questions such as: What ways of knowing Calculus within MEng are relevant for college Calculus instructors? By what epistemological principles (core assumptions, concepts, and norms) do engineering faculty interpret student

errors and evaluate student solutions involving Calculus concepts, and how do these principles compare to those prevalent in current work in MKT? What are features of contexts where Calculus within MEng are likely to arise, and what knowledge is needed to detect and explain these forms of MEng so they are visible to students? In investigating such questions, we advance not only our theoretical understanding of mathematical content for teaching in service courses, but also our potential for implementing the wealth of existing materials into Calculus courses beyond the institutional context in which they were developed.

Towards a Unified Group Scaffolding Framework: Insights From MGTAs

Pablo Duran Oliva
Virginia Commonwealth University

Sezai Kocabas
Virginia Commonwealth University

Supporting students' collaborative work requires more than simply placing them in groups; instructors must actively shape participation and discourse through scaffolding. Group scaffolding refers to the set of instructional strategies that help students coordinate, distribute responsibility, and build shared understanding in groups. Despite its relevance for undergraduate active learning environments, existing theories have tended to isolate central elements, including teacher guidance of student reasoning, discourse moves shaping participation, and classroom norms structuring collaboration. In this paper, we analyze episodes of instruction by mathematics graduate teaching assistants (MGTAs) to motivate a unified theory of group scaffolding. Our framework integrates four interdependent dimensions: (a) norms setting, (b) task and material design, (c) discourse moves, and (d) access distribution. We argue that this theory both advances research on collaborative learning in undergraduate mathematics and informs professional development efforts that prepare instructors to foster more equitable and effective group work.

Keywords: Group Scaffolding, Active Learning, Discourse Moves, Norm Setting

Active learning has been used to characterize student-centered instructional approaches focused on heightened engagement with mathematics through structured activities (Doolittle et al., 2023). The implementation of these approaches in undergraduate mathematics initially centered on gateway courses, but it has also expanded to upper-division courses, including linear algebra, geometry, and logic (Theobald et al., 2020). This widespread adoption implies that mathematics graduate teaching assistants (MGTAs) are now frequently required to implement these pedagogical strategies.

Typically, classroom activities in these courses are often designed as problem-solving and discussions in group settings, allowing students to investigate, communicate, and reflect together while receiving feedback from peers and instructors (Laursen & Rasmussen, 2019). Yet, mathematical discussions in groups are dynamic, constantly influenced by a number of socio-cognitive and instructional factors that could create unequal conditions for students to achieve similar learning goals. Esmonde (2009), for instance, examined cooperative structures and found that students often assumed roles such as "expert," "novice," or "facilitator," with experts dominating quiz settings while facilitator roles promoted more equitable participation. Moreover, Reinholz and Johnson (2022) provided compelling evidence that active learning, when implemented without additional instructional support for cooperative learning, can lead to performance gaps across certain student groups.

Effective instructional practices require more than simply grouping students; structured approaches, including rotating roles, designing open-ended tasks, and framing explicit group norms, can help to distribute authority and promote deeper engagement among groups (Cohen & Lotan, 2014; Esmonde, 2009; Laursen & Rasmussen, 2019). Furthermore, other strategies such as circulating to pose probing questions, monitoring participation patterns, and amplifying marginalized voices could foster both collaborative learning and sense of belonging (Kogan & Laursen, 2014; Reinholz & Shah, 2018).

While some of these practices are typically associated with the well-established notion of scaffolding—the instructional support provided by a more knowledgeable other to help learners progress beyond their independent capabilities (Wood et al., 1976), active learning settings require attention to group scaffolding. Unlike traditional scaffolding, which targets individual learners, group scaffolding refers to strategies that support the collective participation, discourse, and problem-solving of the group as a whole (Webb et al., 2025).

Some theories have identified overarching elements involved in group scaffolding, including discourse moves that shape participation (Chapin et al., 2009) and classroom norms that structure access to collaboration (Yackel & Cobb, 1996). These elements, however, have largely been treated in isolation, suggesting the need for a more cohesive framework that integrates these perspectives into a unified account.

The purpose of this report is twofold. First, we explore the possibility of a general framework for group scaffolding in undergraduate mathematics, drawing on instances of novice instructors coordinating collaborative activities in active learning classrooms. Although some studies have reported difficulties experienced by novice instructors in using group scaffolding (Winter et al., 2002), their experiences provide contrasting cases that highlight the affordances and limitations of group scaffolding in practice. Second, we consider how this framework can inform the design of professional learning opportunities for novice instructors. Research has shown that MGTAs often default to individualistic instructional practices, downplaying student-to-student interaction (Winter et al., 2002), and may prioritize procedural efficiency over conceptual learning, offering prescriptive guidance with little time for reflection ([Reference removed for blind review]). Our central research question is: how can a detailed analysis of group scaffolding in periods of MGTAs instruction reveal the critical elements required for a comprehensive theory?

Conceptual Framework

Scaffolding was first introduced by Wood et al. (1976) to describe the process by which a more knowledgeable other supports a learner's progress beyond what they could accomplish independently. Grounded in Vygotsky's (1978) theory of the Zone of Proximal Development, scaffolding involves providing temporary, adaptive support—such as prompting, modeling, or structuring tasks—that enables learners to engage in more sophisticated reasoning. As students gain competence, this support is gradually withdrawn, fostering independence and deeper understanding. Traditionally, scaffolding has been conceptualized as a one-on-one interaction between teacher and learner.

In student-centered environments, however, learning often occurs in small groups where students engage collectively in problem-solving and discussion. In these contexts, instructors need to carefully attend to the dynamics of group participation, shared reasoning, and broad access to mathematical ideas. Group scaffolding refers to instructional moves, task designs, and resources that deliberately support the group as a collective—facilitating broad participation, encouraging explanation and justification, and helping students build on one another's contributions. Unlike individual scaffolding, which centers on the dyadic relationship between teacher and student, group scaffolding emphasizes how instructors shape the social and cognitive ecology of collaborative work.

Although active learning reforms in undergraduate mathematics have increased the use of group work, research suggests that group scaffolding remains underutilized, especially among novice instructors such as MGTAs (Reinholz & Shah, 2018; Winter et al., 2002). Moreover, the use of group scaffolding has often been found to be incomplete, leading in some cases to students defaulting to unequal roles, limited participation, and superficial task completion.

Research on scaffolding group work identifies a number of strategies that could support broad collaboration. Assigning roles and setting group norms clarifies expectations and fosters equitable engagement (Cohen & Lotan, 2014; Esmonde, 2009; Horn, 2012), while structured tasks and discourse moves coordinate problem-solving and promote peer-to-peer discourse (Boaler, 2008; Chapin et al., 2009; Lotan, 2003). Reflection, self-assessment, and journaling encourage metacognition and shared responsibility (Bielaczyc & Collins, 1999; Gillies, 2016), and instructor facilitation and visual representations provide just-in-time support and anchor joint understanding (Cobb et al., 1997; Roschelle & Teasley, 1995).

Three studies have attempted to identify the most essential elements involved in group scaffolding. First, Wood et al. (1976) focused on teacher-to-student interactions, suggesting that effective scaffolding involves breaking tasks into manageable steps, maintaining student engagement, and transferring responsibility to learners (fading). This perspective highlights the teacher's role in providing just enough structure to support students' problem-solving without taking over the process entirely. Although it is not discussed by these authors, the two initial phases of this process are closely connected to instructors' learning goals. While breaking a procedural problem into more manageable steps and maintaining engagement, instructors can ask students to justify each step, providing opportunities for students to deepen their conceptual understanding.

While this framework focuses on the interactions between teachers and individual students, Calor et al. (2022, 2024) extended these ideas at the group level identifying three principles: diagnosis, contingency, and fading. Group scaffolding is a process that requires an initial assessment of the group collaboration (diagnosis), after this assessment, support is adapted to the specific needs of the group at that moment (contingency), and then support is gradually removed as the group becomes more independent, shifting the responsibility for learning back to the students in the group (fading).

Chapin et al. (2009) emphasized the role of discourse moves in shaping participation during mathematical discussions. Their framework identifies specific teacher discourse moves, such as revoicing, asking students to restate or expand on peers' contributions, and pressing for reasoning, that can sustain dialogue and promote deeper engagement with mathematical ideas. These strategies not only support individual student reasoning but also serve as group scaffolds by making ideas public, encouraging broader participation, and fostering a collective sense of inquiry. The focus on discourse highlights that scaffolding is not limited to structuring tasks but also emphasizes the role instructors play in mediating talk to create wider opportunities for collaboration.

A third perspective comes from Yackel and Cobb (1996), who theorized the role of classroom norms in shaping how students access and engage in collaborative mathematics. They distinguished between sociomathematical norms—taken-as-shared understandings of what counts as a valid mathematical explanation or justification—and more general interactional norms, such as expectations for listening to and responding to peers. From this perspective, scaffolding is inseparable from the broader social and normative structures that govern participation in a classroom. Instructors contribute to scaffolding not only through immediate interventions but also by setting norms that could enable or constrain collaboration. This framework underscores that effective group scaffolding must be understood in relation to the classroom's ecology of participation, rather than as a series of isolated teacher actions.

Methodology

This paper is best understood as a conceptual study with empirical grounding. Our aim is to theorize group scaffolding in undergraduate mathematics instruction by bringing together existing strands of research (e.g., scaffolding, classroom norms, talk moves, task design, access to opportunties to learn) into a unified framework. To motivate and situate this theorizing, we draw on a small set of illustrative episodes collected in the context of a professional development program for MGTAs. The episodes were drawn from classroom observations of MGTAs in undergraduate mathematics courses. Although MGTAs were relatively new to teaching, they all participated in a professional learning opportunity intended to provide opportunities for them to reflect on a number of instructional issues related to students' participation in the classroom, including classroom norms, students' identity, and discourse moves. We selected four short episodes that highlight variation in how instructors attempted to scaffold group work. These episodes were not chosen to be representative but to serve as eliciting cases (Flyvbjerg, 2006) that reveal different dimensions of scaffolding—norm-setting, task design, use of tools, feedback practices, and participation. We analyzed each episode through iterative discussions, asking: What forms of scaffolding are visible here (structural, discursive, participatory)? What is missing or underdeveloped? How does this episode help identify the critical components of a unified theory of group scaffolding? The methodology follows a theory-building through exemplars approach (diSessa & Cobb, 2004), in which empirical material is used to motivate and refine conceptual categories.

Conceptual Framework

Four episodes were selected to inform a unified framework of group scaffolding, representing contrasting cases of different aspects of group scaffolding. Each episode is accompanied by a brief analytic commentary. Rather than reporting outcomes (e.g., student learning), we focus on how each episode illustrates different approaches to scaffolding group work and what those approaches reveal about potential dimensions present in a unified theory.

Episode 1: Group Work at the Board. An MGTA asked students to work on the whiteboard in groups, restricting each group to a single marker. This design choice created a structural scaffold for participation by requiring shared control of a resource. The establishment of explicit norms or facilitation moves, however, was not clear, which could prompted a dynamic in which some students dominated the discussion and others were marginalized from it. This episode illustrates the importance of material tools as scaffolds but also the limits of tool-based scaffolding in the absence of norms and discourse supports.

Episode 2: Optional Group Work. Another MGTA invited students to work in groups but framed group work as an option. Consistently, when several students chose to work individually, the MGTA did not encourage further collaboration but attempted to monitor each student's work, visibly increasing the demands to attend to individual needs. Here, the absence of norm-setting undermined the possibility of collaboration. The episode shows how scaffolding is not just about offering opportunities for collaboration but about structuring access so that participation is expected and supported.

Episode 3: Prescriptive Group Monitoring. In a different class, an MGTA required students to work in groups and regularly circulated among them to monitor their progress. However, the instructor’s feedback was mainly prescriptive, telling students what to do rather than prompting them to reason collaboratively. This scaffolding emphasized teacher authority

rather than group autonomy, showing how certain forms of monitoring can unintentionally reduce opportunities for decentering authority and promoting student-to-student discourse.

Episode 4: Inquiry-Oriented Group Monitoring. Finally, an instructor also required group work but engaged in monitoring that was inquiry-based, using open-ended questions and encouraging all members to contribute. This episode reflects a more integrated enactment of group scaffolding: task structure, norms of inclusion, and talk moves worked together to promote collaborative reasoning. However, even here, isolated moments of uneven participation persisted. It is possible that this uneven participation could have faded in subsequent classes, but it could also suggest a need for other types of other group scaffolding strategies (e.g., role assignments, status interventions).

These episodes show a spectrum of developing scaffolding practices: from structural-only (Episode 1), to secondary (Episode 2), to prescriptive (Episode 3), to more fully integrated (Episode 4). An overall analysis of these episodes highlights the following central dimensions of group scaffolding closely interconnected: Norms setting (e.g., whether group work is required, how roles are structured, how ideas should be shared), task and material design (e.g., open-ended problems, tools like markers to regulate access), discourse moves (e.g., prescriptive vs. inquiry-based feedback, individual vs group questioning), and access distribution (whether the participation of each peers in a group is supported). These results lay the groundwork for our proposed unified theory of group scaffolding.

Toward a Unified Theory of Group Scaffolding

The analysis presented above reveals both the affordances and limitations of MGTAs' attempts to coordinate group work. Together, they illustrate the existence of multiple dimensions associated with group scaffolding instead of isolated elements previously identified in the literature–task design, discourse moves, or classroom norms. Effective group scaffolding emerges through the interaction of these elements that jointly support broad participation in mathematical reasoning. Drawing from prior theories (Chapin et al., 2009; Wood et al., 1976; Yackel & Cobb, 1996) and extending them through the analysis of our episodes, we propose a unified theory of group scaffolding that integrates four interdependent dimensions illustrated in Figure 1. The following is a brief description of each of these elements.

Norms and Expectations. Group scaffolding requires the establishment of clear expectations for participation, including both general interactional norms (e.g., listening to peers, giving space to contribute ideas) and sociomathematical norms (e.g., what counts as a valid explanation). As Episode 2 illustrated, in the absence of such norms, group work may fail to materialize altogether.

Task and Material Design. The design of mathematical tasks and the structuring of material tools shape opportunities for collaboration. The one-marker activity in Episode 1 demonstrates how material resources can serve as structural scaffolds, channeling participation toward collective work. Yet, without accompanying discourse supports, such tools may also reinforce uneven participation.

Discourse Moves. Instructor talk is central to sustaining collaboration. Prescriptive feedback, as seen in Episode 3, may reduce opportunities for students to engage with each other's reasoning. In contrast, inquiry-oriented talk moves (Chapin et al., 2009), such as revoicing and pressing for justification, can prompt groups to develop shared understandings and sustain mathematical dialogue.

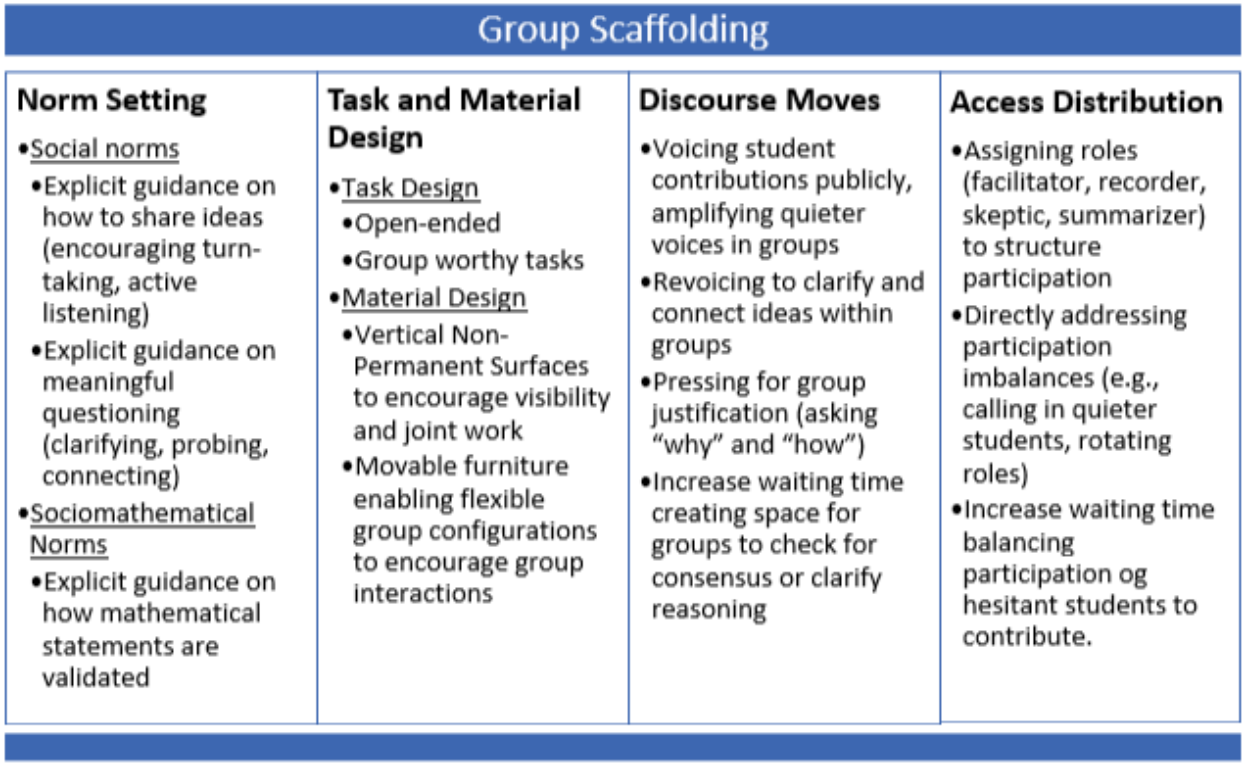

Figure 1. Central Dimensions of Group Scaffolding

Access Distribution. A comprehensive theory must also account for how scaffolding practices distribute opportunities to learn (Esmonde, 2009) across all group members, widening access to mathematical content, discourse, and positionalities to all students. As Episode 4 showed, even when inquiry-based scaffolding is present, participation may remain uneven, presenting obstacles to collaborative learning. Mediation strategies, such as assigning roles (Cohen & Lotan, 1997) or directly addressing participation imbalances (Esmonde, 2009), are necessary to ensure that scaffolding supports the learning of all students, not just the most vocal.

We argue that group scaffolding can be conceptualized as the dynamic coordination of these four dimensions, with instructors navigating among them in response to student activity. Rather than a checklist of strategies, the framework positions scaffolding as a relational and situated practice that integrates structural, discursive, normative, and broad supports. This unified perspective provides a basis for analyzing classroom practice and designing professional development that makes visible the complex work of orchestrating group learning in undergraduate mathematics.

Toward a Unified Theory of Group Scaffolding

This unified theory of group scaffolding proposed here has direct implications for the design of professional development (PD) for novice instructors. Traditional PD often emphasizes either structural strategies, such as assigning roles, or general encouragement of active learning without fully addressing how norms, discourse moves, tools, and equity interact in practice. By contrast, our framework suggests that PD should make these dimensions explicit and help instructors learn to coordinate them in response to classroom dynamics. One promising approach is the use of video-based reflection, where novice instructors analyze episodes of classroom practice—both their own and others'—through the lens of the four scaffolding dimensions. Such an approach

not only highlights the complexity of group orchestration but also makes visible the affordances and limitations of different scaffolding strategies.

In addition, PD should provide practice-based repeated opportunities for instructors to rehearse and refine scaffolding moves. For example, role-playing activities can allow instructors to practice inquiry-oriented monitoring and equity-promoting talk moves in a low-stakes environment, while structured debriefs can help them connect these practices back to the broader framework. Importantly, PD must also attend to the developmental trajectory of novice instructors. Our analysis of episodes suggests that instructors may first lean on structural scaffolds before developing the capacity to integrate discursive and practices that effectively broaden participation. PD, therefore, should be sequenced to support growth across these dimensions rather than treating scaffolding strategies as isolated techniques.

Conclusion

This study proposes a unified theory of group scaffolding in undergraduate mathematics, integrating four interdependent dimensions: norms setting, task and material design, discourse moves, and access distribution. By grounding our analysis in episodes of MGTA instruction, we illustrate how partial and emergent scaffolding practices highlight both the challenges instructors face and the critical elements required for effective group work. These episodes serve not only as empirical grounding but also as pedagogical resources for making visible the complex work that instructors must learn to do. Our contribution is twofold. First, we extend prior theories of scaffolding, discourse, and norms by showing how they can be synthesized into a coherent account of group scaffolding that better reflects the realities of undergraduate mathematics classrooms. Second, we argue that novice instructors provide a particularly generative site for theory-building and PD design, as their developing instructional practice could make visible gaps in instructional practice. For the field of undergraduate mathematics education, this unified theory provides a lens for analyzing group work and a guide for strengthening professional development opportunities that move instructors beyond fragmented approaches toward more integrated, collaborative scaffolding. Future work should further test and refine this framework in diverse classroom contexts, with attention to how it supports not only instructor development but also students' opportunities to learn collaboratively.

The Case for Complexity Theory and Formal Science to Study the Structure of Mathematics

Cory Wang
Middle Tennessee State University

Mathematical structure refers to the characteristics, topology, and relationships within and between mathematical concepts invariant to external contexts and interpretations which instantiate the concept. Research on mathematical structure is typically guided by the post-positivist and interpretivist research paradigms, which respectively emphasize the impact of human observations and interpretations on mathematical concepts, both of which are external to the intrinsic structure of mathematical concepts. This report proposes a shift to complexity theory, a research paradigm standard to modern physics and engineering which emphasizes physically necessary mathematical principles over observation and interpretation, to faithfully study structure intrinsic to mathematics itself. I propose the Tornado Theory as a theoretical framework emerging from the tenets of complexity theory and current mathematics education literature which could guide future research on mathematical structure. Finally, potential analytical techniques for the Tornado Theory based on network- and information-theoretic principles are introduced.

Keywords: Mathematical structure, complexity theory, nature of mathematics, network theory, reification

Why is the Structure of Mathematics Important for Mathematics Education Research?

Mathematical structure is a frequently occurring concept in mathematics education research which cuts across numerous domains of mathematics education literature (Gronow et al., 2022). Mason (2003) defined *structural* features as the internal characteristics, topology, and dynamics of a system which are invariant to factors external to the system. This is in contrast to *surface-level* features, which refer to the effect external contexts, interpretations, and examples have on a system (Mason, 2003). When applied to mathematical content, *mathematical structure* refers to the topological and dynamical properties of a mathematical concept independent of the contexts, interpretations, and examples which instantiate the concept (Alcock & Simpson, 2004, 2005; Dawkins, 2012; Dive, 2003; Martin, 2013; Sfard, 1991, 2003). For example, the powers of i and rotation by 90 degrees are two mathematical concepts with different surface-level features but identical structural features, because these two concepts represent the same mathematical idea (the cyclic group, i.e. oscillation, with a period of 4) but are instantiated in different contexts and facilitate different contextual interpretations.

The importance of student understanding of mathematical structure has been well-documented in mathematics education literature. Skemp (1976) differentiated between relational and instrumental understanding of mathematics, the former referring to connections between concepts and the topology of these connections and the latter referring to isolated mathematical concepts and skills. Baroody et al. (2007) and Star (2005) expanded upon Skemp's ideas, claiming deep conceptual and procedural knowledge build upon each other to generate highly connected and meaningful schema. Relational understanding of a concept therefore requires coordination of conceptual and procedural knowledge and attending to the *meaning of a mathematical concept for* connections to other mathematical ideas rather than the *meaning of* concepts in isolation (Baroody et al., 2007; Brownell, 1947). This focus on connections requires a shift in attention from surface-level features to structural features (Alcock & Simpson, 2004,

2005; Dawkins, 2012; Lehrer & Schauble, 2020; Martin, 2013; Mason, 2003; Sfard, 1991, 2003). Therefore, student attention to mathematical structure is critical in developing a relational understanding of mathematics.

In order to shift students' attention from surface-level to structural features, mathematics instructors need to consider both the structure of mathematical concepts and its relations with surface-level features which students may be inclined to focus on (Mowat, 2010; Strom et al., 2001). This enables mathematics instructors and mathematics education researchers (MERs) to develop hypothetical learning trajectories which scaffold students to shift from surface-level interpretations to structural thinking while remaining faithful to the structure of mathematical concepts (Ekici et al., 2020; Leikin & Dinur, 2007; Simon, 1995). Mathematical structure is therefore a key component to frameworks characterizing pedagogical content knowledge (PCK) (Ball et al., 2008; Gronow et al., 2022; Rowland, 2013; Vale et al., 2011).

Thus, attention to mathematical structure is critical to relational understanding of mathematics for both students and instructors. Given the importance of mathematical structure, it is valuable for the MER community to consider mathematical structure from a theoretical perspective to guide MERs in answering questions such as: what is mathematical structure? What topological properties emerge from and govern relationships between mathematical ideas and domains? How can mathematical structure be characterized and used by teachers to inform their instruction? How does mathematical structure evolve over time as new mathematical ideas are discovered or created? The *Structure of Mathematics (SOM)* refers to these general meta-mathematical explications of mathematical structure. In this report, I will first review existing literature on SOM and discuss a philosophical dilemma surrounding current SOM research. Next, I will suggest a shift in research paradigm which mitigates this dilemma by invoking complexity theory from modern physics and engineering. Finally, I will propose the Tornado Theory, a framework based on complexity theory, which could guide future research in SOM.

Literature Review

MERs have begun studying SOM by using qualitative techniques and graph theory to construct and analyze graphs representing connections between mathematical concepts (Hensley, 2025; Lapp et al., 2010; Mowat, 2010; Strom et al., 2001). These studies typically did not provide an explicit theoretical framework for SOM and implicitly assumed SOM could be extracted from student concept maps. Strom et al. (2001) created directed graphs modeling concept maps of second graders' mathematical arguments involving the area of shapes. Lapp et al. (2010) studied linear algebra concept maps constructed by undergraduate students as an undirected graph. Hensley (2025) used topological data analysis (TDA) to study concept maps created by calculus students and identified topological gaps as missed connections in students' understanding of calculus.

Mowat (2008, 2010) criticized the use of concept maps to characterize SOM, asserting concept maps are architectural structures designed by external observers of mathematics rather than originating from the connections between mathematical concepts themselves. Instead, Mowat (2008) described an explicit theoretical framework drawing on Lakoff and Núñez's (2000) theory of embodied cognition. Mowat's (2008, 2010) framework models SOM as a nested network where nodes represent conceptual domains and links represent conceptual metaphors. Most nodes contain few connections, but a few nodes (known as hubs) contain many connections, making these networks display a hub-and-spoke topology. Mowat (2008) posited this hub-and-spoke topology has a high risk of cascading failure. Thus, learners need to construct links between non-hub nodes to gain a deeper understanding of mathematical concepts. Mowat

(2010) provided a proof-of-concept of her framework by using data from semi-structured interviews with mathematicians, teachers, and MERs to extract conceptions about exponentiation from semantic connections, creating a network of concepts related to exponentiation. This framework will be discussed in further detail in the Tornado Theory section.

An alternative approach involves extracting emergent connections between concepts from texts to form a network, which has been used to study both SOM and the structure of other STEM disciplines. In particular, this approach was conducted by Chai et al. (2020) on biomedical research papers, Christianson et al. (2020) on linear algebra textbooks, and Tschisgale et al. (2023) on German Physics Olympiad questions. These studies typically used collocation analysis, where the strength of connections were determined by the location of words rather than implicit meaning. Although some of these studies are not in mathematical contexts, they leveraged network-based approaches similar to Mowat (2008, 2010) to characterize the structure of knowledge.

Mowat's (2008, 2010) critique of the usage of concept maps reflects an issue underlying current research on SOM. Because SOM fundamentally studies *structure* as internal properties independent of external contexts and interpretations, frameworks and methodologies used in SOM research should reflect the focus on internal rather than external aspects. Similarly, Hensley (2025) posited existing methodologies used in SOM research such as qualitative coding, frequency analysis, and adjacency matrix analysis focus on contextual, surface-level components of mathematical concepts rather than topological and structural relationships between mathematical concepts. In other words, current SOM frameworks and methodologies focus on the *meaning of* mathematical concepts rather than the *meaning of* mathematical concepts *for* the construction of the larger structure of mathematics (Brownell, 1947; Hensley, 2025).

In particular, Strom et al. (2001) and Lapp et al. (2010) explicitly referenced interpretivism as their high-level research paradigm, which situates knowledge and reality with respect to cognitive interpretations and social factors (Heath & Bleiler-Baxter, 2025; Stinson & Walshaw, 2017), both of which are external to the structure inherent in mathematics (Dive, 2003). Despite Mowat's (2010) and Hensley's (2025) urges for a focus on structure over context, their methodology drew upon the interpretation of exponentiation (Mowat, 2010) and calculus (Hensley, 2025) made by students, teachers, mathematicians, and MERs, which are again external to the structure inherent in mathematics. Literature outside mathematics education (Chai et al., 2020; Christianson et al., 2020) typically used post-positivist techniques such as collocation analysis to reduce the interpretive influence of textual analysis, but the post-positivist paradigm introduces factors external to mathematics in another way. In post-positivism, empirical observations hold authority on reality and knowledge (Stinson & Walshaw, 2017). Empirical observations, however, are influenced by the interpretation of the observer and thus also external to the structure inherent in mathematics itself and an unreliable source of knowledge for SOM (Davis & Sumara, 2008). Collocation analysis has a further drawback of assuming connections between words could be fully represented by their spatial relationships on a page, which is an oversimplification (Borge-Holthoefer & Arenas, 2010).

Therefore, there exists a disconnect between the ontological and epistemological foundations of the current research on SOM. By definition, SOM requires extraction of characteristics, dynamics, and topology internal to a mathematical system. On the other hand, SOM studies are informed by worldviews which extract information from unreliable sources such as empirical observations, cognitive interpretations, and social structures. This begs the question: ***how can we directly study internal properties of mathematical systems when the very nature of research is***

external? In the next section, I propose an alternative high-level theoretical worldview, complexity theory, which provides an approach to answer this question.

A High-Level Paradigmatic Shift: Complexity Theory and Formal Science

Complexity theory is a high-level paradigm arising from the scientific and engineering movements in the post-war twentieth century (Davis & Sumara, 2006, 2008). At this time, the shift from Newtonian physics to modern physics inspired scientists and engineers to study the universe and its objects as chaotic systems defined by irreducibly complex ensembles of moving parts rather than deterministic systems constructed from components. Complexity theory therefore posits the irreducibly complex nature of individual systems make it futile to study the theories and laws governing individual systems. Rather, learning about the universe entails learning about the mathematical relationships governing nonlinear, chaotic, and complex systems (Davis & Sumara, 2008). For example, Newtonian physics is grounded by observations of the natural world made by scientists before the twentieth century. Mathematical relationships were created to model and explain these observations. The mathematics of Newtonian physics could therefore be considered as *artificial interpretations* of the physical world. On the other hand, although quantum mechanics was initially inspired by observations made in the late nineteenth and early twentieth centuries, mathematicians and physicists in the mid- to late-twentieth century found quantum mechanics follow directly from the mathematical relationships of linear algebra, functional analysis, category theory, and braid theory (Baez & Lauda, 2011). Mathematical relationships are therefore *physically necessary* for quantum mechanics to exist in its current form (Baez & Lauda, 2011; Dive, 2003; Halvorson, 2011; Townsend, 2012) rather than *artificially necessary* to explain human interpretations of the universe.

In other words, in Newtonian physics, observations precede mathematical relationships, which are artificially created to explain observations. In quantum mechanics and complexity theory, mathematical relationships precede observations, and observations serve as evidence of the physical necessity of mathematical relationships for the universe and the human experience to exist (Dive, 2003; Lakoff & Núñez, 2000; Thagard, 2020). Schelling's (1971) seminal work applying complexity theory to the social sciences summarized complexity theory as follows, "[the] rich will get richer, the advantaged will gain more advantage – not because of intention, but because of the laws of nonlinear dynamics" (Davis & Sumara, 2008, p. 170). Such a worldview places the physically necessary system of mathematical relationships at the forefront of research. To a complexity theorist, external sources of authority such as empirical observations, cognitive interpretations, and social structures are peripheral to the physically necessary, internal mathematical relationships which govern complex systems (Davis & Sumara, 2008; Dive, 2003). Thus, complexity theory suggests investigations of SOM should leverage physically necessary mathematics to study internal structure to avoid external interpretations.

Formal science (not directly related to the formalist view of the nature of mathematics) is an example of applying complexity theory to research. Dive (2003), Franklin (1994), Ramoo (2024), and Thompson (2007) described the formal scientific process as based on abstraction and mathematical reasoning rather than empirical observation and statistical testing. In formal science, researchers do not test hypotheses by designing experiments and collecting data, which is the case in traditional, empirical science (Ramoo, 2024; Thompson, 2007). Rather, researchers convert the system to be studied into an abstraction using mathematical frameworks. This abstraction ideally removes external, surface-level features, enabling the researcher to focus solely on internal, structural features. Then, researchers study the system and formulate solutions by analyzing the abstraction using mathematical relationships. It is critical the mathematical

relationships used are physically necessary. This ensures the analysis process does not introduce additional surface-level features which may corrupt intrinsic structural relationships (Dive, 2003; Ramoo, 2024; Thompson, 2007). Complexity theory and the formal sciences are commonly used in engineering and industrial mathematics, where the goal is to design solutions whose effect cannot be observed at the time of design. Formal science is also commonly used in modern physics, where many phenomena such as quantum entanglement and the Higgs boson cannot be observed without precise and expensive instrumentation. Therefore, physically necessary mathematical frameworks must first be applied to formulate the initial engineering design or discover physical phenomena prior to experimentation or testing (Dive, 2003; Franklin, 1994).

Although it is impossible to confirm the physical necessity of mathematical frameworks, the robust coherence between mathematics derived from category theoretic principles (Baez & Lauda, 2011; Halvorson, 2011), the physical world (Thagard, 2020), and the human experience (Lakoff & Núñez, 2000) suggest mathematical frameworks based on category theory is, to the best of human understanding, physically necessary (Baez & Lauda, 2011; Dive, 2003; Franklin, 1994). Common mathematical frameworks used in the formal sciences include game theory, control theory, information theory, and network theory (Dive, 2003; Franklin, 1994).

In particular, network theory provides a promising direction for applying complexity theory to SOM for two reasons. First, existing literature on SOM typically leverage network theory and its derivatives such as TDA to model structure (Chai et al., 2020; Christianson et al., 2020; Hensley, 2025; Mowat, 2008, 2010; Lapp et al., 2010; Strom et al., 2001; Tschisgale et al., 2023). Furthermore, a set of network-theoretic tools have been developed to extract structural features from social scientific data such as semantic texts and social networks (Barrat et al., 2008; Borge-Holthoefer & Arenas, 2010; Scott & Carrington, 2014). Therefore, leveraging network theory situates SOM in existing literature. Second, network theory extracts topological and structural relationships, aligning with the goals of studying SOM. In the next section, I will develop an emergent theoretical framework used to abstract SOM with network theory, the Tornado Theory. Other mathematical frameworks may reveal additional information related to SOM such as dynamic evolution of mathematical structure (control theory) or the impact of human activity on the discovery, creation, and teaching of mathematical structure (game theory). A full picture of SOM and its impact on the discovery, creation, teaching, and learning of mathematics involves integrating abstractions and implications from a variety of mathematical frameworks. Thus, a framework purely based on network theory is intrinsically limited, and future theoretical work should develop SOM frameworks from other mathematical perspectives.

Mid- and Ground-Level Framework: The Tornado Theory

The Tornado Theory (TT) describes SOM from a network theory perspective by synthesizing the theoretical frameworks of Mowat (2008) and Sfard (1991). Sfard's (1991) reification theory described the structure of mathematical knowledge as emerging from an iterative process of condensation and reification. Any mathematical concept can be represented as a concrete, embodied *process* or an abstract, decontextualized *object*. The process representation of a concept, due to its concreteness, is easier to construct, but the object representation of a concept is required for the concept to be transferred to contexts independent of its original construction pathway (Dive, 2003; Sfard, 1991; Sfard & Linchevski, 1994). *Condensation* refers to the initial construction of a mathematical concept from old concepts, which requires old concepts to be transferred to the context of the new concept. Thus, old concepts can only be used in condensation if they are represented as objects decontextualized from how they were initially constructed. On the other hand, because the new concept is constructed in the context of old

concepts, the new concept is initially represented as a process (Sfard, 1991, 2003; Sfard & Linchevski, 1994). For the new concept to be used in novel situations, it must be re-represented in a form independent of the context of its construction. This decontextualization is known as *reification*, and the reified concept could then be used in the condensation process of further mathematical ideas (Sfard, 1991). Therefore, mathematical concepts could be characterized through an iterative cycle of condensation and reification known as the *Tornado*, which Sfard (2003) described as "the driving force behind the incessant growth of knowledge" (p. 359).

For instance, consider integration, which is tied to area and differentiation. During its initial construction, integration is constructed as a process in the context of area and differentiation. Integration, however, has other meanings, such as smoothing and frequency domain division. In order for integration to be used to construct further concepts such as low-pass filters (based on smoothing) and Fourier Transforms (based on frequency domain division) (McClellan et al., 2015; Oppenheim et al., 1994; Rønning, 2021; Wang, 2025), integration must be reified into an object, i.e. represented independently from the contexts of area and differentiation. Continuing the cycle, although Fourier Transforms are initially constructed as a process in the context of integration, Fourier Transforms have other meanings such as an inner product on the L_2 Hilbert Space (Ekici et al., 2020; Debnath & Mikusinski, 2005; Rønning, 2021). In order for Fourier Transforms to be used in the context of Hilbert Spaces, it must be reified as an object, i.e. decontextualized from its initial construction contexts of integration and the frequency domain. This condensation-reification cycle known as the Tornado continues iteratively to drive the discovery of new mathematical concepts.

Mowat's (2008) network theory approach to SOM could be used to operationalize the topology of mathematical concepts formed by the Tornado. In particular, mathematical concepts may be arranged as a network with nodes representing individual concepts and links representing connections between concepts. Each node contains a network structure within itself representing the structure of the concept, with nodes of this sub-network representing sub-concepts building up the greater concept. Each sub-concept is represented by another network describing the structure of the sub-concept (Mowat, 2008). This nested network continues like a Russian doll.

Inspired by existing research on network theory characterizations of semantic networks (Albert & Barabási, 2002; Barrat et al., 2008; Borge-Holthoefer & Arenas, 2010; Newman, 2003), Mowat (2010) leveraged the Barabási-Albert Model (BAM) to describe the topology of each network layer. BAM posits the number of nodes N with exactly k links in a network can be approximated with the relationship $N[k] = \psi k^{-\gamma}$, where ψ is an arbitrary constant and γ characterizes the overall structure of the network (Albert & Barabási, 2002; Mowat, 2010). If $\gamma > 1$, the number of nodes quickly decreases for higher numbers of links, meaning most nodes have few connections and few nodes have many connections. Thus, the network displays a hub-and-spoke structure, which is easily constructed but has a high probability of cascading failure. If $\gamma < 1$, the number of nodes decreases slowly for higher number of links, meaning there are a significant number of nodes with many links. Thus, the network displays a distributed structure, which are difficult to construct or interpret but are robust and adaptable in novel situations due to the low probability of cascading failure (Mowat, 2010; Strom et al., 2001).

The BAM and Russian doll structure described by Mowat (2008, 2010) reflects and provides a mathematical abstraction for the Tornado. Condensation refers to the construction of a new layer of networks from old network layers in the Russian doll. Mowat (2010) claimed these new layers follow a hub-and-spoke structure (i.e. $\gamma > 1$) due to their ease of construction. This hub-and-spoke structure is analogous to the process representation of the Tornado. A hub-and-spoke

network, however, is difficult to apply to contexts outside its initial construction process due to its high probability of cascading failure. The hub-and-spoke network needs to be converted into a distributed network (i.e. decreasing γ), analogous to the object representation of the Tornado (Mowat, 2010; Sfard, 1991, 2003; Sfard & Linchevski, 1994). Reification, which Sfard (2003) claimed to be "the driving force behind the incessant growth of knowledge" (p. 359), could therefore be represented by BAM as a decrease in γ of the network representation of the concept.

Although BAM was used by Mowat (2010), other formal scientific approaches could also be leveraged to demonstrate TT. For instance, Ferrer-i-Cancho (2005, 2006) established an information-theoretic approach to network analysis. Network construction is dependent on a fundamental tradeoff between "maximizing information transfer and saving the cost of [construction]" (Borge-Holthoefer & Arenas, 2010, p. 1285). The tradeoff is represented via the energy function $\Omega = \lambda I(N; C) - (1-\lambda)H(N)$, where $I(N; C)$ represents the amount of information intrinsic to concept C transferred via its network representation N, and $H(N)$ represents the entropy, or complexity, of the network itself. The key parameter is $\lambda \in [0,1]$, which represents the nature of the network: $\lambda = 1$ represents a fully faithful representation of the concept at the expense of ease of network construction, and λ close to 0 represents an easy-to-construct network at the expense of faithfulness to the intrinsic structure of the concept (Borge-Holthoefer & Arenas, 2010; Ferrer-i-Cancho, 2005, 2006; Ferrer-i-Cancho & Solé, 2003). Lower λ values correspond to higher γ values in BAM, a hub-and-spoke network, and a process representation of a concept. Higher λ values correspond to lower γ values in BAM, a distributed network, and an object representation of a concept. Thus, reification can be represented in Ferrer-i-Cancho's framework as an increase in λ value. Using techniques developed in information theory (Krippendorff, 1986; Shannon, 1948), it is possible to extract values for $I(N; C)$ and $H(N)$ and demonstrate reification via variation in λ values.

Conclusions and Implications for Future Research

The frameworks developed in this report provide a starting point for researchers seeking to study SOM. Complexity theory was proposed as a high-level paradigm relevant to studying SOM because post-positivism and interpretivism places observations and interpretations external to the structural components of mathematics at the forefront of research (Heath & Bleiler-Baxter, 2025; Stinson & Walshaw, 2017). The need to focus on internal structure rather than external observations and interpretations could be accomplished through complexity theory and formal science. The Tornado Theory, as proposed in this report, represents one approach to ground research on SOM based on both formal scientific frameworks (Borge-Holthoefer & Arenas, 2010) and existing mathematics education literature (Sfard, 1991, 2003).

Future research should develop and apply sub-theories of the TT such as BAM and Ferrer-i-Cancho's framework to analytically uncover topological and structural relationships between various mathematical concepts and domains. To remain faithful to complexity theory, all steps of the research process should reduce the impact of external observations and interpretations. The sub-theories should be based on physically necessary mathematical relationships such as the principles of network theory and information theory. For example, interviews and surveys may not be appropriate, as these methodologies focus on participants' interpretation of mathematical structure rather than mathematical structure itself, even if the participants are experts. Rather, researchers should use mathematical relationships to analyze the abstractions provided by these sub-theories to arrive at conclusions about SOM. Finally, frameworks based on other formal scientific theories such as control theory and game theory should be leveraged to arrive at a holistic view of SOM.

Conceptualizing Culturally Meaningful Participation in Undergraduate Mathematics

Jocelyn N. Rios
University of Northern Colorado

Aditya P. Adiredja
University of Arizona

Participation in undergraduate mathematics courses is viewed as an important metric for assessing student learning and motivation, especially in active learning classrooms. However, engagement has been understood through a narrow lens, which overlooks the way students—especially students of color—engage with mathematics courses and positions them as disengaged. In this theoretical report, we introduce the idea of culturally meaningful participation in undergraduate mathematics to capture the organic ways that students of color draw upon cultural resources to create spaces for engagement in or with their mathematics courses. We draw upon Yosso's Community Cultural Wealth Framework and the notion of Ong's STEM counterspace to support our theorizing. We argue that CME recognizes the assets that students bring to support their engagement with mathematics and also illuminates how these assets are drawn upon. We argue that CME has the potential to support broader anti-deficit efforts in undergraduate mathematics education.

Keywords: participation, culture, community cultural wealth, language, counterspaces

> En unas pocas centurias*, the future will belong to* the mestiza*. Because the future depends on the breaking down of paradigms, it depends on the straddling of two or more cultures. By creating a new* mythos-- *that is, a change in the way we perceive reality, the way we see ourselves, and the ways we behave*-- la mestiza *creates a new consciousness* (Anzaldúa, 1987).

The undergraduate mathematics education landscape has changed significantly over the last 30 years. Driven by social progress and university commitments to DEI, mathematics classrooms now serve a more racially and culturally diverse student body. However, racially minoritized students remain underrepresented in STEM education (National Science Foundation, 2016), persist in STEM at lower rates (Whitcomb & Singh, 2021), and often experience inequitable learning experiences (Eddy et al., 2015). These patterns underscore the ongoing need for equity and inclusion efforts in both research and practice.

While there have been important efforts to improve access in undergraduate mathematics (e.g., including equity in IBL, Laursen & Rasmusen, 2019), as a field, we still struggle to understand how to center identity and culture in these efforts. Often, culture is an integral part of students' identities, shaping how they interpret the world and interact within it. As the quote above reminds us, students' abilities to straddle multiple cultural worlds and transform dominant narratives can foster new ways of imagining participation in mathematics education.

In this paper, we introduce a theoretical perspective for understanding student participation through a culturally responsive lens. This perspective, which we call c*ulturally meaningful participation,* counters deficit narratives about students of color by highlighting the cultural resources that they draw upon to foster meaningful mathematical engagement in undergraduate mathematics courses. It acknowledges that mathematics classrooms are racialized and gendered spaces, which inevitably shape how students navigate their engagement. As such, we argue that culturally meaningful participation needs to account for ways students engage with mathematics and their course outside of the formal classroom space. To build this idea, we first discuss how student participation has been conceptualized in undergraduate mathematics.

Undergraduate Mathematical Participation

Classroom Participation

The shift from lecturing to active learning has significantly reshaped the undergraduate mathematics classroom experience and how instructors and researchers perceive student engagement through different ways of participating. In lecture-based classrooms, participation generally involves sitting, listening, taking notes, and occasionally asking or answering questions. In contrast, in more active classrooms, students are expected to work collaboratively, discuss ideas with peers, and explain their thinking to the class. Active learning classrooms give more opportunities for students to speak and share their ideas, and largely this type of visible forms of classroom participation have become the main indicators (and measurements) of student engagement, learning, and motivation.

The shift in perspective on participation is consistent with the social turn in mathematics education research, which reflects an inherent change in the conceptualization of learning towards "the person-acting-in-*social- practice,* not person or their knowing on their own" (Lerman, 2000, p. 25; see also learning as participation metaphor in Sfard, 1998). Studies have examined participation as an important metric related to equity (e.g., Ernest et al., 2019; Reinholz et al., 2022). This type of work importantly highlights systemic inequities in the classroom. However, when we view their findings alongside common reactions from teachers related to increasing participation, they begin to tell a story. For example, teachers in Rios & Lozano (2025) shared comments such as, "It is hard to get them out of their comfort zone /…/ it's like an elastic band, you can try to pull them out but sometimes they want to snap back," or "At risk" students have a "tendency to hide in the background." Together they become a part of a broader discourse concerning the underparticipation of students of color in mathematics classrooms.

This deficit discourse often manifests in the classroom as deficit positioning of students who "do not" participate. For example, Rios (2024) specifically documents how a multilingual student from Guatemala felt that her teacher positioned her as not engaged or interested because she was often quiet during class time, when in fact it was a coping mechanism for the linguistic microaggressions she experienced by her group members. Other studies have also documented that active participation in the classroom is often more challenging for students of color, given the racialized and gendered nature of our society and its role in classroom dynamics. For example, Battey et al. (2022) reported that "withdrawing participation" was a common response among their participants in managing "cognitive labor from discouraging events" (p. 104).

We argue that the reliance on visible and normative forms of participation creates space for deficit interpretations of students of color's participation in undergraduate mathematics. Along with the social turn in mathematics education, deficit narratives might evolve from fixating on deficiencies in students' mathematical sensemaking (Adiredja, 2019) to perceptions of underrepresented students' "struggle" with classroom participation. As the field continues to work on understanding ways to make the undergraduate classroom more inclusive (e.g., Downing & McCoy, 2021; Jett, 2013), we now consider other spaces that might be more culturally affirming.

Participation Outside of the Classroom

Much of the learning in an undergraduate mathematics course occurs outside of the classroom, especially with lecture-based courses. Traditionally, built-in support at universities for learning outside of the classroom consists of attending office hours and going to mathematics

tutoring centers. So, another way to assess students' participation is through their use of these support services. Research has documented the (racialized) nature of attending office hours for many students of color as related to confirming negative stereotypes (Dauber & Hsu, 2025; McClain, 2014). Thus, relying on such a normative form of participation, again, leads to deficit positioning of students of color.

For this reason, research has begun exploring the importance of STEM *counterspaces* in higher education (Ong et al., 2018). Counterspaces are spaces that lie outside of traditional course structures but provide students of color with environments where their academic and personal identities align and are affirmed with others who share their identity. Examples of such counterspaces include cultural resource centers for different social identities (e.g., African American Student Center) and national organizations like SACNAS (Society for the Advancement of Chicanos/Hispanics and Native Americans in Science).

While these spaces have been shown to support identity development (e.g., Leyva, 2021; McGee & Martin, 2011), they tend to exist outside of the academic departments. A notable exception is the work of Uri Treisman (Treisman, 1992). Treisman observed the cultural practice of Chinese students forming study groups with other Chinese students, where they worked on mathematics collaboratively and built community with upper classmen. This can be seen as an example of a culturally affirming space created by students where they engaged in mathematical learning.

Building on this idea, we are curious of other ways that students of color engage in practices that support their learning that are culturally meaningful for them. In particular, if we can identify cultural resources that students use to support participation in mathematics, then we can begin to challenge deficit discourse as related to underparticipation of students of color in mathematics. To help us conceptualize what other cultural resources students might use, we draw upon Yosso's (2005) Community Cultural Wealth (CCW) framework from higher education.

Community Cultural Wealth (CCW)

The Community Cultural Wealth (CCW) framework (Yosso, 2005) challenges deficit perspectives about the achievement and college readiness of students of color (Valencia, 2010). CCW focuses on the resources and capitals nurtured by their communities. Yosso argues that cultural wealth are vital resources that help students of color successfully navigate higher education. CCW identifies seven capitals: 1) aspirational capital, the ability to maintain hopes and dreams in the face of oppression; 2) linguistic capital, the intellectual and social skills from understanding of multiple languages; 3) familial capital, "cultural knowledge nurtured among familia (kin) that carry a sense of community history, memory and cultural intuition" (p. 79); 4) social capital, resources for and from the community; 5) navigational capital, skills to navigate spaces that were not created for them; 6) resistant capital, knowledge and skills learned from opposing inequalities and injustices; and 7) spiritual capital, "a set of resources and skills rooted in a spiritual connection to a reality greater than oneself" (Huber, 2009, p. 721).

A few studies have applied this framework in the context of undergraduate STEM education (Dika et. al, 2018; Peralta et al., 2013; Luna & Martinez, 2013; Samuelson & Litzler, 2016). These studies have primarily focused on identifying different forms of capital—primarily familial and aspirational—rooted in students' communities as motivation for students in pursuing and persisting in their education (e.g., Dika et al., 2018; Samuelson & Litzler, 2016). In contrast, Rios-Aguilar et al. (2011) discuss the notion of *using* cultural capital, that is, the "the mobilization of cultural resources" (p. 170), in understanding the experiences of students of color in STEM. The authors highlighted the important distinction between the possession of cultural

capital vs. the activation of cultural capital and what contexts allow students to activate these resources. To contribute to this work, we are interested in how students draw upon these forms of capital in their mathematical practice (not just that they have them), and how these capitals impact students' engagement beyond serving solely as motivation.

Defining and Illustrating Culturally Meaningful Participation

We assert that students of color possess important culturally nourished resources that they can draw upon to support their mathematical practice at the undergraduate level. The CCW framework identifies such resources which center language, identity, community, connection, and resistance. We call this *culturally meaningful participation in mathematics*—the practice by which students participate in important mathematical activities as part of their mathematics courses as a result of drawing upon their community cultural wealth. We argue this type of practice allows students of color to creatively navigate these spaces, without leaving their identities, communities, and values behind for the sake of STEM assimilation.

To illustrate what culturally meaningful participation in undergraduate mathematics (and STEM) courses might look like by drawing from two datasets: 1) interviews with five undergraduate students who self-identified as Hispanic/Mexican and participated in a summer calculus bridge program (previously analyzed and discussed in Adiredja & Rios, 2019), and 2) interviews with 28 multilingual, undergraduate students about their experiences in precalculus and calculus courses that use active learning (discussed in Rios, 2024). Both datasets are rich in examples of how students found avenues to engage in and access supports in their courses, by leveraging what we recognize as community cultural wealth. We start with two short examples of social capital before delving deeper into examples of participation that stem from students' linguistic and resistance capital.

Illustrating social capital, Marco was a student studying STEM who identified as Hispanic and grew up in a small, "tight-knit" border town. When Marco started taking STEM courses at the university, he already had an established support system of friends and cousins from his home town who were also pursuing STEM. He described going to their dorm late at night to get help on an assignment, and he jokingly added that they were also "cooking up some chicken" for him. This form of social capital, rooted in his hometown community, became his main way of participating in his courses. In another example, Ahmad, a student who arrived in the U.S. as a refugee from Iraq, sought support from his father when he was struggling in his calculus course. His father then connected him with his own former high school mathematics teacher, who was still in Iraq, and provided Ahmad with tutoring over video chat. This became an important (social) resource for Ahmad and a way that he was engaged in the course, which was facilitated through his father (familial capital). This was a different way of participating than attending office hours that could have been easily overlooked by his instructor. Ahmad was drawing on a valuable (family-based) resource to support his learning and engagement in calculus.

"My time to shine"

To illustrate culturally meaningful participation using resistance capital, we share Lesli's experiences in calculus. Lesli identified as half Mexican and half Puerto Rican, and was a determined and accomplished undergraduate student studying chemistry. In her Calculus II course, Lesli navigated what were likely racialized and gendered interactions and to integrate into a community by joining in a high-status study group. This study group worked together on calculus in the library and were not initially accepting of Lesli:

> I walked in and they were working on some questions, and everyone was kind of skeptical, like, 'Oh, this is a new girl' /.../ I was having issues with a similar type of problem that they were having. So I asked them questions on how they did them and what not. And I could sense already that they were like, "Oh no, she doesn't know enough."

Lesli sensed their gendered skepticism, but resisted:

> So then we worked on another question, and that question for them was super hard. No one could get it, out of all the people who were there, probably six guys /…/ Thankfully that was a question that I knew like off the top of my head because I had spent a good hour working it out by myself earlier that day /.../ I was like, "This is my time to shine!" /.../ After that it was like, I had been accepted.

Lesli summarized the experience of being accepted by stating: "I feel like you kind of have to prove yourself to get in. That's why my mom calls it 'the mafia' because not everyone gets in".

Despite having to prove herself, which we interpret as drawing upon her resistance capital, Lesli attributed much of her success in calculus II to her participation in this study group. She described the members of her study group as her closest friends: "I've been able to find a group where we truly care about each other and about each other's learning because we've developed that kind of friendship."

We learned that Lesli's ability to resist was rooted in her community and cultural upbringing. As a student from the "South side," Lesli shared:

> Just coming from a high school like Central, I know when I was in high school people would talk about, 'Oh she's a central [an under-resourced school] girl who won 2nd place at the national medical spelling bee /…/ She came out of central, from the South side, where she shouldn't have, and all those accomplishments'. So I came from a place like that, and so I feel like my background helped me to be able to handle criticism and skepticism and indifference.

Here, Lesli acknowledged the narrative and lower expectations people placed on her. At the same time she reclaimed this experience by recognizing that being from her community allowed her to develop important tools for handling microaggressions:

> Indifference can pretty much kill you, if you let it kill you. And I think from the interaction that I get with other groups that may look down on me. Beside skepticism, criticism, looking down, I think it's the indifference that hurts the most I'd say. You know we as humans, we have to get over it and we have to just ask questions and you have to force yourself to interact with them /…./ it's just a matter of re-centering yourself and re-wiring yourself to believe that what you're doing is worth the sacrifice and un-comfortableness /…/ In my experiences I have had to make myself notable, like you know, I am here too. I am a thinking human being. I have a brain you can ask me too. I'm here to help you too.

Being able to navigate and ultimately resist these deficit narratives were a part of Lesli's lived experience—something that was meaningful to her and a source of pride. Thus, for Lesli, being able to participate in a high-status study group, and the benefits she gained from it, exemplified a culturally meaningful participation.

"Speak tu propia lengua, no?"

To illustrate how linguistic capital can foster culturally meaningful participation, we share examples from two students: Veronica and Sai. Veronica grew up in Mexico and moved to the United States during high school. As a bilingual STEM student, Spanish was very important to Veronica and she used this cultural capital to find community within her STEM courses.

Veronica described how Spanish helped her form a special connection with other Spanish-speaking students:

> I just came from [Mexico], I still have my Mexican culture, no? So I think language is a big plus for me. Not just academic wise, just conversation you know. You can just talk more easy. You can joke more easy /…/ In upper division [STEM courses], you mostly see Americans and when I see somebody that speaks Spanish too, I get like 'oh wow, you speak spanish? Me too!' and then we just speak Spanish from there on now. And it's kind of really nice to speak your own language, no? Cuz you can say different things.

Veronica explained that when she had a question, the first resource she turned to was these friends because she could explain her question in Spanish. Veronica also described getting help for her STEM courses from a bilingual graduate student, because he could explain in Spanish:

> Last semester I had a lab TA that-- He was Mexican. And then, I would actually go to his office hours because he could explain to me in Spanish, and um, I just think it's a-- I don't know how to explain, you just have a connection.

She often attended his office hours instead of her professors, sharing: "I feel like I ask [professors] things and they get something else for some reason and they give me that answer and I don't really like saying, 'Oh. That's not what I meant'". Instead of utilizing more conventional course supports, Veronica drew on cultural knowledge—Spanish—and the connection through shared language identities to find support systems in her STEM courses.

Similarly, Sai, an international student from India, found a "good support system" in his calculus II class by leveraging his linguistic capital as a Hindi speaker:

> So whenever I see an Indian in my class I message him personally and try to be friends with him and whenever I talk to him I use Hindi and for solving math I use English while talking to him in Hindi. So bilingualism has introduced that concept of familiarity. /…/ I've seen this happen a lot of times, just switching that mode from English to Hindi is the form of connection. We're like, we come from the same background, we share the same you know, history, same language and that ends up, you know, bonding us together.

Additionally, Sai intentionally enrolled in a section of calculus II taught by an Indian graduate student, because he knew he could connect with him and would be able to ask questions in Hindi. Sai was one of the few students that regularly attended office hours, which he attributes to feeling "more of a connection" and "more comfortable" with a Hindi-speaking instructor.

Both Veronica and Sai's course experiences offer another illustration for culturally meaningful participation. They both used their linguistic capital to find community and spaces where they could participate in mathematics in a way that affirmed their linguistic (and cultural) identities.

Discussion and Implications

In this paper, we argue that a narrow, normative lens on assessing participation misses the humanistic dimension of how each student navigates who they are in their mathematics courses. It also neglects the important role of culture and identity in how students choose to participate. To capture this, we propose the notion of *culturally meaningful participation* to highlight that students of color bring meaningful cultural resources they draw upon to facilitate participation in undergraduate mathematics courses. As the examples we share illustrate, participation often occurred through unofficial channels and spaces outside of the classroom (e.g., study groups, lab TA's office hours, tutoring with a family friend). These examples serve as counterstories capturing the dedication students have for their education and the rich ways they participate in

their mathematics courses. By leveraging their resources to participate, students do so in a way that, from our perspective, affirms their culture, community, family, and lived experiences.

Our conceptualization of culturally meaningful participation in undergraduate mathematics contributes to broader anti-deficit effort in undergraduate mathematics (Adiredja, 2019; Peck, 2021). As we noted, relying on traditional forms of assessments of participation, whether it is through verbal participation in the classroom or attending office hours contribute to deficit discourse about students of color's participation in mathematics. Our work expands the definition of participation beyond traditional measures, which recognizes students' cultural resources they use to participate in mathematics, and also disrupts such deficit discourse. Theorizing about and illustrating culturally meaningful participation has the potential to provide a lens for researchers and practitioners to think about equitable participation in mathematics.

We hope that empirical studies can begin to further document and track the kinds of participation we introduced in this paper. In teaching, addressing issues of underrepresentation in classroom participation, we can go beyond the fixation of getting students of color to speak more. Instead, we can begin discussing the potential of grouping students based on a shared cultural identity, helping students connect with others and form study groups outside of the classroom, connect students with TAs or other instructors who share an important identity, or even noticing and celebrating acts of resistance and perseverance in the classroom. We argue that centering cultural responsiveness in discussions of participation can help researchers, instructors—and mathematics departments more broadly—recognize the resources students bring to their mathematics courses and reimagine learning experiences that mirror the stories of participation rooted in culture that students engaged in and valued.

Preliminary Reports

Epistemological Frameworks of Advanced Math Majors: A Case Study

Rebecca Dibbs
East Texas A&M University

Karson Lamar
East Texas A&M University

Mehmet Celik
East Texas A&M University

Although students' epistemological frameworks have been extensively studied in introductory undergraduate courses and lecture-based advanced mathematics courses, there has been less work on students' epistemological frameworks in advanced student-centered courses. The purpose of this case study is to examine the beliefs held about mathematics learning of nine students in a flipped real analysis course using Schommer et al.'s (1992) mathematical epistemological framework as a theoretical perspective. The findings suggest that although there were minimal differences in beliefs when grouping students by major or final course grade; overall, the typical participant's epistemological framework was grounded in effort, a desire for understanding, and belief that there must be at least some reliance on their instructor and peers to provide instruction and support their learning in the course.

Keywords: epistemological framework, flipped classroom, real analysis

An epistemological framework is the set of assumptions a learner holds that taken as a whole define how they believe knowledge is understood. Students' epistemological frameworks influence how they perceive the quality of a class, their motivation, and even what content they focus on learning in a course (Ji et al., 2021). Although students' epistemological frameworks have been extensively studied in introductory classes (e.g. Krupnik et al., 2018), there has been less work on students' epistemological frameworks in advanced student-centered courses. If we better understood what advanced mathematics students believed about mathematics and mathematics learning, we could help them adopt more productive beliefs and more effectively tailor our pedagogies in advanced student-centered mathematics courses. Prior literature on lecture and student beliefs suggests that although mathematics students vary widely in their beliefs of what understanding is and how to be a successful mathematics student, students agree lecture is key to learning, which makes student-centered courses with little lecture challenging to conduct (Zolt et al., 2023). Although lecture is a common instructional method, formal understanding of what is written vs informal understanding of what is said vary widely from class to class (Umgelter & Geisler, 2023). Students tend to struggle to record or recall the informal content of lectures, as it is rarely written down (Fukawa-Connelly et al., 2017).

Student beliefs about mathematics and mathematics learning affect their motivations, behaviors, and academic success (Limeri et al., 2023). However, student beliefs about learning have been primarily studied in early undergraduate mathematics students (Ji et al., 2021), even though students' interpretation of instruction is filtered through their epistemological framework and beliefs about learning, even in advanced coursework (Krupnik et al., 2017). Further, there have been calls for more research on beliefs and affect in advanced mathematics students (Melhuish et al., 2022). The purpose of this study was to investigate the epistemological frameworks of real analysis students in a flipped real analysis course, and was guided by the research question: what is the typical epistemological framework of an undergraduate enrolled in an advanced student-centered mathematics course?

Theoretical Perspective

For this qualitative study, we chose Schommer et al. (1992) as the theoretical perspective for students' epistemological frameworks. There are ten implicit assumptions in Schommer et al. (1992); although these assumptions were developed for students reading mathematics textbooks, we chose this theoretical perspective because it encapsulated all of the beliefs that have emerged as themes in prior epistemological framework literature (e.g. Limeri et al., 2023). These assumptions are: (1) learning is supposed to be quick (2) you can't learn how to learn (3) concentrated effort is a waste of time (4) success is unrelated to effort (5) ambiguity is something to be avoided (6) single answers are preferred (7) external sources authority are the preferred way to check answers (8) the ability to learn is innate (9) integration of concepts makes learning harder (10) learning typically occurs in the first attempt. We based the interview questions on these assumptions, reverse coding half of the questions.

Methods

Participants were recruited from a flipped real analysis class with extensive daily activities and class discussions at a rural research university in the southern United States. Nine students consented to a 45-minute semi-structured interview about their epistemological frameworks and perceptions of the course. All participants were mathematics majors or second majors; a second math major is larger than a math minor but contains fewer required courses and credits than a full major. Eight participants were male or male-presenting non-binary. Seven participants self-identified as white and two self-identified as Hispanic. At the time of the interview, four participants were earning A's, two were earning B's, and three were earning a C or below. Real Analysis requires a prior course in proofs as a prerequisite, so it was at least the second proof-based mathematics class for all participants, though it was the first student-centered proof-based class for most participants.

After the interviews were transcribed, the authors coded each question for evidence of one of the ten beliefs in the theoretical perspective for each individual student. The initial coding was then discussed until all differences were reconciled. Although we tried comparing participants based on achievement level in the course and whether their primary major was math or physics, there were no clear differences in belief patterns when grouping students using these variables and we did not have enough female participants to compare by gender. Instead, student beliefs were classified as universal (all nine participants held the same belief), common (six to eight participants held the same belief) or uncommon (five or fewer participants held the same belief).

Findings

There were three universal beliefs, five common beliefs, and two uncommon beliefs held by participants. Overall, the beliefs held by participants were consistent across participants, and generally positive. However, our sample was not particularly representative of a typical real analysis course, as two-thirds of our participants were taking this class as an advanced mathematics elective for a second major rather than as a requirement for a primary major.

Universal Beliefs

Although there were no clear epistemological framework patterns when considering students by achievement, there were beliefs held by all nine participants: it is possible to learn how to learn, effort aids success, and connecting concepts is important in mathematics. Maya, a math major and prospective high school teacher, believed it was possible to learn how to learn:

> Yeah. I think I would have to say yes [you can learn how to learn], just because the whole metacognition part of the taxonomy and the exercises you find to help you get to that part of that pyramid. I'm like, yeah, I could see how you would need to learn how to learn. We see this because not everybody learns in the exact same way.

Leon, a physics and math double major, gave a typical response when asked if mathematics can be learned:

> I think it's possible to learn it [mathematics]. There are people who are going to enjoy it and it'll become easier, but generally, I think it can be learned. I sure hope it can be learned. I'm tutoring people to do it.

The second belief about mathematics held by all participants was that effort aids in their success in both mathematics in general and real analysis in particular. Luca, a physics major with a second major in math, explained that without effort, he would likely not be passing, "Probably, I would say, if I didn't put forth effort I would be failing right now." Carter agreed, adding, "Yes, very much so. Highly correlated. Yeah, sometimes it's slower than other times. Sometimes it's very grinding. You've already experienced some of that with my proofs."

The third universal belief about mathematics was that making connections between concepts was very important in learning mathematics. Albert, a physics major with a second major in mathematics, gave a typical answer when he was asked how important was it to connect concepts in mathematics in general and real analysis specifically:

> Very, because then I'll know how to use them in other problems that are similar to this. Like you said earlier about how a problem could have multiple answers. I say yes, because I remember that we could solve a certain problem using different methods, and with how those methods tell us, like, the result of those methods could also tell us the same answer, but in different forms. That's what I say.

Taylor, also a math and physics major, agreed, emphasizing the importance of the building connections between his two chosen majors:

> I think it's very important. As a person who's taking and has taken a lot of physics classes, taking the math classes makes physics a lot easier and sometimes there'll be something I learned in math class, and then we talk about it in physics on a deeper level, and it's using calculus or analysis that totally makes the physical concept come quicker.

Common Beliefs

Five of the ten components of the epistemological framework were classified as common beliefs, where six to eight of the participants held the same view of mathematics in general and real analysis in particular. The first was that repetition is important to learning, a belief eight participants held. Maya, a mathematics major with an emphasis in secondary education, explained that repetition was learning:

> That's how I learn, period. A lot of the stuff is me looking at an example of how to do it, doing it, and kind of figuring out how you get from step one to B. And a lot of it is just doing it over and over again until I understand the thought process behind why I need to do it. And I'm like, okay, yeah, I can replicate it. And even if the question is not exactly like the one I just did, I'll still be able to figure it out.

Wade, a physics major with a second major in math, was the only one who disagreed with the consensus:

> [Repetition is] Not so important. I think, I don't necessarily find myself going back on all notes and rereading them. I find it more beneficial to try to use those ideas and things in different contexts. I find that to be the best strategy for learning for me.

Two common beliefs had seven participants holding a consensus belief: It is not normal to learn real analysis quickly and instructor quality is important. Taylor, a math major who switched to a physics major during real analysis, explained that he found the proof-based class challenging, and did not agree that it was normal to learn real analysis quickly: "Well, I don't know [if it's normal to learn real analysis quickly]. I've only taken one Real Analysis class. It feels like for me it's faster than what I was ready for. I'll say that." The two students who believed real analysis was relatively quick to learn were both high achieving students; as Jeremy, a mathematics major, explained: "Um, if it's just what's covered in this class, I don't think it'd be too hard to learn it at the same rate as we go through it in class on our own." The other belief held by seven students was that instructor quality was important to mathematics learning. Wade provided a typical explanation of why an instructor matters so much in advanced mathematics:

> It's very important. I think it's important in keeping passionate about a subject. Recently, I've done a lot of self-study, so I suppose in that case, quality of the book that you choose is important to keep you motivated. I think having a good teacher can inspire you to want to do more on the subject, which then is probably the best thing that they could do for you. And that's, I think, a good way.

Carter, a mathematics major, disagreed. He said that although instructor quality is nice to have, learning is possible even without an instructor:

> Again, ideally, high quality instruction is great, right? It only improves what you get. You could work with a lot less, that's for sure. You could work with nothing. I mean, these things weren't around. These weren't originally ideas. Eventually, they came about.

There were two beliefs with a six-student consensus: effort helps you understand things more and problems with multiple solutions are in general a positive thing. Interestingly, all nine students classified a proof as a problem with multiple solutions. Wade gave a typical answer, explaining that pushing past the initial urge to quit and focusing on a problem he did not immediately know how to solve was generally successful:

> Yeah. You know, a lot of problems, you look at them and think you want to just give up right away, and I think if you force yourself to sit down, like consider for however long, you're at 20 minutes, whatever, I think that some progress is better than no progress. With some progress, you do understand things better. It usually is.

Three participants partially disagreed with the consensus, stating that effort only sometimes helps, and occasionally there is no amount of effort that will move you forward in a problem. Luca, a physics major with a mathematics second major, when asked if trying harder helped him understand better, replied, "Sometimes, sometimes I just get more confused."

Problems with multiple solutions were generally seen as at least an interesting phenomenon. Carter, a mathematics major, explained, "I mean, those are the exciting ones, right? I think that's enough said." The three students who disagreed with Carter tended to be among the lowest-achieving participants. As Maya explained:

> I don't like them. Because I guess, I say as I'm a mathematics major, it's like math is very logical, and so it should only have one specific answer. And so you really cause problems. I'm like, I know this is technically right. I don't like it.

Uncommon Beliefs

The two beliefs where there was little consensus among participants were whether or not it was normal to learn mathematics quickly in general (4/9 yes, 4/9 depends on the context, and 1/9 no), and how to verify correctness on solutions (4/9 external sources such as peers or instructor, 3/9 internal sources such as intuition and logic, 2/9 a combination of internal and external sources). Lewis, a physics major with a second major in mathematics, felt that mathematics was generally something he learned quickly, "It usually doesn't take too long for me to figure out concepts or I don't feel like anything goes too fast for me to follow usually." Jeremy felt that the speed of learning was context dependent, "Like what is the math and what is quick? So it's very context-dependent." Wade, was the only student who felt that it was not normal to learn math quickly, as he explained, "No, I don't think so. I think it depends what you want to learn, I guess. If you want to learn it well, I think you need to spend a lot of time digesting topics."

Albert used external sources to verify his work, "[I use] My peers, the book, and the instructor [to verify my work]." Taylor trusted his intuition that his first answer was correct, "Often I don't check that it's right. I think I'm pretty careful in my calculations. And so, usually I'll just go with the first answer that I get, and trust my gut." Carter, one of the participants that used both internal and external sources of authority to verify his answers, discussed the value of office hours to fine tune answers, but felt that the most valuable way to check his answers was internal consistency:

> Well, I'll make sure it's consistent with other things, so... It's hard to think about this specifically, but pull any other facts, I suppose, and make sure that it doesn't lead to inconsistency. Check for consistency.

Discussion

Overall, the typical participant's epistemological framework was grounded in effort, a desire for understanding, and belief that there must be at least some reliance on their instructor and peers to provide instruction and support their learning in the course. These beliefs were remarkably consistent across participants, which suggests in part that there may be a set of adaptive beliefs students must adopt to be successful in advanced mathematics courses; it would be interesting to compare students' epistemological frameworks in an introductory proofs course to these participants. Our findings align with prior work on undergraduates' epistemological framework (e.g. Limeri et al., 2023; Krupnik et al., 2017) in that most students hold fairly productive beliefs about learning, but are still very reliant on external authority as a source of conviction for their work.

However, there are several limitations to this inquiry. The participant pool was overwhelmingly white, male, and majored in physics with a second major in math, so they may not have been particularly representative of a typical population of real analysis students since this class was an elective and not required for 6/9 participants. Despite these challenges, the consistency of beliefs the participants in this study hold provide a foil for future research on traditionally underrepresented groups in advanced mathematics classes. Future research on advanced students' epistemological frameworks should include a variety of advanced math classes as well as more diverse participant pools.

For the RUME conference, we hope to receive feedback from our peers about the theoretical framework of our study. What alternative framings might provide additional insight on the data? How does the context of a student-centered class add to the findings?

Graphs are essential across STEM fields, yet students often lack opportunities to develop graphing competencies. One challenge is that the ways graphs are used vary across disciplines. This study develops a framework for characterizing graphs in undergraduate STEM contexts by examining features such as coordinate systems, reference frames, and the objects of interpretation. Preliminary analyses of STEM resources highlight differences—such as spatial versus quantitative coordinate systems—and similarities that can inform cross-disciplinary instruction. Our goal is to support more coherent approaches to graphing instruction, preparing students to interpret and construct graphs in ways that align with disciplinary practices.

Keywords: Graphs; STEM; Undergraduate Education

Graphical representations are common in STEM fields for modeling, communicating, and analyzing phenomena. Graphs are tools used for understanding and communicating scientific phenomena (Larkin & Simon, 1987; Meira, 1995). Researchers (Knorr-Cetina & Amann, 1990; Tabachneck-Schijf et al., 1997) have shown how scientists and engineers require graphs to complete certain tasks. Relatedly, graphs are ubiquitous in STEM textbooks and practitioner journals (e.g., Lemke, 1998; Roth et al., 1999). Hence, supporting students in developing meanings for graphs is critical for supporting the next generation of scientists.

Despite the importance of graphs, results from research (e.g., Lai et al., 2016; Ruf et al., 2024) and assessments (e.g., Nation's Report Card, 2005) indicate U.S. students are not being provided sufficient opportunities to develop graphing meanings relevant to STEM. One possible explanation for this is that there are fundamental differences in the ways graphs are created, used, or interpreted within and across STEM fields (e.g., Lee & Guajardo, 2023; Paoletti et al., 2020) and that these differences are uncategorized or under-described in STEM education. Our primary goal in this study is to develop frameworks that explain the various ways graphs are used and expected to be interpreted across undergraduate STEM fields. To accomplish this goal, we intend to address the question: *How can we characterize graphs across STEM fields?* In this preliminary report, we characterize a graph based on the types and number of quantities represented, the underlying coordinate systems, and the way information is intended to be represented. By creating such a framework, we intend to develop and support a more coherent, connected, and holistic approach towards supporting students' developing graphing meanings.

Examining Several Graphs Across STEM Fields

We use the six graphs in Figure 1 to exemplify differences in graphs across STEM fields. We acknowledge that interpreting aspects of these graphs requires domain-specific knowledge (i.e., knowledge about the particular quantities in the graph), as such knowledge is important for

interpreting graphs (e.g., Altindis et al., 2024; Roth et al., 1999; Roth & Bowen, 2003; Zimmerman et al., 2023). Our goal is not to present a complete understanding of each graph but instead to present some high-level differences across the graphs. Additionally, we highlight similarities across these graphs that could be leveraged in undergraduate STEM courses.

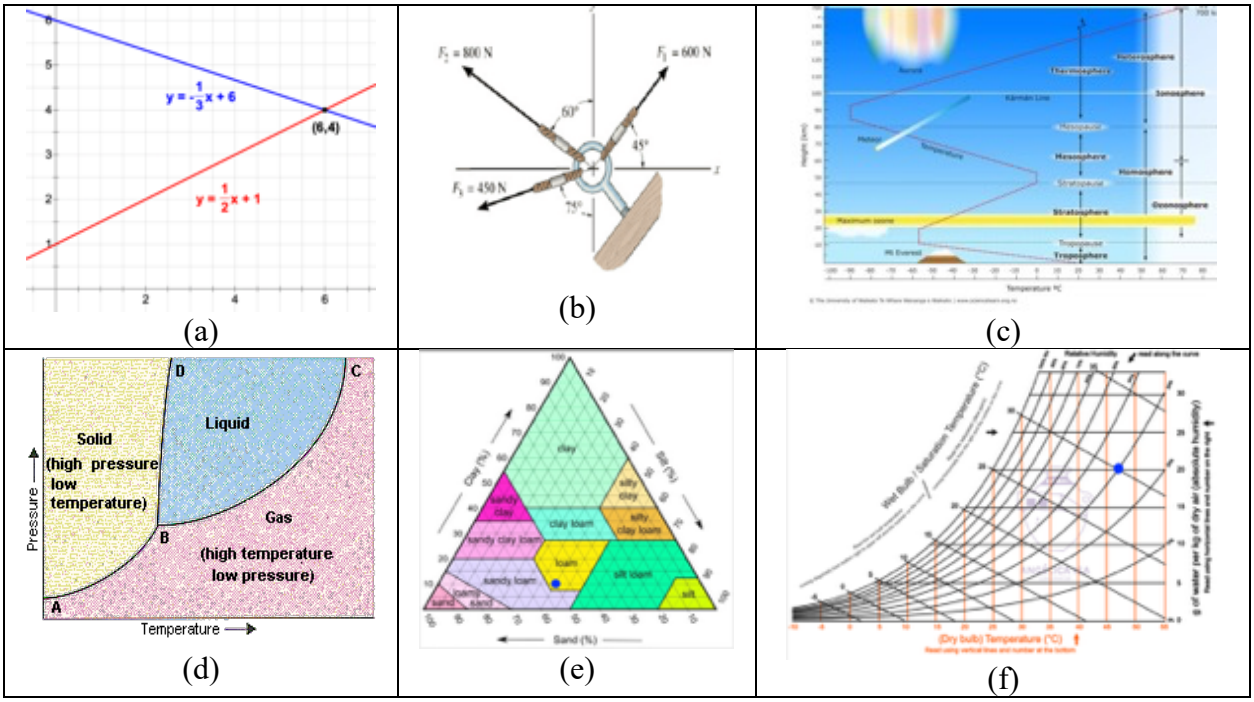

Figure 1: Graphs from a (a) Mathematics, (b) Engineering Statics, (c) Astronomy, (d) Chemistry, (e) Soil Science, and (f) Meteorology.

Figure 1a represents a solution to a system of equations, typical in an algebra class. Figure 1b is a graph from an Engineering Statics textbook (Hibbeler, 2013) used to mathematize the direction and net force exerted on a screw eye by ropes pulling in different directions with different forces. Figure 1c, from a unit on the Atmosphere (University of Waikato Te Whare Wananga o Waikato, 2025), uses the vertical height axis to classify the atmosphere based on altitude. Additionally, the dotted line shows the relationship between height and temperature in different atmospheric regions (e.g., in the troposphere, as height increases, temperature decreases). Figure 1d shows a phase diagram used in Chemistry (Bodner Group, 2025) to represent the effect of pressure and temperature on a hypothetical substance. The graph is divided into distinct areas, representing solid, liquid, and gaseous states of the substance. A person can determine the state given any (pressure, temperature) combination.

Figure 1e shows a soil texture triangle (Hennion, 2025) from the Environmental Science field relating the percent of soil comprised of clay, silt, and sand. Each point totals to 100% of the soil composition. For example, the blue point corresponds to a loam soil that is 10% clay (moving from the point left to the clay axis), 50% sand (moving from the point down-and-to-the-right along the lines to the horizontal sand axis), and 40% silt (moving from the point up-and-right to the diagonal silt axis). Finally, Figure 1f shows a psychometric diagram from a meteorology context (such diagrams are also used in medicine via growth charts for children and in ecology via graphs with isoclines). The graph is intended to show the relationship between temperature, absolute humidity, and relative humidity. For example, the blue point shows that if the

temperature is about 47 degrees Celsius (moving from the point down to the horizontal axis) and there are 20 grams of water per kg of dry air (moving from the point right to the vertical axis), then the relative humidity is at 30% (moving up-and-to-the-right along the curve).

At first blush, there are major differences across each of these graphs, given the different domain-specific information they are intending to convey. However, using our preliminary set of frameworks, we can identify commonalities. First, most graphs rely on a Cartesian coordinate system (all except Figure 1e). Second, some graphs are used to represent a physical space or phenomena (Figure 1b, the vertical axis of Figure 1c), whereas other graphs are representing a space distinct from physical space (Figures 1d, e, f). Some graphs are explicitly coordinating two quantities (Figure 1a, b, c, d), whereas others are explicitly coordinating 3 quantities (Figures 1e, f). Further, we note the graphs in Figures 1d and 1e have regions representing distinct states.

We also note curriculum developers likely intend these graphs to serve different purposes. For instance, some graphs are likely intended to help students understand or visualize some aspect of a phenomenon (Figure 1b, 1c). Several graphs could be intended to make inferences about a single moment represented by a point in the graph (e.g., Figures 1a, c, d, e, f) or could be used to make inferences about how two quantities change together in context (e.g., the red line in Figure 1c, following curves in Figure 1f). Hence, while the graphs may seem extremely different at first glance, there are features of these graphs that can be categorized both by using existing theory and by developing new theory. After providing a brief overview of relevant research, we describe our preliminary analysis. Throughout, we return to these six graphs to highlight ways we are leveraging theory to characterize similar and distinct features across these six graphs.

Background, Analysis, and Theoretical Constructs Explaining Aspects of Graphs

Researchers have shown that students of all ages experience persistent difficulties as they engage in creating and interpreting graphs in their STEM courses (e.g., Glazer, 2011; Lai et al., 2016; Potgieter et al., 2008; Ruf et al., 2024). We make two observations from this body of research. First, many of these studies have identified alternative conceptions of graphing and provided insights into varying difficulties students might experience in producing graphs, resulting largely in deficit accounts of students' mathematics (e.g., Leinhardt et al., 1990; Mevarech & Kramarsky, 1997; Moritz, 2003; Ruf et al., 2024). Second, most of this research examined students' interpretations of pre-constructed graphs or students' graph constructions on pre-constructed axes; these researchers did not pay particular attention to the ways students understood the underlying coordinate system (CS) and/or the quantities represented by the CS. Our ongoing research exploring students' developing meanings for graphs is novel relative to this work, as we have begun to create theoretical constructs to help explain nuances in students' conceptions for CSs and the reference frames (RFs) they intend to represent. These constructs can be divided into categories based on (a) the types of CS, (b) the number and types of RFs, and (c) the object(s) students are expected to interpret within the graph space.

Preliminary Analysis

To explore our research question, we have begun preliminary analysis of several STEM textbooks and resources. To analyze the graphs, we conducted a content analysis, which "takes texts and analyses, reduces and interrogates them into summary form through the use of both pre-existing categories and emergent themes in order to generate or test a theory" (Cohen et al. 2007, p. 476). Consistent with this methodology, we used pre-established frameworks, as described above, to categorize, code, and analyze graphical representations in STEM textbooks and resources. Following the main steps of content analysis, we defined a sample of texts, the

unit of analysis, and the categories and codes for analysis. We then coded and categorized data. We acknowledge that codes were attributed to each graphical representation based on *our* interpretations of the author's intention of the graphical representation.

Coordinate Systems

A CS is a representational space an individual uses to systematically coordinate quantities (Thompson, 2011) to organize a phenomenon. This space typically involves coordinating two (Figure 1a–d) or more (Figure 1e–f) quantities. Across STEM fields, there are a variety of commonly used CSs, such as Cartesian (Figure 1a, c, d), polar, and logarithmic CSs.

Depending on the purpose the coordination serves, we have distinguished two types of CSs, *spatial* and *quantitative* (Lee, 2017; Lee et al., 2020). A *spatial CS* is a system of measurements through which an individual organizes or coordinates spatial elements in conceived or experienced space. Figure 1b is an example of a 2D spatial CS intended to mathematize the physical space of the screw eye, and Figure 1c contains an example of a 1D spatial CS if we only attend to the different categorizations of atmosphere by height. In contrast, a student may abstract quantities from a phenomenon and coordinate them in some new representational space, different from the space in which the quantities were originally conceived. We call this new structure, used to coordinate abstracted quantities, a *quantitative CS*. Figure 1d–f are all examples of quantitative CSs, because each represents quantities in a space that is different from the physical space in which the phenomenon is occurring.

We note there are often graphs in math classes that do not clearly fall under either of the two types (e.g., Figure 1a), as there are no obvious situational quantities involved. However, we have found the distinction between quantitative and spatial coordinate systems useful in characterizing the types of graphs used in middle school textbooks (Lee & Guajardo, 2023) and STEM textbooks and journals (Paoletti, et al., 2020). Further, this distinction proved explanatory in describing different ways students construct and interpret graphs (Paoletti et al., 2025). We note we have also explored other types of CSs in our work, including polar CSs (Moore, Paoletti, et al. 2013; 2014). Hence, we conjecture these distinctions are likely to be important in exploring different uses of CSs in undergraduate STEM education.

Reference Frames

A CS comprises RFs. RFs are mental structures through which an individual gauges the extent of various attributes of objects or phenomena (Lee, 2017; Levinson, 2003). RFs have been central to studies in spatial cognition (e.g., Levinson, 2003; Taylor & Tversky, 1996), children's conception of space (e.g., Piaget & Inhelder, 1967; Piaget et al., 1960), and quantitative reasoning (e.g., Joshua et al., 2015; Lee et al., 2019). RFs relate directly to the reference points and organizational structure (e.g., axes) an individual uses in a CS. For example, if we only focus on the categorization of atmosphere based on height, we can interpret Figure 1c as representing a single RF (height). If we use the dotted-red graph to consider the relationship between height and temperature, we can consider the graph as coordinating two RFs.

It is typical for CSs to represent two RFs (e.g., Figure 1a, b, d). There are various goals curriculum designers may have when tasking students to interpret a graph representing two RFs. They may ask students to interpret the meaning of a single point in a moment (Moore et al., 2025). For example, they may ask students to look at the dotted-red line in Figure 1c and ask them what the average temperature is at an altitude of 15 km. They may also ask students to make inferences about how two quantities change together, such as asking students to interpret the dotted-red line to describe how height and temperature change together in the mesosphere

(i.e. as the height increases, the temperature decreases). Reasoning about two quantities changing together is called covariational reasoning (Thompson & Carlson, 2017).

There are also examples across STEM fields of graphs intended to represent three (or more) RFs in quantitative (Figure 1e–f) and spatial (e.g., a 3D analog of Figure 1b) CSs. When students are tasked to coordinate three (or more) quantities, they are asked to engage in multivariational reasoning (Jones 2002; Panorkou & Germia, 2024). Researchers have noted that students as young as middle school and high school (Bagossi, 2024; Panorkou & Germia, 2024) can engage in multivariational reasoning to interpret graphs such as those in Figure 1e. By exploring the prevalence of such graphs in undergraduate STEM courses, we can develop curricular materials that better prepare students to interpret such graphs in STEM fields.

Types of RFs. In addition to attending to the number of RFs represented in a graph, our research has identified novel ways students interpret graphs as representing continuous versus ordered-discrete RFs (Olshefke-Clark et al., 2024, accepted). Whereas students are often tasked with interpreting graphs as representing continuous quantities (typically using covariational or multivariational reasoning), other times we expect students to attend to distinct regions of a graphical space (e.g., Figure 1d, e). In these latter cases, curriculum designers may expect students to attend to these discretized chunks represented within the graph space when interpreting the graph—either regions as a whole, or to individual points within these regions, rather than considering lines representing changing quantities (e.g., the type of soil in Figure 1e or the state of the matter in Figure 1d). However, the extent to which curricula in STEM fields are expecting students to interpret graphs based on points, lines, or regions is an open question.

Implications and Feedback Questions

We anticipate the types of CSs (spatial v. quantitative; Cartesian v. non-Cartesian), the number of RFs, the types of RFs (continuous v. ordered discrete), and the object(s) students are expected to interpret (points, lines, regions) within the graph space will prove explanatory when examining the ways STEM curricula use graphs to represent phenomena. By exploring the prevalence and function of these different features of graphs in STEM curricula, we can develop curricular materials that math teachers can use to better prepare students to interpret (or construct) graphs in their future undergraduate STEM coursework. Further, by comparing the different types of graphs used across STEM fields, we may identify tendencies for certain fields to use certain types of graphs and develop curricular materials specific to those fields to better prepare students to interpret graphs as curricula developers intend.

Although we believe our criteria will successfully characterize many types of graphs we encounter in STEM textbooks, we also expect there will likely be other significant features of graphs of which we are currently unaware. Thus, we have several feedback questions related to our current framework: Are there important features of graphs across STEM fields that our framework may not capture? If so, what are they? Are there other extant frameworks characterizing graphical features that may be useful in this study?

We also conjecture that our framework may be useful in analyzing graphs beyond curriculum. For instance, we are curious if RUME attendees have insights into the question: How might our current (or a revised) framework be used in analyzing graphs used in STEM instruction? Would this framework be useful in analyzing the ways in which instructors expect students to interpret or construct graphs? Hence, we hope to obtain feedback that will inform both the theoretical framework and new avenues we can extend this work into to better explore the use of graphs across undergraduate STEM fields.

Persistence in the Margins: An Autoethnographic Study of a First-Generation, Low-Income Mathematics Major

Jesse D. Combs
Lesley University

Andrew S. Richman
Lesley University

Although research on persistence and attrition in the undergraduate mathematics major remains limited, existing studies point to structural, curricular, and identity-related barriers that shape student trajectories. This autoethnographic study extends that conversation by exploring the lived experience of a first-generation, low-income undergraduate math major in the United States, using digital journaling to explore persistence, barriers, and systems of support. Guided by Tinto's theory of student departure, the study highlights the impacts of financial uncertainty, faculty interactions, and institutional and social demands on students' academic integration, sense of belonging, and self-image as a mathematician. Persistence emerges as an act of resistance. This study contributes to the literature on equity in undergraduate mathematics education by highlighting the complex interaction between identity and institutional structures. In doing so, the study offers insights for the creation of inclusive advising and pathways that support the success of students from disadvantaged backgrounds in mathematics.

Keywords: Persistence, First-Generation, Low-Income, Mathematics, Autoethnography

Introduction and Relevant Literature

Research in undergraduate mathematics education has long emphasized the gatekeeping role of mathematics courses in science, technology, and engineering (STE) pathways (Olson & Riordan, 2012; Seymour et al., 2019; Seymour & Hewitt, 1997). This emphasis has led to a plethora of research on the topic of how mathematics courses serve as barriers to persistence and retention of a wide range of STEM majors (Enderson & Ritz, 2016; Leyva et al., 2022; Olson & Riordan, 2012; Seymour et al., 2019; Seymour & Hewitt, 1997; Whalen & Shelley, 2010). Because of this dominant narrative, there has been a large focus on Calculus 1 (D. Bressoud et al., 2015; Johnson, 2016; Rasmussen et al., 2014). While this focus has been crucial in reimagining undergraduate mathematics instruction, it positions mathematics as a service discipline. This focus risks misrepresenting the experiences of mathematics majors, who differ significantly from other STE students. Only 2% of students enrolled in Calculus 1 intended to major in mathematical sciences (D. M. Bressoud, 2021), and unlike some STE majors (e.g., biological science, engineering) who declare during year 1, most math majors (64%) declare after (Chen, 2013). This misalignment suggests that while research on calculus 1 has generated valuable insights for STEM persistence broadly, it does not adequately capture the distinct pathways, challenges, and experiences of students intending to major in mathematics in the United States. These statistics underscore the need to look beyond calculus 1 to understand the persistence and attrition of undergraduate mathematics majors.

Although research specifically centered on undergraduate math majors in the US remains scarce, a small body of researchers has begun the exploration within this population. First, Ellington and Frederick (2010) focused their work on Black, high-achieving mathematics majors, finding that family support, program resources, and prior math experiences shaped persistence and identity as high-achieving. Later, Bahi et al. (2015) employed a time-series analysis to estimate a 23% probability of switching by the end of the first semester, noting no differences among genders. Zhuhadar et al. (2019) used survival analysis techniques with n=272,

showing that attrition risk increases later in the major and indicates that 3000-level courses better predict dropout as opposed to introductory calculus. And, more recently, Hubbard (2023) made an attempt at 'dispelling the myth' that there is a specific course that deters students from completing a math major and instead investigated persistence in between math courses within a specific institution. The author found that while median pass rates were 73%, persistence varied across demographics. Of worthy note, females are passing at higher rates but persisting less than males, and Black students are passing at lower rates but maintaining a higher persistence rate. Collectively, the present literature underscores the complexity of persistence and attrition of the undergraduate mathematics major. This literature supports the assumption that the factors that support a student's persistence (or lack thereof) are equally complex. What has not been investigated are factors such as structural, curricular, and programmatic barriers alongside identity, external factors, motivation, and holistic experiences in the major. The current study aims to fill these gaps.

Given these gaps, my socioeconomic identity (first-generation and low-income), and the call-to-action previously mentioned, an autoethnographic approach seemed fitting to investigate the complexities and the whole undergraduate journey of a mathematics major. Understanding the factors that influence persistence and attrition of the mathematics major is critical for the RUME and the larger mathematics community as we seek to address equity, access, and the definition of success in mathematics. By centering the lived experience of a mathematics major, this autoethnographic project aims to contribute a more nuanced understanding of how disciplinary identity, institutional structures, and personal identity interact to shape persistence. I seek to reopen dialogue and expand conversations within RUME beyond mathematics as a gatekeeper and towards mathematics as a discipline whose majors deserve focused scholarly attention.

Theoretical Framework

To answer this call-to-action, a theoretical framework is needed that considers the complex natures of equity, access, and the definition of success in mathematics. This study is grounded in Tinto's Theory of Student Departure (Engle & Tinto, 2008; Tinto, 1975, 1988). Tinto theorizes student attrition as the result of the interplay between characteristics of the individual (the student) and the institutional environment. His framework categorizes departure factors into three dimensions: academic and social integration, commitment, and external influences.

Academic and Social Integration

Persistence is shaped by the extent to which students engage with academic structures, achieve in coursework, and the degree to which students develop meaningful social connections with peers, faculty, and the broader campus/institution community.

Commitment

A student's commitment to educational goals and the institution is a key predictor of persistence. Higher levels of commitment correspond with greater likelihood of degree completion.

External Factors

Persistence is also mediated by factors beyond the institution. These factors include, but are not limited to, socioeconomic status, familial responsibilities, and aspects of personal identity.

While Tinto's framework serves as the foundation for this study, my application of it is situated within a constructivist epistemology and informed by a critical theoretical lens. From this perspective, knowledge is understood as socially constructed, and research is positioned as a means of interrogating systemic inequities in education. Thus, I extend Tinto's model by considering how inequities (tied to identity, access, and belonging) shape students' opportunities to persist in the undergraduate mathematics major. Consequently, external factors are more accurately conceptualized as factors beyond the locus of control of the student, not beyond the institution.

The decision to use the autoethnography aligns with this theoretical framing and understanding. Autoethnography situates lived experiences as a valid and rigorous form of knowledge (Bochner & Ellis, 2022; Creswell & Poth, 2016). In doing so, the autoethnographic methodology allows for the disruption of dominant narratives about success in mathematics. Within this study, the method also serves as a form of healing, allowing for critical reflection on the ways my lived experiences as a first-generation, low-income mathematics major interacted within the broader community to impact persistence. Therefore, healing is not conceptualized as separate from inquiry but as integral to the process of making sense of persistence in undergraduate mathematics. This framework informed the design, including the research questions and interpretation of this study.

This study is guided by the following research questions.

1. What personal and systemic factors influence my persistence as a first-generation, low-income undergraduate mathematics major?
2. What barriers did I encounter during my undergraduate journey, and how did they impact my academic and personal development?
3. What types of programmatic and institutional support could have better supported my persistence and success within the mathematics major?

Methodology

As stated by Bochner and Ellis (2022), evocative autoethnography emphasizes the personal narrative as a means of creating resonance and connectedness for readers. In alignment with this approach, I engaged in structured, digital journaling over a period of seven days, writing for approximately twenty minutes each day. These writing sessions were guided by prompts developed with both the literature and theoretical framework in mind. The aim was to elicit memories and reflections on persistence, barriers, institutional support, and self-identity changes. The use of digital journaling provided a space to revisit and reconstruct my undergraduate journey while connecting my experiences to systemic patterns identified in prior research.

Data analysis occurred through iterative, open coding (Creswell & Poth, 2016) of the journal entries, with attention to both emergent themes and connections to the theoretical framework. I sought to highlight how individual agency, social and institutional constraints, and factors outside my locus of control interacted to shape my trajectory through the mathematics major.

Validity was addressed through transparency and reflexivity. Throughout the journaling process, I documented my decisions, acknowledged my positionality, and considered the ways my interpretations were shaped. Autoethnography does not aim for generalizability in the traditional academic sense. But it does offer transferability through resonance and connectedness, inviting readers to draw connections between my lived experiences and broader patterns in undergraduate mathematics education.

Preliminary Findings

In this section, I present the preliminary findings from the analysis of this autoethnographic study. The purpose of this autoethnographic study is to explore and gain a better understanding of the nuances of the factors that led to my persistence and shaped my navigation through the undergraduate math major here in the United States. I wrote, *"I had to finish this degree. But I didn't want to be in math spaces anymore. I gave up on my dreams of medical school or an advanced degree in math. I believed what I was told that I did not belong in this community… that I did not know enough math… that I guess I will just teach instead… I could not go back to poverty. This sentiment stays with me even to this day, but I'm healing."* This reflection highlights the treacherous navigation of my academic journey and its impact on my sense of belonging. Through open coding of the digital journals, four major themes emerged: (1) persistence as resistance, (2) navigation of higher education, (3) identity and belonging in math spaces, and (4) external factors. At the time of this submission, my analysis has focused on theme four, external factors.

Financial Uncertainty and Institutional Constraints

Financial uncertainty, which led to institutional constraints, significantly shaped both my academic choices and relationship to the institution. I write, *"I had acceptances at many places... Yet, I felt like I had no actual choice… Without financial support, I was not going to be able to go to college."* These institutions varied by location (both in- and out-of-state) and level of institution (private, public, liberal arts, state schools, new-ivy, and ivy leagues). Yet, it became internally apparent that the decision of a specific institution was not mine to make. Instead, it was my lack of financial security that was going to make the decision. Ultimately, the institution that was chosen was a small, liberal arts college, located in the Appalachian region of the country. I wrote, *"For better, for worse, I don't know. I am giving up a lot of resources and access to a larger world with this decision. But I also have no other real option."* This exemplifies a critical point in Tinto's (1993) theory, where he argues that external obligations, lack of institutional integration, and decreased resource level increase the likelihood of departure. The implications of this forced decision limited my access to robust faculty options and resources.

Faculty Gatekeeping and Limited Academic Support

The institution had only two faculty during my undergraduate timeline, one of whom was my primary advisor, and the sole instructor for any course beyond calculus, limiting my academic experience to their problematic approach. This faculty member questioned my belonging and ability in mathematics. I recalled, "*You just don't get it... Someone like you doesn't belong in math."* These were common occurrences, according to the journal entries, and "*were confirmation of insecurities I had worked to overcome."* Tinto (1993) emphasizes that academic integration is essential for student persistence. I understand academic integration to be the meaningful and validating relationships with faculty and institutional academia at large. In direct contrast, I experienced integration as a gatekeeper. I wrote, *"I was made to feel minuscule and disposable."* Any option to request another advisor was not available. I wrote *"No path to escape [their] authority."* Efforts were made to report the pattern of mistreatment. However, those efforts were met with indifference and redirection. I recalled the frequent, *"Maybe you should just change your major."* But this did not exonerate my feelings. These experiences created a climate in which seeking support felt dangerous or risky, while fostering doubt about my ability to learn mathematics, turning persistence into an act of endurance rather than growth.

Overworked and Social Demands

Tied directly to financial constraints and a desire to be involved in campus activities, affairs, and institutional structures, I navigated undergraduate life dominated by work, constant social demands, and mathematics. I held a federal work-study position every semester. I worked, yearly, as a campus (math, chemistry, physics) tutor and peer mentor. I was a collegiate athlete. I was elected Vice President for the student government association. I even held off-campus work at a local department store and as a server at a local restaurant. I wrote, *"I had to. I wanted to feel like part of the college, like I was making it better for those like me. I also had to pay for school. I had to pay to live."* Balancing these responsibilities left little room for recovery from setbacks. Tinto (1993) argues that external demands that reduce time and academic engagement can lead to attrition. Though I chose to persist, I found that my identity as a first-generation, low-income student was pushed aside by the institution's lack of mechanisms to reduce these external and social demands. *I wrote, "This was saddening, infuriating, considering the institution prided itself on its large (about 50%) portion of first-generation and low-income students 'success."* Internally, I understood this to reinforce that the institution of academia was not built for students like me. Tinto (1993) suggests that departures often occur due to insufficient institutional integration, rather than lack of motivation; my experience affirms this and illustrates how persistence can function as an act of resistance.

Discussion and Conclusion

This study highlights the ways institutional structures, financial pressures, and faculty dynamics shaped the persistence of a first-generation, low-income mathematics major. My experience underscores that support structures, or the absence of, directly impacts students' academic engagement, sense of belonging, and ultimately their identity as mathematicians.

The current findings align with prior research emphasizing the importance of institutional agents and structures shaping outcomes for first-generation students (Burnett, 2017; Engle & Tinto, 2008; Jehangir, 2010; McCain et al., 2024). However, my findings add nuance by showing how unchecked faculty authority and institutional rigidity can transform structures of support into barriers. This connects to survivor narratives among low-income students, suggesting that persistence often requires enduring trauma rather than accessing support (Cota, 2024; Hahn, 2023; Wallace, 2018). Furthermore, my analysis contributes an additional layer to the complexity of persistence by showing how deeply power dynamics (faculty-to-student and lack of options of teaching faculty) can function as a structural condition that limits students' capacity to learn and enhances harm.

I am interested in thoughts from the audience about the following: (a) feedback on my analysis that would inform my exploration of the other three themes, (b) possibly expanding this work through a larger quantitative or mixed methods study to examine systemic factors across mathematics courses and majors, or (c) employing a duoethnographic methodology (Burleigh & Burm, 2022) with another first-generation, low-income mathematics (or STE) student. The latter two studies could explore the variance among institutions, regions, and the complexity of self-identity and mathematical identity formation. These studies could further illuminate the intersection and interplay of identity, systemic (academic and social) constraints, and persistence.

Lastly, this work makes clear the importance of inclusive advising, support structures, and pathways that reflect the realities of students from disadvantaged backgrounds (*Disadvantaged Background*, n.d.). Not only recognizing but addressing these systemic and academic barriers is critical to fostering persistence and furthering the conversation of equity in undergraduate mathematics education.

"…it's more of a healthy skepticism…": Descriptions of Undergraduate Students' Mathematical Convictions and Proclivities

Mario A. Gonzalez
McNeese State University

This study used a survey containing two open-ended questions and a ranked choice question. I investigated undergraduate students' mathematical convictions relating to whether they experienced a lack of conviction. Students were asked about their proclivities when an instructor presents a proof to the class. Preliminary findings show that few students experienced a lack of conviction with either theorems or proofs. For theorems, a lack of understanding was often cited. For proofs, students cited doubts about the rigor of those proof types such as picture proofs. Students' proclivities seemed to show that their focus was on understanding a proof's content. Further evidence provided by follow-up interviews corroborated this interpretation and that students may in fact reflect on matters of conviction in mathematical settings.

Keywords: Mathematical conviction, mathematical proof

Mathematical convictions are described as the ways in which one is persuaded about the truth of a theorem given a mathematical argument or statement. Nebulous concepts in mathematics education, like mathematical convictions (Brown, 2018), continue to challenge researchers in the ways we investigate them. This study contributes to the growing field of knowledge around mathematical convictions by investigating undergraduate students' mathematical convictions and proclivities. The purpose of this study was to determine whether and how students consciously operate in a way that foregrounds mathematical convictions. I also investigated the roles that theorems, proofs, and instructors have in matters of students' convictions.

Background Literature

I note that mathematical proofs are often defined as "…valid arguments that establish the truth of a mathematical statement. By an argument, we mean a sequence of statements that [begin with an assumption and] end with a conclusion" (Rosen, 2012, p. 73). Indeed, many textbooks describe mathematical proofs in this way which often do not mention matters of conviction. So, this leads to questions regarding how and why students may be convinced.

Aspects or characteristics that students often cite as contributing to whether they are convinced by a mathematical proof or argument are familiarity with the content and method (Brown, 2018; Chazan, 1993; Healy & Hoyles, 2000), example-use (Healy & Hoyles, 2000; Weber et al., 2022), and whether one understands that proof (Brown, 2018; Selden & Selden, 2003). A contentious aspect reported in the body of research relating to mathematical convictions is that of authority. For undergraduate students, this may be observed by students referencing that the instructor said that the mathematical statement was true or the mathematical proof was valid (Brown, 2014). For mathematicians and educators, a classical perspective is that students are convinced that a theorem is true if and only if they have a mathematical proof. However, prior research described students as being too difficult to convince (Fischbein, 1982) or too easily convinced by mathematical objects that were not proofs (Harel & Sowder, 1998). Interestingly, Weber et al. (2022) described mathematicians' behaviors like students rather than the typical mathematician behavior described in previous research.

Methods

I used a survey intended to capture characteristics of undergraduate students' mathematical convictions and their proclivities as they engage with mathematics. In this preliminary report, I report parts of that survey and the follow-up interviews pertaining to those parts of the survey.

I contacted 231 instructors across the U.S. teaching undergraduate algebra or analysis courses in Fall 2024. Fourteen (6%) agreed to use the survey in their course(s). Two instructors implemented the survey as an assignment, four implemented it as extra credit, and nine forwarded the survey to their students to complete voluntarily. There was a total of 212 students enrolled in these instructors' course sections ($M = 15.14$, $SD = 8.72$). There were 95 students (45%) who responded to the survey. A student's response was removed from analysis if: 1) the duration to complete the survey was less than five minutes, 2) the student was a graduate student, 3) the student did not consent to the study, or 4) the student did not sign the consent form. After this, there were 71 responses (33%) remaining. The average time to complete the survey was 33 minutes while the median time to complete the survey was 11 minutes.

Research Instruments

There were two open-ended questions. The first asked, "was there ever an instance where your professor presented a theorem, and you were not convinced the theorem was true?" If the student responded with "yes," the question continued by asking for further details such as the course in which it occurred, the theorem itself, and why he or she was unconvinced. The second open-ended question asked, "is there a type of proof that you find unconvincing?" If the student responds with "yes," the question continued by asking for further details like type of proof, examples of when it was used, and why he or she was unconvinced by this type of proof.

A ranked choice question had students indicate behaviors they engaged in and their importance during a scenario. These behaviors were generated from assumptions about students' proclivities and prior research regarding students' mathematical epistemologies as it relates to standard practices in the classroom. The prompt was, "when my instructor presents a mathematical proof to me or the class, I personally focus on…." They then rank the following six behaviors on whether they engage in them and how important they are: 1) Trying to understand the content of the proof, 2) Checking whether the proof is valid, 3) Becoming convinced that the theorem is true, 4) Writing what the professor writes or says, 5) How this would be useful for the exam(s) or assignments, and 6) Anticipating the next line of the proof.

Follow-Up Interviews

Students were invited for a follow-up interview if they met two of three criteria: 1) described a theorem that they were not convinced was a mathematical truth, 2) described a proof type that they were not convinced proves, or 3) indicated that they focused on becoming convinced that a theorem is true when the instructor presents a proof. I conducted five follow-up interviews with five different students. The average interview time was 10.8 minutes ($SD = 3.47$ minutes).

I refer to these students as S, K, B, U, and C. Student S was beyond their fourth year with a major in mathematics and completed five proof-oriented courses. Student K was a third-year mathematics major and had completed one proof-oriented course. Student B was a second-year majoring in applied mathematics and had completed one proof-oriented course. Student U was a fourth-year majoring in mathematics and had completed three proof-oriented courses. Student C was a fourth-year majoring in mathematics and had completed three proof-oriented courses.

The questions in the interviews were tied back to responses to the criteria for why they were invited. For example, asking about the role(s) an instructor played or plays in becoming (un)convinced. Also, each student was asked whether they found themselves wondering about whether they're convinced in courses and whether not being convinced is ever an issue.

Results and Preliminary Analyses

Results of the Open-Ended Questions

The results for the open-ended questions are presented below in Table 1. Thirty-eight students (53%) said that they did not experience an instance where their instructor presented a theorem and they were not convinced that theorem was true. Twenty-four students (34%) said that instances of not being convinced by an instructor's presented theorem were due to not understanding. Four students (6%) said that they did not believe that theorem they encountered to be a mathematical truth. These instances included an instructor presenting a theorem relating to converging sequences without justification, the infamous invalid claim that "all horses are the same color," and the reverse triangle inequality. These students described stated their lack of conviction stemmed from the statements not being "obvious" or "fundamentally incorrect."

Most students (83%) said that there was no type of proof that they did not think proved. Four students (6%) said that they were not convinced a proof type proved. They described proofs by picture, proofs by examples, and proofs of uniqueness. For proofs by picture, two students said that pictures can be interpreted differently and drawn in misleading ways. For proofs by examples, the student said having an artificial intelligence program attempt to prove a theorem only used examples which "did not cover all cases." For the student who mentioned uniqueness, they said the proof of "square roots are not rational" and that "when we just name the same variable two different things, it makes sense that it will always come together."

Table 1. Results of the Two Open-Ended Questions

Was there ever an instance where your instructor presented a theorem and you were not convinced the it was true?*				Is there a type of proof that you find unconvincing?*			
	Yes.				Yes.		
No	Did not believe the theorem to be true	Believed it was true, but did not understand why	Other	No	Do not believe that that type of proof proves	Believed it proves but do not understand why	Other
38	4	24	4	59	4	4	2

*There were three instances of a student declining to answer either question.

Results of the Ranked Choice Question

The results of the ranked choice question are presented below in Table 2. I note that a rank of 6 indicated the most importance, a rank of 1 indicated the least importance, and a 0 indicated no importance (i.e., not ranked at all). These rankings were tabulated and then weighted according to the students' rankings. The table is organized from most important to least important. These results show that students indicated understanding the proof's content as frequent behavior and notable importance while checking the proof's validity was infrequent and less important.

Table 2. The results of the Ranked Choice Question

Rank	Students' Focus During Instructor Proof Presentation					
	Trying to understand the proof's content.	Writing what the instructor writes or says.	Becoming convinced that the theorem is true.	Anticipating the next line of the proof.	Usefulness for the exam(s) or assignments.	Checking whether the proof is valid.
6	40	10	3	4	7	3
5	13	14	14	14	6	4
4	5	9	13	13	9	8
3	3	7	9	4	11	12
2	0	5	4	5	11	8
1	1	6	2	5	6	4
0	9	20	26	26	21	32
Weighted	4.72	2.86	2.50	2.44	2.38	1.77

Results from the Five Follow-up Interviews

Four students mentioned that they viewed the instructor as a support mechanism in the process of becoming convinced or resolving issues of certainty. Student C said that instructors "provide tools necessary to be able to understand the proof by giving examples or other theorems." Student S described an instructor's role as engaging with the class by asking whether the theorem or proof makes sense. They emphasized that it was important for the instructor to engage students' thinking with questions relating to specific justifications in a proof. Student K described the instructor's role as a "kind of… comforting thing. I [can] ask them any question, even if it's very complicated." Student U described the instructor's role as "presenting the pieces that you need to follow to be convinced that you or one of the ways you could be convinced a theorem is true." They continued by mentioning that probing questions were especially helpful to "start actually building the theorem."

Few students mentioned strong feelings toward the role of becoming convinced as they engage with mathematics. For example, Student K said, "generally speaking, if it's a complex theorem, I'll break it down into a million pieces and I won't trust it at face value…. I just… can't move on." They continued by saying, "I'll be second guessing myself [otherwise]. Just something I can't help." I asked Student U if being unconvinced is ever an issue, they said that "it's [never] stopped me from trying to engage with a topic…. Perhaps it's more a healthy skepticism that I…probably would benefit from having more than blindly [believing] in the book every time." In other words, "…not being convinced of a theorem just by reading it." Student U believed they developed healthy skepticism by saying, "it's gone in a bit of a weird shape graphic because I started off just blindly believing everything…" and gestured a graph like Figure 1. The reason Student U gestured like this was due to their introduction to proof course instructor who helped develop a sense of skepticism, but as Student K progressed through subsequent mathematics courses, they had rebuilt "blind trust" in textbooks "because…the [questions] we use [in courses] are simply prove this is true or prove this is not true."

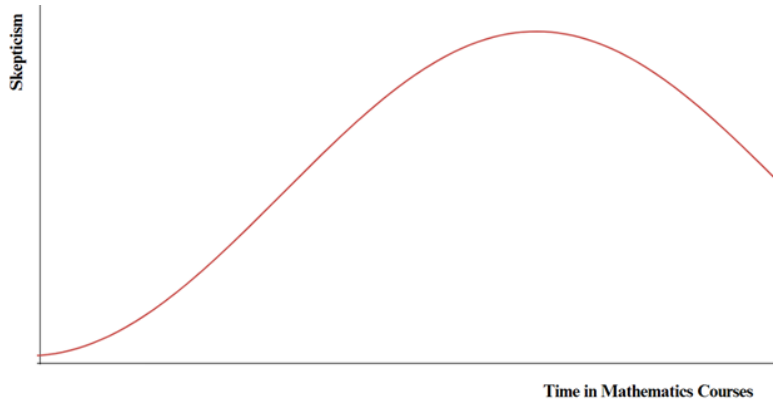

Figure 1. Recreation of Student U's Gestures about Skepticism and Mathematics Courses

Discussion and Conclusion

The open-ended questions revealed that most undergraduate students in this study are convinced that the theorems their instructors present are true and that the proof types they encounter are valid. The instances of students not being convinced that the instructors' theorems were tied to a prevailing desire for more justification and reasoning—a mathematical proof. The instances of students not being convinced by a proof type included picture proofs, proofs by examples, and proofs by uniqueness. Notably, students were articulate about their reasons for why proof types were unconvincing. These reasons relied on skepticism, or doubts, about the rigor of the proof type rather than a misunderstanding.

The ranked choice question revealed that students primarily focused on and find importance in understanding the content of a proof while checking whether the proof is valid was often less important and frequent. This provides some evidence about the role of an instructor. The students in this study seemed not worried about whether an instructor was providing invalid proofs. This is reasonable given the standard structure and practices of mathematics. Interestingly, becoming convinced that the theorem is true was third when the rank was weighted. So, becoming convinced is among the list of proclivities but other mathematically relevant behaviors take priority. In other words, there is evidence that students knowingly think about becoming convinced in their courses. This provides evidence that some students' mathematical epistemologies encompass mathematical convictions given that the scenario was written to exclude specific details such as content, location, and instructor.

The results from the follow-up interviews provide some evidence that students indeed consciously reflect on matters of conviction. For some students, it appeared as ways they come to know and understand mathematics. This reflection was shown to be fostered in the class for one student but not others. Nevertheless, the instructor's role for these students provides understanding which has been observed greatly influencing whether students are convinced (Brown, 2018; Selden & Selden, 2003).

Preliminary Nature of This Report

I do not anticipate having further analysis developed because the analysis is limited by the research instruments' wording. Therefore, I wish to avoid making higher inferences than warranted by the data. However, I wish to develop further research instruments, avenues, and questions pertaining to how reflections on whether one is convinced is taught or enculturated in courses and how these mechanisms influences students' epistemologies as they engage with mathematics (proofs and theorems or otherwise).

Students' Challenges in Double Integration Over Non-rectangular Regions

Man Kin Leung Biyao Liang Igor' Kontorovich
The University of Hong Kong

Double integration is challenging for many students. It involves the interrelationship between three variables x, y, z within an object in 3D space expressed in both algebraic and graphical representations. When the integral domain is not a rectangular region, values of x and y along its boundaries may become dependent. However, how students perceive interdependency of variables and what mental actions are involved in double integration have not been fully explored. To answer these questions, multivariational reasoning framework is used in this study to analyze students' cognitive activities. Interview data collected from a university-level calculus enrichment course is analyzed to explore student's reasoning. The findings suggest that students demonstrate several mental actions of multivariational reasoning when performing double integration over different regions. They also suggest some possible directions of extending the theoretical framework of multivariational reasoning to adapt some specific concepts such as range and change of variables in double integration.

Keywords: multivariate calculus, double integral, multivariational reasoning, visualization

Introduction

Double integral is typically taught in multivariate calculus, and it is widely applied across STEM disciplines (Jones & Dorko, 2015). Despite the prolific research in students' understanding of single variable calculus (Thompson & Harel, 2021), relatively less attention is drawn to multivariate calculus (Martínez-Planell & Trigueros, 2021).

Students' thinking towards double integration over rectangular region has been studied as the generalization of definite integration to bivariate function, regarding the two independent input variables (Jones & Dorko, 2015). However, the case of non-rectangular regions has been under-explored until recently (Craig & Pehlivan, 2025). Such problems appear in vector calculus and engineering applications, regarded as a common challenge for students (Khemane et al, 2023).

The difficulty of transitioning from single to double integration may be explained by the complexity of multiple variables and the challenge of visualizing their interrelationship in 3D space. With non-rectangular regions, these two factors are further amplified. The cognitive activities involved when handling multiple variables has been studied by Jones (2022) as multivariational reasoning. Jones categorized types of multivariation structures and induced some mental actions from students' reasoning. This provides a suitable theoretical framework to analyze students' thinking processes in double integration. In this paper, task-based interview data is analyzed to explore students' mental actions of multivariational reasoning involved in double integration over different regions, and to inform potential development of the framework.

Literature Review

The concept of double integration is rooted in bivariate functions and definite integration. A bivariate function is commonly represented in the form of $z = f(x, y)$. With inputs (x, y) as a point in a 2D region, the graph of a bivariate function is a simple surface in 3D space. Trigueros and Martínez-Planell (2010) used APOS theory to study how students transition the concept of single variable functions to bivariate functions in different representations. They found that this process is not straightforward especially when graphical representations are involved.

Definite integrals are associated with a bounded region for the input variable. In the case of positive single variable function, a definite integral can be constructed as the area under the graph over an interval. Jones and Stevens (2022) combined several frameworks into a more general concept of "integral with bounds". Their approach attends to different layers of thinking, involving numeric, graphical, and symbolic representations.

The transition from definite integrals of single variable functions to bivariate functions is indirect. Jones and Dorko (2015) studied how students generalize the concept of multivariate integrals based on single integral. They found that for most students, the generalization is based on the concept of "area under the curve". Martínez-Planell and Trigueros (2020) explored how students relate Riemann sums of bivariate functions to double integrals.

The above studies involve rectangular regions only. Non-rectangular regions are essential to mathematical applications for engineering problems, which makes them research-worthy. Khemane et al (2022, 2023) identified students' common difficulties in distinguishing between rectangular and non-rectangular domains, and swapping the order of integration. Craig & Pehlivan (2025) analyzed students' conceptualization of the bounds of non-rectangular regions. However, these studies did not explicitly delve into students' perception of the interrelationship between variables, and its role in the reasoning process. This study aims to bridge these gaps by exploring students' use of multivariational reasoning (Jones, 2022) in double integration.

Conceptual Analysis

Double integration involves three variables x, y, z being interrelated to each other given a bivariate function, and some constraints on the boundary of the integral domain. To analyze how students perceive and represent this interrelationship, multivariational reasoning by Jones (2022) is adopted in this study. Based on the idea of covariation (Thompson & Carlson, 2017), Jones studied students' cognitive process in coordinating multiple variables. This framework begins with a categorization of multivariation structures into independent, dependent, and nested types, followed by several mental actions involved in students' reasoning processes. Based on this categorization, the conceptual analysis (Thompson, 2008) is described. Double integral over a rectangular region $\int_{y_1}^{y_2}\int_{x_1}^{x_2} z(x,y)dx\,dy$ is associated with independent multivariation since the output variable z varies with two independent input variables x, y. The case of non-rectangular region can be regarded as a special type of dependent multivariation. If the region is vertically simple, the double integral can be written as $\int_{x_1}^{x_2}\int_{y_1(x)}^{y_2(x)} z(x,y)dy\,dx$ where the range of the inner variable y depends on the outer variable x. If the region is horizontally simple, the double integral can be captured through $\int_{y_1}^{y_2}\int_{x_1(y)}^{x_2(y)} z(x,y)dx\,dy$, when the range of x depends on y. Figure 1 illustrates these three cases and their associated multivariation structure.

Jones' (2022) framework is further extended to conceptualize students' cognitive activities associated with multivariational reasoning when performing double integration:

1. *Recognition of in/dependence* is involved when students identify the interrelationship between variables given an object before conducting double integration.
2. *Coordination of simultaneous changes* is involved in setting up iterated integral with inner and outer variables, with the range of inner variable dependent to the outer one.
3. *Switching variables/constants* occurs when students perform inner integration, regarding the outer variable as constant. It also occurs when swapping the order.
4. With one variable regarded as a constant, students can regard the bivariate function as a single variable function, hence *reduce into an isolated covariation*.

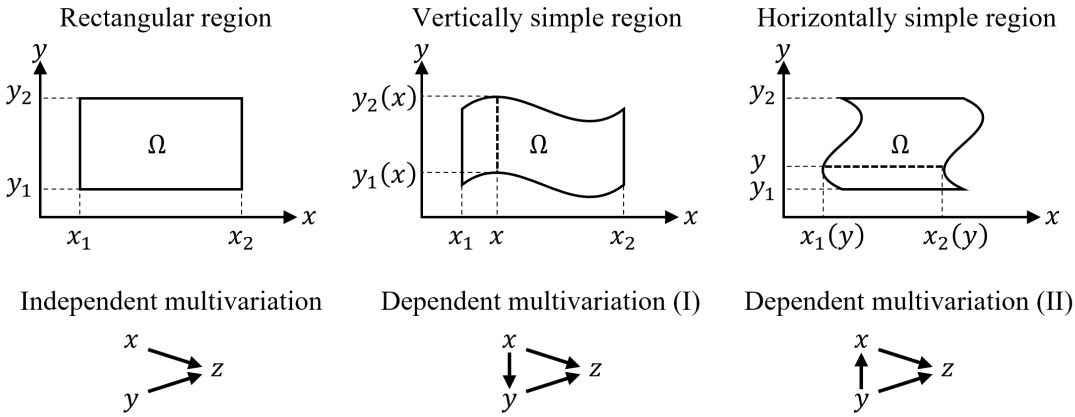

Figure 1. Typology of integral domains and associated multivariation structure.

Method

The data for this study was collected in a university-level enrichment course offered to high-achieving secondary students in Hong Kong. This five-weeks course conducted in summer 2025 by the first author covered single and double integration. The pedagogy involved lectures on function, calculus and visualization, along with interactive activities using dynamic geometry software. After completion of the course, 11 students were recruited for individual task-based interviews, each lasting between 1 to 2 hours. The students were given a bivariate function $z = x + y$ and regions on the xy-plane: square, triangular, quarter-circular (Figure 2). The first two regions correspond to independent and dependent types of multivariation, respectively. The typology of the third region depends on the coordinate system used. Hereby, it can become dependent when x, y are used or, independent for r, θ in polar coordinates.

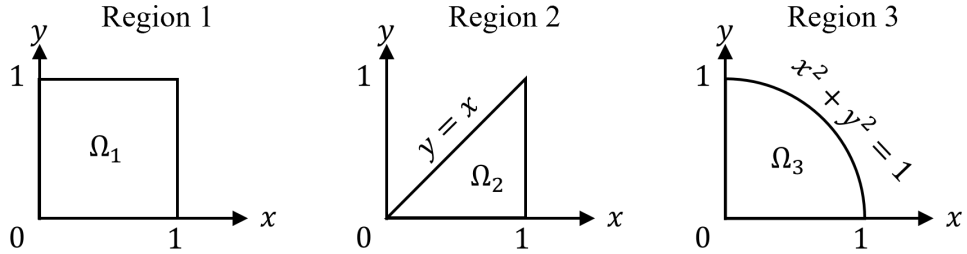

Figure 2. Integral domains used in interview task.

The students were asked to imagine and sketch the graph of the function, express the range of values and dependence of the variables, and eventually evaluate the volume of the solid objects, namely D_1, D_2, D_3, underneath the graph of function and lying on the three regions. These solids and regions were described by the interviewer in words without showing the figures in the beginning. At different stages of the interview, students were provided with dynamic computer graphics illustrating the objects in 3D space virtually to assist their visualization and problem solving. Transcription of the interview recording with students' writing, drawing, hand gestures and usage of computer graphics were analyzed based on Jones' (2022) framework.

Preliminary Findings

The findings below are presented for each task, based on the responses from three students (in pseudonyms), who demonstrated different levels of multivariational reasoning. Due to the preliminary nature of this report, the data from other interviewees has not been included.

Ranges of variables and their interrelationship given a solid object

After provided with the computer graphic of D_1, students were asked to identify the ranges of values of x, y, z within the solid. Henry recognized the base of D_1 as a square and responded that $x = 1, y = 1$ without addressing the ranges of x, y. Consequently, he said z is a line segment going up to a point of 2 and thereby replied $z = 2$. He admitted that z is determined by x, y with the relation $z = x + y$, as a single value. This case indicates a confusion between value and range of variables, which may be rooted in the perception of length when discussing a line segment, rather than the varying positions of a point on it. This can be regarded as the level of "*no variation*" (Thompson & Carlson, 2017) which is before co- or multi-variation take place.

By contrast, Carl claimed that "x is 0 to 1, y is 0 to 1, and z is 0 to 2". After the interviewer asked "if $x = 0.3, y = 0.4$, can z go up to 2?", he realized that the ranges of the variables might not be independent. Then, he stated that the solid is "sandwiched" between two planes $z = 0$ and $z = x + y$, hence modified his answer as z being from 0 to $x + y$ dependently. This graphical interpretation allows a range of z dependent to the position with x, y coordinates within a region. This demonstrates the mental action of *recognizing dependence* of the range of z on x, y, as he realized that values of x, y restrict the allowed values of z. It is notable that Carl did not address this dependence relationship in the beginning, until he applied the graphical representation. This suggests that visualization can enhance students' understanding of interrelationship of variables.

Double integral over triangular region

In the discussion about D_2, Henry thought it would look like a square considering the equation $y = x$, consequently he said that when x increases, y and z also increase. After being asked to consider the solid's projection on the xy-plane, he drew the line of $y = x$ and claimed that the region is a triangle as the line cut through the previous square region into two halves, without drawing the whole triangle with other boundaries. Henry could setup the iterated integral with $dydx$, without explaining why x and y goes from 0. He regarded "starting from 0" as a common habit in integration. When being asked to integrate with a different order $dxdy$, he directly swapped the integral domain $[0, x]$ of y to the outer integral (Figure 3) without rewriting it as an independent interval $[0,1]$. The mental actions of *switching variables/constants* and *coordination of simultaneous changes* seemed to be missing from his reasoning.

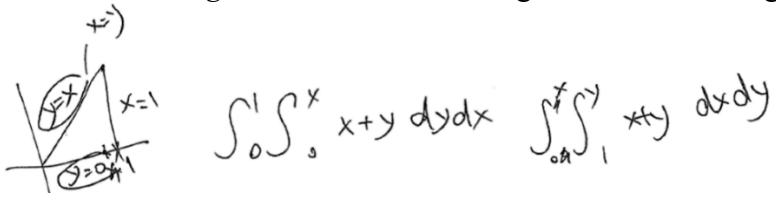

Figure 3. Graph and integrals written by Henry.

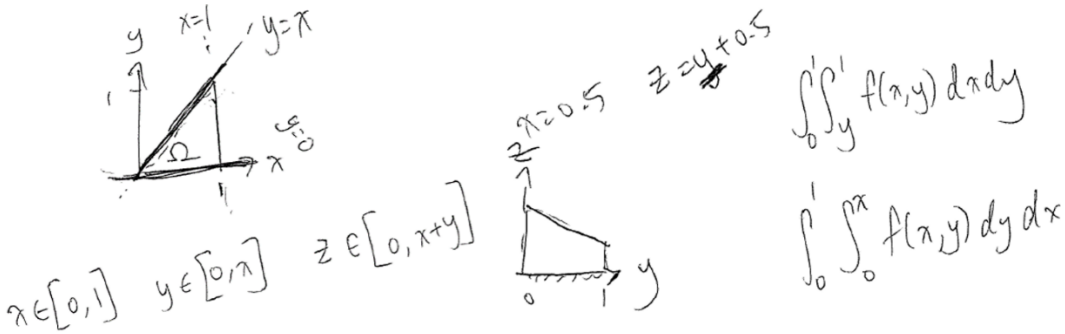

Figure 4. Graph and integrals written by Carl.

Carl, in comparison, could describe the ranges of variables in D_2 using intervals and drew the region accurately. He suggested that y depends on x while z depends on both x, y in this solid. He also rejected the saying that "z depends merely on x" with a visual counterexample: when $x = 0.5$, the solid would have a trapezium cross-section on the yz-plane with $z = y + 0.5$ on top, along which value of z varies with y. Referring to the region, he could write down iterated integrals in both orders of integration correctly (Figure 4). From the framework, Carl could mentally *switch the variable x as a constant* and hence *isolate y, z as a covariation*.

Double integration over quarter-circular region

Dave was asked about D_3. He realized that the base of D_3 is a quarter-circular region with boundary $x^2 + y^2 = 1$ and the axes. When asked about the dependence of variables in D_3, he divided it into two cases with x, y being dependent on the boundary due to the equation, and they are independent inside the region. He then claimed that z is independent to x, y, yet he could clearly describe that z always lie between 0 and $x + y$ within the solid. This response shows a diverse thinking when *recognizing dependence relationship* within non-rectangular region.

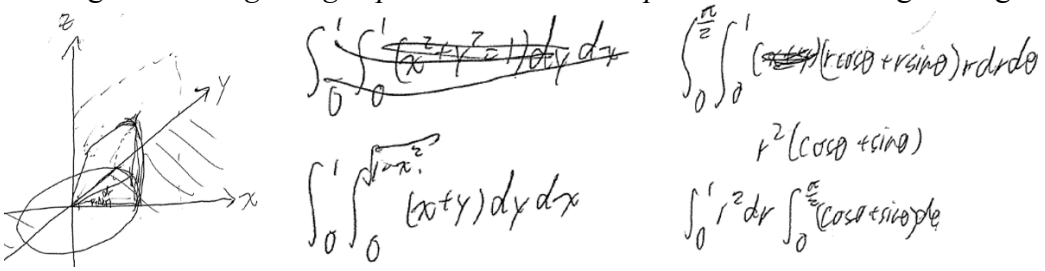

Figure 5. Graph and integrals written by Dave.

When asked to evaluate the volume of D_3, Dave first wrote an iterated integral with both x, y from 0 to 1, and then deleted it. He then wrote another iterated integral with the upper value of y dependent on x, although he agreed that this way is tedious in calculation. Instead, he thought of using polar coordinates. He figured out the ranges of r, θ to set up the iterated integral, then evaluated it with separation method (Figure 5). This case illustrates *recognition of dependence relationship* is involved when students determine their approach of integration.

Concluding Remarks

With the conceptual analysis derived in this study, multivariational reasoning framework (Jones, 2022) is useful for analyzing students' understanding of interrelationship of variables within bounded regions. Students who could complete the tasks with clear explanation of their approaches demonstrated a few mental actions in the framework. However, the conceptualization and expression of double integrals require an understanding of the dependence among the ranges of variables, which is not covered in the framework. The terms "dependent" or "independent" are defined based on values but not ranges of variables. A discussion of range seems necessary for extending the framework to explain students' cognitive process prior to double integration. Compared to rectangular regions, non-rectangular regions with boundary equations impose dependence relationship between ranges of x, y, hence require a higher level of multivariational reasoning associated with visualization. Moreover, the framework can be extended to explain the reasoning processes involved in the transformation of variables and coordinate systems.

In this preliminary report, only three cases have been analyzed due to time and page limits. Although some conceptual analysis has been done, the new extended framework has not been fully developed. Analysis of other interviews in future would validate the new framework.

Acknowledgement

We would like to express our gratitude to the course principal investigator Prof. Yiu Ka Fai Cedric of the Hong Kong Polytechnic University and his collaborator International Education Research Center (Hong Kong) for granting us the permission to use the materials and data collected from the "Mathematics Gifted Education Course".

One equity-oriented Networked Improvement Community (NIC) aimed to interrogate their use of "rigor" and its potential ramifications for the undergraduate mathematics program. In this preliminary report, we use critical discourse analysis on journal and interview data from this NIC to uncover how overloaded the word "rigor" is in mathematical spaces. These preliminary results reveal that rigor is conflated with difficulty, deep understanding, and other notions associated with teaching and learning mathematics. Findings suggest that there is a need to clarify and agree upon what we mean when we say "rigor" within our mathematical circles. We end with discussion and implications for practice.

Keywords: rigor, power, discourse analysis

"Mathematics is a language" is often an adage said by mathematics instructors to frame their course as one where students will be tasked (or challenged) to learn how to "speak math" (Wakefield, 2000, p. 272). As mathematicians, we may often obsess over the clarity or specificity of our phrasing and word choice when we speak or do mathematics, especially when writing proofs. This obsession perhaps demonstrates a desire to be understood exactly as we intended. Often there is an unsaid trust within mathematical circles: that when mathematicians talk, especially when using their mathematical register (e.g., Herbel-Eisenmann et al., 2015), our message is interpreted how we intended. Discourse beyond mathematical proofs, though, is not as clear-cut as mathematical logic. We should examine the assumptions we make when this unsaid trust spills into other discourses. Do we agree on what we mean when we use certain words? Many phrases, even in the RUME community like 'active learning,' are interpreted, conceptualized, and operationalized differently depending on who and where phrases are used (see Williams et al. (2022) for an analysis of various conceptualizations of 'active learning').

Amongst all the fascinatingly complex, intellectually-stimulating words to unpack, we highlight "rigor" in this study for the alarming ways rigor has been used to justify a gatekeeping logic in undergraduate mathematics (Hagman et al., accepted; Leyva et al., 2021) and the drastically different experiences with and operationalizations of "rigor" even amongst the authors. As we discuss in this report, there are also positive aspects to rigor; this report is not meant to vilify rigor. However, if mathematics departments and instructors place a large value on enacting rigor, then it is paramount that we, educators and instructors, interrogate the use of the word "rigor". Therefore, we ask the following research questions: When individuals in mathematical spaces use the word "rigor", what other words are used in relation to it and what do these other words reveal about the diverse ways in which rigor is conceptualized?

Literature Review

At the heart of this report is a desire for *transparency* in the sense of Gutiérrez (2013) where we interrogate taken-for-granted constructs and dominant notions in our mathematical culture, such as mathematical rigor. This does not mean we aim to construct a singular definition; as Riley (2017) argued, definitions of rigor are socially constituted and thus reflect a myriad perspectives on and experiences of rigor. As evidence of this myriad of conceptualizations, Draeger et al. (2013) proposed a model of academic rigor from the point of view of college faculty which posits meaningful content, active learning, higher-order thinking, and expectations comprise the "anatomy" of academic rigor. Later, Draeger et al. (2015) drew upon student data to develop a model of academic rigor from the perspective of students whose anatomy of rigor involved grades, difficulty, high workload, and interest.

As early as the 1920s, mathematicians like Pierpont (1928) have discussed that "absolute rigor"—mathematicians' goal as they scrutinized the foundations of mathematics in light of recent paradoxes at the time—is unattainable (p. 23). Almost a century later, our understanding of rigor has grown from a topic of concern to theoretical mathematicians to a central idea shaping classroom practices and education policy. Leyva et al. (2021), Marsellas (2021), and McNeill & Gresalfi (in press) interrogated rigor in relation to inclusion, care, and equity (or lack thereof) in the mathematics classroom. In policy making, matchmaking K-12 students into different course sequences comes with language that highlights the varying levels of "rigor" present in sequences (Oaks & Guiton, 1995; Herbel-Eisenmann et al., 2018).

Our goal for transparency around *rigor* is to reveal the ambiguity surrounding this word's meaning; when someone says rigor, they may not refer to the same things as others in the same spaces. We contribute to the emerging body of work on rigor and its continued presence in mathematics circles through uncovering the connections "rigor" has with other concepts and notions popular in mathematics instruction discourse. Our overall goal is to start conversations, so that when we say "rigor" in undergraduate mathematics, we can know what we mean.

Conceptual Framework

We conceptualize rigor as part of some mathematical cultures, where culture is broadly composed of the behaviors and values which are learned, shared, and exhibited by a group of people (Hagman et al., accepted; Yosso, 2005). In our view, rigor is a central cultural value within many mathematical cultures in postsecondary contexts. Rigor informs the expectations mathematics instructors have about their students' learning (Draeger et al., 2013) and what teaching practices are valued or necessary for the course to be mathematically rigorous (Leyva et al., 2021). It also informs the interpretation of workload and difficulty of the course for the students (Draeger et al., 2015). Broadly, we approach rigor as deeply involved in different aspects of mathematics teaching and learning—from the perspectives of faculty and students.

Data

This analysis is within a larger study that investigated Networked Improvement Communities (NICs) under ACT UP Math (EES #2201486). Through this project, education researchers with equity specializations partnered with three mathematics departments to initiate equity-oriented changes, supported by equity-oriented professional development, quantitative and qualitative data, and a broader network of support across the three departments. Hagman et al. (accepted) focused on one NIC at Kappa University and investigated how their NIC's goal of addressing rigor served as fertile ground for reckoning with tensions between the perceived value and operationalization impacts of rigor. The present report uses interview transcripts and journal

reflections to investigate the variation among meanings of rigor that were unearthed through our analysis of rigor as it relates to equitable instruction.

The Kappa NIC was composed of four faculty affiliated with the introductory mathematics program, two graduate students who had taught in this program, and two undergraduates who had taken classes within this program. Research participants opted into the NIC with interests of contributing to equity-oriented change and were all equally paid by ACT UP Math grant. The two NIC faculty co-leaders (Tiersa, Skylar) invited faculty (Anna, Senna) and purposefully selected out of an applicant pool the graduate (Parker, Kiara) and undergraduate students (Ricardo, Timothy). Pseudonyms were chosen by participants. The NIC identified as predominantly white women, and included one woman of color and two men.

Preliminary Nature

In Hagman et al. (accepted), we focused our argument in demonstrating how discourses around rigor reveal a culture of power (Delpit, 1998) in undergraduate mathematics education. This focus resulted in some analyzed data not being appropriate for that argument. We realized there is bountiful discussion to be had with focusing on the data centering only on how the word "rigor" itself was used, how other words served as a synonym or antonym for "rigor", and how "rigor" made distinctions in mathematics education. Therefore, we aim to share our current findings from Kappa, gather feedback from the RUME community towards a more complete manuscript using data from all three NICs, and spur motivation for others to investigate how "rigor" is used in their mathematical spaces.

Analysis

We selected a subset of data for analysis by locating instances of the word "rigor," taken together with relevant context. We leveraged critical discourse analysis—a method that examines how ideologies related to societal power relations shape discourse, both implicitly and explicitly (Fairclough, 1989, 2013). Our multi-stage analysis was methodologically aligned with reflexive thematic analysis, which generally includes six phases: familiarizing yourself with the dataset; coding; generating initial themes; developing and reviewing the themes; refining defining and naming the themes; and writing up the analysis (Braun et al., 2023). First, we read through all responses to the journal prompt "What does mathematics rigor mean to you?" as a basis for our preliminary codebook which included synonyms and antonyms as categories. The second stage consisted of developing our codebook using the subset of data which mentioned "rigor" and its surrounding context. We found "distinctions" as another category which referred to things that are described as distinct from rigor but could not necessarily be interpreted as an antonym. Each excerpt was coded by at least two authors, wherein interpretations of an excerpt were reconciled within partner-to-partner or full author group discussions. In the final stage, we focused on each category of synonyms, antonyms, and distinctions to find themes within the discourses.

Findings

We organize our findings by giving empirical illustrations of words used in relation to rigor: synonyms, antonyms, and distinctions. Distinctions refer to phrases used in relation to rigor not necessarily as similar or as in opposition. For synonyms and distinctions, similarly-used words or phrases were grouped together. There was only one instance for antonym.

Rigor as a Synonym

Deep/true understanding, justification, analytical/logical. When speaking about rigor, all

faculty in the NIC highlighted the educative benefits of rigor for students from their perspective. Senna, Skylar, and Tiersa each said that deep or true understanding is itself rigor or is required for rigor in their responses to "what does math rigor mean to you." For example, Senna shared, "I would say that something is mathematically rigorous if it requires a student to truly understand why something is true, and to be able to effectively communicate their ideas behind the concept." In her journal, Anna focused more on rigor's place in argumentation saying that rigor "means clearly constructed arguments toward a finding or conclusion. It means clearly constructed analytical/logical thought about the concepts over completing mechanics." As was in Draeger et al. (2013), faculty members of the NIC understood rigor through a positive lens of benefiting students in providing higher-order thinking or meaningful learning. This is not to say students are also not making these positive connections. For example, Ricardo shared,

> … [A] rigorous class would normally have expectations that students can extrapolate based on what they've learned, reaching conclusions that might go beyond what's being explicitly taught in lectures, which is a positive, challenging, and potentially rewarding experience.

However, overall, the faculty tended to speak about rigor more positively than students.

Difficult(y) and challenge. As for the students in the NIC, "difficult(y)" and "challenge" were used in relation to rigor. As a representative example, Timothy shared in his journal,

> I think that mathematical rigor is like difficulty and challenge in mathematics. And when I think of that rigor a lot of different things come to mind. I picture myself struggling in some of my math classes, not really understanding the content, um, feeling challenged, feeling like I don't, um, know what's going on, feeling like I'm not doing well.

As was in Draeger et al. (2015), students in the NIC understood rigor through a lens that they are being challenged and their experiences in class are made difficult for the mission of rigor.

Unnecessarily hard. Related to difficulty and challenge was the phrase "unnecessarily hard" which many NIC members picked up on from their department's ACT UP Math data. This had been particularly moving for the faculty members of the NIC who had not realized that mathematics at Kappa had such a negative reputation with the undergraduate students. During an interview, Skylar shared her dream with respect to the NIC's goal of transformation,

> My dream would be to change the narrative of "Kappa Math," so that it is no longer perceived as "unnecessarily hard." I think we are working towards this as a NIC, and that key steps will be interrogating our own perceptions of rigor and students as experts, as well as trying to better understand the source of this narrative for students so that we can address it.

We highlight here the importance of the descriptor "unnecessarily" and how Skylar (and also Tiersa) adopted the phrase from students. The sobering effect of "unnecessarily" gave a clear target for the NIC to strive for in their change efforts.

Clarity and precision. We found that students and faculty aligned in their perception that rigor is (or adds to) the clarity and precision that is required in discussing mathematics. Tiersa, for one, highlighted how rigor is linked with mathematical notation, stating that "I also feel that notation and precision in language are important." Kiara understood rigor as "being very focused on precision and careful detail checking." She added that, "it's all done meticulously and within a very set way of communicating in a set way of doing the things, um, that's like agreed upon." Again, we see that rigor is discussed in relation to clearly communicating ideas to others with a pronounced focus on precise notation as it relates to proof writing.

Rigor as an Antonym

Manipulating formulas. The idea that rigor is in diametric opposition from the manipulating formulas was the only instance of rigor being described using antonyms. When describing what

mathematical rigor meant to her, Skylar said it required students to "truly understand why something is true, and be able to effectively communicate their ideas behind the concept" and added that "**by contrast,** most of my students come from high school very adept at manipulating formulas." By contrasting manipulating formulas with rigor, Skylar echoed the associations mathematicians and faculty make with rigor and higher-order thinking (Draeger et al., 2013).

The two undergraduate students Timothy and Ricardo also echoed this diametric opposition. Timothy, in his response to "what does mathematics rigor mean to you," described experiences in high school as different from those at Kappa, "[rigor is] also **not like math in a high school** sense… where you're just given formulas and you have to plug them in and call it a day." For Ricardo, he understood that mathematical rigor is associated with the depth of content "**as opposed to** being explicitly told how to solve specific types of problems." Both students understood that the rigor they are experiencing at Kappa not only goes deeper but is disjointed from manipulating formulas. So, while faculty in the NIC began to understand the association of rigor with "unnecessarily hard" as a synonym, students also began to understand the association of rigor with "deep understanding" by viewing manipulating formulas as an antonym for it.

Distinctions

Excerpts coded as distinctions clearly described something as different from rigor, but not framed in opposition, i.e., an antonym. For example, the question of inclusivity in mathematics classroom was brought up in the context of rigor, "How can we keep rigor in the classroom, but in a way that doesn't feel exclusionary or daunting to the students?" (Senna). With regards to the NIC's change efforts, Skylar further discussed in an interview that she hoped to make "Kappa Math" a "kinder, gentler, more welcoming" department after hearing students' perspectives on rigor. And in her journals, Tiersa reflected on care and rigor (challenge),

> I think that before spending time with focus group data, I might have argued that "rigor" in our courses is part of what makes them rewarding. After looking at the data, I think that in rigorous courses with high expectations, students may need additional care and support in order to appreciate the challenge.

Thus, what we saw here are faculty members of the NIC making a distinction between rigor, inclusivity, and care—that both can exist simultaneously in a way that they hope would improve the undergraduate mathematics experience.

Implications & Discussion

As we aimed to demonstrate, "rigor" is an ambiguous word in our spaces. Draeger et al. (2013) and Draeger et al. (2015) already showed the different perspectives on rigor from a faculty perspective versus from a student perspective, and here we confirm this difference in the context of one undergraduate mathematics program. As demonstrated by this NIC, it is imperative for mathematical spaces to discuss these differing perspectives—wherein faculty in the NIC learned that their "Kappa Math" had a negative reputation while students in the NIC learned that rigor could be positively enacted and rewarding. Moreover, as in Hagman et al. (accepted), the interrogation of rigor can lead to an interrogation of power. In the case of Kappa, their interrogation of rigor led to student perspective and voices to be valued as their change and improvement efforts emphasized rewriting the "unnecessarily hard" narrative of Kappa. Thus, we urge the RUME community to interrogate our use, conceptualization, and operationalization of "rigor," so that when we say "rigor" in undergraduate mathematics, we know what we mean. So, our initiating discussion question for RUME is: *what does mathematics rigor mean to you?*

Acknowledgments

Thank you so much to everyone who contributed to the ACT UP Math project. The ACT UP Math project was originally funded by the National Science Foundation (EES #2201486) until funding was terminated by DOGE April 19, 2025. All findings are those of the authors and not necessarily of the former funding agency.

Investigating GTA Beliefs That Might Reinforce Inequity in Pre/Calculus Courses

Elizabeth Roan
Texas State University

Bernard Smith
Indiana University

Krystal Brand
Indiana University - Indianapolis

In this preliminary study, we examine the beliefs of graduate teaching assistants and investigate how seemingly identity-neutral beliefs may reinforce deficit narratives in precalculus and calculus courses. Drawing on the Attributions of Mathematical Excellence (Jacobson et al., 2022), we report the analysis of one participant's attributional beliefs and how they may explicitly and subtly reify deficit discourses. Our findings underscore the need for critical conversations about instructor beliefs regarding success and struggle in undergraduate pre/calculus. We recommend training programs provide graduate teaching assistants the opportunity to engage in reflective dialogue to identify opportunities to disrupt harmful narratives in undergraduate mathematics education.

Keywords: Equity, Beliefs, Calculus, Precalculus, Teaching Assistants

Deficit narratives are built around mathematics being perceived as "objective" and "universal"; thus, all students are expected to experience mathematics in the same way. When students, especially those in marginalized groups, do not ascribe to the master narrative of mathematical experiences, educators often hold learners personally responsible for their struggles and underachievement while also refusing to make visible the mathematical understandings the students do hold (Adiredja & Louie, 2020). With this narrative in mind, instructors can often tout a racial- and gender-neutral perspective in mathematics. While this mindset can be seen as an avenue to mitigate harm based on identity, Leyva et. al. (2021) argues that students can still interpret their experiences in the classroom as racialized or gendered, even when race and/or gender is not explicitly mentioned in their classroom. The classroom environment is shaped by the instructional practices instructors utilize, and as prior research has empirically shown, teacher beliefs have a significant impact on their instructional practices (Schommer, 1990; Pajares, 1992; Wilhelm et al., 2017). Therefore, our research seeks to explore instructors' beliefs regarding mathematical success and struggle in college precalculus and calculus classrooms. Our research goal is to shine a light on instructors' beliefs that might explain why "seemingly neutral behaviors and comments" (Leyva et al., 2021) might reinforce or disrupt racist and sexist disparities in precalculus and calculus, especially among new and early career instructors in higher education. The goal of this report is to share preliminary results of our work towards our broader research goal, by sharing our analysis of one participant's beliefs along with a discussion on how those beliefs explicitly and subtly reify deficit narratives about students. We focus on precalculus and calculus because those undergraduate courses tend to serve as gatekeepers and impact interest and career choices within the STEM fields (Riegle-Crumb & Humphries, 2012; Levya et al., 2021).

Empirical Background and Theoretical Framework

Deficit discourses in mathematics education attribute faults in students' academic success and intellect to perceived defects of the student or their community (Adiredia & Louis, 2020). For example, some deficit discourses in mathematics education claim that Black and Latinx students are responsible for their own underachievement (Nasir & Shah, 2011), that "women and

Latinos are not good at mathematics" (Leyva, 2016, p. 109), or that Mexican and Black families and cultures do not value schoolwork (Solórzano & Yosso, 2002; Adiredia & Louie, 2020).

Recently, Jacobson et al. (2022) used theories from social psychology to characterize these deficit and anti-deficit discourses in mathematics education with their attributions of mathematical excellence (AME) framework. Within this framework, an attribution is a belief about a perceived cause to an effect. The AME framework allows researchers to characterize the attribution beliefs teachers hold about students' mathematical success or struggle into types informed by larger deterministic beliefs that tie back to the deficit discourses in mathematics education. There are four categories of attributions in the AME framework: genetic, personal, social, and educational. The genetic category, informed by the theory of Genetic Determinism (Keller, 2005), describes attributions with factors related to a student's genetics, like biological sex. The personal category, informed by the theory of School Meritocracy (Wiederkehr et al., 2015), describes attributions with factors related to students' personal characteristics, like effort. The social category, informed by the theory of Social Determinism (Rangel & Keller, 2011), describes attributions with factors related to students' upbringing and socialization. Lastly, the educational category describes attributions with factors related to students' prior educational opportunities. AME are thought to be productive in that AME-E challenges deficit discourses, or unproductive (all other types) which contribute to deficit discourses +. Importantly, the AME framework highlights how seemingly identity-neutral attribution beliefs correspond with negative racial and gender stereotypes (Jacobson et al., 2022). For example, the explanation that greater effort begets academic success (AME-personal) corresponds with the discourse in mathematics education about Black and Latinx students being underachievers. We seek to answer the research questions: *What are graduate instructors' beliefs around mathematical success and struggle in the context of precalculus and calculus?* and *In what ways do graduate instructors' beliefs about mathematical success and struggle reify or challenge deficit discourses in the context of precalculus and calculus?*

Methods

We employed a basic qualitative research design for this project (Merriam, 2015). We purposefully selected graduate teaching assistants serving as instructors for precalculus and calculus courses, because they are typically responsible for leading recitations, which generally involve greater interaction between students and instructors. In total, we interviewed four graduate students who were all enrolled in a doctorate program in mathematics, with different concentrations. The data for this research was collected using semi-structured zoom interviews designed to investigate teachers' attributional beliefs about the causes of students' successes and struggles in mathematics. Interview questions focused on what each participant believed to be the underlying cause of their students' successes or struggles in (pre)calculus courses. For example, the interview included questions like, "Why do some students succeed in (pre)calculus while others struggle?" Based on our prior work, (Roan et al., 2025), we anticipated that our participants' beliefs would be interconnected so we used follow-up questions such as, "Why do you think this happens?" which aimed at determining clusters of influential factors. To analyze the data, we categorized the attributions made in the interview based on the categories in the AME framework: Genetic, Social, Personal, and Educational. To explore the interconnectedness of our participants' attributions, we conducted causation coding (Saldana, 2021), which was used to create a visual model of our participants' attributional beliefs. Working together, the research team coordinated to ensure that their individual coding efforts standardized. This type of collaboration provides what Saldana (2021) calls "crowd-sourcing reality checks" that increase

the interrater reliability and interpretive congruence ensuring code agreement. This process also allowed for the consensus in coding "dialogical intersubjectivity" (Saldana, 2021) of unclear causes provided by the participants. As Saldana (2021) contends, "this dialogic exchange of ideas in a workshop and collegial atmosphere attunes the research team to new and varying perspectives before more intensive scrutiny" (p. 53) as analysis of the data progresses. To identify chains of influential factors, we applied three aspects of causal coding during analysis based on Saldana (2021) recommendations. Following a structure that maps antecedent or starting conditions → mediating variables → outcomes, where the arrow (→) denotes what a causal relationship "leads to". Given that multiple causes can result in multiple outcomes, subcodes were employed to represent the complex, multidimensional nature of belief system networks. These codes were then translated into causal diagrams, which visually illustrate the intricate relationships that are often difficult to fully convey through text alone.

In this report, we share preliminary results of our analysis by sharing some results from the analysis of one participant, pseudonym Frida. Frida was a graduate teaching assistant in a mathematics department at a large midwestern university. She identified as female and white European. Frida was an instructional assistant leading recitation for calculus one and calculus two multiple times, but she had never explicitly taught Precalculus. Frida was an instructor of record for a course designed to be a brief introduction to calculus one time.

Results

In this report, we will highlight two prominent clusters of Frida's attribution beliefs, one that explicitly places a deficit on students, and one that does so subtly. We note that the attribution clusters as reported are not self-contained. These beliefs are connected to a larger belief system present in the data, but we do not share this larger system due to space.

Frida said that mathematical success is performing well in the course, learning the material well, learning to study mathematics, and applying oneself. When asked what factors influence students' mathematical success in calculus, Frida said

> . . . some of them, probably genetic environment, like genetic factors. Some people just have a higher IQ than others. I guess environmental influences. What level of math exposure have they had to in previous courses. What's the level of education their parents have had, like these environmental sociological factors. Genetic, obviously, too. And then, I guess where it boils down more to the student is, have they learned maybe efficient ways to think about math . . .

In this quote, Frida attributed students' mathematical success to a) genetic factors, such as baseline intelligence and lineage, b) educational factors, like students' prior educational experiences, c) social factors, like education level of the parents, and c) personal factors, like efficient learning, and experiences. For this report, we focus on the first two attributions from Frida's quote. Frida connected genetic factors and success in college calculus as follows:

> . . . the genetic influence, the IQ, there's probably very little you can do to change like that baseline intelligence. . . . I've seen that also in myself and classmates like at a certain point, like even with work, even with trying to like, apply good study strategies. There's that certain point where IQ just does play that significant role.

In the quote, Frida explained that students who are very successful in college calculus, from her perspective, have a very high "baseline intelligence". For her, baseline intelligence is a genetic trait. She noted that this does not necessarily mean that students with a "low IQ" cannot be successful in mathematics, only that they will always be less successful than their peers with a "high IQ". When asked to describe the students with a high IQ, Frida explained "I've kind of

noticed males either tend to be really high on the IQ spectrum, or a bit low, and females tend to be more average in the middle. That's just from what I've observed." In this quote, Frida made the connected attributions that biological sex influences whether a student has a "high IQ", which influences mathematical success.

Frida explained prior educational experiences and success in college calculus as follows "If some of them have say, taken AP calculus before. They're also able to get to that next level." In this quote, Frida acknowledges that students who have taken AP calculus in high school are more likely to "get to that next level" of understanding, an indicator she had previously stated as her evidence for if a student was successful. When asked to describe the students are who have taken AP calculus before, Frida said they "have parents that are maybe in STEM themselves" or are "students that know pretty early on in high school, they're going into STEM, or they're going to be a math major". Based on these quotes, we inferred that Frida made two attributions, that taking AP calculus in high school is influenced by 1) whether a student's parents are in STEM, and by 2) a student's interest in STEM. Due to space, we only detail the first attribution in this report. When asked to explain why the students' parents being in STEM influenced the students taking of AP calculus, Frida said

> When you grow up, what you see is the norm you observe. So, I guess, maybe just seeing that, being familiar with it [math], [makes math] probably less of an obstacle and barrier. . . maybe some natural advantage. [pause] They have the, I guess, personal help at home if they need it.

In this quote, Frida makes three different attributions. First, Frida made the attribution that having parents in STEM influences how STEM is normalized for students, which influences whether the student sees STEM as a barrier, which influences whether they take AP calculus in high school. Second, Frida made the connected attributions that having parents in STEM influences whether students have a natural advantage in STEM which influences whether they take AP calculus. We infer that Frida meant natural advantage to be genetic in nature. We made this inference based on her prior statements regarding the connection between students' mathematical success and their parents. Specifically, she said that the parents were related to "environmental sociological factors. Genetic, obviously, too". Lastly, Frida connected the attributions, having parents in STEM influences the quality of help received at home, which influences whether students take AP calculus in high school. Together, these attributions formed an attribution beliefs cluster where each outcome was attributed to a prior attribution outcome see Figure 1.

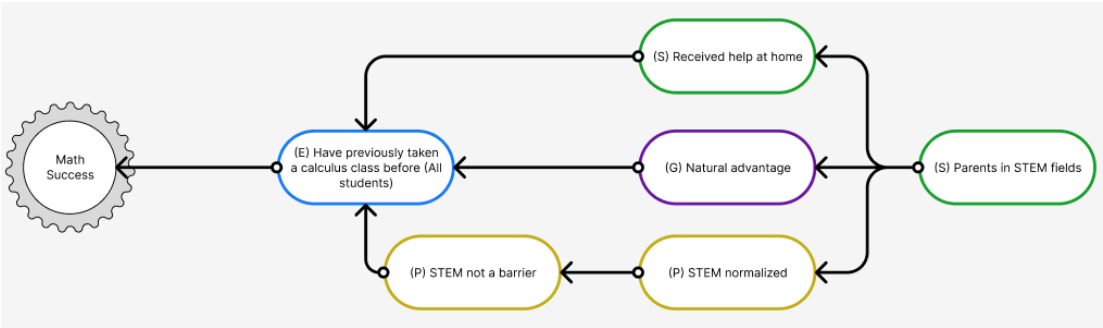

Figure 1 Part of Frida's attribution diagram that shows an anti-deficit explanation based in deficit explanations. The colors correspond to the categories of AME: Genetic (Purple), Social (Green), Personal (Yellow), and Educational (Blue).

Preliminary Nature of Proposal and Discussion

In this proposal, we presented an in-progress analysis of graduate teaching assistants' beliefs about the nature of success and struggle in mathematics education. Specifically, we reported two attribution clusters of one of our participants, Frida. In the first attribution cluster, Frida attributed biological sex to innate intelligence, which directly influences success in college calculus. From our interpretation, this attribution cluster shows beliefs that explicitly place a deficit on the student. She further explains that males tend to be high on the IQ scale while females tend to be average. This reifies the deficit narrative that women are innately less intelligent than men. In the second attribution cluster, Frida attributed success in college calculus to prior experience with calculus. This could be seen as an anti-deficit explanation of student success because Frida attributed students' success in college calculus to experiences in AP calculus in high school. That does not explicitly put a deficit upon the students nor their families. However, Frida connected experience in AP calculus to factors like having support for mathematics at home, feeling that STEM is not a barrier, and having a natural advantage, all of which stem from having parents in STEM fields. Those are unproductive explanations because Frida is attributing students' success to traits belonging either to the student or to their families. From our theoretical framework, this attribution cluster shows that productive beliefs based around educational opportunities can be traced back to deficit narratives, such as who belongs in STEM. Here, seemingly neutral attributions (i.e., parents in a STEM fields), when viewed through our theoretical lens, become linked to beliefs in genetic (Keller, 2005) and social determinism (Rangel & Keller, 2011). When put into the context of the ways in which women and people of color have historically been marginalized in STEM fields, Frida's belief becomes deficit in nature, steeped in both racist and sexist ideologies. This indicates that anti-deficit beliefs can be shaped by deficit narratives

Our findings also connect to the idea of "objectivity discourse", in which instructors consider experiences to be race- and gender-neutral, while concurrently acknowledging students' experiences differ (McNeill et al., 2022). McNeill et al. (2022) noted that holding conversations to address these perspectives can be useful. We agree with this notion and respond to the call by Jackson et al. (2017) to shift teachers' perspectives on their students' capabilities by recommending that instructors should be given the opportunity to reflect upon their beliefs regarding students' success and struggle. Given the population of our study, we focus our suggestion for graduate preparation programs. Prior research indicates that the level of pedagogical training for graduate students varies vastly per institution (Harris et al., 2009). Additionally, research on graduate teaching assistant training has focused on more cognitive aspects of teaching (e.g. Speer, Gutmann, & Murphy, 2005; Ellis, 2015). While there is research that target equity in math education through graduate assistant training (e.g., Taylor et al., 2025), we see a vital need for graduate programs to hold conversations around student success and failure, especially for instructors teaching gateway courses like precalculus and calculus.

We intend to continue data analysis and gather feedback from the RUME community. We welcome any feedback on the presentation of the data, particularly regarding the diagram in Figure 1. We also welcome feedback on connections to literature to support situating our study with the larger conversation regarding equity in undergraduate mathematics education. Lastly, we recognize that connections between the participants' beliefs and deficit narratives revolve around race and gender. Thus, we ask the reader: in what ways might we add a more critical lens within the research design and analysis?

Kinematics graphs offer potential for developing relationships between derivates and antiderivatives, but students experience challenges with recognizing the meaning of the area under a velocity graph as change in position. We designed a series of playful math tasks offering structured exploration, in which students worked in virtual environments to develop relationships between speed, time, and distance in tabular and graphical formats. Preliminary analysis suggests that students can use rate reasoning to develop accumulated distance under constant velocity graphs, which then can be developed under linear graphs via Riemann sums.

Keywords: Mathematical play, calculus, kinematics, velocity, position

Graphs related to kinematics, such as position, velocity, and acceleration, play an important role in calculus instruction (Barniol et al., 2024; Doorman & Gravemeijer, 2009), offering a rich potential for addressing the relationships between derivatives and antiderivatives (Doorman et al., 2022). An understanding of the kinematics concepts requires students to make sense of the relationships between the graphs of position (the function), velocity (first derivative), and acceleration (second derivative), as well as conceptualizing the antiderivative as the area under the curve between, for instance, the velocity and the change in position (Dominguez et al., 2017). Despite the centrality of these ideas, research indicates student difficulties in making connections between kinematics concepts and their graphical representations (McDermott et al., 1987). In particular, it can be challenging for students to recognize the meaning of the area under the curve for a velocity or acceleration graph (Bajracharya et al., 2012; Beichner, 1994; Martínez-Miraval & García-Cuéllar, 2020), much less to construct meaning for why the area under a velocity curve, for instance, represents change in position.

We became curious about the viability of helping students meaningfully develop the area under a graph (such as a velocity graph) as change in position (i.e., distance traveled) through playful exploration. In working with a group of pre-service secondary mathematics teachers, all who had successfully completed a calculus sequence, we implemented a task to promote an understanding of the relationship between position, velocity, and acceleration in terms of integrals and derivatives (Ely et al., 2025). The task required students to move an astronaut 10 miles in 10 minutes via a constant acceleration (or a series of accelerations) for specified time periods. For instance, if one uses an acceleration of $a(t) = 0.2$ miles / min^2 from $t = 0$ to $t = 10$, the astronaut's velocity is the antiderivative, $v(t) = 0.2t$, $0 \le t \le 10$. One could then find the total distance traveled by integration, either by reasoning with the area under the velocity graph or symbolically as $\int_0^{10} v(t)dt = 0.1t^2 \big|_0^{10} = 10$ miles. We found that our participants struggled to distinguish between acceleration and velocity and did not draw on their understanding of integration to determine exact distance values, findings that mirrored the literature. This led us to

wonder whether we could we support students to reason about change in position from velocity graphs. Specifically, could we help students meaningfully consider the area under a velocity curve as a representation of distance traveled by leveraging structured exploration through playful math tasks? Our preliminary findings suggest that students can use their rate reasoning to develop accumulated distance under constant velocity graphs, which then can be developed under linear graphs via Riemann sums with instructor scaffolding.

Background and Theoretical Framing: Area as Distance and Mathematical Play

Areas Under Velocity Curves

We anticipated that students might be able to leverage both geometric reasoning and rate reasoning to develop area as a measure of distance. Regarding the former, the Mean Speed Rule could be relevant to students' reasoning. The rule states that if, over a period of time, Object A has a constant velocity and Object B constantly accelerates (or decelerates) with the same average velocity as A, then the two objects will travel the same distance. Mathematicians at Oxford developed this in the early 1300s, three centuries before coordinate geometry and without referring to area under a velocity curve. One of these scholars, William Heytesbury, reasoned with situational symmetry to justify the rule: If one object constantly accelerates from a velocity of four to eight (no units specified), and another decelerates from four to zero, the latter will offset the former at each moment, so they together must traverse twice the distance of a third object moving at a constant speed of four (Katz, 1998).

Regarding rate reasoning, students may be able to leverage their unit rate understanding to reason about why one can multiply a height by a width to yield an area in the first place (beyond simply relying on the trick of 'canceling units', e.g., ft/sec · sec = ft). Izsák (2025) suggested a general multiplication image that treats velocity as a unit rate. From this perspective we can see a y-value on a velocity graph, such as 20 ft/sec, not just as a one-dimensional height, but as a rate of 20 ft in 1 sec, corresponding to an imagined two-dimensional stack of 20 squares in a 1-sec-width column. With this image, each square is a foot, so one can imagine each second on the x-axis accumulating 20 ft in distance as represented by the area of a two-dimensional column with a width of 1 sec.

Mathematical Play, Exploration, and Feedback

We define mathematical play as entailing exploration, self-selection of goals, immersion, and enjoyment (Ellis et al., 2025). Of particular importance to our focus is exploration, which is a key element of play (Gresalfi et al., 2018) and which can occur in a physical or virtual environment, or even in an imagined realm in which students can run mental simulations. Exploration often starts with free play (Mason, 2019), in which learners familiarize themselves with the task, the environment, and its affordances. It entails asking questions such as "what happens if I try this?" and noticing the results of one's actions. As learners' actions become more goal-oriented, they will attend to the feedback from those actions and modify their subsequent actions in response (Williams-Pierce & Thevenow-Harrison, 2021). Over time, one's actions can then become increasingly anticipatory, with students ultimately able to make mental simulations without having to carry them out in the environment (Simon, 2011).

Researchers have discussed mathematicians' playful activity in terms of exploration and feedback (e.g, Holton et al., 2001; Mason, 2019; Su, 2020). For instance, Su (2020) described an inquiry phase, in which one engages in pattern exploration and reasons from empirical feedback to build conjectures from specific examples. Holton and colleagues (2001) similarly described a

process in which mathematicians produce tentative examples without a clear direction to make sense of the problem space before then becoming more systematic and intentional in generating specific cases and conjectures. Mathematicians are adept at engaging in exploration and generating their own feedback, often relying only on paper and pencil or even engaging in purely mental simulations. Students, however, may need more structured environments in which they can try out different actions and observe empirical feedback. For that reason, we designed a series of playful math tasks that encourage exploration while also providing a method for intrinsic feedback. These tasks place students in a virtual environment in which they can explore what happens when they input different speed/time values or acceleration/time values to achieve various goals, such as making an astronaut reach 10 miles in 10 minutes. By providing visual feedback, our intention was to help students structure their exploratory actions so that they could shift to more anticipatory actions over time, specifically by developing their own velocity graphs to make objects travel a specified distance in a specified time.

Methods

We collected data with 7 high-school students (2 9th-grade students, 5 10th-grade students) during an 8-session summer design experiment (Cobb et al., 2003). The sessions took place over a two-week period and each lasted 90 minutes. The students worked in small groups using iPads, and 6 members of the author team were present to observe, engage students in questioning, and run the cameras. We collected video data and screen recordings on each group's iPad as well as all written work. We designed a series of playful math activities to structure students' exploration of constant rate via speed situations, in which students could input various speed and time values to achieve goals such as helping a character reach a specified destination at a particular time. This report is based on the engagement of one trio of students, Adam, John, and Zilar (pseudonyms), during two activities called *Go Karts* and *Describe My Journey*.

Go Karts is a Desmos activity that shows a red go kart that moves at a constant speed of 10 ft/sec, traveling 200 ft in 20 sec. Students can input up to five velocity/start time/end time values in a table to make a blue go kart reach the finish line at the same time. For instance, one could input the following four entries to make the blue go kart tie with the red go kart: 40 ft/sec from 0 sec to 1 sec; 0 ft/sec from 1 sec to 10 sec; 15 ft/sec from 10 sec to 18 sec; and 80 ft/sec from 19.5 sec to 20 sec. Once they have chosen values, students can hit play and watch both go karts run the race to observe the outcome of their actions. We then shifted from tabular inputs to a graphical input, providing students with a blank graph velocity / time graph. Students could then draw graphs to make their go kart tie with the red go kart. Our intention was to support students in creating constant graphs (such as a constant function at 10 ft/sec) and to use their rate reasoning to consider how much distance would be traveled after 1 sec (10 ft), 2 sec (20 ft), and so forth, relating distance traveled to the rectangular area under the constant velocity function. We then anticipated that students might explore linear and piecewise linear graphs, using geometric reasoning similar to the mean speed rule to calculate the areas of triangles under the velocity graph to determine distance traveled. The second activity was *Describe My Journey*, in which groups of students created and traded velocity/time graphs. Each group's task was then to describe the go kart's journey based on the provided graph.

Our coding process is preliminary and ongoing. We began by transcribing the video of the students' activity and enhancing the transcript with relevant images, pauses, and descriptions of the students' gestures. We then completed an initial reading of the data noting where in the tasks students reasoned about velocity and distance. Once we identified those data portions, we examined the supports for students' reasoning, including the use of feedback from the playful

math tasks as well as more direct scaffolding from the teacher-researchers (TRs). Our continuing process will next shift to analyzing the interrelated nature between students' exploration, empirical feedback, and emerging conjectures and strategies.

Results

The students explored different graphs with the *Go Kart* activity, developing first a constant graph at 10 ft/sec for 20 sec, and then reasoning geometrically about symmetry above and below the $v(t) = 10$ line to develop piecewise constant velocity functions that yielded a total distance of 200 ft. For instance, they created a graph for the function $v(t) = \begin{cases} 12, & 0 \le t \le 10 \\ 8, & 10 < t \le 20 \end{cases}$ and were able to predict that for the first 10 sec the go kart would travel 120 ft and then it would travel 80 ft for the remaining 10 sec. They also created the piecewise constant function seen in Figure 1a, predicting before running the simulation that their go kart would tie with the red go kart. Adam explained, "The velocity's 30, and that's feet per second, so 30 feet per second and that's 5 seconds, so 30 times five that's 150 feet. So, 150 feet, so that's, and you're trying to go 200. So, you have 150, and, it stops twice so that's not adding anything. And the last one, it's 5 seconds, or, 10 velocity, so five times 10 is 50, and that's 200." The students could also predict that the graph provided by a TR (Figure 1b) would beat the red go kart because it would travel a total of 216 ft in 20 sec (14 ft/sec for 12 sec and 8 ft/sec for 8 sec). However, during the creation of these graphs, the students did not produce linear functions. It was unclear to us whether they would be able to develop area under a linear velocity function to determine total distance traveled.

During the next activity, *Describe My Journey*, Adam, John, and Zilar worked with a graph produced by their classmates (Figure 1c). They could calculate slope values and make sense of the graph in terms of the go kart's journey. They interpreted the constant portions of the graph as constant speeds and they interpreted the portions with negative slope values as periods of deceleration. They could also interpret the portions of the graph below the *t*-axis. For instance, for the portion of the graph from $t = 5$ to $t = 15$, the slope is -1.1. Adam described the go kart as going backwards for 10 seconds, accelerating at a rate of "1.1 feet per second per second." Similarly, for the portion of the graph from $t = 19$ to $t = 25$, Adam explained, "So you decelerate at 1 feet per second per second for six seconds. This one isn't even that hard!" Describing the final portion of the graph (below the *t*-axis with a positive slope), John explained, "You slowly go back to zero. So, you're slowing, you're backing up until you're at zero."

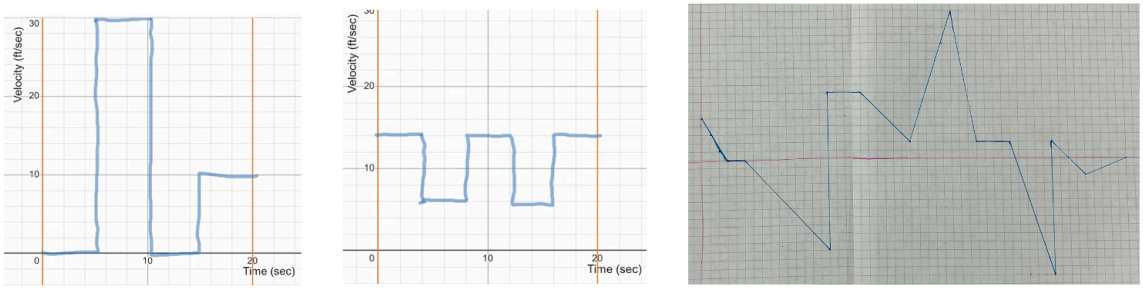

Figure 1. Student-produced velocity/time graph of a go kart's journey (a), instructor-produced graph (b), and student-produced graph for the Describe My Journey activity (c).

At no time during their interpretation of the graph did the students determine distance traveled. A TR therefore asked the students how far the go kart traveled during the constant portion of the graph from $t = 15$ to $t = 19$ where $v(t) = 8$. Adam responded, "You're going 8 feet

per second for 4 seconds. So, you're going 32 feet." After the students then determined the distance traveled for the other constant portion of the graph, the TR asked about the linear portion from $t = 19$ to $t = 25$. John reasoned, "You de-accelerate at a rate of one foot per second per second per six seconds" and Adam replied, "So, you go six feet?" John replied, "Well, you start at eight and you end at two for velocity." Adam responded, "You're going 1 feet per second for six seconds," and John objected, saying, "Well, you're *de-accelerating* at a rate of 1 foot per second," and Adam and Zilar both agreed. The TR asked, "Tell me more about the speed. So how is it changing?" John responded, "It's decreasing at one foot per second, per second. From eight feet per second, per second, to two."

The TR then suggested breaking that portion of the graph into a finer picture and asked the students to consider what would happen in the first second. John said, "You go down by one foot per second, per second." The TR asked, "Now, if I ask you how much you travel in that one second, what would you say?" John hesitantly responded, "Seven point five?" The TR asked why that would be the case, and John traced a horizontal line across the portion of the graph from $t = 19$ to $t = 20$ and hesitantly said, "Because if you're going at eight and seven, would it average out to these 7.5 straight line?" We interpret John as imagining a constant line at $y = 7.5$, and the TR suggested that the students pursue this idea further. Adam said, "Like, six point five," indicating the amount traveled in the next second, and John said, "five point five," and Adam continued, "Four point five plus three point five plus two point five…" and John concluded, "Which is thirty."

Preliminary Questions and Discussion

We had anticipated that the students would make a connection to area under piecewise constant velocity graphs by perceiving the area of rectangles as in Figures 1a and 1b. However, there was little mention of area in the students' conversation. Instead, they often appeared to be reasoning with rates but not directly with area. The students understood that x ft/sec meant traveling x ft in 1 sec, $2x$ ft in 2 sec, and so forth by iteration. Our initial observation, both from the data reported here and from our similar work with pre-service teachers, is that students with this reasoning can then approach the problem of finding the distance traveled with a linear velocity with a Riemann sum, leveraging reasoning similar to the mean speed rule; this seems to be a natural concept that emerges from reasoning with rates to determine accumulated distances. This suggests that certain cognitive activities related to calculus are shared by secondary and undergraduate students.

Our initial analysis indicates that the exploration and feedback students engaged in when creating and analyzing graphs for the *Go Kart* activity supported their ability to predict distances using constant and piecewise constant velocity graphs, as over time they began to be able to make those predictions without needing to run the simulations. We would now like to better understand how to leverage structured exploration and feedback to make the area connection more salient for students, or even to perhaps necessitate it (Harel, 2013) through the task structure. We will therefore engage the audience in the following discussion questions: (a) What is the role of exploration and feedback in supporting students' development of area as distance traveled under velocity curves? (b) What adjustments to task structure could we make to support the transition from constant velocity graphs to linear and piecewise linear velocity graphs?

Embedded Math Tutor's Noticing: A Collaborative Exploration and Change of Practice

Jose Contreras
Michigan State University

Embedded tutor (ET) programs have increased significantly in recent years to respond to new state requirements to phase out remedial math courses and increased need for tutoring support brought about by the COVID-19 pandemic. Despite this increase, ETs have remained understudied. ETs can face limitations in the classroom when instructors are underprepared to integrate ETs into their lessons. In particular, instructors can be unaware of the physical limitations ETs encounter in their practice, which can prevent them from delivering needed support to students. To better understand how ETs develop their practice this study uses the construct of teacher noticing to analyze interviews with an ET as they reflect on video recordings of their instruction. Findings demonstrate how an ET identified and addressed classroom features that limited their access to students. This study presents implications for faculty to ensure the presence of a collaborative work relationship between ETs, Instructors, and faculty.

Keywords: Embedded Tutor, Teacher Noticing, Tutoring

Embedded tutors (ETs)—who provide in-class support and out-of-class tutoring (Chaves et al., 2023; Racchini, 2020)—are understudied despite their increasingly important role in undergraduate education. Colleges and universities have leaned on ETs as alternative support systems to remedial math, which have been shown to decrease retention rates (Bahr, 2008) and to have disproportionately negatively impacted the success rate of minoritized students (Bahr, 2010). State legislation that began a phasing out of remedial mathematics, like in California, prompted some universities to begin ET programs as an alternative support system for students (Duffy & Burkander, 2023). The COVID-19 pandemic was another motivating factor that prompted universities to place ETs in virtual classrooms, at a time with remote learning had created distance between students and traditional tutoring (Chaves et al., 2023). While ET programs have increased in popularity over the past decade, there is evidence to suggest ETs' teaching assets are being underutilized because faculty and instructors are not prepared to shape instruction to include the ET (Cawley et al., 2022). However, existing research on the practices of ETs' is not yet extensive (Channing & Okada, 2020), providing limited guidance for how instructors can better leverage ETs' strengths in the classroom.

Evidence based training programs could provide a space for collaborative learning for both the instructor and ET. Training programs could provide information the instructor needs to best integrate ETs into their classroom and lessons. Training programs could also help ETs voice principles they draw on in their practice and recognize the assets they could be utilizing in the classroom. This study hopes to provide evidence that could inform ET and instructor training programs. This study uses the construct of teachers noticing to analyze a conversation between an ET and I as we reflect on classroom video recordings of their practice. In particular my research questions is: How can we collaboratively work through limitations to an ET's practice that are imposed by the classroom environment?

Theoretical Perspective

For this study, I build upon teacher noticing, and in particular I deploy Star and Strickland's (2008) classroom feature framework as an analytical framework to investigate what ETs attend

to and interpret as important features of the classroom. Although there are multiple definitions of teachers noticing, these definitions share three common components (Wei et al., 2023). First, teachers draw their attention to what is noticed, which they label as *attending*. Second, teachers then interpret what they are attending to, which they label as *interpreting*. Finally, some definitions of teacher noticing have a third step related to the teacher's *response* after they have interpreted what they have attended to. The classroom feature framework was developed to evaluate preservice teachers' development of teaching practices (Star & Stickland, 2008).

Teachers' connections between broader teaching principles and the classroom environment are mediated by what they notice (Star & Strickland, 2008). Star and Stickland claim that the most fundamental component of noticing is the identification of "important or noteworthy" classroom situations. To inform a survey for preservice teachers, they identified five classroom features: Classroom environment (e.g., desk arrangements, materials, and class size), classroom management (e.g., teacher physical presence, changes of pace, and moves to deal with disruption), tasks (e.g., warm-ups, taking notes), mathematical content (e.g., representation of the math) communication (e.g., student to student interactions or teacher to student interactions). While Star and Stickland acknowledge the limitation of their framework for its lack of exhaustion, possibility of category overlap, and the arbitrary choice of important and unimportant features, I argue it is sufficient for this study as it was for theirs. Similar to teachers, ETs knowledge and experiences are mediated by what they notice. The framework captures a variety of classroom features "in order to assess the full range of what novice teachers do and do not notice" (p.112). ETs are also novice educators in the classroom, and the framework serves to provide a foundation of what is recognized as a limitation.

Literature Review

ETs have a measurable positive impact on retention rates (Channing & Okada, 2020) and grades (Hayes, 2021). While retention rates and grades are important markers of success for students, there is a social component of success within mathematics spaces that are important for long-term student engagement with mathematics. When ETs are in the classroom, students can "gain a familiarity with the tutor" (Racchini, 2020, p.49). Tutors can leverage this relationship to provide psycho-social support (Henry et al., 2011).

While it is important to make clear the demands of an ET in the classroom, those demands must be supported by training instructors in addition to ETs. Specifically, instructors must know the purpose of the ET program, and the function of the ET in their classroom so that everyone is "held accountable for the success of the program" (Chavez, 2023, p.170). Instructors must integrate ETs into classroom activities, introduce and emphasize their role in the classroom, and communicate with the ET and their supervisor (Chavez, 2023). When instructors are not trained to integrate an ET in the classroom or emphasize their role, that ET can struggle to build rapport with the classroom (Cawley et al., 2022). For example, when an ET is relegated to inaccessible parts of the classroom, then opportunities to impart their wealth of knowledge or to act as a role model in the classroom for students are limited. An incomplete understanding of ETs practices can contribute to the underutilization of an ET in the classroom and limit the efficacy of classroom support for students.

Research that could inform the development of ET training programs is sparse. Even when scholars have identified characteristics of a successful tutoring program, their grounding in student or faculty perceptions—rather than ETs' experiences—limits their applicability to improve training programs. For example, Chavez and colleagues (2023) generated their model of ET from a survey sent to a listserv of Learning Center Professionals, group discussions, and

reports from four participating colleges that analyzed their own program. The ET program best practices construct provides principles for ETs to draw on during their practice, like ETs should get to know students, or that ETs should not enforce classroom discipline. The framework, however, does not propose a model for an effective classroom environment for ETs, or a model for ETs practices. For example, while the framework promotes the importance of frequent communication between instructors, students, and ETs, the framework does not adress how a classroom should be constructed to promote communication or how an ET could navigate a classroom layout that creates space between an ET and a student, as seen in Cawley and colleague's (2022) investigation. To better support ETs in their practice, research exploring ETs' classroom practices, and how they may be improved, is needed.

Methodology

Context

This study took place at a research-intensive Midwest state university during the 2025 spring semester. The participant of this preliminary report, Lucy (pseudonym), was an ET assigned to college algebra stretch A. College algebra stretch is a sequence of two courses that break up the college algebra curriculum into two semesters --- college algebra stretch A and college algebra stretch B. Students enrolled in this course during the spring semester were students who did not pass the same course in the previous semester or who just started the sequence. Classroom instruction included direct instruction, independent activities, and group activities. Lucy engaged with students primarily during individual or group activities. Lucy, an undergraduate student, was responsible for grading, proctoring exams, holding tutoring hours, and providing in-class tutoring support.

This study employed a purposive sampling method; ETs were recruited using a mix of a priori criteria and contingent criteria (Bryman, 2012). A priori criteria restricted the sample to ETs for college algebra stretch because I had the opportunity to build rapport with these ETs through my role as a lead TA. As a lead TA, I facilitated group meetings and discussions to address common issues that emerged during their practice. The contingent criteria selected for scheduling compatibilities, as well as consent from the instructor and students. From the four studied participants, Lucy was selected as a focal case because preliminary coding revealed strong alignment with the framework and their practice uniquely responded to classroom limitations.

Data Generation

Data generation began during the 10^{th} week of the semester, at which point I started taking video recordings of the classroom and audio recordings of ET-student interactions. Lucy and I reviewed these recordings from the classroom to motivate both of our 30-minute conversations. When I emailed Lucy the link to the recordings of the classroom, I asked who they were attending to in the classroom and what moments stood out to them. My first conversation with Lucy took place in the same classroom environment where she served as an ET. The second conversation was held in a room nearby due to scheduling conflicts.

The goal of this study was to investigate how Lucy and I could collaboratively move through limitations on her practice. I made the methodological decision to center Lucy' experiences, since an over reliance of student and instructor perspectives produced findings that are limited in their potential to improve training programs. I began the conversation by asking Lucy how she felt reviewing her video recordings. She responded that she felt uncomfortable but also indicated

she had attended to the space she took up in the classroom. At the beginning of the conversation, Lucy set the stage for what she wanted to talk about, and I followed her down this line of conversation. Lucy's responses aligned with Star and Strickland's (2008) classroom features (i.e., classroom environment), and Cawley and colleagues (2022) findings that suggest desk layout limited ET-student interactions. My follow-up question aimed to have Lucy consider whether the space she took up in the classroom was limited by the desk layout. The conversation that ensued is presented in the findings below.

Data Analysis

Data collection and analysis overlapped and mutually influential (Holmes, 2014). During classroom recordings I took analytic notes to document how ETs navigated the classroom environment. Preliminary analytic themes guided the data collection conversations. Once data was collected, I deductively coded the transcripts (MacLure, 2013) from both of our conversations to identify moments when Lucy was attending to the classroom environment (Star & Strickland, 2008), and where our conversations focused on working through environmental limitations.

Findings

The answer to the research question "How can we collaboratively respond to classroom characteristics that limit an ET's practice?" came from Lucy's and my conversation about classroom layout. In Lucy's opening response in our first conversation, she indicated that she was aware she is primarily "walking up and down the aisles staring people down". In response, I offered my opinion that the room is "awkwardly structured" and asked whether they felt they were influenced by the layout "to be in certain parts of the room". While I made the decision to explore the topic of classroom layout, Lucy responded, "that was one thing I was sort of thinking about as I was watching back the videos". By being in the room shown on the left side of Figure 1, Lucy was able to point to specific rows that she walked down "because that one has the most space". She elaborated that being able to walk into aisles enabled her to "catch people's eye more". Furthermore, Lucy hoped that by walking down the aisle more often, even though some aisles were "skinny", she would be able to "get more people to reach out if they have questions". Lucy's solution to the limiting "skinny" aisles was to just find a way through them, but I offered an alternative solution. While some aisles were made wider through an intervention with another ET, I also proposed that we could make a third column of tables as shown on the right side of Figure 1. Lucy responded positively to the suggestion and believed that it would "get more people to talk to us". At the end of our conversation, I summarized three major points of discussion, but in response Lucy only reiterated her "love" for the "idea of rearranging desks" or "just trying to walk up and down the aisle a bit more". In summary, prompted by the video recordings, Lucy attended to her position in the classroom, and I guided the conversation towards an investigation of the classroom environment. Lucy attended to the limitations of "skinny" aisles on her practice, and through both of us suggesting solutions, we arrived at a plan of action to respond to the limitation.

After our conversation, I arrived early at Lucy's class, asked the instructor for permission, and proceeded to rearrange the tables. During our second conversation, when asked about the impact of moving to a three-column table layout, Lucy celebrated the change. Lucy felt that the classroom felt more "active" and "loved" the change but proposed that there were other factors at play that could have contributed to the "active" classroom. Later in the conversation, however, we were able to identify a moment in the classroom recording where she was interacting with a

student who had been difficult to reach in the past. Lucy proposed that they did not frequently interact in the past because their seat was "in a row and not at the edge of the row". Lucy was referencing that in the previous classroom layout, there are only 10 students who sit at the edge of a row, but the new layout places twenty students at the edge of the row. At the end of our conversation Lucy shared that she felt she has "really grown as a [ET]" by "having these talks and conversations". The second interview validated Lucy's interpretation that the table orientation was limiting her interactions with students and showed the impact that a relatively minimal change to the classroom limitations could have on an ETs' practice.

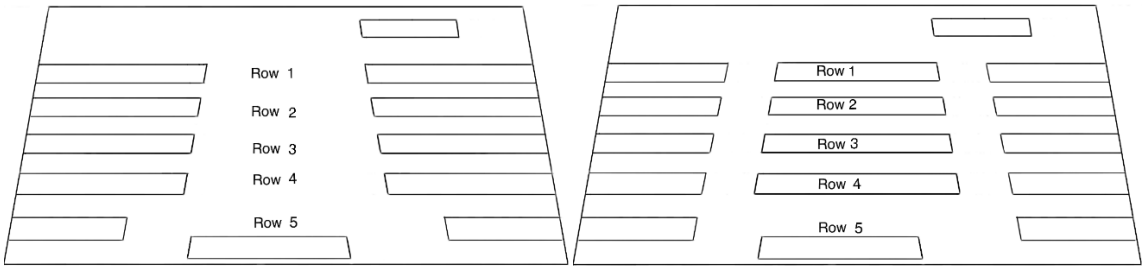

Figure 1: Sketch of the classroom before and after rearranging desks

Discussion

This preliminary report develops knowledge of ET practices that may provide needed evidence-based strategies for ET training programs. While the instructor was able to shape tasks of the class to allow the ET to gain familiarity with some of the students, as expected by Racchini (2020), the instructor had an incomplete understanding of what Lucy was attending to in the classroom. Reflecting the findings from Cawley and colleagues (2022), Lucy was relegated to parts of the classroom that were inaccessible to some of the students. While Lucy showed a desire to adhere to principles of getting to know the students (Chavez, 2023), there was a breakdown of communication between the ET and the instructor. These findings suggest that two-way communication between ETs and instructors could lead to collaborative problem solving to maximize the potential reach of the ET.

This preliminary report is a product of initial deductive coding using the classroom feature framework of one participant of the study. Future research will include the deductive coding of three other participants' conversations, and thematic analysis of these conversations, identifying aspects of ET practices that both align with and depart from Star and Strickland's (2008) framework for noticing of classroom features to expand our understanding of ETs' assets.

Indifference as a Key Aspect of a Global Perspective on Equivalence Relations

Hudson Payne
Oklahoma State University

John Paul Cook
Oklahoma State University

Equivalence is a central concept of mathematics and is a fixture in the K-16 curriculum. Though equivalence has been very well-studied overall, very little is known about how students reason with formal equivalence relations in advanced mathematics. Recent research has demonstrated that one component of productive reasoning about equivalence relations entails the ability to flexibly move between viewing equivalence from both an elementwise (local) perspective and a set-oriented (global) perspective. Building on this work, we report on a pilot study intended to aid the development of a conceptual analysis of equivalence in advanced mathematics - in which we seek to refine the notion of a global perspective on equivalence. In this preliminary report, by showcasing excerpts from task-based clinical interviews with two advanced mathematics students, we propose 'indifference' as a beneficial way of reasoning about equivalence from a global perspective.

Keywords: Equivalence Relations, Indifference, Global Perspective

Equivalence is an idea that transcends many areas of mathematics, from the relatively concrete equality of representations of rational numbers and algebraic expressions to the more abstract notion of decontextualized equivalence relations. Though equivalence has been extensively studied in the mathematics education literature, nearly all of it has focused on students' conceptions and uses of equivalence in K-12 contexts (e.g., Kieran, 1981; Knuth et al., 2006). At the advanced level, the existing research has focused on how students reason with the standard properties that define equivalence relations (e.g., Chin & Tall, 2000; 2001; Asghari, 2004b; Hamdan, 2006; Brandt, 2013). At the moment, the literature is not positioned to address how advanced mathematics students might productively leverage notions of equivalence relations themselves to help solve a problem. Payne & Cook (2025) highlight a distinction between an element-focused local perspective and a set-focused, global perspective on equivalence relations, arguing that the flexibility to transition between these two perspectives is productive for students. These perspectives are broad categories of student reasoning; as defined, their grain-size does not detail how students may identify two elements as equivalent, or the ways in which students might reason about sets of related elements. In the case of a local perspective, this gap has been filled by research that has, for example, examined how students might reason about equivalent fractions (e.g., Smith, 1995) and numerical expressions (e.g., McNeil et al., 2006). Other work has examined general ways of reasoning about equivalence that are relevant across multiple types of objects (e.g., Cook et al., 2022). The same cannot be said for a global perspective, as little has been done to investigate students' reasoning with sets of equivalent elements. Put another way, since a global perspective requires attention to a set of related elements, most equivalence literature has a local focus (e.g., Kieran, 1981) leaving reasoning about equivalence from a global perspective understudied. Building in part upon the work of Payne & Cook (2025) with respect to equivalence relations, we work to answer the question: What aspects of a global perspective on an equivalence relation are productive for students? Based on the equivalence relations literature, and data collected from pilot interviews with advanced undergraduates, we hypothesize that a productive feature of reasoning from a

global perspective is the ability to adopt an indifference towards the choice of element within an equivalence class.

Literature and Theory

This is a pilot study to inform a dissertation project aimed at developing a conceptual analysis (Thompson, 2008) that describes ways of knowing equivalence relations that are propitious for students. The literature offers a few insights regarding such understandings. Several authors have previously used the term *global* to describe a perspective that considers sets of equivalent elements, though authors use this term in slightly varying ways. With respect to equivalence relations, Payne & Cook (2025) articulate a *global* perspective on an equivalence relation as being characterized by reasoning about collections of equivalent elements (such as equivalence classes). These authors indicate both that advanced mathematics students reason about equivalence relations in a way that matches this description, and that it is productive. Adopting this definition, a global perspective will refer to reasoning that involves sets of equivalent elements, and a *local* perspective will involve particular equivalent elements. To illustrate, in Arnon et al. (2001) students reasoned about lines with rational slopes as proxies for equivalence classes of fractions (which would require a global perspective) *prior* to learning algorithms to transform fractions into their equivalent forms (which would require a local perspective). However, *most* equivalence literature at the K-12 level has focused (implicitly) on local perspective. Since equivalence classes emerge as a fundamental aspect of equivalence in advanced mathematics, there is a need to study the global perspective as well. Moreover, many studies which focus explicitly on equivalence relations at the undergraduate level concern how students work with their reflexive, symmetric, and transitive properties, and on how these properties relate elements to each other, (e.g., Asghari, 2004a; 2004b; 2005), but do not investigate the specific ways in which students use equivalence relations as a problem-solving tool.

A productive approach that emerged from some earlier work (Payne & Cook, 2025) with students working on equivalence relations tasks involved the students' awareness that when reasoning about equivalence classes, the existence of equivalence classes often made it unnecessary to specify a choice of element from within an equivalence class. This observation warranted further study, though most of the original tasks were not positioned to investigate the strategies that students used when reasoning about an equivalence relation as a global property of a set. In addition to this empirical example, we also find some hints at the notion of indifference in the literature. For example, Piaget et al. (1977, p.155) describe elements of an equivalence class as "indistinguishable", and one of Hamdan's (2006) students describes equivalence relations as unable to discriminate between related elements. Similarly, in the context of teaching homomorphisms one instructor in Rupnow (2021) observed that they could "take any [pre-image of a coset of the kernel] as a representative" (p. 11) due to the induced equivalence relation, though these are comments made in passing, leaving indifference yet to be investigated directly. Since these strategies remain under-investigated, and since we hypothesize that this a productive understanding for students working with equivalence relations tasks, this study was geared towards eliciting more instances of articulated indifference towards particular elements.

Methods

Since the ultimate purpose of this project is to develop a conceptual analysis (e.g. Thompson, 2008) of how students reason about equivalence from a global perspective, the first author conducted task-based clinical interviews (e.g., Clement, 2000) with advanced mathematics

students. One goal of conceptual analysis is to build models of student's thinking (Thompson, 2008). Hence, we conducted task-based clinical interviews (e.g., Clement, 2000) intended to explore the mental processes of the participants. Since literature informing a global perspective on equivalence relations remains somewhat sparse, pilot interviews were conducted to be largely exploratory, and to guide the development of a more targeted interview protocol in a future dissertation study. The first author individually interviewed three undergraduate Introduction to Abstract Algebra students three times each in 60-minute sessions and recorded all verbal and written responses on an iPad. We will relate episodes from two of these students, Andrew and Brian, in which they used indifference as a problem-solving tool when reasoning about equivalence relation tasks. The tasks are reproduced below:

Table 1. Two of our tasks, on which we report in the results section.

Task A - Even and Odd Functions - Andrew (pseudonym)	
Task: Suppose f(x) is an even function and g(x) is an odd function. Let $$h(x) = \frac{f\left(\frac{g(x)}{2}\right)}{x^2}$$ If $h(5) = 2.2556$, is $h(-5) = -2.2556$? Answer: No, since $h(x)$ is an even function	Rationale: Function parity partitions the set of all real-valued functions into four subsets: Functions that are even only, odd only, functions that are neither even nor odd, and the function that is both ($f(x) = 0$). The task can be answered by deciding if $h(x)$ is odd, and does not require specification of $f(x)$, $g(x)$, or $h(x)$
Task B - Concentric Circles – Brian (pseudonym)	
Let $(x, y)R(w, z)$ if and only if $x^2 + y^2 = w^2 + z^2$ be a relation that partitions the plane into curves. What is the maximum distance between two points on curves containing $(1,2)$ and $(0, 4)$? Answer: The maximum distance is $4 + \sqrt{5}$	Rationale: If the student observes the equivalence classes are circles, this becomes a matter of finding the distances between points on the opposite sides, but this does not require that students specify the locations of either point.

Tasks were designed to require students to reason either about the partition structure induced by an equivalence relation, or about sets of equivalent elements to observe students' productive use of a global perspective on equivalence relations, and begin to identify useful strategies to approaching these tasks, one of which was hypothesized to be indifference towards the choice of element.

Following Clement (2000), the first author conducted an *interpretive* analysis, which was generally in agreement with Thematic Analysis (e.g., Braun & Clarke, 2006). The notions of a global perspective and indifference both served as initial, a priori codes. Other codes emerged during the analysis that extend beyond the scope of this preliminary report. After each interview was transcribed, the first author coded each transcript for instances of both a *global perspective* and *indifference* towards the choice of element within an equivalence class or a subset of a partition, based on student's observable behaviors. Student's reasoning was inferred to be from a global perspective if they referred to, or made representations of, sets of elements that were

related by an equivalence relation, or alternatively if they reasoned about subsets of the corresponding partition. Once a student's reasoning was inferred to involve a global perspective, student's speech was coded as indicating indifference if it contained words or phrases such as "regardless", "independent of", "no matter", or "I didn't specify" in reference to some element of an equivalence class that featured as part of their productive problem solving.

Results

In task A, Andrew quickly recognized that this problem was related to determining whether $h(x)$ was an even or an odd function, though he could not recall at first precisely what it meant for functions to be even or odd. Citing examples of functions that he knew to be even or odd, he was able to recover a definition that he found useful:

> *Andrew*: for $f(x)$ to be even, that means that say $f(1) = f(-1)$, or in more general terms like $f(x) = f(-x)$, like how cosine works.
>
> *Interviewer*: Okay. So then what about odd functions?
>
> *Andrew*: So well basically, $g(1)$ should equal $-g(-1)$, or in general terms $g(x)$ should equal $-g(-x)$. [...] like how sine works [...] that's why I felt like it was saying, "Is it odd?" is because, now I see that's the definition that we're working with there. [...] So going back to the question, 'is this part odd or even', is kind of how I'm looking at that.
>
> *Interviewer*: How would that information help you answer the question?
>
> *Andrew*: still going off of this… if $h(5) = 2.2556$, is $h(-5)$ negative? That feels like asking if h is odd. So I think I'm kind of trying to work through and see if I can say that h is odd, and then that will definitely include that being true. And if it's even, that would definitely disqualify it from being so.

Here, we claim that Andrew is demonstrating a global perspective about a partition of the set of functions by parity, since his goal has become to assign the function $h(x)$ to one of the subsets of that partition, and based on the properties of that subset, he will be able to solve the task. However, Andrew goes on to use indifference as a tool in his problem solving, based on an approach to building $h(x)$ by dividing an even function by x^2, and deciding that it would still be even, independent of a particular choice of $f(x)$.

> *Andrew*: So I was able to determine [$h(x)$ was even] using the fact that $f(x)$ was an even function [...] I really only used that $f(x)$ was an even function and made a determination that an even function divided by x^2 would still be an even function, and that's what got the answer. [...]
>
> *Interviewer*: Okay. So even though you didn't have a specific function for $f(x)$, you were able to determine that $h(x)$ was an even function?
>
> *Andrew*: Yes. [...] Based on just the reasoning through the character of a general […] even function [...] Like how I talked about an even polynomial. Reducing it, like dividing by x^2, would always retain its identity as an even function, [...] So regardless of the specific identity of $f(x)$, the specific function, as long as it's even, which it is, then $h(x)$ will be even, regardless of the specifics. [...] the reasoning solely ended up relying on $f(x)$ being even.

We infer that Andrew reasoned from a global perspective because he used a partition of the set of functions. In particular, he used the assignment of elements to certain subsets of that partition to assign other elements to the appropriate subsets. Andrew did not initially recall the formal definitions of even or odd functions, but he used examples to jog his memory and recover the characteristics common to all even and odd functions, which let him proceed without a

specific choice of f(x) or g(x). As Andrew noted, his reasoning relied only on the fact that f(x) is even, "regardless of the specific identity", which we argue indicates indifference towards the choice of representative.

Brian adopted a similar indifference in his work on task B, solving the task without determining the exact locations of two points on opposite sides of the circles. After he determined the radii of the circles and added them to find his answer, the interviewer followed up with questions about his reasoning:

Interviewer: Did you ever find the coordinates for, uh, either of those points in your problem-solving to find that distance? So what I'm asking is not, [..] "can you tell me what they are?" What I'm asking is "did you ever find them?"

Brian: I guess I didn't find $(0, 4)$, it's given to me. [...] And then I didn't exactly determine this coordinate. Like I never wrote out, uh…, $(0, -\sqrt{5})$. But it's kind of what was going on in my head. Like I knew I was looking for [the opposite] y-value.

Interviewer: Okay. So were you thinking about it in terms of like where that coordinate was or were you thinking about it more in terms of like the diameter and radius in the circle?

Brian: I think more, I was, initially I was like, okay, I need to find this point on the graph, but the properties of the circle will tell me what that exact value is. [...] So once I started thinking about the circle, I kind of left the coordinate idea behind.

Here, we infer that Brian reasoned from a global perspective; he indicated that his reasoning relied on the circles, which are the equivalence classes under this relation. We also consider his reasoning to indicate indifference towards the particular representative, since he notes that in his thinking about the circles, he "left the coordinate idea behind". Here, the symmetry afforded by the equivalence classes enables any choice of point on either circle to be as good as any other, and it is the consideration of the entire equivalence classes that enabled Brian to disregard the coordinates.

Discussion & Questions

We seek to address two gaps in the literature about equivalence relations: the lack of information on the global perspective on equivalence relations, and how equivalence relations are used by students as a problem-solving tool. Our hypothesis addresses both gaps, in the sense that from a global perspective on an equivalence relation, a productive strategy that becomes available is indifference towards the choice of a representative from an equivalence class. In our excerpts, Andrew and Brian productively used indifference to reason about equivalence relations from a global perspective supporting this hypothesis.

Preliminary Nature of the Report

Due to the unexplored nature of indifference as an idea linked to equivalence relations, this pilot study was conducted with the intention of developing a model to be subsequently refined, gaining viability through a cycle of interpretive analysis (Clement, 2000). There remains work to be done to document and articulate other productive forms of reasoning that accompany the use of equivalence relations. To the audience, we pose the following questions: As mathematicians and educators, what are some of the productive strategies that you would consider to be associated with the use of equivalence relations, particularly as global statements about equivalence? and in what mathematical settings do you observe or implement these strategies?

Preservice Teachers' Reasoning About Area and Volume Measurements

Osmond A. Asiamah
University of Delaware

Teo Paoletti
University of Delaware

This preliminary research report examines how undergraduate elementary preservice teachers (PSTs) reason about area and volume measurements prior to receiving instruction in mathematics content course in algebra, geometry, and measurement topics. This is a pilot study for a larger project. The preliminary analysis results from the pre-assessment data of 27 PSTs indicate that they lack productive reasoning about area measurements and their conversions, and they also employ direct linear dimensions conversion strategies on the volume task. This highlights the need for instructional unit to focus explicitly on developing PSTs' productive reasoning about area and volume measurements.

Keywords: area measurement, preservice teachers, quantitative reasoning, volume measurement

In most countries' curricula, area and volume are fundamental measurement concepts that students must learn and apply. Both the Common Core State Standards for Mathematics (CCSSM, 2010) and researchers (Battista & Clements, 1996; Huang & Wu, 2019; Panorkou, 2021) have emphasized the importance of deep and progressive meanings for these concepts. From early elementary grades through college level, students are expected to develop productive meanings for area and volume measurements. Such a foundation, which emphasizes visualization and reasoning over rote memorization (CCSSM, 2010; Huang & Wu, 2019; Panorkou, 2021), is crucial for more complex geometric reasoning and problem-solving topics like optimization, integrals, related rates, volumes of solids of revolution in their later school years (Dorko & Speer, 2013, 2015).

Research has consistently shown that K–12 students are not being provided sufficient opportunities to develop more productive meanings for area and volume measurement. Students frequently struggle to visualize and mentally structure 3D arrays, leading them to count visible faces in an image instead of imagining the total number of unit cubes (Battista, 1999; Battista & Clements, 1996; Eames et al., 2013; Sisman & Aksu, 2016; Vasilyeva et al., 2013). Further difficulties include misapplying or confusing volume formulas with those for surface area or height, and conflating volume with weight (Curry et al., 2006; Ergene & Isiksal Bostan, 2022; Ho & McMaster, 2019; Kim & Oláh, 2019; Seah & Horne, 2018; Sisman & Aksu, 2016; Vasilyeva et al., 2013). Given the challenges faced by K–12 students, there is an expectation that preservice teachers (PSTs) will be equipped to support students in developing productive meanings for these concepts. However, research on PSTs (e.g., Chamberlin & Candelaria, 2018; Hong & Runnalls, 2022; Zembat, 2010) shows significant similarities between the challenges they encounter in developing meanings for area and volume measurements and those faced by children. These findings collectively emphasize the importance of providing instructional opportunities to help PSTs (and students generally) develop more productive meanings for area and volume measurements. Considering the challenges faced by PSTs, it is essential to implement targeted instructional strategies in teacher education programs that foster a deeper conceptual grasp of these mathematical concepts. By closing these knowledge gaps, we can better prepare PSTs to support their future students in gaining more productive meaning for area and volume measurement. In this preliminary report, we address the research question: *How do PSTs reason about area and volume measurement before and after receiving instruction focused on developing meanings for*

area and volume as quantities? Data collection is on-going in the Fall 2025 semester, so in this paper, we only present results on PSTs' meanings for area and volume by examining their responses before the short instructional unit. We will have additional data and further analysis completed prior to the 2026 RUME conference. Further, we note that the results of this study will serve as a foundation for the first author's dissertation work.

Theoretical Framework

Quantitative reasoning entails conceiving situations in terms of quantities and relationships between them. To conceptualize a quantity, one must identify a particular measurable attribute of an object, recognize an appropriate unit of measure, and conceive of a measurement process (Smith III & Thompson, 2008; Thompson, 2011, 2023). For area and volume, students must first conceive of a 2D or 3D space as a measurable attribute, respectively. With respect to area, students can use either standard units (e.g., square units; Cullen et al., 2018) or non-standard units (e.g., rectangles; Simon & Blume, 1994) to cover the measurable 2D space or a dynamic sweep of a line segment in a perpendicular direction through a distance to generate a rectangular area (Panorkou, 2020). The process of covering the space with the unit is the measurement process described by Thompson and colleagues. With respect to volume, students could also use standard or non-standard units. This may entail conceiving of a 3D object with an array of 2D cubic units iterated in the third dimension (Curry & Outhred, 2005; Curry, Mitchelmore, & Outhred, 2005, 2006) or a dynamic sweep of an area through a length (Panorkou, 2020, 2021).

Research on PSTs' Reasoning about Area and Volume Measurement as Quantities

Research on PSTs' reasoning about area and volume measurement reveals significant difficulties in relation to the three criteria Thompson described for quantities construction. With respect to conceptualizing a measureable attribute, several researchers have argued that PSTs often define area as "length × width" rather than the amount of space within a region, thus lacking meanings for these procedures that connect to a process of measuring an attribute (Livy et al., 2012; Ma, 2020; McNeal et al. 2024; Simon & Blume, 1994).

Related to the importance of units, researchers have found that many PSTs could not accurately identify the units involved in area measurement tasks because they lack experiences that give meaning to the concept of "square units," (Browning et al., 2014; Ghosh Hajra et al., 2016; McNeal et al. 2024). Similarly, Dorko and Speer (2015) examined students' understanding and use of units when calculating area and volume. They found that only 26.6% of students used the correct units for all tasks, while 73.4% made at least one mistake in applying or omitting units in area and volume calculations. The most common error was using length units (such as cm or m) instead of area units (cm^2) or volume units (cm^3).

The findings from these studies highlight the importance of supporting PSTs to develop more productive meanings for area and volume as quantities (as defined by Thompson) units. Ultimately, strengthening their meanings for area and volume measurements will not only enhance their mathematical reasoning but also enable them to teach these fundamental concepts more effectively to future students.

Methods

In this section, we describe our participants and the setting of the course, followed by an overview of the data sources used.

Participants and Setting

The participants for this study are elementary PSTs taking a required undergraduate mathematics content course within a four-year teacher education program at a university located in the Mid-Atlantic region of the United States. The participants were sophomores and juniors. We invited all 30 participants in the cohort class to take part in a pre- and post-assessment test. The goal of the course is to provide PSTs with the opportunity to develop productive meanings for algebra, geometry, and measurement topics and to learn how these topics are developed throughout the K-8 curriculum. All students in the class will participate in the same instructional activities. Additionally, three PSTs are actively taking part in a short teaching experiment (Steffe & Thompson, 2000), of which the first author is primary teacher-researcher, to explore more in depth the efficacy of the task sequence.

Data Sources

PSTs will take the same assessment both at the beginning and end of the semester, administered online through a Desmos Activity. The pre-assessment consisted of several tasks. Of relevance to this report, the first two tasks (Figure 1) required converting between area measurement units, one involving standard units (Task 1) and the other involving non-standard units (Task 2). Task 3 (Figure 2) required finding the volume of a box involving a non-standard unit and performing unit conversions.

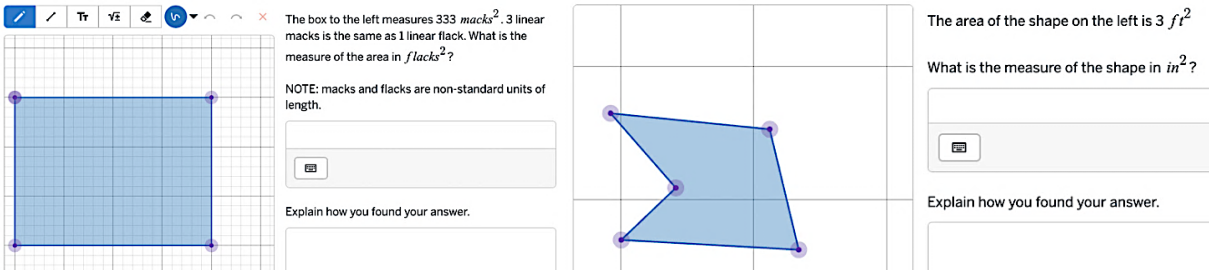

Figure 1. Tasks 1 and 2

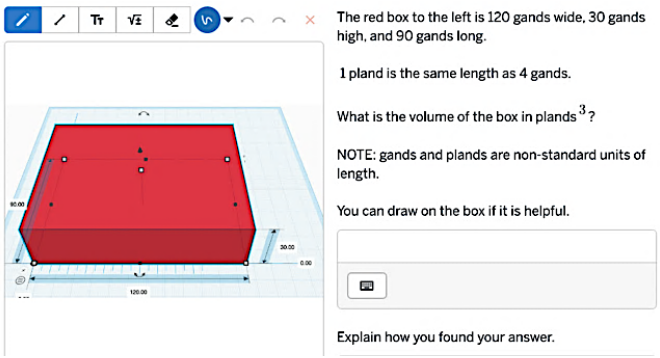

Figure 2. Task 3

Analysis

To code the PSTs' responses to pre- and post-assessment items, we will begin by individually reading through the PSTs' responses and making notes about ways they reasoned about area and volume in each problem. We will then meet to compare observations and develop codes that could apply across problems. We will likely use both a priori codes (e.g., relying on formulas) and emergent codes (e.g., converting linear units before determining area or volume). Once we agree

on features for coding, each author will independently code several pre- and post-test responses for each problem, and we will calculate interrater reliability. Whereas we will present the results of this analysis at the conference, due to the time constraints for preparing this report, we will focus on PSTs' numeric responses to the tasks to highlight the ways such analysis is likely to provide powerful insights into their reasoning.

Preliminary Analysis and Results of the Pre-assessment Test

We first present a summary of the PSTs' responses to the three tasks. For each task, we present the PSTs' numeric values, regardless of whether they included units in their response. We note that for the two tasks in Figure 1, only 2 PSTs obtained the correct numeric values for the tasks (37 and 432, respectively); these were the same two PSTs. The majority of PSTs provided a value that was likely determined by multiplying or dividing by the linear conversion fact (e.g., dividing 333 by 3 and multiplying 3 by 12).

Table 1. PSTs' Responses to Pre-Assessment Tasks on Area and Volume

Task 1 (n = 27)		**Task 2** (n = 27)		**Task 3** (n = 24)	
Answer	№ of ans. (as %)	Answer	№ of ans. (as %)	Answer	№ of ans. (as %)
37	2 (7.4%)	432	2 (7.4%)	5,062.5	13 (54.1%)
111	22 (81.5%)	36	23 (85.2%)	81,000	6 (25.0%)
1110	1 (3.7%)	32	1 (3.7%)	1,296,000	2 (8.3%)
100	1 (3.7%)	9	1 (3.7%)	972,000	1 (4.2%)
99.9	1 (3.7%)			5,062.3	1 (4.2%)
				32	1 (4.2%)

In contrast, a majority of PSTs (54%) obtained the correct response (5062.5). The most common incorrect answers were probably obtained by multiplying the three given dimensions (120×30×90), then dividing or multiplying this value by the given linear conversion factor, thus obtaining 81,000 or 1,296,000, respectively.

We were initially surprised by the large discrepancy between the number of PSTs who correctly answered Task 3 (Figure 2) compared to Tasks 1 and 2. However, as we preliminarily reviewed the PSTs' written responses (which we will more formally code once both pre- and post-assessments are complete), a possible explanation became apparent. Rather than determining a conversion factor to determine an answer (i.e., there are 4×4×4 plands^3 in 1 gland^3), we found that many PSTs directly converted the three given linear measures before multiplying; this strategy was not available to them in the area problems (Tasks 1 and 2), as no dimensions were provided. For example, one PST on Task 3 justified her correct answer by saying:

> I divided each measurement by 4 to convert gands into plands, because if 1 pland is the same as 4 gands, there will be a smaller amount of plands to take up the same amount of space. Then I multiplied the length times width times height to get the volume.

On Task 2, the same student explained how she determined there were 36in^2 in 3ft^2 said:

> There are 12 inches in a foot, so for every 1 foot^2, there are 12 inches^2. There are 3 ft^2, so 3 times 12 inches per 1 foot is 36 inches^2.

Hence, the PST was able to determine a correct solution to the volume problem by converting linear measures and then multiplying, a strategy not available in Task 2, as no linear measures

were provided. We observed numerous other similar responses from PSTs who successfully converted linear dimensions in Task 3 but not in Tasks 1 and 2.

Discussion

Our preliminary findings corroborate what other researchers have noted. Namely, prior to intervention the PSTs' meanings for area and volume seem to rely on procedures (Chamberlin & Candelaria, 2018; Hong & Runnalls, 2022; Livy et al., 2012; Koçak et al., 2017; Ma, 2020; McNeal et al. 2024; Simon & Blume, 1994; Zembat, 2010). With respect to Tasks 1 and 2, these procedures do not seem to reflect a robust meaning of either area as entailing a process of using a unit to measure an attribute (e.g., reasoning about using different units to cover a space; Thompson 2011, 2023). However, our prompt for Task 3 may be limiting our ability to explore PSTs' meanings for converting between units of volume. We plan to add an additional volume question to the post-assessment test without linear dimensions provided to better explore their meanings for volume conversions.

As we continue to code the pre- and post-assessment responses, we will further analyze the data as described in the methods. We anticipate several codes as being relevant based on the literature (e.g., Dorko & Speer, 2015), such as "omission of unit, but correct numerical value," "use of wrong unit, but correct numerical value," "omission of unit and wrong numerical value," and "use of wrong unit and wrong numerical value." This coding process will provide a clearer picture of the changes in their PSTs' meanings for area and volume measurements, and after the course. We are hopeful that the instructional unit will support them in developing such productive meanings, and these meanings will be reflected in students' post-test responses.

Implications and Questions for Feedback

Based on the preliminary analysis and results of our pre-assessment test, we highlight two main implications that can be drawn from these preliminary findings. First, a significant number of PSTs answered Tasks 1 and 2 incorrectly, indicating that the PSTs' meanings for area measurements and their conversions are not robust enough to address a variety of tasks related to area. This implication highlights the need for instructional unit to focus explicitly on developing productive reasoning related to area and volume measurements. Second, the findings revealed that PSTs employed direct conversion strategies in the volume task (Figure 3), which were not easily applied in the two area tasks due to dimensions not being apparent. This highlights the need to further explore and develop PSTs' meanings for both quantities as measurable attributes entailing a unit and measurement process.

Based on these preliminary findings and implications, we intend to ask the audience for the following in their feedback:

1. In what ways do you think this study can be expanded upon? Are there other critical ideas to explore that support PSTs in developing productive meanings for area and volume measurements?
2. In what other directions can the analysis focus, especially when both pre- and post-assessment data sets are available after the course?
3. Apart from quantitative reasoning, are there other theoretical frameworks to consider grounding the study in?

Student Agency in the Collaborative Development of Novel Interactive Textbook Questions in Calculus and Linear Algebra

Johannah Crandall
University of Michigan

Janice Kang
University of Michigan

Michael Ye

Vilma Mesa
University of Michigan

In this preliminary report, we present results of examining the collaborative process used by teams of students, teachers, authors, and researchers to develop novel interactive questions for free, open calculus and linear algebra textbooks. Of concern is student agency as both a temporally-based social process and an ecological phenomenon as collaborators understand and construct the role of student. Discursive practices of the collaborators contributed to student positioning. In some cases, this resulted in an absence of student voice in the development of content, while in others, student agency yielded meaningful pedagogical changes in the development of questions.

Keywords: role construction, positionality, agency, undergraduate mathematics textbooks

In this time of rapid development of free, open curriculum materials, particularly textbooks, effective methods are needed for generating content that supports both student engagement and teacher pedagogical needs. Attending to the reality that teachers and students interpret and mediate the use of curriculum resources to produce an enacted curriculum different from the intended one (Rezat et al., 2021), the PROTEUS project positions Students and Teachers alongside textbook Authors and educational Researchers, in a "STAR team," to propose, revise, and evaluate novel textbook questions that will engage a wide range of math learners. The success of this collaborative approach to generate content differently than the author would generate in isolation depends upon the various stakeholders drawing on their lived and practice-based experiences in mathematics classrooms. We are interested in the agency of the students in this unique collaboration fraught with differentials in content expertise and echoes of classroom power dynamics.

Theoretical Framing

Discursive moves can position students as agents in the context of the undergraduate mathematics classroom Mesa and Chang (2010). While the PROTEUS project uses collaboration outside the classroom, we acknowledge that participating teachers' and students' positioning is inevitably linked to social structures forged in the classroom. Thus, our conception of student agency in this context draws upon Emirbayer and Mische's (1998) definition of agency as a process shaped by past, present, and projected (future) social engagement. While our design has attempted to position the students as experts of their own (past) experiences, the students navigated uncertain positioning and power dynamics as they worked alongside content experts who in other contexts hold positions of authority relative to students. We furthermore rely upon Biesta and Tedder's (2007) expansion of agency as an ecological phenomenon wherein the interaction between an individual and their context-for-action leads to the transformation of environmental structures. Our design aspires to make equitable space for all stakeholders, students in particular, to shape the very processes engaged in by the team. Power differentials among stakeholders naturally make such a realization of student agency troublesome.

Methods

PreTeXt-Runestone: Open Textbooks Engaging Undergraduates in STEM (PROTEUS) is a collaborative project led by the four organizations, one of which serves as the independent evaluator. Together, these organizations coordinate the development of interactive questions for PreTeXt-authored textbooks (https://pretextbook.org/) in calculus and linear algebra, ensure their integration into the XXX online textbook platform, and evaluate their effectiveness in authentic classroom settings. In the content development stage, we seek to answer the question: *What are the strategies and heuristics used by teams of stakeholders to create content for three types of interactive questions (Reading Questions, Parsons Problems, Matching Exercises), for calculus and linear algebra that will engage students with learning the material?, w*hile in this report, we address the subquestion: *How is the role of the student constructed by the teams?*

This study uses qualitative research methods within a phenomenological paradigm to explore how students' roles are constructed and understood during collaboration (Ernest, 1997; Wood, 2017). To capture authentic experiences and perspectives, we employed bottom-up research methods that allow codes and themes to emerge directly from the data rather than imposing a priori categories (Blair, 2015). Specifically, we investigated students' utterances in team meetings to develop interactive questions to be added to four textbooks for calculus (*Active Calculus* [AC], Boelkins, 2022; *APEX Calculus* [APEX], Hartman et al., 2018) and linear algebra (*A First Course in Linear Algebra* [FCLA], Beezer, 2022; *Understanding Linear Algebra* [ULA], Austin, 2022).

Participants

Each STAR team was composed of one or two students, two teachers, the author of the respective participating textbook, and one or two researchers. The eight teachers were recruited from the authors' networks because of their familiarity with the textbooks and their experiences teaching with them. Three educational researchers, who specialize in mathematics education at the undergraduate level, participated in two STAR teams each. Researchers coordinated the team meetings and oversaw the design-based research process (Bakker & van Eerde, 2015) of iteratively developing and testing new textbook questions.

There were seven students across the teams; each was pursuing an undergraduate degree and had recently completed or was currently taking calculus and/or linear algebra. Students varied in terms of race and ethnicity identity (including Asian, Black or African American, White, or Other with two students identifying as Hispanic/Latinx), gender identity (4 women, 1 men, 2 agender), and prior mathematical experiences. Six of the students were between 20 and 21 years of age, with one over 23 years old. Several of the students had experience tutoring and some completed their teaching practicum concurrently with their participation in the study. They were primarily recruited through the teachers in our teams and through networks of instructors in the state of Michigan. Each student was assigned to either a linear algebra team or a calculus team depending on their background and the needs of the study. Students were asked to contribute their authentic perspectives on how learners engage with interactive questions, to represent the kinds of difficulties students encounter, and to provide feedback based on their experiences.

Outside of their activities developing textbook questions as a team, the STAR members contributed their feedback through surveys and interviews with the external evaluation team. All participants provided informed consent and were compensated for their participation.

Data Collection and Analysis

Data for this analysis were drawn from 51 STAR team meetings during the 2024-25 academic year, which were video recorded through Zoom and subsequently transcribed verbatim. To familiarize ourselves with the data, the first three authors read the transcripts multiple times to understand the meeting content and participants' discursive patterns. Using NVivo (https://lumivero.com/products/nvivo/) qualitative data analysis software and guided by the central research question of this study, we engaged in iterative cycles of independently coding transcripts and comparing results until we achieved strong agreement on the discursive segments that contributed to the construction of the student role. We concluded that it was important to distinguish between participants' references to the *General Population* of students and to the *STAR Students* themselves. Furthermore, we distinguished between STAR student *References* and *Utterances* in team dialogue*,* as utterances *made by* students, *directed to* students, or *about* students contributed in different ways to role construction. Finally, we attended to *Critical Events* (e.g., a decision to revise a question) in which to examine these categories of utterances and how they positioned students (Author & Colleague, 2010). We are in the early stages of textual and discourse analysis to identify how references to students were framed, how student voices appeared (or were absent), and how discursive practices shaped the construction of the student role within meetings. This approach has been chosen to move our analysis beyond surface-level categorization and examine the underlying meanings, assumptions, and institutional logics embedded in the conversations (Bloome et al., 2008).

Findings

Critical events were identified during team processes of norm setting, topic selection, proposing and vetting of questions, posing of conjectures about thinking the questions may elicit, and evaluating responses to the questions in both interview and classroom settings. As team members interacted in a variety of ways with students' articulation of difficulties, representations of textbook use, and descriptions of personal classroom experiences, students were positioned by both discourse and team processes. By authentically representing their own experiences, students surfaced conceptions that influenced team decisions about question design.

Positioning Students Through Discourse

Utterances contribute to the constructed position of participants in dialogue (Author & Colleague, 2010), and as the teams held regular meetings, utterances from each of the four STAR roles positioned students and delineated the (often implicit) scope of their expected contributions. Student utterances were predominantly embedded among those of other roles, such as teachers and authors, and occurred most often as responses. Thus, teacher, author, and researcher utterances shaped the discursive environment in which student utterances were elicited, or into which they were injected. For example:

> *Author*: I think there, there are the basic [questions] about understanding how composition works that have no reading at all associated with them. And then the, you know, read the chain rule formula, and then try to use it, and then kind of the more synthetic ones at the end, where you're trying to put a few things together.
>
> *Student*: I think still having a reading section like the very first section where it discusses a little bit about composition, might be useful for those questions, instead of just having no reading section.
>
> *Researcher*: I agree, I agree.
>
> *Author*: So what, what it would be? What do you think it would be? Let me see.

Researcher: …Do we want to have two batteries of questions, one that is contextual and the other is more related to the, to the actual symbols? That might be a good way.

Student: I like that idea. It's first having them look at it as symbols and then translating it into an actual context. I think it's, it's a lot more difficult to apply it to a, to a full context. So I do think it's important that we actually add a question that speaks on that.

This sequence from a calculus team highlights the "transactional" achievement of agency (Biesta & Tedder, 2007). Both author and researcher position the student as authoritative by being solicitous of and responsive to the student's experience with learning the chain rule topic.

Student Agency Through Team Processes

Participation in structured team processes both supported and evidenced student agency. All team members, students included, took turns taking meeting notes, allowing the documentation of team discussions and decisions to reflect the differing focus, perspective, understanding, and voice of the team member whose turn it was. In this excerpt from a linear algebra team, the student offers a clarification of terminology as the team makes decisions about their development process:

I defined what a cycle is right here, but if somebody would like to change what the definition of a cycle is, from—I was explaining that one cycle is that, like, it's written or edited, and then it has gone through the, through the interviews. That is one cycle. And then, and if we edit it again, and then it goes through a cycle, or an interview, that's a second cycle.

The responsibility of note taking served to elicit a glimpse of the STAR student's perceived capacity to take action ("I defined") and their sense of immersion as a team member ("we edit"), empowering them to shape the team's operational environment (Biesta and Tedder, 2007).

Student Agency in Surfacing Conceptions

One of the linear algebra teams had a single student member, (alias) Melody. During the team's work to develop novel questions for the eigenvector section of their textbook, Melody proposed the short-answer question: *Describe the relationship between Eigenvectors and Eigenvalues.* A practice promoted by the researchers within each team was to listen to the question proposer's rationale for their proposed content. Melody explained their inspiration:

I know there's a formula, and I can't name it off the top of my head right now, for the relationship between eigenvectors and eigenvalues. But I sometimes think that it's forgotten, the why behind what is happening. And it's just memorized what you have to do.

Their proposed question differed categorically from those of the author and teachers, each of whose proposed questions in the same topic probed a relationship between an eigenvector and a *matrix*. Furthermore, their verbal justification brought to the team's attention the student experience of fixating on a process without internalizing a relationship. The author on the team suggested that Melody's proposed question begin the question set for the textbook section. After team discussion and revision, the altered form of the question read: *What does it mean for a vector* $\boldsymbol{v}$ *to be an eigenvector of a matrix* $\boldsymbol{A}$*?* Notably, all members of the team continued to refer to this fundamentally altered question as "Melody's question," positioning the student as agent not only of surfacing student conceptions, but as an agent influencing the textbook content that would address those conceptions.

Agency as Social and Ecological Phenomenon

Evidence of the highly contextual nature of the constructed student roles came at the very end of the 2024-25 academic year, when the four separate STAR teams joined together in a week-long workshop in Ann Arbor. The students' roles, previously constructed in the liminal environment of the Zoom meeting and delineated primarily through discourse (or its absence), were given an opportunity for physical embodiment, such as spatial positioning of students with respect to other members of the teams, behaviors and mannerisms accompanying the distribution of tasks, and differentials in the enacted use of students' time and resources and content experts' time and resources. Perhaps most importantly, interpersonal norms were drastically rewritten in the in-person setting. Marked changes in student roles emerged during the workshop, underscoring both the sensitivity of role construction to environmental factors (Biesta and Tedder, 2007) as well as issuing from activities of social engagement (Emirbayer and Mische, 1998).

Implications and Future Work

While the findings presented here are preliminary in nature, early stages of analysis provide evidence that discursive practices positioned students differently across teams. Some students were positioned so that they exerted agency in developing novel content and providing feedback to questions that others produced, whereas others were positioned so that they only provided feedback for questions that others produced. In this latter situation, it appeared as if students' agency was made invisible relative to how the teams were expected to operate.

Limitations of the study include the less consistent attendance of STAR team meetings by students than by other members, inevitably diluting student voice in the process and impacting the construction of students' roles. Furthermore, one might argue that the first act of role construction was the decision by the research team to associate members of the STAR teams with their experience-wise labels (Student, Teacher, Author, Researcher) as they were emplaced in their team environments. However, beyond this structural necessity, specific roles, in the functional sense, were not imposed on members of the teams. The design choice to ask students (relative content novices) to participate as equals alongside authors, teachers, and researchers rather than to replicate classroom positioning (Wagner & Herbel-Eisenmann, 2008) was, to varying extent, a source of tension in the teams.

Our larger investigation of question development heuristics will be informed by what we learn about how teams used student expertise and it will allow us to see how the work in the teams helped subvert the social construction of institutionally-constructed roles of teachers and students. We suspect that in this setting the students' perception of the textbook's authority (Wagner & Herbel-Eisenmann, 2014) is being challenged as well.

Mathematical writing is often portrayed as objective and authorless, yet prior work shows that mathematicians' writing contains nonobjective and authority-related features (Burton & Morgan, 2000). We build on this foundation by analyzing 51,325 single-authored mathematics papers from arXiv, focusing on proofs and surrounding narratives. Using curated dictionaries of hedges and evaluative adjectives and mathematics-specific rules, we document their frequency and explore whether gender and publishing output of the author relate to their use. Preliminary results indicate that both features appear to vary with author characteristics. These findings suggest that linguistic choices in mathematics are tied to identity and status, complicating the myth of purely objective discourse.

Keywords: proof genre, mathematician practice, language analysis

The discourse about mathematical proof and writing has often espoused values of author independency and its absolute nature (Dawkins & Weber, 2017). Davis and Hersh (1998) are often quoted for describing the ideal mathematician's writing as "conceal[ing] any sign that the author or the intended reader is a human being" (p. 2). Yet, others point to the fact that mathematical writing and proof are very much the product of humans both in terms of communication styles (Tanswell & Rittberg, 2020) as well as the infusion of authority markers (Burton & Morgan, 2000). That is, a product created by humans cannot be truly dehumanized. Students come to mathematics with diverse linguistic communication styles and rhetorical patterns, some of which align more closely than others with the conventions of proof and mathematical writing. For those whose styles diverge, there may be additional cognitive load in adapting to the ways of writing that have become normative in mathematics. Thus, it is important to understand the features of mathematical writing beyond the idealistic dehumanized products.

This preliminary work builds on Burton and Morgan's (2000) analysis of mathematicians' papers and interviews, which showed that presenting writing in research articles is not dehumanized. They identified markers of authority, such as positioning something as "obvious" (positive authority) or expressing doubt and qualification (negative authority). They suggested that status shapes their use. For example, women may avoid negative authority because their belonging in the field is less secure. In the 25 years since, little work has examined how author identity relates to linguistic choices in mathematical writing. With large corpora now available, we can investigate such questions at scale. In this preliminary report, we focus on two authority markers (hedging and evaluative language) asking: (1) What forms of hedging and evaluative language appear in proofs and surrounding narratives? (2) How do author characteristics such as gender and publication record relate to their use?

Literature Background on Mathematician Writing

Many scholars have focused on the proof product as a particular genre of writing with many distinct linguistic conventions (e.g., Bowers & Küchle, 2020; Selden & Selden, 2013) with

slightly different norms (Lew and Mejía-Ramos, 2019; 2020) depending on context (e.g., student proof or proof in a research article). If we turn to studies specifically on mathematician writing in publications, we find few studies with the majority in linguistic journals. Studies have explored publication patterns in terms of genders of authors and relationship to journal quality (Mihaljević-Brandt, et al., 2016), revision processes (Andersen et al., 2021; McGrath, 2016), and corpus analyses of particular features such as explanatory language (Mejía-Ramos et al., 2019) and use of imperatives (Tanswell & Inglis, 2023). Furthermore, scholars have established that mathematical research articles are quite distinct from standard forms lacking traditional structures such as "Methods" or "Discussion" (Graves et al., 2013) and features such as establishing research gaps (Graves et al., 2014) as well as different types of phrase frames (e.g., "is [also, fairly] easy to see that", Cunningham, 2017). Mathematics articles can be deconstructed into two types of writing, mathematical (e.g., proofs, definitions) and meta-mathematical (the surrounding narrative) (Kuteeva & McGrath, 2015). Andersen et al. (2021) studied the revision process of a graduate student and his advisor writing an article identifying how the mathematical and meta-mathematical have different roles and ways of justifying and engaging with the reader. This suggests any analysis of research articles should attend to these types of writing separately.

If we turn to our focus, we identified Burton and Morgan (2000), McGrath and Kuteeva (2012) and Alasmary (2022) as empirical studies that address authority in mathematical research articles in ways that are relevant to language choices such as hedging and evaluating. They all support the larger claim that mathematical writing is not purely objective in mathematical or meta-mathematical sections. McGrath and Kuteeva used Hyland's (2005) stance and engagement framework to provide counts of words in a set of 25 research articles finding frequent use of imperatives, infrequent use of hedges, but frequent use of boosters ("really") and attitude devices ("obviously"). Alasmary compared graduate level texts, doctoral dissertations, and a set of published research articles (34 articles) via analysis of four-word lexical bundles finding that participant-oriented (affective and engagement with reader) were found the least, but they were found more often in journal articles than in the dissertation set. Burton and Morgan's (2000) qualitative analysis of 59 articles similarly found establishing positive authority (affective judgments such as "obvious") was more common than negative (e.g., hedging). Paired with interviews, they also provided the conjectures we discussed in the introduction.

Theoretical Orientation

We situate this work as a direct extension of Burton and Morgan (2000), who used Halliday's (1973) systematic-functional grammar to analyze 53 mathematical papers. They considered both ideational (presentation of mathematics) and interpersonal functions (relationships between author, subject, and audience). Our interest lies in the interpersonal function, particularly authority. Burton and Morgan showed how authors positioned themselves with positive or negative authority: deferring to others, signaling incompleteness, or hedging (negative), versus asserting expertise through evaluative words such as clearly or obvious (positive). Such markers disrupt the notion that mathematical writing is purely objective.

Burton and Morgan documented variations across their sets of papers in terms of both positive and negative authority markers. In their sample, men more often used markers of negative authority. They conjectured that, women are positioned as not fully belonging in the field and therefore cannot risk using the traditional language of mathematical power. They further suggest that negative authority provides a risk and that, "risk is, of course, relative to the author's preexisting status within the community" (p. 441). They supported this conjecture with

the fact that their outlier in terms of many positive and negative authority markers was a well-established male mathematician in the field. High-status likely means someone's authority is not going to be questioned regardless of using negative authority or even positive authority (which can be perceived as too self-assured for a novice mathematician.)

Building on this foundation, we focus on two authority markers well-studied in other fields: hedging and evaluative language. Hedges (e.g., might, suggests) serve to "express tentativeness" and to qualify "confidence in the truth of a proposition." (Hyland, 1996, p. 433). They serve as a means of negative authority. The author is claiming they do not have complete knowledge of the field. In contrast, evaluative language (e.g., clear, important) positions the author with positive authority. These are adjectives that serve for to assign a value-judgment (Stojanovic, 2015) on a noun and tend to be gradable (scaled between two polarities). Following Burton and Morgan (2000), we make several conjectures. First, hedging language will be more prominent in papers written by men and well-established mathematicians. Second, evaluative language will vary with experience in the field.

Methods

To explore this question, we make use of SIGMathLing's 1.58 million document data set from arXiv.org (Ginev, 2020) years ranging from 1990 to 2020. As we were interested in automatically extracting proofs, we removed all papers that did not use the LaTeX "proof" environment or which had poorly formatted proof environments, yielding a set of 277k papers. For the scope of this paper, we then narrowed this data set to papers whose subject area was research mathematics, excluding papers whose primary subject was not prefixed with "math" and papers whose subjects were in computer science or philosophy. We also filtered to papers that were single authored with identifiable gender in a final dataset of 51,325 papers. To identify gender, we ran author first-names through gender-guesser.py, a python library based on a list of 40k names alongside genders collected by Jörg Michael (2007). We note the limitations of this binary approach and making such strong inferences from names. We then organized authors based on how many papers they had on arXiv into deciles to document output as a proxy for establishment in the field of mathematics. The lowest decile was labeled "Vlow," the next two as "low," deciles four through seven as "mid," deciles eight and nine as "high" and the 10th decile as "Vhigh." For each paper, we then subdivided the portions into "proof" and "nonproof" based on the usage of the proof environment in LaTeX. We also removed any mathematical symbols and replaced them with the generic "formula."

To measure "hedging" and "evaluative" language, we began with existing dictionaries from other projects (Ulinski and Hirschberg, 2019 and Rockladge, et al. 2018, respectively). Initially, we used these sets of words to calculate their frequencies in the entire set of mathematics papers. From this process, it became apparent that words that may have served as hedges or evaluative language in non-mathematical contexts were not always adaptable directly. For example, "estimate" may be a hedge in some contexts, but in mathematics papers was often referring to a precise output of an algorithm. Similarly, a word such as "ideal" would be an evaluative adjective in most settings but is more frequently an algebraic structure in mathematics papers. This necessitated a careful look at each hedge and evaluative adjective. For each word, we selected a sample of papers that used the word to evaluate the contexts. The research team then indicated if the usage seemed to be meeting the definition of hedge or if it had a more precise mathematical meaning. This led to developing and testing several rules. For example, "most" was identified as a hedge when it was part of the phrase "most of" rather than in contexts where

it was describing something precise. In other cases, simple rules did not function well such as was the case for "may." When "may" operates like "might" it is a hedge. Yet, it commonly operated like "can" where something is mathematically permissible. For this hedge, we used semantic embedding to encode the words around each usage in a vector and to compare its distance to the average vectors of "might" and "can". If "may" was much closer to might, it was maintained as a hedge. Presently, we are in the middle of this process reporting a set of 13 hedges and 12 evaluative adjectives (see Results) that we are successfully picking up as intended in our corpora. For each of the hedges and evaluative adjectives, we counted their frequency for each paper in the proof section and the narrative section. We also calculated relative frequency by dividing the frequencies by the total number of words in each respective section. Each of these are treated as outcome variables where gender and publication level were predictor variables. For the scope of these preliminary reports, we provide descriptive statistics and a preliminary logistic regression on the binary of existences of hedging or evaluative adjectives.

Results

In our analysis of 51,325 papers, we found that 66.8% of them had at least one hedge (of our thirteen) in the narrative sections, and 8.6% of the papers had at least one hedge in the proof sections. We found that 88.3% had evaluative adjectives (of our twelve), and 62.7% had at least one evaluative adjective in their proof sections. Figure 1 provides counts of the evaluative adjectives and hedges (meeting our rule requirements) from the analysis.

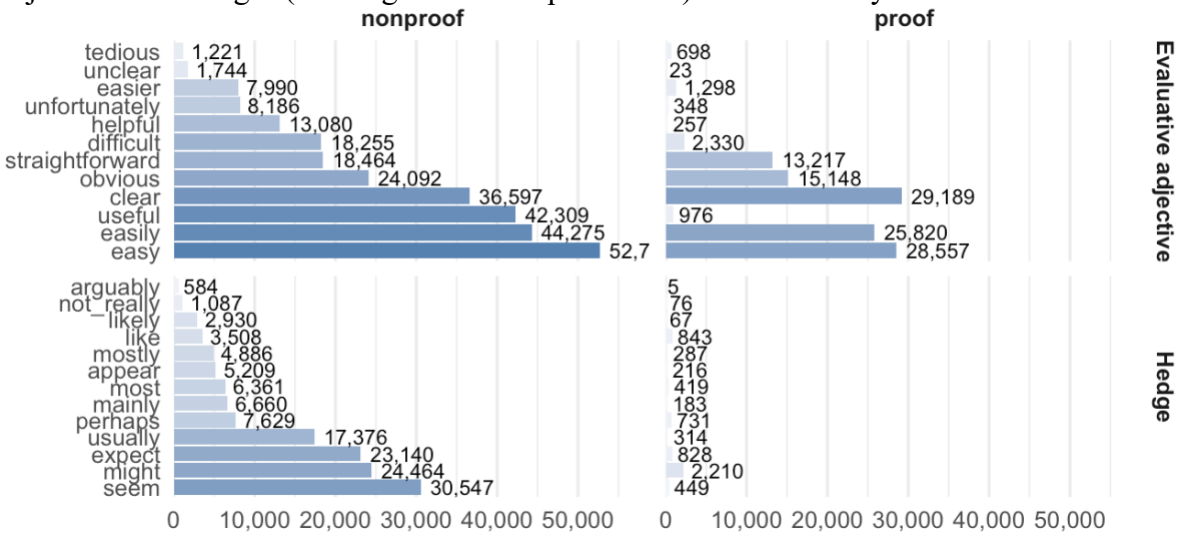

Figure 1. Frequencies of a Preliminary Set of Hedges and Evaluative Adjectives

In Figure 2, we present boxplots representing the relative hedge use (relative to wordcount) broken out by gender and then publishing category for non-proofs. Note that the proof section has so infrequent hedges that these are not boxplots but outliers. In Figure 3, we provide the boxplots for Evaluative Adjectives Relative Frequencies in both proof sections and on proof sections.

Presently, we have run only preliminary models looking at the relationship between gender, publishing output, and the focal language. For each proof and each nonproof, we gave a set of binary variables (has hedge; has evaluative adjective). We found that gender and publishing output were significantly (at the p=0.05 level) related to whether we identified evaluative adjectives in the mathematical (proof) and metamathematical (non-proof) parts of a paper. We

found that both were also predictive of the existence of hedge language in the metamathematical (non-proof) section, but not significantly predictive of hedge language in the mathematical (proof) section. To provide a brief illustration, we share the results for existence of evaluative language in proof whose equation is: $\text{odds}(eval)=1.227\times(1.248)^{GenderMale}\times(1.039)^{publishing_group}$. According to this model, a woman who is in a low output publishing group would be estimated to have a probability of 56% of using evaluative language in the proofs of her paper. A man in the same publishing group would be estimated at 61%. At the other end, a woman in the high publishing group would have a 59.8% chance of using evaluative language in their proof while their male counterpart would have a probability of 65%.

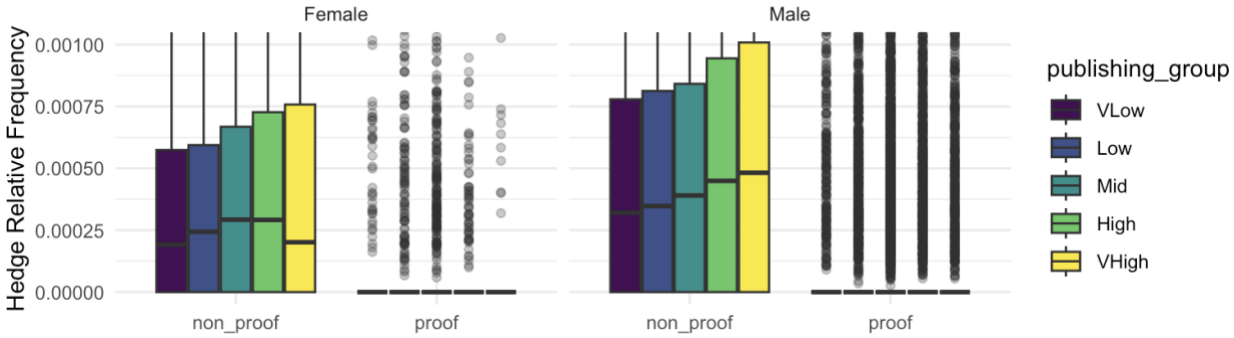

Figure 2. Relative Frequency of Hedges Across Gender and Publication Output Group Narrative Sections.

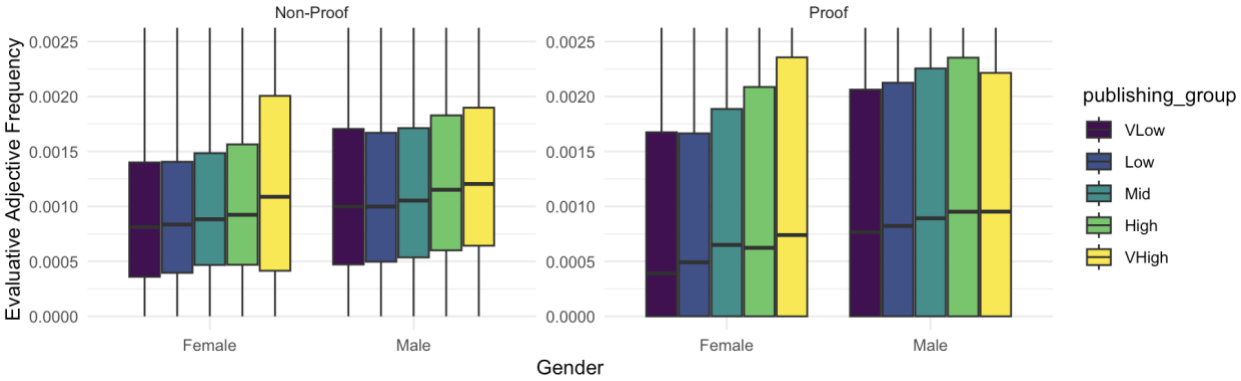

Figure 3. Relative Frequency of Evaluative Adjectives Across Gender and Publication Output Group in Narrative (left) and Proofs (right).

Preliminary Nature of Proposal and Discussion

In this proposal, we are presenting an in-progress analysis of a large corpus of mathematician writing. Our goal was to directly build on Burton and Morgan's (2000) results and conjectures about authority in mathematical writing. We found that the types of markers mentioned by Burton and Morgan did appear in the larger data sets at rates high enough to conduct further analysis. Furthermore, some of their conjectures about status in the field are proving viable. Currently, we have only processed a total of 25 words for this analysis. We intend to continue this process and gather feedback from the RUME audience about how we might consider other factors related to status and address authority markers beyond the set of hedges and evaluative adjectives. We believe the community will find the methods involved interesting. Furthermore, as both scholars and instructors, these results can challenge how we discuss proof and its values based on the reality of how proofs are communicated in published journals.

"I" Find it Difficult Because...: Identifying What Features Students Report as Affecting Difficulty to Understand a Proof

Lino Guajardo
Central Michigan University

Kristen Lew
Texas State University

The student perspective provides valuable information into what students find to be difficult when reading proof. Such information can be used to productively support students as they face these difficulties. In this preliminary report, we investigate what students report as contributing factors of how difficult a proof is to understand. For this report, we focus on data regarding two proofs from the introduction to proof setting. Our findings indicate that the density and width of a proof are key contributors towards the difficulty rating given to the proofs.

Keywords: Reading proof, student perspective, difficulty

Scholars have identified various ways students encounter difficulties with proof (Moore, 1994; Selden & Selden, 2008), typically focusing on students constructing or validating proofs. Meanwhile, understanding a written mathematical proof is also a difficult task. Proofs are full of challenging features, such as the level of abstractness (Rowland, 2001; Weber, 2004) and various writing norms and conventions (Dawkins & Weber, 2014; Lew & Mejia-Ramos, 2019; Melhuish et al., 2025). These norms and conventions include minimizing unnecessary warrants (Dawkins & Weber, 2017, Selden & Selden, 2003), excluding references to people (Dawkins & Weber, 2017, Melhuish et al., 2025), and following the rules of academic language writing (Lew & Mejia-Ramos, 2019). Overall, scholars have identified that students have difficulty with the abstract nature of proof (Alcock, 2010; Weber, 2004), with the complexity of proof (Alcock, 2010), in understanding the mathematical content (Moore, 1994; Selden & Selden, 2008), and having to make implicit warrants and information explicit (Samkoff & Weber, 2015). All of which is taken from an expert's perspective. Though, one may wonder what do students find to be difficult in understanding proof and what impacts this perception of difficulty?

Few existing studies investigate students' perspectives in the reading and understanding of proof (Guajardo & Lew, 2024; Guajardo, Lew, & Melhuish, 2025), particularly regarding what students find difficult in understanding proof (Selden & Selden, 2008). We argue that knowledge of students' perspectives on proof and proving can provide valuable insight into both the teaching and learning of mathematical proof. Namely with students' perspectives, researchers can explore student interactions with proof with greater depth. Additionally, instructors can leverage findings about student perspectives to better understand what students take from class and how to adapt instruction to build on to students' perspectives and existing knowledge base.

In this paper, we offer some preliminary insight into what students find to be difficult in understanding proof. The study presented is part of a larger dissertation study, focused on understanding students' perspectives about various aspects of proof. Here, we present a subset of the data to answer the research question: What do students indicate as factors that contribute towards a higher rating of difficulty to understand a proof?

Theoretical Framing

To situate our study, we conceptualize our thinking of abstraction and complexity of proofs. For abstraction, we take on Hazzan and Zazkis' (2005) three levels of abstraction:

> (a) abstraction level as the quality of the relationships between the object of thought and the thinking person, (b) abstraction level as reflection of the process–object duality, and (c) abstraction level as the degree of complexity of the concept of thought. (p. 103)

In using these levels of abstraction, we consider abstraction to be an individual's perception of the separation between the concept and a concrete model. Separations may be perceived as larger due to the student having less experience with the concept (first level), having a process conception (second level; Dubinsky, 1991), or in dealing with a compounded concept (third degree). With this definition, we can identify how participants view the abstract nature of the concepts throughout the study by considering how they talk about their experiences with the concept, the utility of the concept, and any compounded nature of the concepts.

In terms of complexity, we refer to complexity here differently than Hazzan and Zazkis' third level of abstraction above. For complexity, we use Hanna's (2014) discussion of the width of a proof, "the number of distinct ideas one has to keep in mind" (p. 31). We expand this idea by including the number of moving pieces in a proof one must keep track of (high cognitive load) rather than just the memorization of key ideas or crucial steps to construct a proof.

Methods

Eight undergraduate students, who completed an introduction to proof (ITP) course the semester prior, participated in this study. Table 1 provides participant demographic information.

Table 1. Participant Information

Participant	Race/Ethnicity	Gender	Grade Received in ITP
Adrian	White or Caucasian	Non-binary	B
Claire	White or Caucasian	Female	B
Erik	White or Caucasian	Transman	A
KTRM	Latin/Hispanic	Female	C
Marie	Latin/Hispanic	Female	A
Olivia	Mixed Race	Female	B
Tifanni	Latin/Hispanic	Female	A
Zeus	Latin/Hispanic	Male	B

Participants met with the first author for seven semi-structured interviews. Four of the interviews were task-based interviews where participants read a provided proof (GCD, Partition, Function, and Cardinality) and attempted to understand it to the best of their ability. Participants then answered a series of questions, some of which asked how difficult the proof was. For this analysis, we consider participants' responses to the following questions from the task-based interviews: (a) How well do you feel like you understand this proof?, (b) If you could [rate] this proof in difficulty from 1-10 (ten being very difficult, 1 being not difficult at all), how would you [rate] this proof?, and (c) If given the chance to rewrite the proof, would you change anything about it? We also consider data from the exit interview which included discussion on what participants find to be difficult with understanding proof and reflections on the ratings they gave

the proofs throughout the study. For this report, we focus on the two proofs rated most difficult to understand: the Cardinality and the Partition proofs (see Table 2 for the theorem statements).

Table 2. Theorem statements for Cardinality and Partition proofs

Proof	Theorem
Cardinality	The sets $\mathcal{P}(\mathbb{N})$ and $\mathbb{R}$ have the same cardinality.
Partition	Suppose R is an equivalence relation on a set A. Then the set $\{[a] \mid a \in A\}$ of equivalence classes of R forms a partition of A.

To determine the two highest rated proofs, we conducted a points allocation method of ranking based on participants individual rating of each proof: 4 points was awarded to the highest rated proof (most difficult) and 1 point was awarded to the lowest rated proof (least difficult). The Cardinality proof was rated highest by the participants, and the Partition proof was rated second highest. Deductive coding was applied to data from the relevant task-based and exit interviews. The data relevant to the Cardinality proof were coded independently by both authors. Coding was discussed to resolve any discrepancies and reach agreement. Data relevant to the Partition proof was then split equally amongst both authors and were independently coded.

Six codes related to features of proof identified through the larger dissertation study (Guajardo, 2025) were used: abstractness, density, length, width, and writing. Using our definition of abstraction from Hazzan and Zazkis (2005), abstractness was coded when participants explicitly voiced how abstract the proof was or when they discussed visualizing the content in a more concrete way. Density focuses on participants discussing the amount of information hidden from the reader, to which they must deduce on their own. Length was coded when participants referenced the length of the proof as contributing towards the difficulty. For width, we used our definition that was adapted from Hanna's (2014) discussion of width to code when participants were stating difficulty due to having to keep multiple distinct ideas in mind as they were reading. Lastly, the writing code refers to participants indicating the language, notation, or structure of the proof caused difficulties.

Results

Participants considered features of proofs that contributed to the difficulty (or ease) in understanding a given proof. For example, a feature of a proof could be the proof method used. Table 3 shows the features we identified for each participant as contributing towards the difficulty of the proof. When discussing the features of the proofs that affected their difficulty ratings, participants did so independently of other proofs (bolded in Table 3; typically during the task-based interview) and comparatively between proofs (standard font in Table 3; typically during the exit interview). When talking about the features of proof independently of other proofs, participants expressed abstractness, density, length, width, and writing as playing a role in the difficulty rating of the two proofs. While nearly every feature was mentioned for each proof (Table 3), we focus on the density and width features due to length restrictions. Participants primarily expressed density and width as key factors for the difficulty of these two proofs – both in their discussions of the proof individually and their comparisons across proofs.

Table 3. Features discussed by Participants. Bold font indicates feature was discussed individually. Standard font indicates feature was discussed only comparatively. Symbols +, - indicate if that feature was comparatively reported to increase or decrease the difficulty (respectively).

Proof	Features of Proof					
	Abstractness	Density	Length	Line Structure	Width	Writing
Cardinality	**Erik Zeus -** + Adrian + Claire +	**Adrian Claire** + **Marie** + **Olivia Tifanni**		KTRM +	**Adrian** + **Erik +** **KTRM + Marie + Zeus** Claire +	**Marie** Adrian -
Partition	**Adrian Zeus** + Olivia -	**Adrian Claire Olivia Tifanni - Zeus** +	Erik -	**Olivia** KTRM -	**Claire** KTRM - Marie - +	**Adrian Claire**

For the cardinality proof, most participants indicated density and width played a role in their reasoning for why the proof was difficult to understand. For example, with density participants difficulties with the proof were due to having to unpack a lot of information. Claire explained her rating the proof as having a 4 out of 10 difficulty because the "super specific things of like *why* f, OK, I don't really know [emphasis added]." In this quote, Claire is focusing on the line-by-line arguments made in the proof and unpacking why these arguments are being made. For width, participants expressed having to handle a large quantity of information. Marie expressed the proof was not easy to understand because the proof "gives us like 4 variables in total. The more variables there are, the harder it is to mentally keep track. So even though it's in front of you, that can just be a little harder to keep up with." Here, Marie is having difficulty keeping up with the information presented in the proof. All other features were discussed by at most two participants.

For the partition proof, most participants indicated that density played a role in their reasoning for why the proof was difficult to understand. Similar to their comments regarding the Cardinality proof, participants expressed having to unpack or link information. Olivia explained that she gave the Partition a rating of 9 (and not lower) because she does not "understanding why they're saying what they're saying. Like, at least, when I'm trying to prove an if-then I know what it's supposed to look like. […] with this I'm like, what are we even trying to do here?" Similar to Claire above, Olivia is focusing on having to unpack a lot of information in the proof. As with the cardinality proof, all other features were discussed by at most two participants. This indicates that density and width play a larger role in how participants discuss the difficulty of these proofs.

When looking at how participants compared between proofs, the width of the Cardinality proof was used as justification for a higher difficulty rating than other proofs. In comparing the Cardinality proof to another proof in the study, Adrian explained the Cardinality proof was harder because "it has a lot more stuff […] it's got these different functions and all these different sets that this other one doesn't have." We attribute Adrian's discussion of "a lot more stuff" to having to keep up with more concepts, increasing the width of the proof. Most other features were not mentioned by many of the participants for either proof in the exit interviews. When they were discussed regarding the Cardinality proof, the features were almost exclusively used to explain why the proof was more difficult to understand than others. Participants did not

frequently compare the Partition proof to others and when they did, most participants expressed which features made the proof easier to understand than the others. The participants commonly compared the Partition proof to the Cardinality proof as they were typically rated similarly (either hardest to understand or second hardest to understand).

Discussion and Next Steps

In this paper, we discussed the different ways in which undergraduate students rate proofs in difficulty to understand. Participants expressed various features of the proofs as reasons for their ratings. In our data, the features density and width play a critical role in determining how difficult it is to understand these two proofs. This supports the existing literature that suggests that students have difficulty with unpacking information (Samkoff & Weber, 2015) and have trouble with the amount of information that can be present in a proof (Alcock, 2010), but more importantly contributes student voices to the discussion. In particular, students may use these features to compare between proofs: considering which proofs are denser or wider to determine the difficulty of understanding a proof.

Overall, these preliminary findings reveal the complexities of how difficult a proof is to understand. Additionally, it is important to recognize that these features of proof identified by the participants are inherent in proof and cannot easily be hidden or removed. Rather, it is important for researchers and instructors to work toward better supporting their students. One way this may be achieved is by helping students use strategies to overcome these difficulties caused by the features of proof. Guajardo et al. (2025) describe proof comprehension strategies most used by undergraduate students as they attempted to understand proofs. This repertoire of comprehension strategies, paired with our findings on students' perspectives on difficulties, can be used to help students mitigate the difficulties caused by the features and better comprehend the proofs. More research is needed to better understand how to support students in mitigating these difficulties.

Next steps for this study are to continue analysis of the proofs and difficulties identified by participants. Important factors for these participants were not only features as discussed above, but also non-features (aspects of the reader that impact the difficulty rating of the proofs). Two codes were identified through the data that represent non-features; effort to understand and current understanding. With effort to understand, participants reflected on their actions they did or the actions it would take to understand the proof. For their current understanding, participants reflected on how they viewed their own skills to understand (self-efficacy) or their understanding of the content of the proof. From a brief initial analysis, a non-feature that participants find to be a key factor in the ratings give not the proofs is their own understanding of mathematical concepts and arguments in the proofs.

Preliminary Nature

Analysis is still ongoing and theorical framing is still being developed to help situate the discussion of the results. As we discussed above, there are more factors to the difficulty attributed to a proof than just features of the proofs themselves. We welcome any comments and suggestions in moving forward with the analysis of non-features or in any theoretical components that could be productive to consider for our study. In particular, are there any socio-cultural or cognitive theories that could help in analyzing and situating the non-features?

Acknowledgments

The data collection for this work was supported by Texas State University's Graduate College Doctoral Research Support Fellowship. The analysis and write up of the original dissertation data was supported by the National Academy of Education's Spencer Dissertation Fellowship.

Using Large Language Models for Qualitative Coding of Structured Data on Post COVID Research Based Instructional Strategies

Jacob Lineberry
Virginia Tech

Estrella Johnson
Virginia Tech

Naneh Apkarian
San Diego State University

In the spring of 2025, introductory Physics, Calculus, and Chemistry instructors were surveyed about their usage of active learning techniques and use of Research Based Instructional Strategies. Using open-source large language models running on consumer hardware, responses to open ended survey items data were analyzed to better understand the usage of specific strategies during and after the Pandemic Response Teaching period resulting from the COVID-19 pandemic, as well as for reasons how and why instructors adopted, maintained, or stopped RBIS. While the large language models were able to apply qualitative codes to the data, their effectiveness was significantly varied based on the dataset, initial prompt, large language model used, code specificity, and code prevalence.

Keywords: Large language models, Qualitative Analysis, Research Based Instructional Strategies, Pandemic response teaching

In 2025, we conducted a national survey of instructors of undergraduate chemistry, mathematics, and physics courses. The timing and selection of instructors were designed to understand if there were any lasting changes to how these courses are taught following the COVID-19 pandemic. In part, this survey asked instructors of first year Calculus, Chemistry, and Physics about their awareness and use of research based instructional strategies (RBIS), while providing an opportunity for respondents to explain how and why they use (or do not use) RBIS. The nature of this data offered us information into instructional trends and provided an opportunity to experiment with large language models in qualitative analysis.

AI, particularly in the form of large language models (LLMs), has become more common and powerful. Within education research, these tools have been applied to various forms of qualitative analysis, with varied success. However, their use has raised important questions about the nature of qualitative research, privacy, bias, and transparency. We attempted to address several of these questions by using an open source, locally run LLM to complete the first two steps of Braun and Clarke's (2012) thematic analysis with a graduate student researcher.

Here, we address two research questions. First, to what extent, and why, are instructors in first year STEM courses using, or shifting away from RBIS following the Pandemic Response Teaching (PRT) period? Second, to what extent can an open-source, locally hosted LLM effectively code a highly structured dataset using Braun and Clarke's thematic analysis?

Background Literature and Perspective

By comparing survey responses from a 2019 survey and this one from 2025, Apkarian & Johnson (2026) investigated the extent to which use of class-time and instructional practices changed following the COVID-19 pandemic. Analysis of that quantitative data revealed, overall, no significant changes in reports of how class time is spent with regards to listening to the instructor lecture or solve problems, working individually, working in small groups, and engaging in whole class discussion. Additionally, while there was increased usage of online office hours, supplemental videos, and recorded lectures, starting during PRT and continuing afterward, there were no major shifts to in-class instructional practices (e.g., think pair share,

clickers). Our analysis here of the open-ended survey response data seeks to provide additional nuance to the quantitative analysis completed by Apkarian & Johnson (2026).

Traditionally, analyzing open ended survey responses is carried out with any variety of qualitative analysis methods by an individual or a team. For example, thematic analysis, as developed by Braun and Clarke (2012), prioritizes six key steps, with each working towards identifying overarching themes across a dataset. By carrying out these steps, researchers can identify broader patterns key to understanding how, when, and why instructors prioritize and implement RBIS. That thematic analysis is a well-defined, commonly used approach to analyzing a well-structured dataset makes it both a practical choice for researchers and potentially a good fit for data analysis carried out by LLMs.

The robust and diverse capabilities of LLMs makes them increasingly more prevalent, including in qualitative research. Researchers have long used stochastic models for natural language processing (Chen at al., 2018; Gamieldien et al., 2023; Li et al., 2021; Rietz et al., 2021). While use of LLMs in qualitative research is still new, work on applying them within new methodologies and frameworks is growing rapidly (Naeem et al., 2018; Naeem et al., 2023; Xiao et al., 2023; Zhang et al., 2025). However, qualitative researchers have shown reasonable skepticism about their use. Some studies indicate researchers are generally concerned about hallucinations (when a model invents data and "facts"), data privacy, transparency, and explainability (Schroeder et al., 2025; Feuston & Brubaker, 2021; Springer & Whittaker, 2020; Zhang et al., 2025). Furthermore, results are generally mixed in using large language models for qualitative research. Many studies find significant variation in performance based on prompts used (Wang et al., 2024; Zamfirescu-Pereira et al. 2023), inductive or deductive methods (Bijker et al., 2024; Siiman et al., 2023), and researcher knowledge of LLMs (Chen et al., 2018; Zamfirescu-Pereira et al, 2023; Zhang et al., 2025).

Even with these challenges, LLMs can be a powerful resource. Many highlight the potential for LLMs to serve as an additional coder, where a human researcher and LLM each code the data and compare (Bijker et al., 2024). Other uses include academic writing (Tu et al., 2024), developing a codebook (Bijker et al., 2024), coding data (Marathe & Toyama, 2018; Tai et al., 2024), identifying themes (Castellanos et al., 2025), and supporting new researchers in developing qualitative analysis skills (Gao et al., 2024). In addition, several processes have been developed for using LLMs, usually ChatGPT, for qualitative analysis, like thematic analysis (Dai et al., 2023; De Paoli, 2024; Naeem et al., 2018; Naeem et al., 2023; Zhang et al., 2025).

Methods

The 2025 survey was sent to roughly 17,000 names, the same roster that was used for the 2019 survey. The goal was to capture those who taught before and after the pandemic-induced disruption from 2020-2023. To be eligible, instructors must have taught one of the target introductory courses in the 2023-24 and/or 2024-25 academic year. In total, 933 participants provided usable responses to our survey: 339 chemistry (99 new; 240 repeaters), 279 mathematics (112 new; 167 repeaters), and 315 physics (86 new; 229 repeaters) instructors. Included in the 2025 survey were the following free response questions:

1. What, if any, instructional practices did you start using during the pandemic response period (roughly March 2020-June 2022), that you had not used previously? Include anything that you tried, even if you did not maintain that practice throughout or afterward.
2. Of the instructional practices you mentioned in the previous question, which (if any) do you continue to use?

3. You may use the space below to add any additional comments about your experiences during the pandemic response period, if you wish.
4. You may use the space below for any additional comments about the context and climate of your department, if you wish.

Anonymized data was stored in a Google Sheet. Of the 933 participants, a random sample of 450 were selected to have their responses coded manually by a human coder (the first author). Instructor responses were considered holistically, even if answers to any of the four questions above were missing. Then, the data was coded using three different large language models: Gemma3:12b, Qwen3:14b, and Deepseek-R1:14b. The large language models were run locally using the Python programming language and the Ollama software package. All models were run on the researcher's consumer desktop with an AMD RX 6900 XT GPU. Each model was run using default Ollama settings, and data was input as 30 sample chunks to ensure the context window of each model was not exceeded. The prompt used was carefully designed using common prompt engineering techniques outlined in the literature and was revised 3 times before the final implementation. The prompt carefully defines the role of the LLM, explains the task in multiple ways, and provides an output template. However, the authors specifically did not extensively tune the initial prompt or implement specific techniques to improve performance.

Each run of the models output a text file consisting of codes for each row of data. This text file was then converted to a CSV using Python. This conversion expected consistent output from the LLMs and is likely undercounting codes from the models. If the model provided a synonymous code, instead of a code from the codebook, we would not count that towards our results. Afterwards, Cohen's Kappa and Krippendorff's Alpha were calculated using Python for each run, and an average for each model was calculated for each code. After this programming pipeline was created, we revised our initial prompt to better understand why instructors implemented, maintained, or moved away from RBIS in their instruction. This prompt used a "oneshot" technique, providing examples and non-examples for how the data should be coded. Only the LLMs coded the dataset for this research question and analysis is still ongoing.

Results and Discussion

Each LLM coded the entire dataset, while the first author only coded a random sample of responses from 450 instructors. We present the percentage of rows coded with each code in table 1. Each LLM coded the data 3 times, and an average for each code is reported. Since each row of data could have more than one code, the total percent frequency adds to more than 100%.

Table 1. Percent frequency of each code by "coder"

Code	Deepseek-R1	Qwen3	Gemma3	Human
Adapted existing strategies to Pandemic	14.29%	21.33%	40.09%	1.33%
Alternative Exams	1.61%	3.00%	3.47%	2.67%
Did not use RBIS	0.75%	1.46%	0.43%	0.22%
Experimented	1.57%	2.57%	15.18%	0.22%
Flipped	11.08%	10.86%	9.54%	8.22%
Group Work	17.97%	20.40%	19.08%	9.11%
Increase in tech use	14.22%	20.04%	9.50%	5.11%
Inquiry/Modeling	6.72%	4.86%	3.14%	1.11%
Lab Kits	1.04%	0.54%	1.32%	0.89%

Learning Assistants/Peer to Peer Teaching	0.82%	2.57%	1.68%	1.33%
None	15.93%	31.80%	30.01%	17.11%
Online Assignments	5.72%	8.54%	18.65%	7.56%
Online discussion tools	1.04%	2.64%	7.18%	1.78%
Online Exams/Proctoring	3.39%	6.47%	8.40%	7.78%
Online Lecture	8.82%	9.97%	24.01%	12.22%
Online Office Hours	4.22%	8.29%	9.72%	8.89%
Online simulations	2.00%	6.15%	6.36%	7.56%
Polling/Clicker	6.29%	5.93%	7.43%	4.44%
Posting resources online	1.04%	6.04%	10.97%	5.78%
Recording/Posting Videos	23.94%	25.76%	27.05%	26.22%
Reflection/Exam Wrappers	1.04%	0.39%	2.29%	0.44%
Used new RBIS	5.79%	1.54%	0.32%	0.00%

We calculated Cohen's Kappa and Krippendorff's Alpha for each of the codes, comparing the interrater reliability between each LLM and the human coder (Table 2). While the averages for Kappa and Alpha were between 0.27 and 0.47, we see significant differences in interrater reliability between various codes and across models. Qwen3 had the highest interrater reliability, while Deepseek-R1 had the lowest. Furthermore, we see a significant range in potential Kappa and Alpha values. For example, when using Qwen3, the codes Online Office Hours and Recording/Posting Videos had a Kappa and Alpha value above 0.815, while the codes Experimented and Did Not Use RBIS had a Kappa and Alpha value of approximately 0.

Table 2. Average Cohen's Kappa and Krippendorff's Alpha for each LLM across three runs

Model	Kappa	Alpha
Deepseek-R1	0.285	0.278
Qwen3	0.463	0.454
Gemma3	0.363	0.344

The prevalence of "online" codes aligns with instructors of these introductory courses transitioning from in-person lecture to Zoom. Additionally, we see fewer codes related to the instructional features of the class, such as "group work," "flipped," "polling/clicker," and "learning assistants/peer to peer teaching" than for "recording/posting videos." These relative prevalence indicators broadly match the quantitative analysis from Apkarian & Johnson (2026).

The AI framework developed was meant to be a proof of concept, involving as little programming or AI specific knowledge as possible. This simplicity, coupled with less than perfect human coding (i.e., data was first coded by a graduate student new to qualitative analysis with no second coder, the initial codebook was quite large) could have resulted in specific struggles for the LLM to code the data. However, overall, the models did relatively well with those codes used frequently by the human coder. When removing codes that were used fewer than 10 times by the first author, we find Kappa increased to 0.362, 0.576, and 0.508 for Deepseek, Qwen, and Gemma respectively. In addition to challenges around infrequently used codes, the LLMs struggled to apply the code "None." The "None" code was used relatively frequently by the human coder, 77 times, but was consistently the worst for Kappa and Alpha.

While the interrater agreement between a human coder and the LLMs used varied greatly in the first two phases of Braun and Clarke's Thematic Analysis, our data and learnings suggest, with software and hardware adjustments and technological improvements, open source, locally hosted LLMs can provide valuable support to a qualitative researcher and should be further explored.

Conclusions

We are not arguing for a total reliance on AI or LLMs for qualitative research (Christou, 2023), especially given our interrater reliability results. However, to completely avoid LLMs is likely misguided. Qualitative research has used stochastic tools (Tausczik & Pennebaker, 2010), natural language processing (Bryda & Sadowski, 2024; Gamieldien et al., 2023), and digital tools (MaxQDA, nVivo, etc.) for a long time now. However, LLMs raise questions about bias, accuracy, transparency, and privacy to address within the context of qualitative research.

With regards to questions about bias (Barany et al., 2024; Chen et al., 2018; Pangakis et al., 2023; Schroeder et al., 2025), by relying on open-source models that reveal their weights, training data, and more, we can better understand what potential biases may exist within the model and its training data. With regards to accuracy concerns, many studies have found a benefit and necessity for human checks and interaction with any AI tool in qualitative analysis (Feuston & Brubaker, 2021; Pangakis et al., 2023). For our work, instances of inaccuracy were mostly the model incorrectly assuming the data contained more information than was actually present and thus applying a code where one did not belong. We believe we can minimize this by improving prompts with one-shot techniques, averaging several runs, and other formatting techniques. With regards to concerns about data privacy (Byun, 2023; Schroeder et al., 2025), the use of local models avoids sharing IRB protected data with private companies who are explicit about their use and storage of user chats (e.g., chatGPT). Finally, with regards to transparency concerns, using an open source model allows researchers to both understand and choose the model best suited to their work, as well as better communicate to others what is happening "behind the scenes" with the models used.

Preliminary Nature of this Report

This work is still preliminary, as we believe we can further tune our use of LLMs in thematic analysis to better understand our dataset. While the models struggled with certain types of codes, our analysis suggested a second phase of coding focused on why instructors implemented, maintained, or moved away from RBIS in their instruction. We have completed an initial round of coding using the LLM pipeline, but need to compare and validate with a human coder to determine how well LLM's handled a narrower codebook consisting of more nuanced codes.

Daily Affirmations: Strengthening Marginalized Student Identity in First Year College Calculus Courses

Sam Macdonald
University of Nebraska—Lincoln

This study investigates how marginalized students experienced affirmation of their mathematical identities in first-year calculus. Thematic analysis revealed thirteen forms of identity affirmation, clustered into internal (understanding and utility) and external (peer instruction, community, instructor recognition) categories. While understanding and utility were universally affirming, most affirmations were socially mediated. Findings highlight the critical role of community and instructional practices in shaping identity, suggesting that affirming environments are essential for supporting persistence in STEM.

Keywords: mathematical identity, identity affirmation, calculus

Introductory courses disproportionately drive minoritized students out of STEM pathways (Ellis et al., 2016; Hatfield, 2022). This attrition is especially troubling given the persistent underrepresentation of these students in postsecondary mathematics and STEM fields more broadly (Greene et al., 2008; Riegle-Crumb et al., 2019). Understanding the mechanisms by which early mathematics courses contribute to inequitable outcomes remains a critical concern for both researchers and practitioners.

One promising lens for examining this issue is that of student identity. Identity shapes how students perceive themselves and their relationship with mathematics and is increasingly recognized as a central construct in mathematics education research (Darragh, 2016; Fellus, 2019; Li et al., 2020; Radović et al., 2018; Rodriguez et al., 2018). How students come to see themselves—such as whether or not they identify as "math people"—has been shown to strongly influence their success, persistence, and long-term engagement in mathematics (Miller-Cotto & Lewis, 2020). As these authors argued, this self-perception is not merely internal but is deeply intertwined with the social and cultural contexts of learning, shaping how students engage with mathematical tasks, how they respond to challenges, and how motivated they feel to continue in mathematics.

At the same time, research has highlighted how mathematics learning environments can marginalize students. Solomon (2007), for instance, documented how students often experience disconnection from the mathematical community even when they retain confidence in their abilities. Such findings, along with results about the impact of mathematics learning environments on learning and community (Leyva et al, 2020; Oppland-Cordell & Martin, 2015) suggest that affirming and supporting students' mathematical identities is essential, particularly for those who are under-represented or marginalized in STEM.

This paper reports on an investigation into what was specifically affirming to marginalized students' identities in first-year college calculus courses. By centering student perspectives, we aim to illuminate practices and experiences that strengthen students' sense of belonging and mathematical identity, offering insight into how introductory courses might be reimagined as spaces of affirmation rather than exclusion.

Literature Review & Research Questions

An extensive body of research has examined identity in mathematics and STEM education, and consequently, the conceptual and methodological foundations of this work are varied. Simpson and Bouhafa (2020), in their synthesis of empirical research on identity across STEM published between 2000–2018, highlighted both the increasing prominence of identity as a construct and the persistent challenges in defining and operationalizing it. They note that while identity has been shown to be a powerful lens for understanding persistence and participation in STEM, the literature is fragmented in how it conceptualizes identity and how its dimensions are applied in research.

Radović et al. (2018) further emphasize this complexity, identifying five main categories through which the literature has operationalized identity. The most prominent approach conceptualizes identity as narratives, drawing on Sfard and Prusak's (2005) framework of identity as a collection of stories told by the individual and by others about them. This narrative lens has been especially influential in studies that seek to capture the lived experiences of students navigating mathematics learning. However, as Radović et al. argue, a persistent challenge lies in the relationship between the defining features of identity (e.g., recognition, positioning, affect, agency) and their operationalization. Identity research often combines multiple dimensions, but the lack of clarity about how these interact leaves the field with conceptual fuzziness and limited cumulative insight.

Another pattern in the existing literature is a tendency to emphasize the negative aspects of identity—how deficit narratives, marginalization, and exclusionary practices undermine students' sense of belonging and persistence in mathematics (Nasir & Cobb, 2007; Solomon, 2008). *While this body of work is critical in highlighting systemic inequities, it also creates a gap*: less attention has been paid to the affirming aspects of identity, or to the pedagogical practices that can strengthen students' mathematical identities in positive and sustaining ways.

Taken together, the gaps in the literature suggest an urgent need for research that attends to affirming aspects of identity in mathematics and connects pedagogical practice directly to identity formation. *This study seeks to address these absences by examining the specific ways marginalized students experience affirmation of their identities in first-year college calculus courses.* The study is guided by the research questions: (1) What experiences do minoritized students say are affirming to their identities? and (2) How have experiences in first year mathematics courses affirmed minoritized students' identities relative to mathematics?

Theoretical Framework

While most people have an intuitive sense of identity, defining it rigorously has proven challenging (Wetherell, 2010). In mathematics education, this has led to a proliferation of approaches and definitions, often inconsistent with one another, that has made the field of mathematics identity research difficult to synthesize (Darragh, 2016).

To bring clarity to this project, I draw on two complementary perspectives: Gee's conception of identity as Discourse and Sfard and Prusak's framework of identity as narrative. Radović et al. (2018) define five categories of how identity has been operationalized all align with James Paul Gee's (2000) notion of identity as being recognized as "a certain type of person." For Gee, identities are situated within Discourses—socially and culturally patterned ways of speaking, thinking, acting, and interacting. A Discourse is more than language: it encompasses values, beliefs, practices, gestures, and assumptions that convey belonging to a community. From this perspective, identity formation is not merely an individual psychological process but a fundamentally social one, emerging in relation to cultural norms and institutional structures. This

emphasis on the cultural and social contexts of learning mathematics makes Gee's framing particularly relevant to studying marginalized students in college calculus courses, where recognition and belonging play crucial roles.

To make this theoretical perspective analytically useful for qualitative research, I follow Radović et al.'s (2018) recommendation to be explicit about operationalization. I adopt Sfard and Prusak's (2005) conception of identity as a collection of stories about a person, told by themselves or others. For a story to be part of identity, it must be (1) reifying—transforming a fleeting behavior into a stable trait; (2) significant—meaningful in a person's social or cultural life; and (3) endorsable—validated or accepted by the person as at least partially true. This framework emphasizes how particular narratives come to matter for students, both those they claim for themselves ("I'm the kind of person who struggles in math") and those assigned to them by others ("She's the kind of student who always gets it right").

Identity as narrative is especially useful in connecting learning with its sociocultural context. Narratives like "only certain people are good at math" can be seen not just as individual beliefs but as socially circulating stories that shape students' opportunities to belong in mathematics. By attending to the stories marginalized students tell about themselves and those told about them in classroom contexts, this framework enables me to examine how classroom practices, teacher feedback, and peer interactions contribute to affirming—or undermining—mathematical identities. In this way, the framework provides both a broad sociocultural grounding (via Gee) and a concrete operationalization for analysis (via Sfard & Prusak).

Methods

The population for this study consisted of undergraduate students enrolled in either Calculus I or Calculus III, first and second year mathematics courses with the highest equity gaps in terms of DFW rates at the research site. A list of eligible students was generated by the Mathematics Department. From this list, fifteen students were recruited at the beginning of the semester via email invitation. All participants consented to take part in the study, which focused on their experiences navigating their calculus courses.

To capture students' evolving perspectives over time, each participant completed three semi-structured interviews (Kvale & Brinkmann, 2009), conducted at evenly spaced intervals throughout the semester. Interviews ranged from thirty to sixty minutes and invited students to reflect on their experiences in the course, their perceptions of themselves as learners of mathematics, and the personal and institutional factors shaping those experiences. This design allowed us to explore both immediate challenges and longer-term shifts in students' mathematical identity.

All interviews were transcribed and analyzed through an iterative process of thematic coding (Braun & Clarke, 2006) Each transcript went through systematic reading, with passages flagged when they were broadly relevant to the research questions. The first cycle of coding (Saldaña, 2016) identified broad, overarching categories related to students' academic and identity-related experiences. Particular attention was paid to structural, instructional, and relational factors.The second round refined these initial codes, shifting the focus from individual cases to cross-case analysis (Miles et al., 2014). This involved comparing codes across participants to identify recurring patterns, as well as attending to variations and unexpected insights. Holistic themes resulted that reflected commonalities in students' experiences while also preserving the complexity of individual narratives. These themes provided the foundation for interpreting how institutional and classroom practices affirmed students' mathematical identities in introductory calculus courses.

Results

Analysis of the interview data revealed thirteen distinct experiences that students described as affirming their mathematical identities. These experiences clustered into two broad categories: internal/intrinsic affirmations and external/social affirmations. While internal affirmations, such as achieving understanding and perceiving the utility of the material, were important, the vast majority of identity-affirming influences were grounded in social interactions. For brevity, a detailed illustration will only be provided for the theme of social affirmation here; more illustrations will be provided in the presentation.

Dominating Prevalence of Social Interaction

Students' mathematical identities were shaped most prominently through their relationships with peers, instructors, and broader classroom communities. Peer instruction emerged as a particularly powerful source of affirmation. Several students described how helping classmates not only reinforced their own understanding but also disrupted internalized narratives of deficiency. In the language of Sfard and Prusak (2005), these interactions actively challenged previously "endorsable" aspects of negative identity. As one student explained:

> "I'll have friends who are actually wanting to be math teachers, and they'll turn to me like, how do we do this again, and I'll be like oh, I'm the one that's supposed to know this… because I look like I know what I'm doing… oh, I do know what I'm doing."

Beyond peer instruction, opportunities to engage in community, such as through recitation sessions, study groups, and academic support offices such as CAST, were consistently described as affirming. Even experiences students framed as "internal," such as achieving understanding or recognizing utility, were often facilitated through these external supports.

Understanding and Utility

Although fewer in number, internal affirmations were universally present in students' narratives. Two themes dominated: understanding the material and recognizing its utility. Utility was described as transforming mathematics from an abstract requirement into something meaningful. One student put it succinctly: "I like [math] a lot more now I can actually understand the use."

Understanding was even more prevalent. Many students directly tied their enjoyment of the course to whether they could make sense of the material: "Once I understand it, I will enjoy it… [t]he only reason I'm feeling positive right now is just because I'm understanding it a lot better." These narratives suggest that comprehension and relevance remain central to identity affirmation, though they are often scaffolded by external supports.

Influence of Instructor

Instructors played a moderating role in shaping students' mathematical identities, either affirming or disaffirming students' identities. Positive interactions with professors were frequently reported as affirming, boosting confidence and cultivating a sense of belonging. One Calculus I student reflected: "[He] just makes you like… Oh, I feel seen in this class. So we just want to put more effort in, and at least really kind of enjoy math." In contrast, negative experiences with lecturers undermined students' sense of themselves as capable mathematical learners. Unlike other affirming experiences, the instructor's influence was notably volatile, with the potential to either strengthen or erode mathematical identity. In this study, positive

interactions with instructors were only reported by Calculus I students. There may be a variety of explanations for this, including particular instructors or subject matter, but these comparative factors were not made explicit by any students.

Overall Trends

Taken together, these findings highlight the centrality of social interaction in affirming students' mathematical identities in first-year calculus. While understanding and utility served as universal affirmations, they were frequently mediated by external supports and relationships. For some students, experiences in these courses reinforced pre-existing self-perceptions, while for others, the classroom environment catalyzed meaningful shifts in how they saw themselves as mathematical learners.

Although mathematics is often imagined as a solitary pursuit, this study underscores the essential role of community, interaction, and recognition in shaping marginalized students' mathematical identities. Affirming practices within peer groups, support structures, and classroom communities appear to be crucial levers for fostering persistence and belonging in STEM pathways.

Preliminary Nature of Report

At the time of writing, data collection and initial cycles of coding are complete, and emerging themes have been identified. The primary area of the project still under development is the articulation of the theoretical framework. While the analysis draws on Sfard and Prusak's (2005) conception of identity as narratives, further alignment with broader frameworks (e.g., Radović et al., 2018; Simpson & Bouhafa, 2020) is needed to clarify how different dimensions of identity are being operationalized in this context.

We seek feedback from the RUME community on the following questions:

1. How might we better connect our themes with existing theoretical lenses on identity?
2. What cautions or affordances should we consider in interpreting identity through both internal (understanding, utility) and external (peer interaction, instructor influence) dimensions?
3. Are there underutilized frameworks in the mathematics education literature that might strengthen the positioning of this study?

This feedback will help refine the theoretical framing and situate our analysis within the larger body of work on mathematics identity.

Conclusions

This study sought to identify what affirms marginalized students' mathematical identities in first-year calculus courses. The results suggest that while intrinsic factors such as understanding and utility consistently affirmed identity, the vast majority of affirming experiences were social in nature. Peer instruction, opportunities for community, and supportive instructors emerged as especially powerful drivers of affirmation, capable of disrupting deficit narratives and creating space for students to see themselves as "certain types of people" in mathematics.

In short, this work shows that affirmation is possible and impactful, but not yet systemic. Understanding how to reliably cultivate identity-affirming practices in introductory mathematics remains an area for future research and instructional design.

Understanding departmental teaching culture has been recognized as a useful starting point for implementing instructional and institutional change. However, there is a lack of consistency in the literature with respect to how teaching culture is operationally defined and systematically measured. In order to begin addressing this gap, we highlight findings from a series of focus groups conducted within a math department in the Southeastern United States. Utilizing Reinholz and Apkarian's (2018) Four Frames model, we characterize the department's culture through the four interrelated frames of structures, symbols, people, and power. These frames provide a snapshot of the unique math departmental teaching culture, which can be leveraged not only to assess the effectiveness of future change initiatives, but also to individualize such change initiatives to meet the unique needs of the department.

Keywords: Teaching culture, institutional change, departmental change, Four Frames model

Introduction and Background Literature

The teaching culture within an academic department is "hard to define, understand, and measure," yet plays a critical role in departmental change (Reinholz & Apkarian, 2018, p. 3). Changes in departmental teaching culture have the potential to improve instruction and learning, which in turn can positively impact student learning and persistence, especially within STEM fields (Couch et al., 2024; Henderson et al., 2011). Departmental teaching culture can also be leveraged as a metric through which educational reform can be guided and measured (Lau et al., 2022). Furthermore, teaching culture can be used as an evaluative tool for assessing teaching effectiveness (Dennin et al., 2017).

Despite the utility of teaching culture in departmental change initiatives, research examining departmental teaching culture is relatively inconsistent in both how teaching culture is operationally defined and systematically measured. A large proportion of the research relies on implicit characterizations of culture that draw on everyday language rather than from rigorous and established theoretical frameworks (Mohr et al., 2025). Without a clear definition of culture, these change initiatives leave little room for generalization to other contexts. This minimizes the potential for research in this domain to have broader impacts for institutional change.

This report seeks to address this gap by using an established framework – Reinholz and Apkarian's (2018) Four Frames model – to characterize the teaching culture of a mathematics department in the Southeastern United States. The Four Frames model serves as a powerful

methodological tool that can be leveraged not only to obtain a snapshot of a department's teaching culture, but also to facilitate targeted transformation within a department. We more specifically address the following research question: How do individuals perceive the roles of *structures*, *symbols*, *power*, and *people* within the math departmental teaching culture?

Theoretical Framework

We leveraged Reinholz and Apkarian's (2018) Four Frames model to characterize mathematics departmental teaching culture. This model uses four interrelated frames – *structures*, *symbols*, *people*, and *power* – as a lens through which to obtain a snapshot of culture (see Table 1). It is of particular utility for promoting change in the departmental change context, as it provides insight into both the product of change as well as the process of change.

Table 1: Description of the Four Frames (Reinholz & Apkarian, 2018; Couch et al., 2024).

Frame	Description
Structures	Roles, responsibilities, practices, routines, and incentives that organize how people interact.
Symbols	Cultural artifacts, language, knowledge, myths, values, and vision that department members use to guide their reasoning.
People	The uniqueness and diversity of the individuals in a department with respect to their goals, agency, needs, and identities.
Power	The interactions between people are mediated by power, status, positioning, and political coalitions.

Previous work using the Four Frames model includes analysis of department chairs' perceptions of teaching culture as it pertains to instructional change (Couch et al., 2024). Other work has compared culture across STEM departments (Reinholz et al., 2019) and examined the role of certain groups as potential agents of change, such as course coordinators (Williams et al., 2022).

Methods

Data were collected from focus group interviews conducted with math instructors at an R2 university in the Southeastern United States. In total, 10 instructors participated in a focus group, each containing between 2 and 5 participants as well as 2 facilitators. During each one-hour focus group, participants reflected on and discussed results from a prior departmental survey on teaching culture. In particular, discussion centered around three central themes: the perceived relatedness, competence, and autonomy of the department with respect to teaching. For each theme, participants were shown preliminary findings from their department's survey responses and prompted to discuss how their department's teaching culture could explain the findings. Then, additional data summarizing their overall college's responses to the same survey question was displayed, with prompting for comparison with the mathematics department's data. While the prior survey provided quantitative data related to perceptions of teaching culture, the focus groups provided an opportunity to further explore these data.

Data analysis was conducted by a team of six researchers. After cleaning the focus group transcripts, each transcript was deductively coded by a researcher using the Four Frames model (Reinholz & Apkarian, 2018). After this initial round of coding, the team discussed difficulties and revised the codebook to include more robust examples and details. Then, each coded

transcript was reviewed by a second researcher, with revisions made where appropriate to ensure consensus across the transcripts. Finally, the first two authors inductively coded each of the resultant four frames, focusing on identifying prevalent themes within each frame.

Results

In this section, we will present common themes which emerged from the focus group interviews. These themes will be organized along the Four Frames components.

Structures

Structures refers to the formal roles, responsibilities, practices, routines, and responsibilities which guide the actions and interactions of departmental members. Focus group participants reported on several departmental *structures* which impact instructors' teaching roles within the department, including time constraints and presence of mathematics education research faculty.

Instructors highlighted a lack of time to plan for their courses, contributing to a lack of autonomy and control. Jo, a tenured faculty in mathematics education, reported course schedules are often "not finalized until ... a week or two before the semester begins ... [sometimes] even later than that." Furthermore, instructors feel "a lot of pressure to have everything in its details [for their courses] ready by the first day." The lack of preparation time before the first day of class combined with pressure to finalize all details of a course by the first day resulted in instructors feeling rushed to prepare for their courses.

These time constraints were also experienced throughout the semester. Tenure-track faculty expressed the desire to support all students, but noted that it may be unrealistic to do so: "I want to be confident [in supporting all students], but can I realistically get there? No … I have other obligations." Such time constraints were reinforced by full-time temporary instructors (FTTs) and adjunct professors. Emmy described "it begins to get more and more difficult to find time… I teach 16 hours a week, which is a full load. So between planning, teaching, grading, it's hard to find time [to observe colleagues teach and discuss the observation]." Overall, instructors found it difficult to reflect and modify their teaching due to heavy teaching loads and other duties.

Another structural factor impacting instructors in their teaching role is the presence of mathematics education research faculty. Debbie, a graduate teaching assistant, described the university as being unique due to having "a heavy education presence ... especially in the mathematics department." Further, "there is a lot of ... collaboration amongst educators and mathematicians that does not always happen." Jo described the mathematics education group as not feeling "separate from the mathematics department in any way." The interviewed instructors hypothesized the unique collaborative relationship between mathematicians and mathematics educators resulted in a strong desire for instructors to consistently modify their course structure and teaching techniques to support all students.

Symbols

Symbols refer to the cultural artifacts and values – typically informal – which members of a department use to guide their reasoning. Common teaching *symbols* reported by members of the mathematics department include the nature of mathematics and the value of hard work.

The nature of mathematics refers to perceptions about what mathematics is and how mathematical knowledge is discovered or created. Some instructors described their perspective on the nature of mathematics and how it guides their teaching. For instance, Sophie, a lecturer, described some forms of mathematical knowledge as fixed, citing the Fundamental Theorem of

Calculus. Sophie therefore described difficulty performing iterative modifications of course content and structure due to most of the content taught being unchanged. Similarly, Cathleen, a tenured faculty, described mathematics as "more like music and art than ... the other sciences." Therefore, Cathleen teaches mathematics in a similar way to how she would teach music, as a "skill building discipline." These perceptions of the nature of mathematics sometimes created conflict with instructors' understanding of pedagogical practices. Debbie discussed department members needing to "learn how to balance what is recommended by other extant literature with ... what [we] believe mathematics is ... and what it looks like to effectively learn it."

Instructors also described hard work as a key value in the department. Dorothy, a tenured faculty in statistics, described "people in the [mathematics department] care and they are ... striving" to make a difference through their teaching. This deep level of care is reflected in Dorothy's observation in which members of the mathematics department are always "working hard," sometimes "working too hard." Dorothy elaborated by discussing "hard is not always smart" and that she may "not always [be working] smart to make the most efficient type of changes [which make impacts using] the shortest path." Despite the critique, Dorothy described the culture of hard work as a virtuous and encouraging value about the department.

People

People refers to the uniqueness and diversity of instructors which make up the department. In general, the sentiment regarding a diverse department is positive: "people [in the mathematics department] are different, and that's what makes it so great." Two ways the uniqueness and diversity of instructors are highlighted in the department include differences in teaching assignments and differences in background, training, and teaching preferences.

Dorothy described the mathematics department as having an "incredibly wide range of different mathematical disciplines that people are working in" such as "algebra, statistics, education, combinatorics" and much more. This naturally results in instructors teaching a broad range of courses. For instance, Spencer, a tenure-track professor who teaches theoretical math courses, described the content as "very difficult ... to teach" and it being "very challenging to get across certain material to students." Therefore, sticking to pedagogical suggestions from instructors teaching general education mathematics courses may not be effective for Spencer. Furthermore, being a large university, courses are typically offered in a wide variety of modalities. Dorothy, who teaches "a lot of online [courses]," found it difficult to reach students in the same way her colleagues teaching in-person courses do due to the nature of online courses.

The wide range of mathematical background is also reflected in the diversity of training and preferences with respect to teaching amongst instructors. The large education research presence in the department results in many instructors such as Debbie who have "read so much literature about what it means to be an effective teacher [by supporting] a student in learning." Some instructors also associate different styles of teaching with different types of people. For instance, Emmy described one of her colleagues as being "a math teacher [in the K-12 setting] for a long time and so she has taught in a particular way." In addition, Dorothy described some faculty in the department as being "more ... introverted in working on their projects and therefore less interested in being collaborative in their classes."

Power

Power refers to the political relationships between members of the department which may impact instructors' teaching roles. Aspects of *power* which emerged during the focus groups

include lack of autonomy due to power differentials between faculty based on position and experience as well as a chasm between mathematics and mathematics education researchers.

One FTT, Emmy, described FTTs as unable to "serve on committees or do research work or anything." Furthermore, "while … some [FTTs] have been here for over 25 years, [we are] still referred to as temporary." This power differential between FTTs and tenure-track faculty is further exacerbated by FTT's lack of instructional control and autonomy. For example, Emmy described FTTs not being "voting members of the faculty" and not being "decision makers, but ... get a lot of decisions made about [them]." Emmy reported "mandates" FTTs receive regarding teaching, such as implementing a common final exam in the college algebra, precalculus, and Calculus I courses. Although Emmy reported feeling "free to ask questions [and] challenge policies" which "might lead to modifications," she reported uncertainty in whether her suggestions are "actually changing anything at the departmental level."

Although the relationship between mathematics and mathematics education researchers were reported to be largely collaborative, power dynamics and implicit roles between these two groups impact how instructors view their teaching roles, especially mathematicians. Some mathematicians viewed mathematics education researchers as holding the power and authority with respect to pedagogy, deferring teaching-related judgements to these. For example, Cathleen described thoughts about making changes to the curriculum and her pedagogy, but because she is "not [a researcher in] math education," she does not seek to implement her thoughts.

Discussion

This study examined math instructors' perceptions of their departmental teaching culture through the four interrelated frames of *structures*, *symbols*, *power*, and *people.* Such a snapshot of a department's current teaching culture can be leveraged to individualize future change initiatives to meet the unique needs of the department. For instance, a change initiative in this department would need to require minimal time commitment in order to be responsive to the structural time constraints of instructors (Bleiler-Baxter et al., 2021). Further, due to the strong presence of and reliance on math education faculty within this department, such education-based faculty may be leveraged as early adopters and change agents that can support the diffusion of innovation to the department (Eddy et al., 2022). This snapshot also establishes a baseline measurement of departmental teaching culture that can be used to assess the effectiveness of a change initiative. While these findings are unique to the studied institution, they could serve as a roadmap to guide other institutions in characterizing departmental teaching culture within their own context. Further, the stories of these instructors may resonate and inspire other instructors, promoting relatedness and collaboration across institutions.

Preliminary Nature of Report

This report is exploratory in nature. Future work will dive further into unifying themes across the data. Future exploration of the data will also leverage additional theoretical frameworks such as Self-Determination Theory in order to broaden the impact of our findings. Further, we possess additional parallel data from other STEM departments (e.g., biology, aerospace, geosciences) that can be unified with the math departmental data reported here to form an overarching narrative spanning STEM departmental teaching culture.

During the discussion portion of the presentation, questions for the audience will include: (1) What other analytical frameworks might be useful lenses to explore this data? and (2) Which of these findings do you anticipate can be generalized to mathematics departments at other institutions and which do you think are unique to this math department?

Investigating Student Understanding of the Infinitesimal vs. Limit Definition of Integration Through the Curious Placement of dx

Idris Malik
North Dakota State University

Naomi Whitlock
Arizona State University

Warren Christensen
North Dakota State University

Integrals can be conceptualized with an infinitesimal or limit definition, and holding a certain conceptualization may change how someone frames and solves an integral problem. We present excerpts from two different interview studies where we asked second-semester calculus-based intro physics students integral questions. Student utterances and differing answers to these selected questions led us to define two conceptual resources concerning infinitesimals, which correspond to the different definitions of integration. This work highlights subtle differences in students' interpretation of integration and areas for future study.

Keywords: integration, resource theory, qualitative, interview

Discussions of the infinitesimal vs. limit definition of integration have been on-going in mathematics education for some time (Ely 2020 provides an excellent summary). While many mathematicians prefer a limit definition of integration, applied sciences, such as physics, tend to rely on the infinitesimal definitions of integration (Redish & Kuo 2015). Research also shows that students can hold multiple conceptions of differentials and treat them differently based on these interpretations (Artigue et al. 1990). Students may also favor infinitesimal conceptions of integration despite textbook focus on limits (Nilsen & Knusten 2023). The extent to which this difference in interpreting integrals acts as a barrier for students is unclear. The goal of this paper is not to demonstrate which definition is correct, or which should be taught, but rather to present nuanced findings on this topic and a number of challenges and inconsistencies for these two definitions that we've identified, and the impact they may have on student success in different courses contexts.

The idea that this may be a point of interest came to our attention while conducting interviews using math questions written by a mathematician alongside physics questions written by a physicist. A question we asked, from Jones 2013 which was also written by Jones, was the question $\int_1^2 2/x^3 - x^2 dx$. We observed that this problem does not have parentheses around the integrand. Consistent with a limit definition of integration, integrals have the form of ∫INTEGRAND *dx*, regardless of whether there are parentheses around the integrand terms or not. The implicit notion is that the *dx* is acting as punctuation, and a marker for the variable over which the integrand will be integrated. Within this model, these parentheses are superfluous. Due to the lack of parentheses, the limit definition of integration does not imply that the *dx* is being multiplied across the terms within the integrand. However, within applied contexts the differential (or infinitesimal) *dx*, or *dm*, or *dt*, represents a small bit of that physical quantity and has units associated with that quantity. The *dx*, for example, is multiplied across every term of the integrand, and therefore parentheses are necessary to ensure that the units work out appropriately. Throughout this paper we refer to the differential, *dx*, as an infinitesimal with the qualities just described. We acknowledge that this is not a rigorous mathematical definition, but we hope it's sufficient to understand our findings. We report preliminary findings about the difference in the interpretation of *dx*, and how it impacts student responses when solving integration problems. The main goal of this paper is to answer the Research Question: "To what

extent do students in a second-semester physics course use conventions consistent with infinitesimal definition vs. limit definition of an integral when given a question with a unique placement of *dx* within the integral?"

Theoretical Framework

For this study, we employ the Resources and Framing Theoretical Framework (Hammer et al 2005). Resources and Framing models thinking as consisting of fine-grain "nuggets" that a person has learned and used successfully somewhere previously that are unconsciously brought to bear on a novel task (Hammer, private communication). These resources may have connections to other resources, some of which may be stronger or weaker connections depending on the experience of the person who has used them together in the past (Hammer et al 2005). The accessibility of these resources are influenced by how the individual frames the particular task. Therefore, if someone doesn't articulate a particular resource, this does not mean that they don't possess that resource, rather, the resource was not activated. Within this framework, we as researchers attempt to identify the "good idea" that the individual is attempting to use for a particular problem and if it is successful (i.e., achieves a correct answer), we deem that resource to be productive (Barth-Cohen et al 2023). If the individual is not successful (i.e., gets an incorrect or incomplete answer) we deem that resource to be unproductive. Here, we identify two resources that students may activate in the provided problem, and how these resources connect to either an infinitesimal definition or a limit definition of integration.

Methodology

This study recruited students from the end of a second-semester introductory calculus-based physics class at a large R1 in the upper-Midwest. Students in this course, at minimum, were completing Calculus II in this semester and many were completing Calculus III and/or Differential Equations. Two different sets of interviews were conducted. The first set consisted of three (3 white men) and the second set consisted of four (3 white men, 1 white woman) semi-structured, think-aloud interviews that were conducted and video recorded (Browner 1988). The interviews were transcribed and analyzed through a lens of Resources and Framing (Hammer et al 2005). The protocols featured an array of mathematics and physics questions. The results of one particular question from each interview protocol are presented here. We report on these results combined with textbook observations.

Results & Analysis

Integral without parentheses

We first consider an integral question from Jones 2013. This problem, one among a series of math/physics questions, was given to three individuals. The question was given as was originally written, $\int_1^2 2/x^3 - x^2 dx$, which did not include parentheses. None of the three students articulated any issue with how this question was written. All three students successfully evaluated the integral. None of the students put parentheses around the integrand; they simply used their knowledge for integrating polynomials and achieved the correct result. We claim this demonstrates students' activation of a "*dx* as punctuation" resource, that is consistent with the limit definition of integration. This may seem relatively light evidence for such a claim, but as stated in the introduction, within a model of infinitesimals, the *dx* is a term that is being multiplied by each of the terms in the integrand. None of the three interviewees commented on

the lack of parentheses or drew parentheses before doing the integral. Each of them simply performed the integral. Therefore, we claim that they are treating "*dx* as punctuation."

In discussion with other PER and RUME researchers there was disagreement as to whether or not the lack of parentheses was appropriate, and the extent to which introductory calculus textbooks used parentheses for integrands that had more than one term. An investigation into a number of introductory calculus books showed that all instances of addition and subtraction within an integrand had parentheses around the integrand (Larson & Edwards 2017, Rogawski & Adams 2015, Stewart 2016). It's unclear how prevalent a lack of parentheses is among Calculus instructors and students, and we plan to investigate this further. In discussions with a RUME researcher, they believed the parentheses to be superfluous and were surprised that the introductory Calculus books had parentheses throughout. Additionally, this researcher identified at least one upper-division mathematics textbook that did not use parentheses for integrands that had addition or subtraction within them (Pugh & Pugh 2002). Furthermore, within the same textbook and an additional one there were integrals where the *dx* term was not written within the integral at all (Pugh & Pugh 2002, Abbott 2015). This raises further questions about the practice of experts in mathematics and how that practice is communicated to students.

The curious case of *dx* in the middle of the integral

Within this second interview protocol, four students were given the prompt $\int 2dx(x^2 - 3x)$. The purpose of this question was to investigate how students would contend with this unique placement of *dx*. The interview protocol prompts "What do you think about this integral?" and then after their explanation, a follow-up of "Could you evaluate this integral?" was asked. The following are the four responses given by our interviewees, with analysis to follow.

Student 3. Student 3 (S3) responds to the initial prompt with "The integral of 2*dx* [and makes a motion with their hands to look like air parentheses] times $x^2 - 3x$, so **I think of this as basically a parentheses being here**, that's how I read that." S3 drew in the parentheses on their page as seen in Figure 1, enclosing the integral symbol, the 2 and the *dx*. And then evaluated the integral of 2*dx* to get $2x + c$, and then wrote their final result as $(2x+c)(x^2 - 3x)$.

$$\left(\int 2dx\right)(x^2 - 3x)$$

Figure 1. Student 3's annotation of the question prompt. The parentheses indicate the integral of 2 dx as a separate quantity, the result of which they later multiplied by (x^2-3x).

Student 2. Student 2 (S2) states, "It looks out of order. ***dx* should be at the back.**" S2 then moved the *dx* behind the $(x^2 - 3x)$ term, and evaluated this integral correctly. See Figure 2. Note that the answer of S2 is different from S3.

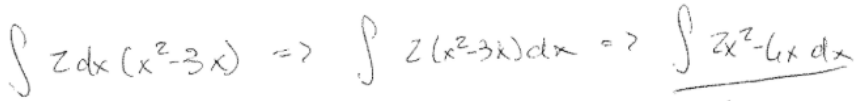

Figure 2. Some of Student 2's work on the given integral problem.

Student 4. Student 4 (S4) states, "Well, **the *dx* could be moved back to the side. So it essentially becomes the integral of two times the quantity $x^2 - 3x$.**" They move the constant 2 out in front of the integral and then write down the expression as seen in Figure 3, moving the *dx* to the right side of the expression, but they do not put parentheses around what is now their integrand. They then evaluate the integral. The interviewer asks, "So I think you kind of already

spoke to this. But is there anything wrong about the way that this is written, initially?" Student 4 replies, "I wouldn't say it's wrong. **It's certainly not what I'm used to, but you can put the *dx* anywhere** in that expression and have it still be true."

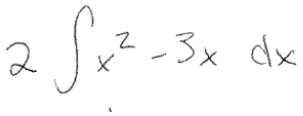

Figure 3. Student 4's first step on the given integral problem.

Student 1. Student 1 (S1) is significantly more descriptive in their thinking about the integral.

S1: "Um I just say it looks weird, but mathematically I'd say–

INT: "Why does that look weird?"

S1: "Because the d– because the *dx* is in front. Um is it, is it the last term? Because what, I was always taught like in high school– was like your– **your *dx* is like**, that's like **the period of your sentence** like that closes it off. But I know mathematicians get mad at you with this, but like when you like, just multiply differentials like you can't like you can't treat them as fractions, but you– you kinda can… **So I would think that it's perfectly logical to just move it [*dx*] to the end based on, uh, one of the properties of multiplication.**"

After this consideration of the *dx*, and, sounding as if they intend to move the *dx* behind the parenthetical term, S1 is asked to evaluate the integral. S1 immediately changes their mind, draws parentheses around the integral symbol and the *dx* and evaluates the integral the same way as S3. S1 states,

S1: "Ooh. Uh actually um. Now I think I'm gonna go back on myself. I– I actually think that this integral is– is done. Because the *dx* would end the integral."

S1: "So, so I, I– looking at it so now I would, I would integrate the 2*dx* to be 2*x* and then this part is almost treated as in parentheses and I have 2*x* multiplied by $x^2 - 3x$, and then we distribute, $2x^3 - 6x^2$, and that would be your answer."

When the interviewer asks for further explanation of the S1's response, S1 states,

S1: "Yeah. Cause, I don't know if this is the case, but like kind of mathematical like ambiguity. Um, **I'd imagine that you could just multiply the *dx* but I think conventionally the *dx* is at the end**. Like I said, with the period in the sentence. Um yeah, but if I saw this, I guess initially I saw it the other way, but if I– if I saw this, I would imagine that the ***dx* is like the ending of the integral, like the integral starts with the integral sign and ends with the differential.**"

When looking at their final results, two students (S2 and S4) treat *dx* as a quantity (infinitesimal), and move it to the right hand side of the integral before evaluating. The other two students (S3 and S1) ultimately leave *dx* where it is and evaluate the integrand of 2, both being specific and drawing parentheses to make it more clear. These two answers are quite different. Depending on the interpretation of the integral, one arrives at one of two different results.

We identify S3 and S1 as using the "*dx* as punctuation" resource. This resource is very consistent with a limit definition of integration. This is the same kind of resource necessary to interpret $\int_1^2 2/x^3 - x^2 dx$, without parentheses. The *dx* serves as the period at the end of a sentence which begins with the integration symbol, and everything in between is the integrand, the terms to be integrated. S2 and S4 identify the placement of *dx* as "looking weird" and "not

what I'm used to," respectively. However, they both move the *dx* term to the end of the integral before evaluating it. We identify this as "*dx* as a quantity (infinitesimal)" resource. This resource is the idea that *dx* within an integral has qualities, such as being subject to multiplicative properties, similar to a variable or a constant and therefore can be moved.

Three of the four students answered this question rather quickly and confidently without a great deal of context or description. S1, however, gave a rather articulate answer that bears further analysis. S1 explicitly states that they were taught in High School that *dx* acts like a period of a sentence, a statement that we would identify as "*dx* as punctuation". They then state that mathematicians don't like it when you multiply differentials like fractions, but that you still can. S1 continues by stating that they can treat *dx* like a term that can be multiplied and that it's logical to move it to the end. These are strong statements that suggest activating a "*dx* as an quantity" resource. However, when asked to evaluate the integral, S1 proceeds with the "*dx* as punctuation" resource and ultimately gets the same result as S3.

A final note on the work of S4 as seen in Figure 3. S4 does not include parentheses around the $x^2 - 3x$, even though there were parentheses around this quantity in the original prompt (See Figure 1.) We connect this lack of parentheses to the "*dx* as punctuation" resource for the "Integral without parentheses" question data. So, we could say that S4 holds and activates "*dx* as a quantity", but then uses notation conventions consistent with "*dx* as punctuation", as they do not deem it necessary to include parentheses on an integral they felt comfortable manipulating. This demonstrates that this individual holds elements of both resources.

Discussion

We have identified two different resources: "*dx* as punctuation" vs. "*dx* as a quantity," and the markers for these resources. We also demonstrated how the activation of one resource, or the other, or both, impacts a student's thinking when solving the two integration problems presented. The activation of one of the two resources can result in different answers to the same problem. While these examples are limited, they demonstrate instances where these two resources could be activated. We highlight a case where activating "*dx* as punctuation" presents no issue for students; there are instances where both interpretations of integration may be necessary, especially in the applied sciences. Although more research in this area is needed, it would seem prudent for both mathematics and physics instructors to be aware of these subtle, yet important, interpretations and distinctions in student thinking.

Future Work

Two questions that we seek to answer are: 1) to what extent is the thinking presented here prevalent among a larger sample of students and 2) to what extent do math and physics instructors think in similar or different ways pertaining to these integral questions. For question 1, we intend to distribute these questions in free-response format to students in Calculus II and Calculus-based Physics II courses in the coming semesters. For question 2, we will be collecting interview data from math and physics instructors to understand not only how they interpret these questions, but also their thinking about the use of parentheses in integrals as was discussed.

Acknowledgments

We'd like to acknowledge the contributions of John Thompson, Mike Loverude, Michael Oehrtman, and John Buncher through numerous conversations concerning these results. This work would not be possible without funding of the NSF DUE 2348883. Part of this work was

done as part of the 2025 NDSU Collaborations in Discipline-based Education Research (CiDER) REU program.

Context Dependence of Student Responses and Explanations on Dot Product Magnitude Tasks

Allison Molinari
University of Maine

John R. Thompson
University of Maine

Preliminary findings from a study exploring student understanding of vector products are presented. We discuss multiple-choice and free-response data from 118 students who completed four dot product magnitude tasks across two semesters of introductory physics instruction. Each semester had a physics-free dot product along with a physics context relevant to the content of each course (mechanical work and electric flux). Performance ranged from 28% to 59% and students do not always answer consistently between pairs of tasks. Coding of explanations revealed four main computational strategies used by students along with two more conceptual reasoning categories. The most common strategy was students using a trigonometric definition of the dot product with varied results depending on the context.

Keywords: vector products, student thinking, physics

Vector quantities are ubiquitous in physics, appearing very early in an introductory physics course and continuing to be used extensively throughout an undergraduate physics curriculum. Since mathematics curricula do not usually cover vectors until the third semester of calculus, it is necessary to explore the use of vectors in a physics setting. A body of work in physics education has explored student understanding of vectors (e.g., Knight, 1995; Nguyen & Meltzer, 2003; Flores et al., 2004; Gire & Price, 2014). Our research questions for this report are: How does context impact student approaches to vector product tasks? What aspects of physics contexts influence student reasoning? While this work is part of a longitudinal study of how student understanding of vectors evolves over time, only introductory-level data is presented here.

Preliminary Nature of the Report

We frame this work from a mathematical modeling perspective, looking at different steps in a modeling process that at its broadest includes connecting the physical scenario and the associated mathematical entities as well as performing mathematical operations (e.g., Redish & Kuo, 2015; Uhden et al., 2012; Zbiek & Conner, 2006). We are interested in the role of context on student understanding of vector products and on how students reason about the relevant mathematical operations. A more fine-grained analysis of student reasoning and modeling with our data has not been completed. In addition to framing via modeling, we believe that our findings are well suited for analysis via dual-process theories of reasoning (Evans, 2006; Heckler, 2011; Kryjevskaia et al., 2014; Spiers et al. 2021), in particular the impact of visual and contextual features on student reasoning. A broad question for readers: What other perspectives and/or frameworks might provide additional insight into student reasoning and especially the consistency of their reasoning across multiple tasks?

Background

The dot product (or scalar product) of two vectors, $\vec{A} \cdot \vec{B}$, can be determined in two ways, either as $AB\cos\theta$, where θ is the angle between the two vectors when placed tail-to-tail, or as the sum of the corresponding components, $A_xB_x + A_yB_y + A_zB_z$.

Work on student understanding of vectors has explored both computational and conceptual issues. On the computation side, Mikula & Heckler (2013) investigated students' ability to

calculate vector components and found that angle placement impacted performance. Heckler & Scaife (2013) compared different notations and saw better performance on algebraic problems than problems using arrow notation. Van Deventer (2008) and Carli et al. (2020) developed isomorphic mathematics and physics questions and observed context dependence of student strategies. Carli et al. reported that the vector product tasks were most challenging among vector concepts in both the math and physics contexts with a maximum performance of 41%. Barniol & Zavala (2014) developed the Test of Understanding of Vectors, a multiple-choice assessment on procedures and properties of vectors without physics contexts. On a more conceptual level, Zavala & Barniol (2013) asked students about the best interpretation of the dot product in three different contexts. They found no significant difference between the results for the two physics contexts (work and flux) but did see a significant difference between the "no context" question and the physics contexts, with better performance in the physics contexts.

Several of the dot product items in the literature have answer choices that are a mix of scalars and vectors, which could conflate evidence of student understanding of magnitude and direction. To disentangle calculation errors from reasoning about the vector or scalar nature of the results, our tasks had separate questions about the magnitude and direction of each product. In matched data on the dot product direction tasks we found no significant shift between correct and incorrect answers, but there was a significant shift from the common incorrect answer to other choices depending on the context and aligned with the physics (Molinari & Thompson, 2025). While the studies above demonstrate that context influences responses, not all these studies have matched data, and we are interested in not only how entire populations complete different tasks but also how individuals respond in different contexts.

Methods

Online surveys were administered after relevant instruction in calculus-based introductory physics in both semesters of the same academic year at a medium-sized R1 institution. Each survey asked separate questions about the magnitude and direction of a vector product (dot or cross) in a "math" context with no physical scenario and a physics context. The physical dot product contexts were *mechanical work* in the first semester (PHY1) and *electric flux* in the second semester (PHY2). *Work*, a common application context in calculus, is the dot product of force and displacement; *electric flux* is the dot product of the electric field and an area.

Each problem statement included a diagram for the situation (Figure 1) and values for the magnitudes of the vectors and angles in each diagram. The question posed was, "What is the magnitude of the dot product $\vec{A} \cdot \vec{B}$ / $W_{BR} = \vec{T}_{BR} \cdot \Delta\vec{r}$, the work done on the block by the rope / $\Phi_E = \vec{E} \cdot \vec{A}$, the electric flux through the area?" Multiple-choice options were numerical values.

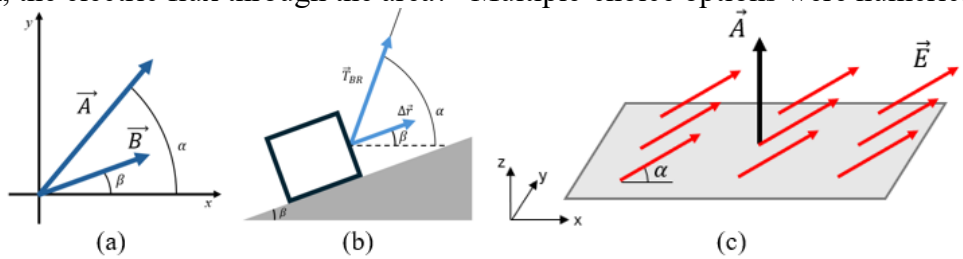

Figure 1. Diagrams provided for (a) math, (b) work, and (c) electric flux tasks.

All three contexts had enough information for students to find the angle between the two vectors ($\alpha - \beta$ for *math* and *work*, and $90 - \alpha$ for *flux*). The *flux* scenario was not a perfectly isomorphic scenario, instead presented in a form more aligned with problems given in a physics

class. Since *math* and *work* had two given angles there were more distractors in those contexts than the *flux* question to allow for options involving the cosine of each given angle.

There were 191 dot product survey responses in PHY1 and 181 in PHY2, with 118 students completing both surveys serving as longitudinal data points via matched responses. We also conducted 4 free-response, think-aloud interviews at the end of PHY2 for additional insights.

For both the magnitude and direction of each dot product task, after participants submitted their multiple-choice answers, the next page of the survey re-presented the questions, reminded students which choice they selected, and prompted them to briefly explain their reasoning for each answer. The final code book (Table 1) is the result of an iterative process in which explanations were coded – independently from the multiple-choice selections – to identify the mathematical approach students used to reach their answer. The first four rows are the main computational strategies used by students; projection/alignment and limiting cases (#5 and #6) were codes that appeared both in conjunction with the main strategies and stand-alone. Codes are independent of correctness: within each main strategy, sub-codes were used to distinguish approaches leading to correct or incorrect conclusions, such as using an inappropriate angle or function. Inter-rater reliability achieved Krippendorff's α coefficients of agreement of .92, .87, and .96 for the *math*, *work*, and *flux* contexts, respectively.

Table 1. Table of dot product task reasoning codes and descriptions. Starred categories (*) could be sub-codes of the first four codes.

Code	Description
1. Trigonometric definition	Multiplying the magnitudes of both vectors by a trig function (predominantly sine or cosine) of a correct or incorrect angle
2. Sum of component products	Decomposing, or attempting to decompose, the vectors and taking the sum of the products of the corresponding components
3. Scalar multiplication	Multiplying the magnitudes of the two vectors
4. Addition	Using strategies of either scalar or vector addition, such as tip-to-tail
5. Projection/alignment*	Discussing vector projections or how aligned the two are
6. Limiting cases*	Using maximum and/or minimum values to support their selection
7. Restating	Stating the answer selected is what they calculated without elaboration
8. Other	Does not fit into any of the above categories (also blank, unclear)

Results & Discussion

Multiple-Choice Results

The overall performance on the four dot product magnitude tasks ranged from 28% to 59%. In the *PHY1 math* context, 52% of students selected the correct response, compared to 59% in the *work* context, 42% in the *PHY2 math* context, and 28% in the *flux* context, as shown in

Figure 2. Distractors of similar types are combined for presentation. "Trig errors" includes the answers that could be reached by using sine of the angle between the two vectors or cosine of any given angle. "Addition" includes both the scalar and vector addition choices.

Consistency between tasks shows evidence of the broader challenge. Table shows the proportion of students who answered consistently, correct or incorrect, between four pairs of tasks. Between the *PHY1 math* and *work* contexts, 58% of students selected consistent responses, and only 30% were consistent between the two semesters in the *math* contexts. Each comparison to the *flux* task has less than 30% consistency between response pairs. Across all four tasks, 10% of the 118 students correctly determined the magnitude of the dot product.

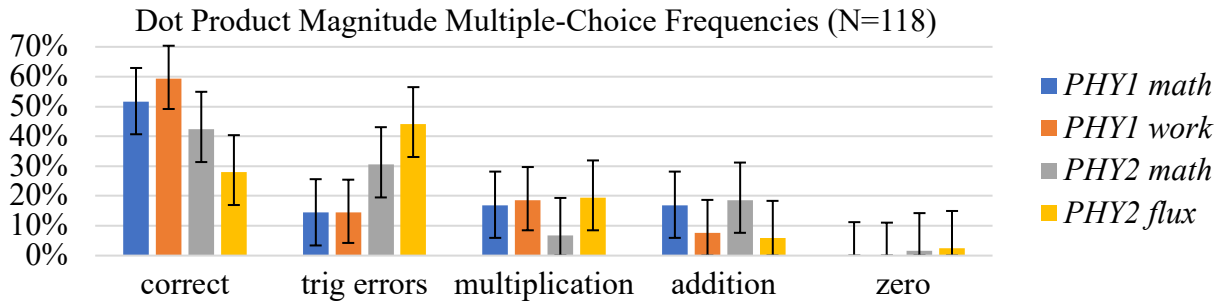

Figure 2. Response frequencies for all four dot product magnitude tasks across the year, for matched students.

Table 2. Multiple-choice response consistency across two tasks by percent of the population, N=118.

Categorization of paired responses	*PHY1 math* vs. *work*	*PHY1 math* vs. *PHY2 math*	*PHY2 math* vs. *flux*	*Work* vs. *flux*
Consistent and correct	44%	22%	16%	19%
Consistent but incorrect	14%	8%	11%	5%
Inconsistent	42%	70%	73%	77%

Explanation Results

To understand why students are selecting the answers they are, we go to the explanation codes. The trig definition approach was the most common strategy explained by students in all four contexts, with about half of the free responses coded as such in each context (shown in Figure 3). Of these students we grouped their multiple-choice responses as correct, trig errors, and other errors (multiplication, addition, and zero). The sum of "restating" and "other" codes (#7 and #8 from Table 1) were more common than the remaining specific approaches, with between 20% and 31% of responses coded as such.

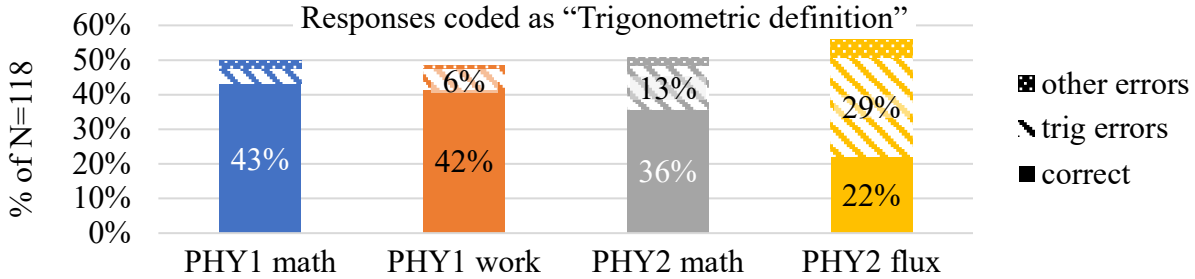

Figure 3. Breakdown of multiple-choice selections of students coded as using trigonometric definition explanations. Percentages not shown are ≤ 5%.

Due to the angles given in each context (see Figure 1), the *math* and *work* trig errors account for three multiple-choice options while there is only one *flux* trig error answer, corresponding to $EA\cos\alpha = EA\sin 90-\alpha$. Within these *flux* responses, the majority explained by saying they calculated cosine of "alpha," "30," "theta", or "the angle between them," effectively taking the dot product of two vectors that are an angle α apart instead of $90-\alpha$. This could be for a variety of reasons, ranging from simply using the angle provided to a conceptual confusion about the area vector (i.e., placing it in the plane of the surface). Most of the trig errors in the *PHY2 math* context were from using sine instead of cosine, which is likely a recency effect due to the coverage of the Lorentz force, which is determined by a cross product, the week prior.

Regardless of approach, only up to 50% of students gave explanations coded in the same category (#1-6 in Table 1) across any task pair. Furthermore, the same approach does not

necessarily lead to the same answer. For example, 43% of students who were coded using a trig definition for both *PHY2 math* and *flux* and 32% of the students who were coded using a trig definition for both *work and flux* gave consistent responses in the respective task pairs.

The projection/alignment code was not prominent but was more common in the physics contexts than in the math context. One student in *PHY1 math*, 8 in *work*, none in *PHY2 math*, and 4 in *flux* used these ideas either as their sole explanation or in tandem with the trig definition approach. Additionally, during the *flux* portion of the interviews, follow-up questions about why students used cosine in their calculations or about the significance of the angle elicited responses about the electric flux measuring how much of the field is caught by the area, with analogies like a sailboat in the wind (which was generated by the instructor), whereas the same follow-up questions in the *math* context were met with answers such as "that's what I'm remembering the equation as" and "'cause dot products use cosine, cross products use sine." Students seem to attribute the operation of a dot product with more physical meaning in physics contexts than when the physics is pared away. Our findings agree with Zavala & Barniol's (2013) results where students were more likely to describe the dot product as a projection in physics contexts than with no context. However, the very low count of the projection/alignment code among our explanations suggests that students are not likely to offer this reasoning unprompted.

A final note on student reflection. Three of the four interview participants started doing their calculations for *flux* by using cosine of the angle given, α, then either by catching it themselves or realizing after a request for an explanation that the angle they needed was actually $90 - \alpha$. Additionally, across all four dot product magnitude tasks, 11 students said they would change their answer after looking at the problem again or thinking about it more.

Conclusions & Implications

From a modeling perspective, the *math* task drops students into the mathematical world, while the physics tasks provide the physical situation and a mathematical model (a dot product) for the quantity in question that should use the same mathematical operations. However, our data suggest that students perform different operations in the two scenarios and thus may not make consistent mathematical choices across contexts, supporting the idea that physicists tend to load meaning onto symbols while mathematicians generally do not (Redish & Kuo, 2015). In our study, the meaning being loaded by the physics seems to influence the mathematical operations performed, an aspect that may not be accounted for in modeling frameworks.

Visual representations of each context and the visual features to which students attend influence what values students use in their calculations. The fact that the survey responses are susceptible to new content being introduced and the difference in explanations across semesters for the same (*math*) task suggests that models for dot products are still dynamic at that later time.

Further exploration of this work will involve utilizing dual-process theories of reasoning as a framework both for task design and data analysis that may help explain inconsistencies across contexts. Further application of findings to modeling frameworks may illuminate specific conflicts between the frameworks and student reasoning.

The presence of physical situations may cue students to reason differently as they do not often call upon the formal geometric interpretation of the dot product to perform calculations. By the time students see the formalism of vector products in mathematics courses, they have likely already seen these operations in a physics class(es), so mathematics instructors may be able to draw on physics contexts to help solidify understanding of vector operations. But these contexts come with their own conceptual overhead and thus need to be introduced with care.

Community College Students' Perspectives on Classroom Environments in College Algebra

AI@CC 2.0 VMQI Research Team[1]

We present a preliminary report on community college students' perspectives of classroom environments in college algebra. Drawing on nine student interviews from four states, we developed and calibrated a coding framework of 34 codes organized into nine categories. Our analysis highlights three broad dimensions of classroom experience: individual factors, relational dynamics, and structural or contextual elements. Students emphasized the role of supportive and responsive instruction, including instructors who re-explained concepts, offered second chances, and adapted to diverse learning needs. They also described participation structures that shaped collaboration with peers, as well as classroom climates that encouraged or at times discouraged active engagement. Beyond their current experiences, students voiced aspirations for more inclusive and collaborative practices. These early findings provide insight into how community college students experience college algebra and point toward future directions for exploring diversity, equity, and inclusion in mathematics classrooms.

Keywords: Community college, classroom environment, equity, diversity, inclusion

Although equity research in mathematics education has emphasized instructional practices and teacher perspectives (Gutiérrez, 2002), far less attention has been paid to how students perceive the classroom environments that support or hinder their learning. Prior work highlights the importance of classroom environments in shaping opportunities to learn, but student voices are rarely centered in the literature. As noted by recent research, we have limited perspectives from students underscoring the need for more studies that foreground their voices (Wickersham & Nachman, 2023). We focus on college algebra, a gateway course that can influence whether students persist in STEM-related fields (Walkington, 2025). Our study takes place in community colleges, where many students are first-generation, low-income, or racially minoritized (American Association of Community Colleges, 2025), and where equitable access to mathematics is especially consequential. By centering students' voices, our goal is to examine how they describe classroom environments and to consider how their accounts affirm, complicate, or extend existing research on equitable practices in mathematics education. Guided by this perspective, we ask: How do community college students describe classroom environments in college algebra?

Conceptual Framework

In mathematics education, equity-focused research emphasizes the importance of classroom environments that provide fair opportunities to learn and supportive conditions for participation

[1] The AI@CC 2.0 VMQI Research Team: Alecsa Agbayani, Claire Boeck, Inah Ko, Megan (Mack) McCormick, Rabia Kirikçilar, Vilma Mesa, University of Michigan; April Ström, Laura Watkins, Patrick Kimani, Maricopa Community Colleges; Irene Duranczyk, Bismark Akoto, Siyad Gedi, Dexter Lim, University of Minnesota; Camden Collins, Mary Beisiegel, Oregon State University.

(Esmonde, 2009a, 2009b). The classroom environment in mathematics education refers not only to instructional practices but also to the social and affective climate shaped by peer and instructor interactions. For example, Cobb and Hodge (2002) highlight a relational perspective on equity, in which classroom norms and interpersonal dynamics determine whether participation feels fair, inclusive, and respectful. Gutiérrez (2002) argues that equity in mathematics education requires not only access to content and achievement but also meaningful opportunities for participation and recognition of diverse student identities. Understanding interactions in diverse classrooms**,** where students vary in race, culture, language, socioeconomic background, ability, gender identity, and more, is essential but complex. Mathematics educators have sought to understand instruction as interactions that occur between teachers, students, and the content, and that take place within a classroom environment that can determine the nature of those interactions (Cohen et al., 2003). By understanding instruction in this way, and the classroom environment as either supporting or constraining the interactions, we seek to uncover individual, relational, and structural or contextual elements that may affect students' participation in mathematics.

Methods

The study follows a grounded theory design that calls for theoretical sampling and multiple iterations of data collection. Participants from eight community colleges were invited to participate in an interview study (four interviews over an eight-month period). The students had to be familiar with college algebra at their college (i.e., were taking or had taken the course). For this preliminary report, we analyzed interviews from nine participants (out of 38) across seven institutions. The sample included five women and four men (ages 18–50) with varied commitments outside school (e.g., full-time jobs, caregiving). Participants identified as African American/Black, White, West Asian, Hispanic, Kenyan, and multiracial (e.g., half Peruvian and half Guatemalan). This purposive sampling aimed to capture a wide range of perspectives while keeping the dataset manageable for early analysis. The first interview asked about general feelings toward mathematics and memorable experiences, peer and instructor interactions (including moments of support and lack of support), and definitions of diversity, equity, and inclusion. These questions provided a baseline for subsequent interviews and explored how students understood classroom interactions in relation to their participation and motivation. Interviews were semi-structured, with open-ended and probing prompts (Roulston, 2013).

Codebook development proceeded in four phases. First, one transcript was coded in Dedoose by three researchers, followed by discussion to clarify meanings and expand initial codes. Second, four additional transcripts were independently coded to seek new codes and refine definitions, producing 41 codes with examples. The transcripts were selected based on the impressions of the interviewers that they could bring different perspectives to the ones already captured. Third, the 41 codes were organized into 11 categories framed by the instructional triangle (teacher, student, and their interactions). For example, the codes *Supportive and Responsive Instruction* and *Commitment to Teach* were subsumed under the category *Instructor*, because they both describe how students perceived their instructors' teaching practices, attitudes, and dedication, rather than focusing on students' own actions or broader classroom conditions. As no new codes emerged, we moved to the fourth phase, using four transcripts from students at colleges not yet represented, to broaden the codebook. These were assigned to two new coders paired with original team members. They coded three transcripts each. The goal of this step was to confirm the definitions of the codes, make sure that they were applied consistently, and determine whether the codes were correctly placed under the existing categories. During this phase, one additional code emerged "Small class size limits opportunities for group

collaboration" which we placed under Factors. During this calibration, some codes were merged and definitions refined. The process concluded with nine categories and 34 codes, stabilized for use in this preliminary analysis (see Figure 1), and pseudonyms are used throughout.

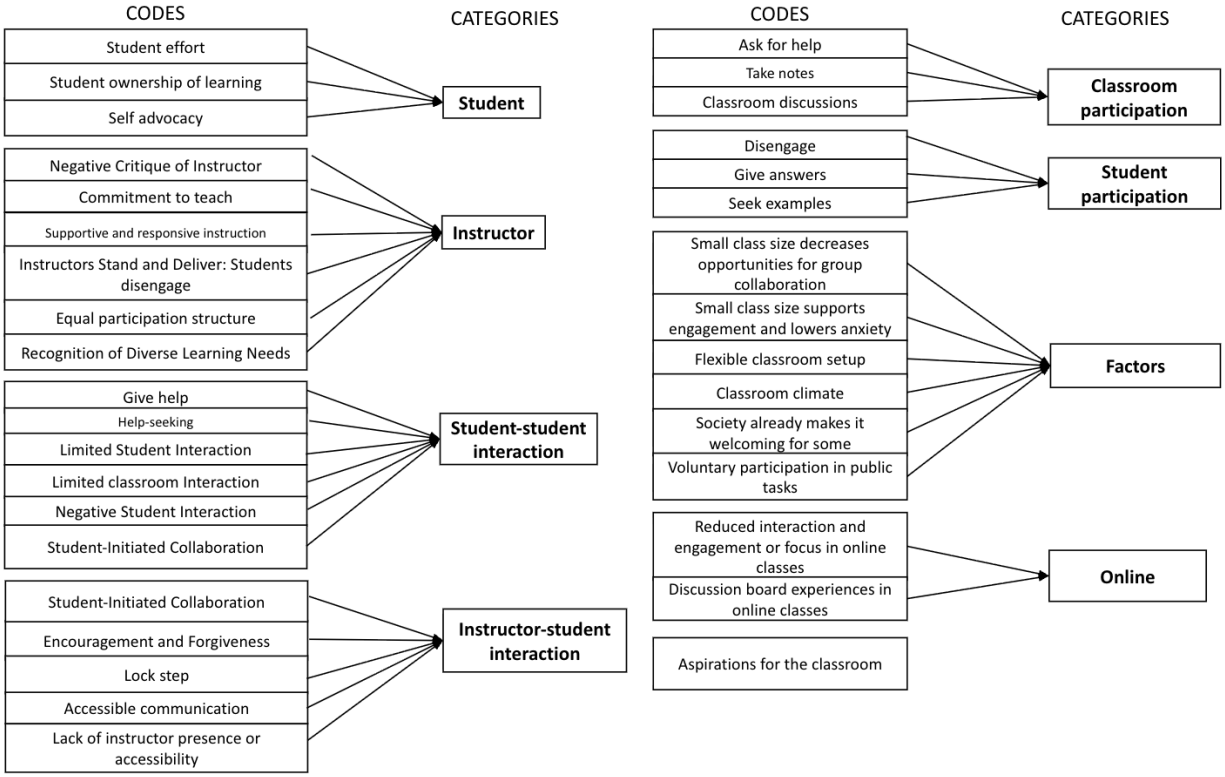

Figure 1. Preliminary codes and categories based on nine transcripts

Preliminary Findings

Our analysis draws attention to the ways students talk about instructors, peers, participation, and classroom environment. In organizing the codebook, we grouped codes into three broad dimensions: individual factors that capture how students described their own role in learning (e.g., student-focused codes such as effort and self-advocacy); relational dynamics that encompass interactions with instructors and peers, highlighting how teaching practices, responsiveness, and student–student collaboration shaped opportunities and constraints for participation (e.g., instructor, student–student, and instructor–student interactions); and structural or contextual elements that encompass broader features of the learning environment (e.g., class size, classroom climate, online formats) (see Figure 2).

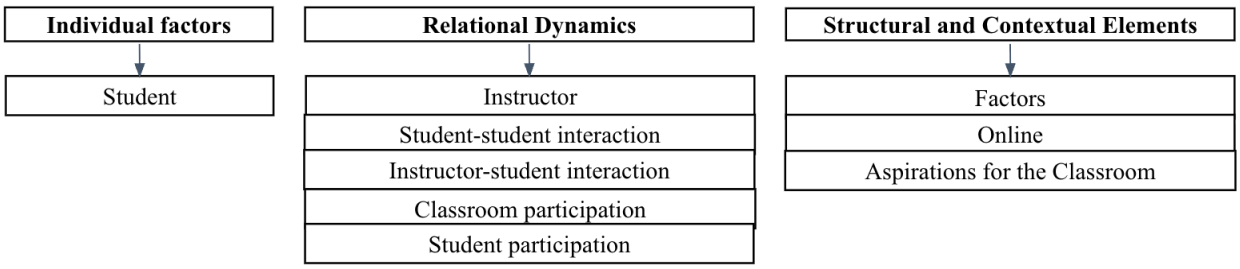

Figure 2. Preliminary categories and dimensions

These dimensions show that students' learning was shaped not only by their own effort and strategies, but also by how supportive instructors were, how much students interacted with peers, and how the classroom itself was structured. Viewed through an equity lens, these individual, relational, and structural or contextual elements show how classroom environments supported or constrained students' opportunities to learn and participate. In the following preliminary findings, we place particular emphasis on individual factors, relational dynamics, and structural or contextual elements, as these codes emerged most prominently in students' accounts.

Individual Factors. Within this dimension, we focus on two features of the classroom environment: Student Ownership of Learning and Self-Advocacy. Through **Student Ownership of Learning**, students described becoming more aware of how their own choices and persistence affected their outcomes. George reflected: "I also helped with a lot of the questions that [the instructor] asked… and at that time I actually got decently good with math." Jacob similarly noted, "I have to put in a lot of time outside of class… when I don't get that done, it really piles up after a while." These reflections show students making connections between their actions and their academic growth, underscoring their sense of responsibility for learning. With **Self-Advocacy**, students highlighted how voicing their needs and seeking support enabled them to navigate challenges. Elena explained: "I think just being more vocal about needing help instead of sitting in that frustration has just helped me." Pilar described this as a personal strength: "I think personally, I'm really good at advocating for myself and asking questions, and I've never had a teacher refuse to answer." Such accounts reflect how students exercised agency in creating equitable opportunities for themselves.

Relational Dynamics. Within this dimension, we highlight four features of the classroom environment: Supportive and Responsive Instruction, Equal Participation Structures, Recognition of Diverse Learning Needs, and Limited Classroom Interaction. **Supportive and Responsive Instruction** refers to instances in which students highlighted instructors who re-explained concepts, offered second chances, or encouraged persistence. Elena said that her instructor "made it very clear that his goal is for us to understand… he will not move on until he's like, 'Are you sure you get it?' and he tries to explain it from a different standpoint." Jacob similarly emphasized that his professor consistently checked for understanding, "going around the classroom… answering our questions, making sure that we're getting it." These accounts align with Gutiérrez's (2002) view that equity requires meaningful access to resources and opportunities. **Equal Participation Structures** collects students' descriptions of opportunities to engage simultaneously in problem-solving or to collaborate informally with peers. Jaime explained how her instructor ensured that "…so, like, people that need the extra extra explanation, it assists everyone. She's including the people that don't understand the same assignments as the people that do." Similarly, George noted the value of simply allowing time for collective work: "…So just let everyone get a chance to study together in class that would help a lot of people trying to get assignments done." Such practices reflect Esmonde's (2009a, 2009b) definition of equity as the fair distribution of opportunities to learn and participate, not only access to content, but also mathematical discourse and identities as knowers and doers. **Recognition of Diverse Learning Needs** captures students' comments about the importance of instructors adapting to varied learning styles and providing multiple entry points into mathematics. As Ayami explained, "We kind of need to branch out and explore different learning styles. Right now, I'm getting tested for neurodivergency, and it's a little bit difficult to just go through the way my current professor is teaching." Similarly, Althea said, "He does a survey… seeing how people, like, learn… 'email me if you need more explanation… and I'll

make a video about it,' because he just did a general video for the whole class." These reflections highlight students' desire for instruction that acknowledges diverse learning needs and aligns with equity-oriented calls for culturally and linguistically responsive pedagogy (Cho et al., 2022; Felton-Koestler, 2019). Finally, **Limited Classroom Interaction** refers to statements about how peer-to-peer communication was minimal or absent. Elena explained, "we all keep to ourselves… it's not too much talking, but there is some limited [interaction]." Althea, reflecting on her online algebra course, noted that "the only time I talked to another peer about math [was] in the tutoring center." Pilar similarly described the atmosphere as "kind of isolating… it almost felt like no one else was in the classroom." These accounts show that when opportunities for peer collaboration were limited students experienced learning as individuals and were disconnected. These experiences resonate with Cobb and Hodge's (2002) relational perspective, which emphasizes that equity also depends on the classroom norms and interpersonal dynamics that shape how participation is defined and enacted. When interaction is minimal, students have fewer opportunities to build mathematical identities and to experience learning as a shared endeavor.

Structural and Contextual Elements. Within this category, we highlight two features related to this dimension: Classroom Climate and Aspirations for the Classroom. **Classroom Climate** captures comments students made about their willingness to contribute to the emotional tone of the classroom and their perceptions of whether student mistakes were treated as learning opportunities or as sources of embarrassment. As Elena explained, "creating that space and that tone that mistakes are okay… we can solve the problem even though it's wrong." Jacob similarly emphasized that his instructor was "not judging… not going to us with a judging tone… not going to be super hard on us for getting it wrong." As Asa explained, her instructor interacted with all students "in the same and respectful" way and kept "trying to explain again and again so the sign translator could translate for those students". These accounts echo Cobb and Hodge's (2002) relational perspective, which argues that equity depends on whether norms and interpersonal dynamics create inclusive and respectful participation. With **Aspirations for the Classroom** we captured students' hopes for more inclusive and collaborative classroom practices. Elena suggested for instructors to check in with all students, not just the ones who frequently participate: "I would just make sure that I'm asking everyone if they understand. I am not just going to the person who always raises their hand… especially to the ones who don't answer or who don't raise their hand." Similarly, Pilar envisioned more group-oriented work: "Maybe like more problems or projects that make people work together and make more groups." These aspirations resonate with Esmonde's (2009a, 2009b) definition of equity as the fair distribution of opportunities to participate.

Next Steps and Questions

Ongoing analysis with all the interviews will identify common themes and better understand perspectives students bring to what an equitable math classroom environment looks like for algebra at community colleges. Questions for the audience, currently we have the following:

1. How might the categories we developed (e.g., student effort, classroom climate, instructor–student interaction) be grouped into broader themes that address equity?
2. What strategies could strengthen triangulation and support stronger claims about students' experiences?

A Preliminary Investigation into Multivariate Calculus Students' Understanding of Trigonometry

Anna Marie Bergman
Fort Lewis College

Alekzander Malcom
New York University

Rosaura Uscanga
Mercer University

This report describes a preliminary investigation into how multivariate calculus students understand trigonometric functions. Trigonometric functions are an essential component of understanding single-variable calculus which in turn is generalized into multivariable calculus. Therefore, an understanding of trigonometry is not only expected but an important component for success in multivariable calculus courses. Replicating a Weber (2005) study investigating trigonometry students' understanding of trigonometric functions, we surveyed multivariate calculus students to see how they understand trigonometric functions. Similarly, we leveraged the idea of procepts (Gray & Tall, 1994) to aid in interpreting students' descriptions of trigonometric concepts and properties.

Keywords: Multivariate Calculus, Trigonometry, Procepts, Student Understanding

Multivariate calculus is an intense course that often introduces students to both 3-dimensional space and vector notation at the start of term so that by the end of the term they can engage with various fundamental theorems of multivariate calculus. Needless to say, there are a lot of expectations on students' prior knowledge and understanding of various mathematical concepts, one such idea is trigonometry. By the time students are in multivariate calculus instructors assume that students have been working with trigonometric ideas for a number of terms. Furthermore, the fundamental theorems of multivariate calculus are often expressed using vector multiplication which can be defined using trigonometric relationships. However, working with a concept and understanding a concept are often different feats and our study aims to start to investigate how students who are expected to "know" trigonometry actually understand it.

Background and Literature

While multivariate calculus has seen considerably less attention than the teaching and learning of single variable calculus, over the last decade researchers have begun to shift focus to investigating student learning of multivariate topics and offering insights on pedagogical approaches. It comes as no surprise that literature on student understanding in multivariate calculus overwhelmingly focus on the understanding of topics introduced in a multivariate calculus course. A recent meta study that surveyed research studies on the learning of multivariate calculus (Martinez-Planell & Trigueros, 2021) found that much of the research deals with the idea of generalization and how students' knowledge of one-variable calculus influences their understanding of multivariable calculus. This research includes investigations into the student understanding of topics such as generalizing single variable functions to multivariable functions (Kabael, 2011), how student's meaning of function properties generalize to multivariate functions (Dorko, 2017), and students' understandings on definite integral of multivariable functions and how they relate to understandings about integrals of one-variable functions (Jones & Dorko, 2015).

An understanding of trigonometry is an important aspect of calculus readiness, as indicated by the Calculus Concept Readiness (CCR) (Carlson et al., 2015). The CCR is an instrument that assesses foundational understandings and reasoning abilities that have been documented to be essential for learning calculus. Five of the twenty-five assessment items on the CCR specifically

address student understanding of trigonometry. However, research also suggests students struggle with trigonometry, specifically with trigonometric comparisons and the recollection of commonly used formulas might be a real hurdle to their understanding of concepts in Calculus II (Ruslimin et al., 2019).

Our work is motivated by one particular study (Weber, 2005) that examined college students' understanding of trigonometric functions informed by Gray and Tall's (1994) notion of procept. Weber used the idea of a procept, described in detail below, to investigate and describe students' conceptual grasp of trigonometric functions, their ability to justify mathematical properties, and their use of multiple representations. Weber found that students did in fact view trigonometric expressions as procepts, often encapsulating processes related to right triangles or the unit circle.

Theoretical Perspective

Building on Weber (2005)'s work, we consider the notion of *procept* as introduced by Gray and Tall (1994). A *procept* is a mental collection of processes along with a concept that represents the result of those processes, summarized using symbolism. For example, Gray and Tall (1994) posit natural numbers as procepts, each symbol, such as 6, denoting the result of a child's process of counting, which later, after additional exposure to counting problems, mask other sophisticated procedures, such as 6 representing variously 4+2, 3+3, 7-1, and so on. Similarly, in calculus, the derivative often denoted $f'(x)$ can be seen as a procept. It both stands symbolically for the result of differentiation of the function $f(x)$, and as shorthand for the procedure itself. In fact, there are two procedures familiarly employed in a first course: the limit definition $\lim_{h\to 0} \frac{f(x+h)-f(x)}{h}$ and alternatively the collection of computational rules, which contains the power rule, the chain rule, the product rule, and so on. Gray and Tall (1994) emphasize that the use of a procept, once internalized by a learner, can allow a delayed computation, by "using symbols both as manipulable objects and as triggers to evoke mathematical processes" (p. 138).

The focus of this study is to revisit Weber (2005, p. 93-94)'s research questions with a new population, multivariate calculus students:

(1) *How do students in a [multivariate calculus] course understand trigonometric functions? In particular, do these students understand trigonometric functions as processes and/or procepts? If so, what types of processes do students think of when reasoning about trigonometric functions?*

(2) *Can students in a [multivariate calculus] course use their understanding of trigonometric functions to justify why trigonometric functions have the properties they do?*

In this preliminary report, we report on the first research question due to space limitations but will explore both questions in the RUME presentation.

Research Methods

Participants

The student participants in this study were enrolled in a semester long Multivariate Calculus course at a small public 4-year institution in the Rockies; taught by the first author. The pre-requisite for the course was Calculus II with a minimum grade of C-. Thirty students were enrolled in the course, 28 of whom participated in the study. Most participants were engineering majors (21), including computer engineering (10), engineering (9), and mechanical engineering (2). Mathematics (2) and secondary mathematics education majors comprised just over 10% of the participants. Lastly, there was one physics major (1), one geology major (1), and one

participant left the question blank (1). When asked when they were first introduced to the sine function and how long ago, on average participants had known of the sine function for at least 5.5 years. The least amount of time reported was 3 years, however two participants stated 'since high school geometry' which was conservatively estimated to 2 years. The most amount of time reported was 15 years.

Data Collection

Unlike the Weber (2005) study which included a pre-test, post-test, and interviews, our study consisted of a ten-question survey administered in class at the end of the term. Three of the questions were demographic in nature (reported above), one question asked participants to provide known applications of sine, and the remaining six, taken from the original Weber (2005) study, are listed below.

1. Describe sine in your own words.
2. Why is sine a function? What is its domain and range?
3. Approximate; $\sin 340^\circ$ and $\cos 340^\circ$
4. What is $\sin 270^\circ$ and why?
5. When is $\sin \theta$ decreasing and why?
6. Why is $\sin^2 \theta + \cos^2 \theta = 1$?

The first three questions were meant to gain a general sense of how participants think about the sine (and cosine) function and whether they view the functions as operations applied to angles (Weber, 2005). The purpose of the last three questions was to test students' recollection of specific trigonometric properties and elicit a justification for each. This preliminary report will discuss the analysis methods and results of Q1 and Q2 due to space constraints, while the remaining methods and results will be shared in the presentation.

Data Analysis

The first pass of analysis aimed to capture evidence of procepts used by the participants as they described the sine function. The original study exclusively referenced two processes leveraged by trigonometric students. The first approach involved reasoning about trigonometric functions using a unit circle model, and the second described trigonometric functions in term of right triangles. Weber (2005, p.93) described these processes in the context of a student's estimate for $\sin 20^\circ$ as:

- Mentally constructing a standard right triangle containing an angle of 20°, and then comparing the length of the side of this triangle opposite to the 20° angle with the length of its hypotenuse. Then, realizing that sine is equal to opposite over hypotenuse, approximating $\sin 20^\circ$ to be about 13.
- Mentally constructing a unit circle on the Cartesian plane and then constructing a ray emanating from the origin of the plane that forms a 20° angle with the positive half of the x-axis. Then, focusing on the point of intersection between the ray and the unit circle, noting that the y-value of this intersection will be a small positive number, such as 0.3.

When analyzing responses to Q1 we coded references to such approaches as "unit circle" and "right triangle" respectively.

Two new ways of describing sine were also found multiple times in our data which we named "wave" and "vertical." Participants who described sine in terms of a periodic or sinusoidal function were coded as "wave." An example of which would be, "Sine is the name of a sinusoidal function that oscillates, depending on the given angle" (P2). Responses that used a

vertical component devoid of a unit circle, such as "Sine is the trig function that is typically used for y-axis related parts of a function and whatnot" (P13) were coded as "vertical." All other responses were coded as "other." Each member of the research team first coded the data individually and came together to discussion any disagreement before reaching complete consensus.

Results

As previously mentioned, in this preliminary report we offer results to the first two questions from our survey. The data set contains responses from 28 participants.

Responses to Question 1: Describe sine in your own words

Most participants described a single strategy (21). Three students offered two approaches, and two mentioned three approaches. Two students did not provide meaningful responses.

Table 1. Student approaches used to describe the sine function

Student descriptions of sine function	
Approach	# of responses
Unit circle (exclusively)	3
Unit circle (total)	6
Right triangle (exclusively)	4
Right triangle (total)	7
Wave (exclusively)	12
Wave (total)	16
Vertical (exclusively)	2
Vertical (total)	3
Other	3

Most participants (16) referenced the "wave" approach, which again was not discussed in Weber (2005). Many of these students mentioned the graph of the function (in Cartesian coordinates), by either illustrating $y = \sin x$ or describing 'waves,' 'periodic functions,' or 'sinusoidal functions.' Twelve of these students only referenced this single strategy. For instance, participant P5 described sine as, "A wave function with period 2π and amplitude 1, starting at the origin."

Seven students described the sine function as constructing a right triangle and measuring the 'opposite' side and the hypotenuse to compute the sine. Five of these students solely mentioned this approach, for example (P16, Figure 1):

Figure 1. P16's interpretation of sine in terms of a right triangle.

Six participants mentioned the y-coordinate from a point on the unit circle. Two of these students only mentioned this approach. For example, student P1 explained, "Sine is the vertical 'axis' so to speak of the unit circle."

Three students were coded as "vertical" and seemed to reference a y direction or vertical component, devoid of a unit circle. For instance, P8 described sine as: "Sine is a direction in the y or vertical direction."

Five students offered multiple approaches. For example, one student used three approaches by describing sine as a "wave" along with right triangles and the unit circle (P3, Figure 2):

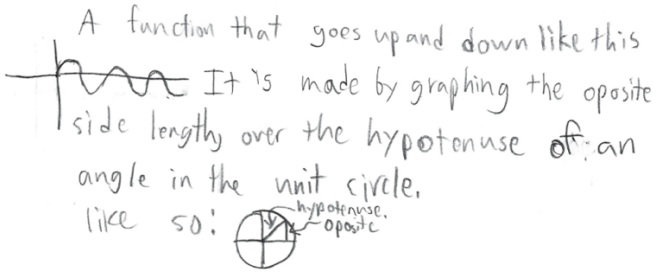

Figure 2. P3's description of sine in terms of wave, right triangle, and unit circle.

Responses to Question 2: Why is sine a function? What is its domain and range?

Many participants (7) ignored the first question, while fourteen wrote responses which could either not be coded or were off topic. Seven responses addressed the question directly. Two of these gave a completely correct answer, emphasizing that a single output was associated with each input. Four more gave a partially correct answer, stating that to each input there is "an" output associated. Lastly, one participant (P27) described a relation, saying "not exactly sure why its [sic] a function, but it relates $\angle A$, X, and H", where they had described sine earlier as relating sides of a right triangle using "the relation $\sin A = \frac{X}{H}$".

When asked about the domain and range of the sine function, a few students (4) gave restricted domains, such as $[0,2\pi]$. Three students skipped answering the question. Two students swapped the domain and range. The slim majority (15) were correct for both domain and range.

Discussion

In this study, we explored multivariate calculus students' understanding of trigonometric functions, in particular the sine function. As expected, this population used more approaches than were found in Weber (2005)'s study. However, we are hesitant to describe the new found approaches ("wave" and "vertical") as procepts since it is unclear to us what process specifically is being encapsulated. We hope further analysis of the remaining interview questions begins to shed light on this and we invite the audience to consider with us.

Consistent with the function literature, most students in our study were unable to, or unwilling to, offer a complete or correct justification of what makes sine a function. We are interested in considering how our current study could serve as a pilot for a follow-up study which would include interviews with participants. We hypothesize that multivariate calculus students have a more robust understanding of function than our survey elicited and if prompted differently, we think the findings would be more sophisticated. We invite feedback from the audience on further ideas for such a follow-up study.

Due to the preliminary nature of this work, we would like suggestions from the audience on the following: (a) What process might lead to a "wave" or "vertical" procept of the sine function? (b) When considering a follow-up study, how might we revise the context of the questions to include multivariate calculus, and would that be advantageous?

A Quantities-based Task for Simultaneously Constructing Limits-at-a-point and Differentials

Alex A. Swindler
Brigham Young University

Steven R. Jones
Brigham Young University

The limit is a key calculus concept, but research has clearly shown how important differential-based reasoning is, as well. Thus, calculus education would benefit from paradigms that construct both in a way that they can coherently co-exist. In this preliminary report, we discuss a small piece of a larger project meant to build one possible paradigm. Here, we describe a single quantities-based task that is meant to develop both limits and differentials together, in the same activity. We also provide preliminary results on two pairs of students' emerging understandings.

Keywords: calculus, limits, differentials, quantities

Much work in calculus has examined the limit as a fundamental concept both for calculus, and for further mathematical study (Cornu, 1991; Davis & Vinner, 1986; Oehrtman, 2009; Viirman et al., 2022). Yet, much work has also demonstrated the benefits that reasoning about differentials, such as *dx* and *dt*, as legitimate quantitative objects affords for first-year calculus (Ely, 2021; Jones & Ely, 2023; Oehrtman & Simmons, 2023). Based on this research record, it appears that the best approach to first-year calculus may be to construct paradigms that can simultaneously, and coherently, include both limits *and* differentials. While a couple of potential approaches exist (Thompson & Dreyfus, 2016), these particular approaches tend to be at odds with the way that differentials are described in the research literature, and how differentials are typically used in STEM fields. Thus, continued efforts are needed in this area, to build differentials-and-limits paradigms that better align with the research record and calculus' client STEM fields. We are currently engaged in building one such possibility, though we readily state others could create distinct paradigms. In this *preliminary* report, we focus on a piece of this larger project, namely a single task meant to introduce limits and differentials simultaneously, in the same activity. Our contribution is to begin a conversation on how these ideas might be constructed in tandem, but in ways that they still match the growing body of research in this area.

"Preliminary" Nature of this Report

Our project has previously constructed a theoretical framework for defining differentials inside of a broader limits structure. However, the tasks we have constructed for learning differentials-within-limits are only beginning to be examined. At the very start of our learning trajectory, we have two quantities-based tasks meant to build both ideas simultaneously, and we are only now testing these with students. We discuss one of these tasks in this report. Our analysis plan and our results are therefore still preliminary, and we seek feedback in these areas.

Background Literature

A major theme in limits research is that a limit consists of both a *process* and an *object* (Cottrill et al., 1996; Dubinsky et al., 2005; Gray & Tall, 1994; Kidron & Tall, 2015; Sfard, 1991). A process is a dynamic action that one can imagine happening. There are actually two main distinct processes one can imagine for limits. First, for the limit $\lim_{x \to a} f(x)$, one can imagine x sweeping through the real numbers on its way to becoming closer and closer to a (Cornu, 1991; Davis & Vinner, 1986). Second, one could instead imagine indefinitely zooming in on the graph of f in the neighborhood of $x = a$ (Ely & Ellis, 2018; Ely & Samuels, 2019). These processes can

lead to some outcome that can now be perceived as its own, self-existing entity, which is called the limit *object* (Sfard, 1991). That is, if we see that $f(x)$ hones in on (or remains at) some value L, we can return that value as the outcome and consider that value as its own object. In fact, we can even see the limit expression $\lim_{x \to a} f(x)$ as representing that value (Gray & Tall, 1994). One problem that students tend to have with the limit process and object, however, is thinking that the quantities in the limit process "collapse" to nothing as the limit "reaches" the object (Oehrtman, 2009). For example, a student might think that a shrinking time interval has vanished to nothing.

Next, a growing body of research has identified many benefits in reasoning with differentials (e.g., *dx* or *dt*) (Dray & Manogue, 2010; Ely, 2021; Jones, 2015; Oehrtman & Simmons, 2023). In this work, a differential is a quantitative object that represents a "tiny bit" of a quantity. While this definition is fairly informal, it is precisely its informal nature that is powerful for calculus education, and it is typically how differentials are understood and used across STEM fields (Amos & Heckler, 2018; Hu & Rebello, 2013; Nguyen & Rebello, 2011; Von Korff & Rebello, 2012). Such understandings allow improved quantitative reasoning for derivatives and integrals, and are also necessary for making sense of scientific relationships stated directly in terms of differentials, such as $dU = TdS - PdV$. Attempts at formally defining differentials can bring in too much theoretical baggage for first-year calculus, just as the formal ε-δ definition of limits has done. Consequently, our framework is based on these *intuitive, informal* ideas for differentials.

Research on differentials also describes that there are two distinct types of differentials. Von Korff and Rebello (2014) described that some differentials have a "change" nature, such as the differential *dt* representing some tiny change in time. On the other hand, some differentials have an "amount" nature, such as *dm* representing a tiny bit of mass (and *not* a change in mass).

Because of the power of differentials in calculus and related STEM fields, some researchers have discarded limits altogether, using only differentials (Dray & Manogue, 2010; Ely, 2021; Keisler, 2011). The issue for us here is that these paradigms essentially require non-standard hyperreals, which are not generally utilized in the mathematics community. Further, limits are an important foundation of further mathematics study, and we think calculus students should develop an understanding of them. Also, doing away with limits makes it harder to convince the wider undergraduate teaching community to adopt differentials in curriculum. Thus, we seek to build a paradigm where limits and differentials comfortably coexist in the same classroom. While some paradigms do exist that treat both limits and differentials (Oehrtman & Simmons, 2023; Stevens & Jones, 2023; Thompson et al., 2013; Thompson & Dreyfus, 2016; Weber et al., 2012), there are two ways in which work is still needed. Some of these paradigms have not explicitly articulated exactly how a differential should be defined in relation to the limit process, nor what the exact relationships between a limit and a differential is. Other paradigms have defined differentials in a way that does not align well with the large and growing research work on differentials. We want a paradigm that not only allows differentials and limits to co-exist, but where the differentials have the meaning and reasoning power described in the research record. Our project is meant to supply one possible approach for doing so.

Theoretical Framework: Differentials-within-limits

Our project previously developed a theoretical framework for conceptually defining differentials within a broader limits architecture that matches the research on differentials. In our framework, a differential is defined as a secondary object that results from *within* the limit *process*. In other words, we do not simply see our approach as differentials-*and*-limits, we see it

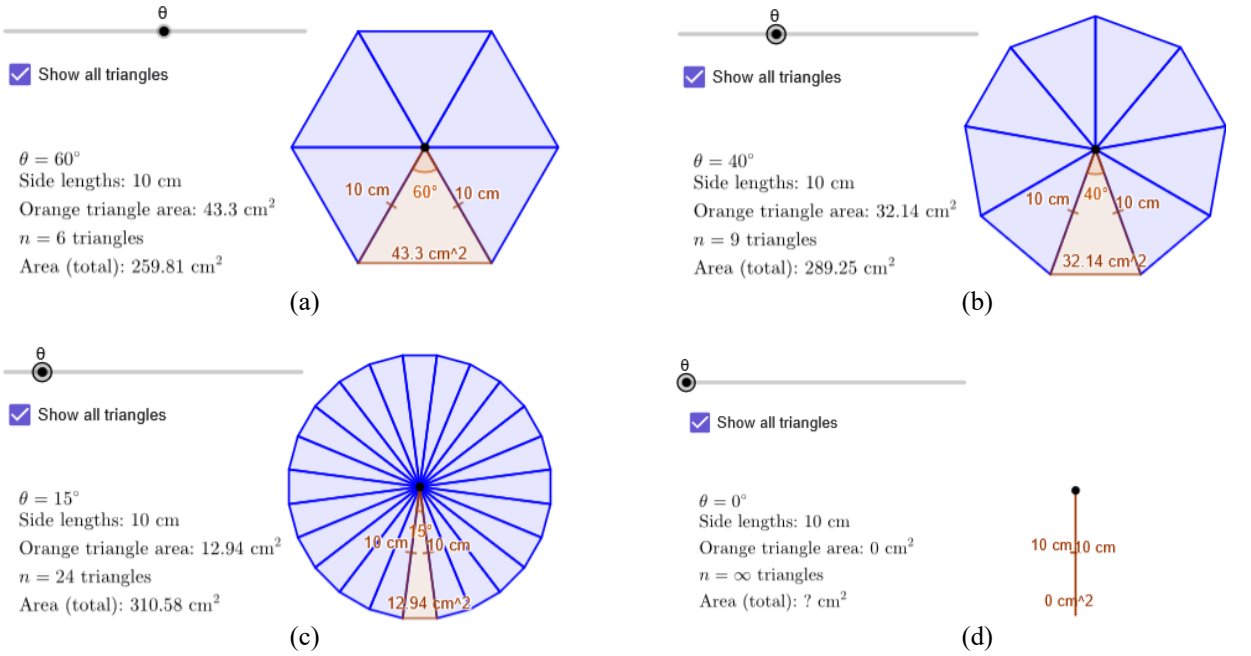
as differentials-*within*-limits. Table 1 provides an abbreviated version of our framework, including some basic definitions and some properties that are relevant to this particular report.

Table 1. Abbreviated version of the framework, with basic definitions and properties.

Differential, based on approaching	In the "approaching" limit process, if one perceives that a variable has become incredibly close to its target (i.e., x approaches close to a), they can "pause" the limit process at that moment and consider the remaining difference between x and a. This difference is defined as a *differential, dx*.
Differential, based on zooming	In the "zooming" limit process, if one zooms to tiny scales, they can again "pause" the limit process at some moment and consider the very tiny amount of a quantity remaining in the zooming window. This tiny bit is an alternate way to produce a *differential, dx*.
Definition #3: Output Differential	One can also create a differential for the *output* variable. In $\lim_{x\to a} f(x) = L$, as x gets close to a, or as one zooms into a graph near $x = a$, one can also imagine a change/amount differential for the output variable, *df* or *dy*.
Property #1: Subjectivity of Closeness	What is "close enough" in the limit process for it to be paused, and for a differential to come into existence, is subjective both on context and the reasoner's perspective. There is no specific point where this must occur. This subjectivity allows differentials to retain the desired informal nature.
Property #2: Lack of Specific Size	As a consequence of the previous property, differentials do not have a single, specific size or value. The differential object is *not* defined by a numeric value, as opposed to the limit object. Rather, the differential object is defined by the conceptual idea of a tiny change/amount.
Property #3: Non-hyperreal	While a differential does not have an inherent size, it still resides in the realm of very small real numbers, and is not a non-standard hyperreal.
Property #4: Contextual Assignment of Values	While differentials have no inherent size, for pragmatic reasons one can still assign a numeric value to a differential in a given situation, when context dictates, by "pausing" the limit process at a point deemed close enough or small enough and using that current state to assign a temporary value to a differential. This is a common practice in STEM fields.
Property #5: Differential as a "model"	A differential is a *conceptual model* of what happens at small scales. They represent what we might expect in the relationship between quantities, when measured or observed at small scales.

The Task

This preliminary report focuses on a single quantities-based task toward the beginning of a larger learning trajectory. The task uses a dynamic Geogebra applet in which the areas of regular polygons converge to the area of a circle (Figure 1). Of course, this context is certainly not new, and has a long history in mathematics (Katz, 2009). Yet, the use of it to simultaneously build both the limit-at-a-point concept and the differential concept is new, as far as we are aware. The task starts with a regular polygon made up of triangles with a certain interior angle, θ (Figure 1a). The students can change θ with a slider to see that smaller internal angles create polygons with more sides (Figure 1b, 1c). The main question is: "What happens to the area as we let θ go toward zero?" It is true that because θ can only take on certain values to create regular polygons, this task technically is the limit-at-a-point of a *sequence*. However, we believe that the ideas built in this task readily extend to the limit of a continuous function.



The tasks allows the students to slide θ all the way to zero, to see that the area is undefined there, since $\theta = 0$ correspond to no triangles, and hence no polygon (Figure 1d). Doing so helps address the collapse metaphor. Once the students identify that the area should converge to the area of a circle (100π cm^2), they are asked to explain the relationship between the shrinking θ and the converging area, A. Afterward, the specific limit notation is introduced, $\lim_{\theta \to 0} A = 100\pi$ cm^2. While this is technically a right-hand limit, we do not attend to that detail at this point.

Next, the students are asked: "When does the area actually become equal to 100π cm^2?" This question is meant to lead to the construction of differentials. When the students identify that there is no such point, they are asked how they decided on the limit. As the students describe very small angles, and an area very close to 100π, we explain that such small quantities can be termed "differentials." The students are then asked to describe the differentials they see in the task. The intention is for them to identify (a) a tiny θ as the (amount) differential $d\theta$ and (b) the discrepancy between the area given by a tiny angle and the assumed "limit" area as the (change) differential, dA. The students are asked how these differentials relate to the limit, and the limit value, and how they serve as a *model* for the context, even though we cannot reach $\theta = 0$.

We enacted this task within a larger set of interviews with two pairs of students recruited from the end of a Pathways College Algebra course that focused on quantitative reasoning. Thus, none of the students had taken calculus before, nor seen limits before, but they were familiar with reasoning about quantities. One pair consisted of two males and the other of two females. This task was one of two that began the interview sequence. While data analysis is ongoing, our initial analysis has focused on using our framework's definitions and properties as starting codes. We are in the process of identifying other themes to investigate further. The analysis and possible resulting outcomes is what we hope to receive feedback on in this preliminary report.

Preliminary Results

Because our initial analysis has centered on our framework's definitions and properties, our preliminary results have been organized around those themes. The following are early pieces of data that provide some evidence of understandings related to aspects of our framework.

Defining a differential: Several statements suggested an understanding of a differential as tiny bits of quantities that exist within the limit process, as exemplified in Claire's statements.

> *Claire*: If the angle is really close to zero, then it would be a differential. And that's just how we would like… that's how we'd like represent it. Because, like, you can't have an angle of zero, but you can have something really, really close to zero.
> *Claire*: So I think it would be, like, the differential of the area would be like the space around the circle that we haven't filled yet.

Change versus amount differentials: Notice that Claire's statements also potentially suggest both an "amount" differential for the angle and a "change" differential for the area. Her imagery of the angle seemed to be based on zooming to small angles, while her imagery for the area seemed to be based on the difference between the polygon's area and the circle's. As another example, Austin stated, "You make the angle so small," suggesting a zoom into tiny angles. His partner, Logan, later said, "So you take 100π minus whatever that [polygon] area is, and that's our differential for area," suggesting a difference between the two areas.

Avoiding collapse: The quantities-based nature of the task seemed to be extremely helpful in avoiding the collapse metaphor. While some students, at the start, thought of the triangles becoming straight lines, they rather quickly realized the issue in doing so. For example, Austin stated, "Because if it hits zero, then… you don't have, like you don't have anything." In the other group, Claire explained, "You can't make a triangle with a zero degree angle."

Subjectivity of closeness and lack of specific size: The students themselves appeared to build meanings for the differential that matches well with these two properties in our framework.

> *Claire*: Uh, yeah, just that we were talking about a differential being anything that's like approaching, or like a number really close to zero. I don't know if we ever went like, how, said how close "close" would be. But if the angle is really close to zero, then it would be a differential… Because, like, you can't have an angle of zero, but you can have something really, really close to zero.

Contextual assignment of values: The students appeared comfortable with occasionally using a very small number to represent a differential as a model for the limit process.

> *Logan*: I mean $d\theta$ would be like 0.0001 or something like that, kind of small number… Which isn't zero, but it's close to zero.

Conclusion and Questions for the Audience

Our early results favorably indicate that this task is successfully helping students construct differentials within a broader limits architecture. They constructed both types of differentials, and gave evidence of thinking of the several of the intended properties for differentials. Because this work is still in its early stages, the following questions will be used to solicit feedback:

1. What are your thoughts on this task as a way to simultaneously construct both limits-at-a-point and differentials? Are there any issues with it you see?
2. Do you agree that these student excerpts are evidence of the definitions/properties?
3. What other aspects of the students' thinking or understanding would you want to see?
4. What kind of disconfirming evidence would you want us to be looking for?

Instances of First-year Calculus in a Calculus-based Physics Textbook

Maxwell Ichinose David Robles Michael E. Loverude
California State University, Fullerton

We examine the presence of calculus concepts and skills in the portions of a standard textbook that are generally covered in the second and third courses of a typical introductory calculus-based physics course. Using the Calculus Concept Framework (Sofronas 2011) three researchers independently coded calculus concepts and skills in eighteen chapters of a calculus-based physics textbook covering electricity and magnetism, geometrical and physical optics, and modern physics. Along with prior work on the first twelve chapters covering mechanics, this analysis suggests that the calculus content is uneven and not well aligned with prerequisites.

Keywords: physics, calculus in the disciplines, instructional practices, textbook analysis

In previous work [redacted], we described analysis of the classical mechanics portion of a common introductory physics textbook using the Calculus Concept Framework (Sofronas 2011) to examine the prevalence of calculus skills and concepts in the first semester of introductory physics. In this paper, we continue this analysis to cover the portions of the textbook that cover electricity and magnetism, geometrical and physical optics, and the introduction to modern physics.

Our goals in this project have been to document and characterize instructional practice in introductory physics with respect to the use of mathematics in general and calculus in particular. We have sought to understand the extent to which calculus is used to scaffold student understanding, following the framing of Biza et al who contrasted calculus as a scaffold vs a filter (Biza 2022). As a scaffold, calculus is used to support learning and understanding; as a filter, it serves to prevent students from progressing without successful completion of calculus.

Introduction and Previous Research

As a means of characterizing calculus practice in introductory physics, we have followed the work of several other scholars in adopting the Calculus Concept Framework [CCF] (Sofronas 2011). The CCF was developed through analysis of interviews with a set of disciplinary experts who were asked to characterize the goals of first-year calculus. One element of the CCF identifies a list of concepts and skills that are essential to calculus understanding and that are generally taught in a calculus course sequence.

Several researchers have used the CCF to guide their analysis of the calculus content in later courses, including later courses in mathematics as well as those in so-called client disciplines. Czocher et al. used the CCF to describe the concepts and skills from calculus were used in a course in differential equations (Czocher et al., 2013). Subsequent work adapted this analysis in disciplines that require calculus, including introductory engineering (Faulkner et al., 2020), and general chemistry (McAfee and Rodriguez, 2024). Until our prior work, there was no similar analysis in introductory physics.

Research questions and methods

The primary research question driving this study has been: What concepts and skills from calculus are encountered by students in introductory calculus-based physics, and when are they encountered? A secondary question that has emerged is, what additional mathematical concepts

and skills are encountered by students? In previous submissions we have reported initial results from the mechanics portion of the text. For this paper we focus on the portion of the text that is generally covered in the second and third semesters of a typical introductory sequence. In addition, we reflect on these results as well as those from prior work to characterize the role of calculus for the whole introductory sequence.

The methodology involved three researchers coding instances of the concepts and skills from the CCF in a commonly used introductory physics textbook. The three researchers independently coded chapters 2 through 12 and 21 through 34 of the text (Resnick et al., 2014) for the presence of absence of each of the skills described in the CCF. We neglected chapter 1 in our analysis, which introduces quantities and units, and chapters 13-20 which cover topics that are skipped in the introductory sequence at our university (fluids, thermal physics).

After each section was coded, the researchers met to discuss codes and coding principles and re-negotiated how codes were to be interpreted. As we proceeded, we recorded inter-coder agreement after independent coding. By the end of the first-semester analysis, the agreement between coders was very high, e.g., 97% agreement for Chapter 11.

Three examples of portions of the text that were coded can be found below in the Results. Each example states what concepts or skills were coded from that passage. Note that the coding was based on the entire section, so the absence of a concept or skill in the included passage does not necessarily mean that the concept or skill is not present in the section that includes it.

There were several repeated instances of mathematical practices that were not present in the CCF. Some were instances of calculus concepts beyond the scope of the CCF, due to being covered in multivariable or vector calculus: dot and cross products, partial derivatives, and ordinary differential equations. We also added concepts and skills to our codebook for units, vectors and unit vector notation, and reasoning with graphs and diagrams. While one might argue that none of these are distinctly calculus, each of these were more common than many of the skills and concepts identified in the CCF and part of mathematical practice for the course.

While all three researchers identify themselves as physics faculty or students, one of the three is a supplemental instruction leader in calculus courses and so is regularly in contact with instructional practices in mathematics. This researcher initially coded some concepts based on practice in a calculus classroom. This made it clear that our coding is from the point of view of physics practice, and that coding might be different were mathematicians doing the coding. As the project has progressed, we have also sought to characterize the ways in which mathematical practice in introductory physics differs from what students encounter in their calculus courses, as well as a broader characterization of the mathematical skills beyond the CCF. These aspects are ongoing and will include interviews with instructors and students.

Results

We summarize the results in tabular form in Figure 1. The number in each cell refers to the number of codes for this concept or skill in each chapter. While we coded all the concepts and skills in the CCF (and a few others), the table displays only a few of the categories. The reason for this is twofold. First, many of the categories were coded very infrequently (or even not at all). CCF categories that were seldom / never coded included: (concepts) Riemann sums, Parametric and Polar Equations, Continuity, Optimization, Transformation; and (skills) Parametric Equations, Polar Coordinates, Epsilon Delta Proofs. Many of these were lower prevalence in the original CCF study. There were two additional skills that we omitted because their coding was so ubiquitous to be meaningless: Listening and Reading Comprehension and Facility with Definitions and Notation.

We added to our analysis several concepts and skills that were not included on the CCF, either because they are not considered calculus or are part of courses after the first year: vectors, units, graphs, diagrams, dot and cross products, and partial derivatives. In the diagram we show only the last three of these. Vectors, units, and diagrams were ubiquitous in the data set.

Some of the integrals that students encounter are no longer integrals of a single variable as students would encounter in first-year calculus. In this textbook, students encounter partial derivatives and functions of multiple variables, as well as path integrals, surface integrals, and volume integrals. These concepts are concentrated in the early sections of second semester physics, which at many institutions has Calculus 2 as co-requisite.

Concepts	Chp22	Chp23	Chp24	Chp25	Chp26	Chp27	Chp28	Chp29	Chp30	Chp31	Count	% of Total Codes
Derivative	0	0	5	0	3	6	0	0	20	9	43	8.62%

											499	100.00%

Figure 1. The prevalence of calculus concepts and skills in the chapters of introductory physics corresponding to electricity and magnetism. The corresponding data for optics and modern physics are not shown, as explained.

Algebra and trigonometry appeared more frequently than any other codes. Manipulating Algebraic Expressions was the single most common code, appearing in all chapters, and represented over 30% of all codes. Trigonometric Manipulations was second more frequent, representing approximately 14% of all codes, though it was more present in some chapters than others. Notably, several of the physical quantities and relationships in electricity and magnetism use vectors and the dot and cross product are both prevalent in this portion of the course.

Whereas derivatives were more prevalent than integrals in the mechanics portion of the class, this trend was reversed in electricity and magnetism, with integrals being coded approximately twice as frequently as derivatives. In addition, for integrals and derivatives, the concept was coded an order of magnitude more frequently than the corresponding skills of computing derivatives or using techniques of integration.

The three semesters of introductory physics have considerably different calculus usage. As described in prior work, the first semester of introductory physics (classical mechanics) features intermittent use of calculus. Derivatives and integrals appear most heavily in chapters on kinematics, work and energy, and rotational motion (2, 4, 7, and 10) but were completely absent from three of the ten chapters in that course. In electricity and magnetism, in contrast, each of the first five chapters, and seven of ten overall, include heavy emphasis on integration, frequently of vector quantities. Students encounter integrals of cross products (Biot-Savart law) and results from vector calculus, including the divergence theorem and Stokes' theorem. Derivatives are less common but are prominent in Chapters 24, 27, 30, and 31.

When the course turns to optics and modern physics in the third semester, calculus essentially vanishes entirely. While we coded through Chapter 37 in this portion of the project, the table in Figure 1 stops Chapter 31. This is because the chapters covering optics and modern

physics had essentially zero calculus concepts coded. These sections follow a common pattern; the only codes were for algebra and trigonometry (as well as diagrams and units, not included in the figure) but essentially zero codes for calculus-specific concepts and skills like derivatives, integrals, or limits. There were single instances of integrals in two sections and a derivative in one, but otherwise calculus is entirely absent for this portion of the course.

Discussion and Implications

Our findings have significant implications for instruction in physics as well as calculus. We make some observations and discuss these implications.

Several of the concepts and skills in the CCF have different interpretations in physics.

Two of the concepts and skills identified in the CCF are limits and approximations. These have specific and formal meaning in mathematics. In physics, students encounter limits and approximations as well, but the instantiation of these ideas looks quite different. The passage shown in Figure 2 came from the chapter on electric fields (22) and this section was coded as including both limit and approximation. This illustrates mathematical moves that are common in physics: a complicated expression is simplified by considering what physicists would call a limiting case. This allows the derivation of an approximate expression (equation 22-8 in the figure) that is conditionally valid. A mathematician might or might not code this differently.

> We are usually interested in the electrical effect of a dipole only at distances that are large compared with the dimensions of the dipole — that is, at distances such that $z \gg d$. At such large distances, we have $d/2z \ll 1$ in Eq. 22-7. Thus, in our approximation, we can neglect the $d/2z$ term in the denominator, which leaves us with
>
> $$E = \frac{1}{2\pi\varepsilon_0}\frac{qd}{z^3}. \qquad (22\text{-}8)$$

Figure 2. An example of limiting arguments and approximations that highlights differences in instructional practices between calculus and physics.

While the contexts are complex, the actual derivatives and integrals are often not.

While the contexts in second-semester physics involve integrals of vector quantities in multiple dimensions, as a practical matter the integrals that are evaluated are often quite simple. As an example, in Chapter 22 the text derives expressions for the electric field of various configurations of static charges, including continuous charge distributions. To derive the electric field of a line of charge, the text begins with a charged ring. To an observer (probably including many students), this might seem more complex, but the symmetry of the charged ring simplifies

> ***Integrating.*** Because we must sum a huge number of these components, each small, we set up an integral that moves along the ring, from element to element, from a starting point (call it $s = 0$) through the full circumference ($s = 2\pi R$). Only the quantity s varies as we go through the elements; the other symbols in Eq. 22-14 remain the same, so we move them outside the integral. We find
>
> $$E = \int dE \cos\theta = \frac{z\lambda}{4\pi\varepsilon_0(z^2 + R^2)^{3/2}}\int_0^{2\pi R} ds$$
>
> $$= \frac{z\lambda(2\pi R)}{4\pi\varepsilon_0(z^2 + R^2)^{3/2}}. \qquad (22\text{-}15)$$

Figure 3: The conclusion of the textbook derivation of the electric field due to a charged ring. While the integral in principle is a vector integral in three dimensions, in practice the integral is of a single variable.

the task. Figure 3 shows the concluding steps. Despite the complexity of the expression for the electric field, the integral to be evaluated is a definite integral of a single variable: $\int_0^{2\pi} ds$. All the complexity of the situation is in setting up and simplifying the integral; evaluation is, in principle, trivial. (Though we note that there is evidence that this may not be so trivial to students.) White Brahmia [2023] has noted that the functions that students encounter with in introductory physics are simpler than their calculus courses might suggest.

In the following chapter, students encounter Gauss' law, which is a physics application of the divergence theorem. The presentation in the text sets up a surface integral over the surface of a sphere but then simplifies the calculation with physical reasoning and symmetry. Notably, the integral is now with respect to an apparent single variable A, but that simplified expression might conceal the complexity of a two-dimensional surface area of a three-dimensional object.

> The drill here is the same as previously. Pick a patch element on the surface and draw its area vector $d\vec{A}$ perpendicular to the patch and directed outward. From the symmetry of the situation, we know that the electric field $\vec{E}$ at the patch is also radially outward and thus at angle $\theta = 0$ with $d\vec{A}$. So, we rewrite Gauss' law as
>
> $$\varepsilon_0 \oint \vec{E} \cdot d\vec{A} = \varepsilon_0 \oint E\, dA = q_{\text{enc}}. \qquad (23\text{-}8)$$
>
> Here $q_{\text{enc}} = q$. Because the field magnitude E is the same at every patch element, E can be pulled outside the integral:
>
> $$\varepsilon_0 E \oint dA = q. \qquad (23\text{-}9)$$

Figure 4. A surface integral that is simplified through symmetry and physical reasoning to a more straightforward (to physicists, at least) example of integration.

In summary, we note several implications and future thoughts. First, the sequence of calculus usage in introductory physics is a mismatch with co- and pre-requisite structures. In many institutions, including our own, first semester physics is a co-requisite for Calculus I. For students in first semester physics, the first integral might appear in week two; at this time in Calculus I, students might not have even encountered derivatives. In electricity and magnetism, students encounter integrals of vector quantities in three-dimensional situations by the second week of the semester, when students in the co-requisite Calculus II are learning single-variable integration. The third semester then has minimal calculus.

Second, and perhaps a result of the above, when calculus does appear, there are often steps taken to reduce the complexity of calculations. Situations with two or more dimensions are regularly reduced to integrals of a single variable. While these integrals are conceptually complex, as examples above indicate, structurally they appear as integrals of a single variable.

Third, the CCF is an imperfect match to the mathematics that students encounter in introductory physics. As we previously reported, many of the mathematical skills required in the course were not included in the CCF, and many of the skills and concepts identified in the CCF appeared rarely (or never appeared). For the second semester of the course, this reflects the need to attend to vector quantities and situations in multiple dimensions, each normally the province of multivariable calculus and outside the scope of the CCF.

While the textbook strongly guides instructional practice, we note that analysis of a textbook provides only an incomplete description of what instructors and students do in class. We have performed several interviews with instructors related to first semester content, and while preliminary analysis indicates that they perceive their practice to be closely aligned with our findings, that work is still ongoing.

College Students' Perspectives on and Use of Exam Note Sheets in Intermediate Algebra

Abigail M. Quick
University of Delaware

Dawn Berk
University of Delaware

Creating and bringing a sheet of notes to a math exam can help students perform better and feel less anxious, but not all note sheets are equally helpful. This study explores how undergraduate students prepare and use exam note sheets in an intermediate algebra course. We surveyed 119 students about how they created and used their exam note sheet and how they perceived the usefulness of their sheet. We also collected students' note sheets and exam scores. Preliminary analyses revealed that most students spent less than two hours preparing their note sheet. Most students felt the note sheet helped them study for and perform well on the exam and lessened their anxiety. Forthcoming analysis will explore relationships between students' exam performance and features and use of their sheet. Findings can be used to develop guidance for students on how to more effectively prepare and use exam note sheets.

Keywords: Note sheets, crib sheets, support sheets, exam studying, college algebra

Sometimes college instructors allow students to bring an index card or sheet of notes to use on exams (sometimes referred to as a "cheat sheet"). These note sheets can usually include anything students think might be helpful on the exam, such as formulas, definitions, or descriptions of procedures. Instructors often allow this resource because they believe it helps alleviate students' anxiety and because they want students to focus more on conceptualization and problem solving and less on memorizing and procedures (Danielian et al., 2020; de Raat, 2012; Edwards & Loch, 2016). Some studies have shown that students report feeling less anxious or stressed about an exam when they are allowed to bring a note sheet (Danielian et al., 2020; Drake et al., 1998; Erbe, 2007). While some research has found that using note sheets is associated with better exam performance (Larwin et al., 2013), other studies have shown no significant relationship to performance (Hamouda & Shaffer, 2016).

The relationship between a students' exam score and their use of a note sheet may depend on the types of information they include and other characteristics of their note sheets (Song & Thuente, 2015). For example, studies analyzing students' exam note sheets have found that including more example problems (Edwards & Loch, 2015) and creating a more densely packed sheet (Ludorf & Clark, 2014) are associated with lower exam scores, while including a lower number of abstract concepts is associated with higher scores (Danielian & Buswell, 2019).

The benefit of a note sheet may not come simply from having it as a source of information during the exam; the process of creating the note sheet can be a valuable part of the study process. While preparing their note sheet, a student may consider which course concepts are most important, strategize about how to organize the information, and determine which ideas they know by heart and what reminders they might need. A high-quality note sheet that reflects a student's understanding and is tailored to their needs is a product of a thorough study process. For example, de Raadt (2012) suggests that the connection they found between including fewer abstract concepts and performing better on the exam may reflect that students who internalize key concepts develop a deeper understanding of the material and are thus likely to perform well.

In this study, we explore how college students in an intermediate algebra course create and use exam note sheets, as well as their perspectives on the utility of the note sheet. We also consider how various features of students' use of note sheets relate to their exam performance.

Insights gleaned from this research can indicate if and how preparing and using an exam note sheet is helpful to students. Instructors can use this information to develop guidance for students on how to prepare and use an exam note sheet in a way that helps them learn material deeply and perform better on exams.

Background Literature and Research Questions

Much of the existing research on the use of exam note sheets has focused on coding students' note sheets for particular features, such as number of example problems and formulas included, organization, and density (e.g., de Raat, 2012; Ludorf & Clark, 2014; Song & Thuente, 2015). Many of these studies have attempted to identify which features are associated with better performance, by comparing students' note sheets to their exam scores (e.g., Capaldi, 2019; Edwards & Loch, 2015). Most of these studies have used small samples, and many analyses failed to reach statistical significance.

Another approach has been to survey students to explore their perspectives on how they create and use exam note sheets (e.g., Danielian et al., 2020; McCaskey, 2013; Peters, 2024). These surveys have revealed insights into how the note sheet fits into students' larger study process and how they see the benefit of the resource. For example, when asked to rate the extent to which the process of making a note sheet helps them study for exams, undergraduate students in an engineering class gave an average rating of 4.11 out of 5, with 5 indicating that making a note sheet helps a great deal in studying (Peters, 2024). Most students felt that the note sheet was effective in helping them perform on the exam as well (Peters, 2024). In another study conducted in an undergraduate engineering class, students reported that preparing a note sheet helped them summarize, retain, and organize content and allowed them to avoid memorization (Danielian et al., 2020). Students also noted that having a note sheet alleviated their stress about the exam (Danielian et al., 2020). Most survey studies involved small samples, and many did not consider exam performance in their analysis.

More research is needed to investigate the relationships among students' perspectives on and use of note sheets, individual features of the note sheets themselves, and scores from the exam on which they used the note sheet. Exploring these three data sources and relationships among them should provide a deeper understanding of how preparation of a note sheet fits into students' overall study process, and how their use of the resource relates to their exam performance. Additionally, only a few studies have explored the use of note sheets in mathematics courses specifically (Capaldi, 2019; Edwards & Loch, 2015). To build on the existing literature on students' use of exam note sheets, this study investigates the following research questions:

1. In what ways do college students enrolled in an intermediate algebra course create an exam note sheet and use it on an exam?
2. How do students perceive the usefulness of their note sheet as an exam resource?
3. What are common features and properties of the exam note sheets created by the intermediate algebra students?
4. What relationships exist between how a student creates and uses their note sheet, characteristics of the note sheet itself, and their exam performance?

Method

Participants and Context

Participants were 119 undergraduate students enrolled in three sections of an intermediate algebra course at a large research institution located in the mid-Atlantic region of the United

States. Students in this course are allowed to prepare and bring one 8.5" x 11" sheet of notes to use on each exam. This course was chosen for study because instructors have noticed wide variability in what students include on their note sheets and want to better support future students in preparing and using their note sheets.

Ninety-one percent of participants were in their freshmen or sophomore year, and 35% were repeating the course. At least 90% of the participants elected to provided demographic information. Of the students who did, 68% identified as women, 30% as men, and 2% as non-binary. Seventy-three percent of respondents identified as white; 19% as Black/African American; 14% as Latine/Hispanic; 9% as Asian, Pacific Islander, or Desi; and 2% as indigenous/Native American. (Percentages add to more than 100 because participants were allowed to select multiple racial/ethnic identities.) Twenty-nine percent of respondents reported being a first-generation college student.

Data Collection

After the third exam of the Spring 2025 semester, we invited all 187 students enrolled in the course to complete a survey about how they created their note sheet, how they used it on the exam, and how they perceived the usefulness of their sheet. The exam focused on systems of linear equations, understanding and manipulating exponents, simplifying and factoring polynomials and rational expressions, and using the zero product property to solve equations.

Survey questions included a mix of multiple-choice, Likert, and open-response questions. Multiple choice questions asked students about their note sheet creation process (e.g., how long they spent creating their sheet and whether they worked with others), as well as what types of information they included and how they used their note sheet on the exam. Likert questions asked students how useful their note sheet was in helping them study for and perform on the exam and whether having the sheet lessened their anxiety/nervousness about the exam. The open-response questions, several of which were inspired by McCaskey (2013) and Peters (2024), asked students to describe their process for creating their note sheet, how they used it on the exam, and any changes they plan to make when preparing their sheet for the next exam.

Students were offered a small number of course points to incentivize participation. We received 128 responses, but some were not included in the analysis because students either did not complete enough of the survey or did not take the exam. There were 119 usable survey responses, a response rate of 64%. We asked the 119 students for consent to analyze their note sheets and exam scores. Seventy-three students allowed access to their note sheets and 72 to their exam scores. In total, 71 students allowed access to all three data sources.

Data Analysis

Preliminary analyses have been conducted. Specifically, we have analyzed the responses to the 18 multiple-choice and 10 Likert items on the survey. We created frequency tables for responses to each question. To analyze responses to the open-ended survey items, we will use inductive thematic analysis (Braun and Clarke, 2006).

We plan to code students' note sheets according to various features and characteristics of each sheet, inspired by strategies used by Capaldi (2019) and Edwards and Loch (2015). For example, we will count how many example problems and descriptions of procedures are included. In addition, we may categorize students' strategies for organizing the information. We will decide precisely which features to attend to after analyzing the survey responses and exam scores in more depth. Insights gathered from these first two data sources could illuminate which

features of the note sheets may be most beneficial to attend to, which will help target the coding process.

We will use chi-square analysis, ANOVA, and multiple regression to investigate correlations between and among the survey responses, exam scores, and quantifiable note sheet features.

Preliminary Findings

We present preliminary findings from analysis of the multiple-choice and Likert survey items. Of the 119 participants, 105 created a note sheet for the third exam. Of these students, 91% reported spending less than two hours making their sheet, and 54% reported spending less than one hour. About a quarter of students (28%) started making their note sheet on the day of the exam, with another quarter starting the day before, and 48% starting at least two days in advance. Only 13% of students reported working with others when creating their sheet.

Regarding the kinds of information students included on their note sheet, a large majority said they included formulas (89%), example problems (84%), and instructions or steps for solving certain types of problems (78%). Students also reported including definitions (43%), graphs (11%), and supportive notes to themselves, e.g., "You can do it!" (9%).

Participants who created a note sheet were asked how often they used it during the exam. Survey responses indicate that 41% of students used their note sheet three to five times, 29% used their sheet one to two times, and 27% used it more than five times. Only 4% of students reported not using their note sheet at all. Most students reported using their note sheet to look for examples of similar problems (74%), steps for solving certain types of problems (70%), or a formula (66%). Students were less likely to use their sheet to look up a definition or fact (29%) or a graph (6%).

Most students reported perceiving the note sheet as a positive resource. Fifty-two percent strongly agreed and 36% somewhat agreed that the process of creating their note sheet helped them study for the exam. Forty-five percent strongly agreed and 33% somewhat agreed that having a note sheet helped them perform better on the exam. Fifty-two percent strongly agreed and 31% somewhat agreed that having a note sheet helped lessen their anxiety or nervousness about the exam.

A small number of students (n=14, 12% of survey respondents) reported that they did not make a note sheet for the exam. When asked why they chose not to make one, half of these students reported that they felt confident about the material and did not feel the need for a note sheet. Other reasons included forgetting to make a note sheet (29%), not thinking a note sheet would be helpful for the exam content (21%), not having time to make one (21%), being unsure what to put on the note sheet (21%), and finding a note sheet they made for a previous exam unhelpful (14%). (Percentages add to more than 100 because participants were allowed to select multiple reasons.) Of the students who did not create a note sheet, 50% strongly agreed and 36% somewhat agreed that having one would have helped them study for the exam. Fifty-seven percent strongly agreed and 21% somewhat agreed it would have helped them perform better.

Discussion

Survey responses revealed that students spent a minimal amount of time creating their note sheets, with more than half of respondents spending less than an hour, and almost all (91%) spending less than two hours. Most students started making their note sheets close to the exam day, with slightly over half starting the day of or day before the exam. As our analysis proceeds, we plan to investigate if and how these characteristics of students' note sheet creation process relate to their exam performance.

Results indicated that formulas, example problems, and instructions or steps for solving certain types of problems were the top three pieces of information included on note sheets as well as the top three used on the exam. Interestingly, while formulas were the most common type of information students reported including on the note sheets, with 89% of students including them, they were only the third most common type of information used, with only 66% of students looking up a formula on their sheet during the exam. When we analyze the note sheets themselves, we will be able to see which formulas students included, which could reveal insights into why they were not as relevant on the exam as students expected. Students' expectations regarding examples and instructions/steps were more in line with their use: 84% of students reported including example problems, and 74% ended up looking for examples during the exam. Similarly, 78% of students included instructions/steps, and 70% looked for them during the exam. The low percentages of graphs and definitions/facts included likely reflects the fact that the content of the exam focused on simplifying and factoring expressions and solving equations and thus did not call for many definitions, facts, or graphs.

The finding that a majority of students (83%) felt that having a note sheet decreased their anxiety or nervousness about the exam resonates with others who have found that note sheets help students feel less anxious or stressed (Danielian et al., 2020; Drake et al., 1998; Erbe, 2007).

Next Steps

In the next phase of analysis, we will investigate how students' exam performance relates to various aspects of how they created and used their note sheets. We will look for correlations between students' survey responses and their exam scores and plan to report on our findings at the conference. For example, we will analyze whether the amount of time a student spent preparing their note sheet is associated with their exam score. We will also analyze students' responses to the five open-ended survey questions and plan to present salient themes at the conference. For example, we hope to describe students' various strategies for deciding what information to include on their note sheet and how to organize the information. The final phase of analysis will consist of developing a coding scheme for the note sheets themselves, based on salient features identified in earlier phases of analysis. After coding the sheets, we will investigate relationships between features of the note sheets and students' exam scores.

Previous studies have suggested that students need guidance in how to use the note sheet resource effectively (Capaldi, 2019; Edwards and Loch, 2015; Ludorf and Clark, 2015). We hope this analysis will reveal insights that can help researchers and practitioners develop guidance for students on how to create a note sheet that helps them learn the material and succeed on exams.

Questions for the Audience

1. What features would be fruitful to attend to when analyzing students' note sheets?
2. What conceptual or theoretical framings would be useful to consider when interpreting our findings?
3. Based on your teaching experience, what advice would you give students on how to prepare and use their note sheet?

Montclair State University

This proposal reports on the impact of a course designed to prepare first-year students for success in Precalculus. The course, Approaches to College Mathematics (ACM), was developed as a prerequisite course in response to one university's high failure rate in Precalculus. In addition to a carefully designed yet flexible curriculum that aims to have students explore familiar topics in fresh ways, the course focuses on growth objectives meant to help students transition to their first semester as a college student. Institutional data and survey data from both students and instructors were collected. Preliminary results show that the overall failure rate in Precalculus decreased the semester after ACM was implemented. Additionally, a high percentage of students in ACM reported feeling that ACM was the right placement for them. Finally, ACM grades and the ACM instructors' sense of their students' mathematical confidence significantly predicted grades in Precalculus.

Keywords: Precalculus preparation, mindset, retention

We report on a study that involved the development and implementation of a course, Approaches to College Mathematics (ACM), for students who require an additional college course to prepare for Precalculus. The study is based on 15 sections of the course from Fall 2024. Going in, we were acutely aware of the unique circumstances that were a reality for these students who, as first-year undergraduates in 2024, had been in eighth grade at the onset of the COVID pandemic. This meant that they had spent most of their freshman year in high school learning mathematics online, even though their teachers had not been supported in online pedagogies given the pandemic's abrupt and urgent demands (Engelbrecht et al., 2020). In other words, it is likely that many of the students entering college in 2024 had significant gaps in their mathematical skills and knowledge, particularly with respect to content covered in Pre-Algebra and Algebra I. In addition to these mathematical obstacles, we knew that ACM students would be navigating additional challenges commonly experienced by students transitioning from high school to college learning.

Because the primary goal of the ACM course was to prepare students for Precalculus, we chose to focus on content and skills that would be foundational to that course (e.g., proportional reasoning, graphing, and order of operations). However, we kept this list relatively short to allow for flexibility and responsiveness in our practice, providing space for instructors to address student misconceptions as they emerged in class. Further, we designed several inquiry-based group work activities for ACM that would promote the development of rich, conceptual understanding. Finally, to prepare ACM students more broadly for learning mathematics at the college level, we incorporated a number of *growth objectives* intended to encourage productive habits of mind and actions. These objectives focused on seeking support from professors, managing time, taking advantage of college resources (such as the tutoring center), and managing stress. Thus, we took on the charge to reconceptualize what it means to prepare

students for college level mathematics, and to investigate the efficacy of our new course. The following research question framed our study: *What is the impact of the Approaches to College Mathematics course on students' preparedness for Precalculus, as assessed by their grades in Precalculus and their own sense of the usefulness of ACM?*

Conceptual Framing

The early history of remedial education began with the passage of the GI Bill in 1944, which sparked a proliferation of postsecondary institutions (Adams, 2000). This meant that thousands of high school graduates, many of whom were not prepared to study mathematics at a college level, suddenly had access to a tertiary education. In this environment, mathematics departments began to offer remedial mathematics courses to help improve students' mathematical knowledge and skills. By the end of the 20th century, remedial mathematics had become "a formal discipline of study, as institutions of higher education recognized that the need to provide remedial education to their students was now a continuing one" (Shaddai, 2018, pp. 389-390).

Whether or not remedial courses in mathematics ultimately result in the intended benefits for students is a matter of debate. While successfully completing a remedial mathematics course may improve the likelihood a student will earn a college degree (Sanabria et al., 2020), the high failure rates in these courses position them as "a systemic black hole from which students are unlikely to emerge" (Jimenez et al., 2016, p. 1). In recent years, this perception has led several institutions to reconsider how best to support their undergraduate students who are not yet ready to study college level mathematics. For example, some institutions have reported improved student outcomes in introductory mathematics courses after experimenting with a co-requisite model (Bertrand et al., 2021; Ran & Lin, 2022). In this model, students that would traditionally be placed in remedial courses are mainstreamed into college-level math courses and provided with additional concurrent supports, such as tutoring services or extra lessons that review prerequisite skills just before they are required in the college-level course.

This need to reconsider 'remedial' or 'developmental' mathematics education for first-semester college students motivates our study. Having tried the co-requisite model, a computer-based self-paced emporium-style model, and other support systems with little success, our department proposed the development of a new course that acknowledges the unique (and varied) needs of this student population. The research team agreed that the overarching focus driving all of our efforts was to prepare students for Precalculus, and that this preparation must necessarily encompass more than just mathematical knowledge and skills. Given that, we eventually landed on two major goals: to enhance students' understanding of mathematics content that is considered prerequisite for Precalculus (math objectives) and to help them acclimate to being a college student (growth objectives). The team met weekly over the summer to develop these objectives and to design tasks that aimed to have students explore familiar mathematics using novel approaches.

Methods

The study took place at a mid-sized state university in the northeastern United States that has experienced substantial growth in the last two decades. Most of the students at this university come through local school districts or community colleges, and the current acceptance rate is roughly 87%. Precalculus is a required course for all STEM (science, technology, engineering, and mathematics) majors. Students take an internally developed placement test before their first semester, and are placed in ACM if their score is below 60%. In Fall 2024, approximately 30% of students were placed into ACM, with the remainder taking either Precalculus or Calculus. The

average class size of each ACM section was 23 students. Of the 343 students enrolled in the course in Fall 2024, 118 consented to participate in the study. Data was collected from both students and instructors. Students completed a survey at the beginning of the Fall 2024 semester in ACM and at the beginning of the next semester, Spring 2025, in Precalculus. This survey included several short-answer questions asking them, for example, why they were studying mathematics, their perception about what it means to be a 'math person,' and whether or not they thought ACM was the right course for them. The survey also included 14 Likert scale questions taken from the Attitudes Towards Mathematics Inventory Short Form (Lin & Huang, 2016).

At the end of the Fall 2024 semester, the seven ACM instructors were asked to report each student's grade (as a percentage), attendance (as a percentage), as well as their subjective assessment of each student with respect to seven categories: content knowledge; readiness for college; academic integrity; classroom presence; mathematical dispositions; and mathematical confidence. These assessments of each student were reported as scores of 1 (low), 2 (moderate), or 3 (high). Additionally, instructors were asked to predict each student's letter grade for Precalculus. Final letter grades for consenting students in ACM in Fall 2024 and Precalculus in Spring 2025 were collected from our institution.

Results

We report on three key findings: the percentage of students receiving either a D, F, or W grade (the DFW rate) in Precalculus, students' perceptions of their placement in ACM (both before and after having taken ACM), and a regression model predicting students' letter grades in Precalculus. In the semester prior to the implementation of ACM, the DFW rate in Precalculus was 34.7% (a rate that has historically been between 30% and 50% at our institution). This rate is significant because STEM students who receive a D grade or lower are unable to take the next required mathematics course. The Precalculus DFW rate in the first semester we held ACM (Fall 2024) was 18.4%, notably (and predictably) lower than the previous semester, due to placing the less-prepared students into ACM. When the ACM students took Precalculus in Spring 2025 (accounting for 61.3% of Precalculus students), the overall DFW rate increased slightly to 20.3%, but was well below the historical average of 30% to 50%. The DFW rate in Precalculus for students who had taken ACM was also comparable to that of those who had placed directly into Precalculus (20.5% and 19.5%, respectively). This last result indicates that students who took ACM were able to earn their required Precalculus credit at rates roughly similar to their peers.

Another notable result had to do with students' sense of whether or not they felt that taking ACM before Precalculus was the right course of action for them. Students were asked to answer the following open-ended question at the beginning of their ACM semester and at the beginning of Precalculus: *Do you believe ACM is/was the right course for you?* Students' responses to this question included straightforward 'yes' or 'no' responses, with some responses being more nuanced (e.g., "I feel like I should've been placed in [Precalculus] instead of [ACM], but it was a nice refresher."). However, we categorized all responses as either 'yes' or 'no,' based on our understanding of the intent behind the more nuanced responses. In the pre-ACM survey, 91.5% were coded as a 'yes' response; by the start of their Precalculus semester, this percentage had dropped somewhat to 80.5%. Despite this decrease, it was clear that the overwhelming majority of students felt as though their placement in ACM had been appropriate.

Finally, in order to investigate whether some of the data we collected about the ACM students might have predicted their subsequent success in Precalculus, we ran a multiple linear

regression model using SPSS. Students' Spring 2025 Precalculus grades[1] were used as the dependent variable; predictor variables included students' ACM final letter grades[1], ACM attendance, the ACM instructors' seven subjective assessments, and the instructors' predicted Precalculus letter grade[1] for each student. The model of best fit ($p < .001$) included only two statistically significant predictors for students' Precalculus letter grades: their final letter grade in ACM ($p = .024$) and their mathematical confidence as assessed by their instructor ($p = .001$). However, this model left much of the variance in students' Precalculus grades unexplained ($R^2 = .187$; see Figure 1).

Model Summary[c]

					Change Statistics					Selection Criteria			
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	R Square Change	F Change	df1	df2	Sig. F Change	Akaike Information Criterion	Amemiya Prediction Criterion	Mallows' Prediction Criterion	Schwarz Bayesian Criterion

b. Predictors: (Constant), InstrConf, ACMLetter
c. Dependent Variable: PrecalcLetter

Figure 1. SPSS output for the multiple linear regression showing students' ACM letter grade and instructors' assessments of students' mathematical confidence as significant predictors of their Precalculus letter grades.

Discussion

In our preliminary investigation of the impact of the ACM course on students' preparedness for Precalculus, we found some encouraging evidence that this new course was associated with improved outcomes for these students. There was a marked decrease in the DFW rate in Precalculus after the ACM course was implemented, from 34.7% in Spring 2024 to 20.3% in Spring 2025. We also found that the vast majority of students placed in ACM in Fall 2024 believed that this placement was appropriate, both before and after they had taken the course. Finally, our multiple linear regression found that students' ACM course grades were significant predictors of their success in Precalculus. Taken together, these results suggest that our implementation of a reimagined prerequisite course for Precalculus had a positive impact on students' success.

Perhaps the most surprising finding in our preliminary analysis was the emergence of only one of the ACM instructors' subjective student ratings as a significant predictor of their Precalculus grade, namely their ratings of students' mathematical confidence. This finding merits further investigation because the term *mathematical confidence* likely meant something different to each instructor. In future iterations of the course and data collection, we intend to clarify the meaning of this term to help determine whether this rating is truly a significant predictor of students' eventual success in Precalculus. We are also interested in investigating the relationship between instructors' ratings of students' mathematical confidence and students' assessment of their own self-confidence in mathematics.

Other institutions have found success in supporting students who are not yet ready for college-level mathematics with, for example, just-in-time teaching (e.g., Bertrand et al., 2021) and co-requisite course enrollment (e.g., Ran & Lin, 2022) models; what seems to have worked at our institution has been a return to a standalone prerequisite course for Precalculus. We

[1] All letter grades (ACM/Precalculus letter grades and instructors' letter grade predictions) were converted to numerical GPA equivalents as follows: A=4, A-=3.7, B+=3.3, B=3, B-=2.7, C+=2.3, C=2, C-=1.7, D=1.

reimagined a traditional 'remedial' mathematics course by focusing on both presenting familiar mathematics content in novel ways and by focusing on growth objectives. The mathematics content was often explored through integrated STEM problems, gamified lessons, student collaboration in different forms (e.g., pairs, small groups, whole group) and an emphasis on creativity and connection-making. Our inclusion of growth objectives recognized the transitional nature of the students' lives and addressed skills that are essential to learning mathematics at the college level that go beyond understanding content, such as seeking out resources, study skills, and stress management. Not only are these unique aspects of our course design likely responsible for the improvements observed in students' performance in Precalculus, but we believe that they also serve as contributions to the research on supporting mathematically-underprepared STEM majors.

We have only reported on three major findings of our study in this report, but anticipate the emergence of additional, notable results as our analysis continues. As mentioned previously, we collected survey data with respect to students' attitudes towards the ACM course and mathematics in general, as well as several open-ended questions addressing their views of mathematics as a discipline. We intend to analyze this data to identify any attitudinal shifts students experienced from ACM to Precalculus, as well as to determine whether the ACM students' attitudes were significant predictors of their eventual Precalculus performance. Additionally, because the ACM course was developed in response to the high DFW rates for Precalculus at our institution, and because we saw a marked decrease in this rate following the implementation of ACM, we will investigate whether this trend of lower DFW rates persists for the cohorts of ACM students as they progress further through the calculus sequence. Furthermore, we continue to collect data from ACM courses. We have begun our Fall 2025 academic year with a new round of data collection for our incoming (approximately 900) ACM students.

There is a continuing need to find new ways to support STEM majors that arrive on college campuses in need of additional preparation to study mathematics at the college level. We look forward to adding our preliminary results to ongoing discussions in the RUME community about addressing this need. Furthermore, we hope that by describing the development of ACM, sharing its design, and presenting these preliminary results, we will inspire others to reimagine 'remedial' mathematics and consider implementing a similar course at their institutions.

Acknowledgments

We thank the ACM team for their dedication to this project, and the ACM students for their hard work and participation in this study.

Identifying Changes for Student-Centered Instruction in Graduate Student Teacher Professional Development Across Mathematics Departments

Sean Yee
University of South Carolina

Shandy Hauk
San Francisco State University

Revee Clegg
University of South Carolina

Providers of teaching-focused professional development (TPD) for novice college mathematics instructors (e.g. graduate students) are a critical part of undergraduate education. Yet, little is known about the work done by Providers, including their local efforts to change TPD. We seek to capture details, summarizing a departmental change journey in a succinct advice packet, so other departments might leverage that advice in their own TPD. This preliminary study used a four frames model (people, power, symbols, structure) with two dimensions (process and product) to document TPD change in 10 mathematics departments. Through qualitative analysis of semi-structured interviews and member-checking with Providers, we identified interactions among key change elements. Preliminary findings suggest attention to certain interactions (e.g. people and power) was more common in successful change than others. Examination of the products and processes of change at the granularity reported here shows promise for sharing across departments for program improvement.

Keywords: Novice College Mathematics Instructor, Teaching-Focused Professional Development, Provider, Systemic Change

For over 30 years, evidence has continued to build the case that student-centered curriculum and instructional practices are effective for students' success in undergraduate mathematics education (Friedlander et al., 2014; Gehrtz et al., 2022; Smith et al., 2021). Productive methods include active inquiry-oriented approaches where collaboration among students is common (Laursen & Rasmussen, 2019). A large proportion of undergraduates' first (and sometimes only) experience with post-secondary mathematics is in classes taught by graduate students (Blair et al., 2018). Graduate students who teach, as assistants for sections adjacent to lectures and as instructor-of-record, are essential in spreading the use of student-centered instructional practices. Recent national initiatives have taken a closer look at teaching-focused professional development (TPD) and the work among faculty who provide that TPD (CoMInDS, 2020; Hauk et al., 2024; National Academies, 2023; Smith et al., 2021). Providers of TPD play a crucial role in shaping the teaching of college mathematics instructors (CMIs), particularly graduate student novice instructors. A *novice* instructor is anyone with fewer than 1,000 hours of classroom experience (e.g., five or fewer years)**.**

The most common forms of TPD include some combination of at least three of the following: pre-semester orientation, seminars, pedagogy courses, course coordination meetings (Yee et al., 2023a; Braley et al., 2023). Providers are change agents – they are on the front lines of their department's changes in undergraduate mathematics education because they are responsible for helping novice CMIs implement those changes. Research on how Providers initiate and/or navigate systemic changes is limited. Each mathematics department has its own profile of characteristics of TPD (e.g. seminar, course, coordination meetings) and institutional context (e.g. master's or doctoral granting, private or public). Here we report on our efforts to identify and disseminate findings about systemic change that is rooted in departments' efforts in novice instructor TPD.

Context and Theoretical Framework

This study is part of a larger federally funded project that initially implemented a national survey to identify information about Providers and the TPD they offer (Yee et al., 2023a, 2023b). The aim of the larger project is the development of an online "Design Tool" (currently in beta-testing) where one can go to see what other departments with similar characteristics are doing with/about TPD for novice instructors. In addition, the tool offers advice from the field from Providers that goes beyond *what* a department has done to succinctly describe *how* it was accomplished. "Advice Packets" include how Providers have designed and implemented opportunities for novices to learn about student-centered instruction, and describe the changes needed to arrive at their current state of TPD, whatever it may be. Each three-page Advice Packet includes a two-page description of the department's TPD change journey as well as a final table about the components of change. Creating these tables has allowed us to explore similarities and differences across TPD programs. Developing the table required a theoretical framework flexible enough to recognize and document the critical factors of systemic change.

Reinholz and Apkarian's (2018) revision to Bolman and Deal's (2008) four frames for systemic change provided a theoretical framework that was both flexible enough and structured enough to meet the needs of the study. Originally constructed to model organizational change, Reinholz and Apkarian tailored the names and descriptions of the four frames to support seeing and describing change in STEM fields in higher education (structures, symbols, power, people):

> *Structures* are the roles, routines, and practices of a department; their enactment and meaning are dependent on *symbols*, which are the norms, values, and ways of thinking in a department; changes are ultimately enacted by *people* whose individuality impacts their intentions and perceptions; and the distribution of *power* determines who makes certain decisions and influences interactions (p. 5).

Bolman and Deal (2008) argued, "Like maps, frames are both windows on a territory and tools for navigation" (p. 13). The purpose of the four frames in Reinholz and Apkarian's framework is to be a department's "analytic tool for understanding change" (p. 2). We have combined the metaphor of frames as windows on a territory and tools for navigation with Reinholz and Apkarian's focus on undergraduate STEM education. This allows us to describe departments' systemic change as well as providing a means to attend to and compare aspects of local departmental culture to support others in navigating in similar landscapes.

Research Questions

Reinholz and Apkarian (2018) describe a framework with both *process* and *product* components for each framing concept. Both the actors and actions must be taken into account. Reinholz and Apkarian say, "The four frames speak to both *what* aspects one may try to change (i.e., the product) and *how* they go about changing it (i.e., the process)" (p. 3). Our research questions parallel this structure:

> **RQ1:** What aspects and frame(s) (if any) are prevalent in Provider reporting about their department's TPD change experience?
>
> **RQ2:** How do certain aspects and frame(s) appear to interact or influence each other in Provider reports of navigating TPD change?

In RQ1, we use prevalence to focus on which frames and aspects within the frames frequently show up as key elements for a Provider of process and product. In RQ2, we are looking to see how the frames and aspects within those frames interact, seeking to see patterns across different Provider/department characteristics and ways of navigating change.

Methods

We report here on analysis of data from 10 Providers (of 95 for whom we have some data). Data sources include responses to our national survey, video-recorded semi-structured interviews, and member-checking feedback on Advice Packet drafts. Provider interviewees were chosen to ensure diversity of national survey responses, instructional characteristics, and geographical location. Of the 10 Providers included here, 2 were at private and 8 at public universities with 7 doctoral- and 3 masters-granting.

Data Collection

Data from the national survey provided information prior to the interview about the size of the department, as well as formats, topics, and activities of local TPD (Yee et al., 2023a). The interview included targeted discussion of (1) department goals for TPD, (2) Provider objectives, (3) drivers of change/stasis in local TPD, (4) specific instructional practices focused on in TPD, (5) description of the current TPD state or completed change, (6) departmental history of change, (7) critical factors for completed changes, (8) interactions of critical factors necessary for change, (9) MAA instructional practices (MAA, 2018) regularly addressed in the TPD.

Data Analysis

As each online semi-structured interview was completed, members of the research team watched the recording of the interview and, in consultation with the interviewer, composed a first draft of the Advice Packet. Using narrative analysis (Atkinson & Delamont, 2010), the research team categorized and summarized the details across Providers' interview and survey responses. The summary aimed for a granularity of description that satisfied the goal of differentiating among Providers and for succinct communication in the Advice Packet for the target audience (other Providers). Thematic analysis across the 9-part structure of the interview used inductive coding based in the four frames, broken into processes and products. Analysis for each Provider was synthesized in a table of process and products of change. This table (referred to as the *four frames table*) summarizes the change journey in the Advice Packet using the Reinholz and Apkarian (2018) framework. Subsequently, we did a constant comparative analysis across all 10 four frame tables to look for patterns across TPD programs.

Preliminary Findings

A critical aspect to the validity of our Advice Packets' trustworthiness is Provider feedback on their Advice Packet. This member-checking is currently ongoing, thus the preliminary nature of this report and a limitation (n=10) on the aggregate analysis of four frames tables. Next, we share details in a vignette and a four frames table that has been member-checked.

Vignette of Big State University (BSU)

Big State University (BSU) is a doctoral-granting institution in the midwestern United States with 60 to 75 graduate students working in instructional positions (as graduate teaching assistant, GTA, or instructor-of-record, GSI). Over a decade of work resulted in the current state of TPD at the institution. Like nearly half of programs in the national survey, the format for TPD included pre-semester orientation, a course on teaching, and regular course coordination meetings. At the same time, this university's program had uncommon characteristics, including the development and sharing of curriculum and instruction materials that generated revenue to support the costs of offering TPD. Some aspects, like shared values development, came from the Provider using the people lens, meeting the needs, skills, and motivations of individuals within the TPD program.

Also through the people lens, and that of power, the interviewed Provider talked about an integration of TPD and course coordination that was led by mathematics education professors within the department.

Table 1. BSU Table of Process and Products of Sustainable Cultural Change Using the Four Frames.

	Change Products	Change Processes
Structures	● TPD includes multi-day pre-term orientation, 1 Pedagogy Course, and weekly Course Coordination meetings. ● Online library of tested resources for Providers, Coordinators, and GTA/GSIs.	● First-Year director initiated a structure where coordination was supported by GTA/GSI creation of workbooks. ● Active-learning centered room changes due to larger classes with GTA/GSI teaching nine credits per year for stipend.
Symbols	● Workbooks from GTA worksheets created royalties to help run GTA TPD. ● Value of modifying classrooms to be student-centered supported by data justifying utility of active learning through curricular changes	● Collected data to refine workbooks/texts for improving instructional practices. ● Textbook adoption moved to open-source textbooks for all math classes. ● Graduate students not unionized; report feeling valued by course release.
People	● Administration and teaching faculty develop a shared vision about curricular coherence with graduate students ● GTAs/GSIs get "course buyouts" when taking the pedagogy course.	● Instructors retain relative pedagogical autonomy; agency for initiatives remains with department members. ● People in leadership valued efforts and time of teaching faculty and GTA/GSIs.
Power	● Director of First-Year teaching faculty elevated to department leadership. ● TPD of graduate students is considered not only important pedagogically, but also administratively.	● Leadership in administration was committed to these efforts by having changes in leadership. ● Change in classroom size, structure, and workbooks initiated by external funding.
*	*GTA=Graduate Teaching Assistant, GSI=Graduate Student Instructor-of-record*	

Table 1 illustrates that the people and power dynamics of change were strongly connected. Administrative **power** advocated for resources to improve TPD that supported the Provider's role. The **people** placed in positions of power made this possible because they valued the Provider's use of data-driven education research and valued novice instructors' ability to improve curricular resources for teaching. The respect of the administrators within the department was the strongest **symbol** when the Provider's role impacted decision-making, which allowed for changes in TPD **structure** with the provider taking a leadership position. Thus, for RQ1, the frames of people and power were more prevalent for BSU, and the aspects of textbooks, worksheets, and administrative support were critical for the systemic change.

Preliminary Connections

Two other departments out of the 10 had similar changes, with Providers indicating a view of connection between people and power. Other department Advice Packets illustrate different connections. Analysis of the four frames tables across all 10 Providers is ongoing (currently member-checking for connections). However, so far, all Providers explicitly spoke to at least two connections among ways of navigating change (i.e., frames). A preliminary analysis across all 10 Advice Packets resulted in Table 2, summarizing which pairs of frames were connected.

Table 2. Number of Connections between Four Frames among All 10 Advice Packets

Connections	Power	People	Symbols	Structures
Power	-	7	0	6
People	7	-	4	2
Symbols	0	4	-	1
Structures	6	2	1	-

In Table 2, notice that people and power was the most frequent connection between two frames (N=7) with power and structure being the second (N=6). Also noteworthy is the absence of discussion of how symbols and power might be connected. Table 2 suggests pathways for answering RQ2. Once member-checking is complete we will explore the stories behind how Providers indicated the connections happened (e.g., the very short vignette of BSU, above, can be expanded into a case story that illustrates the mechanisms of connections and change at BSU).

Discussion and Questions

These preliminary findings illustrate the viability of using the four frames (Reinholz & Apkarian, 2018) not only for self-analysis of STEM departmental change, but as a means to compare and discuss multiple department changes within and across "window frames" (Bolman & Dean, 2008). Specifically, the summary table from BSU illustrated that the four frames can provide means to identify critical change levers within frames (RQ1), while giving a means to compare connections among ways of navigating change (frames) and across departments (RQ2).

The basic questions related to "What works" have been answered in many ways, including in post-secondary TPD for novice CMIs. The question now is "How to make what works, work for us?" Inherent to addressing this question is that it is an iterative process rather than a destination. What holds promise is *scaling across*: "releasing knowledge, practices, and resources, and allowing them to circulate freely so that others may adapt them to their local community" (Wheatley & Frieze, 2011, p. 34). This is in distinction to the idea of reproductive scaling-up that dominates many western educational reforms. This is not to imply that the structures, values, and resources found in one department are not like those found in others. But similarity is not identity. Singular "best practices" do not exist across the different environments. As Wheatley and Frieze note, "scaling across invites communities to learn from one another and solve their own problems in their own particular way" (p. 36). They would also use the term "trans-local" to describe what happens when people carry an idea from one place (e.g., an Advice Packet) to let it loose in a new environment, often nurturing its growth into something quite different. Understanding the products and processes of change can support preparation for scaling across.

Questions for attendees at the session will focus on this idea and include: *How else might we look for connections between the four frames that would better align with how you would naturally investigate a Provider-described change to TPD? What infographics might be useful?*

Acknowledgements

We thank the Providers who have contributed to the development of the Advice Packets. This material is based upon work supported by the National Science Foundation under Grant No. DUE 2021139 and 2020952.

Students' Initial Goals, Beliefs and Conceptions of Proof in an Introduction to Proof Course

Chelsey Van de Merwe
Oklahoma State University

Michael Oehrtman
Oklahoma State University

The shift to proof-based mathematics in university programs often takes place in an introduction to proof (ITP) course. Literature exists describing the nature of these courses and some of the difficulties students experience in the course, but we know little about students' goal, beliefs, and conceptions of proof at the beginning of an ITP course (David & Zazkis, 2020; Bleiler-Baxter & Pair, 2017). Seven students were interviewed during the first two weeks of their ITP course. These same students are participating in a longitudinal study examining how ITP students' goals, beliefs, and engagement patterns evolve during an ITP course. Students were uniformly capable of providing a description of proof compatible with those commonly used in ITP courses, though students' ability to construct proof was varied. Students could identify components of proof writing that were different from other writing (e.g. the use of the word "or"). Students' goal orientations were seen to be malleable at the beginning of the semester, with most students adopting a learning goal orientation (Dweck & Leggett, 1988).

Keywords: introduction to proof, goal orientation, conception of proof

Mathematical proof is sometimes introduced in secondary school in the US, but frequently the first thorough introduction to proof that US students in some STEM programs receive occurs at the university level (Herbst, 2002). To combat the difficulty many students experience adjusting to proof-centered mathematics, many universities designate an introduction to proof (ITP) course dedicated to the comprehension and construction of mathematical proofs (Knuth, 2002; Moore, 1994). While research has been done examining the nature of ITP courses (David & Zazkis, 2020) and examining how students experience particular components of proof (e.g. Bleiler-Baxter & Pair, 2017; Hoffman, et al., 2024), there is not research that addresses students' goals and beliefs at the beginning of an ITP course. This study aims to shed light on students' goals, beliefs about mathematical learning, and conceptions of proof before extensive formal instruction in an ITP course. This study is situated within a larger project studying how students' goals, beliefs, and engagement habits evolve during an ITP semester and an intermediate proofs course immediately thereafter. The data presented in this report provides insights into the students' initial goals and beliefs that will allow us to see how these goals and beliefs change (or not) and affect engagement patterns. The following research question is addressed here: What are ITP students' initial goals, beliefs about mathematics, conceptions of mathematical proof?

Literature Review & Theoretical Framework

Mathematics education researchers have struggled to produce a definition of proof that draws an indisputable line between proof and non-proof (Stylianides, et al., 2017). This problem is sometimes called the "hard boundary problem" (Czocher & Weber, 2020). For example, there is debate about whether non-syntactic proof, such as computer-generated proofs, picture proofs, or probabilistic proofs qualify as proof (Aberdein, 2009). A definition of proof should provide justification for the inclusion or exclusion of such arguments. Experts lack of an explicit definition for proof and, consequently, there is a lack of clarity about proof for new participants in the community.

While the norms of proof writing, and consequently the definition of proof, held by distinct communities may differ, the values that underly those norms are likely similar (Dawkins & Weber, 2017). For example, most communities considering mathematical proof would likely agree that proof should increase mathematical understanding. A proof submitted for publication may be held to the norm that routine calculations or obvious justifications be omitted from the proof; however, in an ITP course a student may be required to show such calculations and justifications. It is critical to understand the norms established within the community from which a proof originates. Instructors of the same course at the same university may even have differing goals and beliefs about norms that should be adopted by students. We suspect that while practical norms differ between communities, the underlying values of what it means to prove something are relatively consistent across mathematical communities. For example, a value held by most communities considering mathematical proof is that a proof should have explanatory power. What constitutes the best way to explain differs between communities. When presented with arguments presented during a classroom discussion about why the sum of two odd numbers is even, a group of pre-service teachers valued a well-explained empirical example over a valid deductive argument (Morris, 2007). Many mathematicians would likely find a deductive argument more helpful in explaining that mathematical claim. The two communities adopted different norms to uphold the same underlying value that proofs should explain. Even subtle changes to setting such as having a different instructor or sitting next to a different classmate can influence the norms a student chooses to adopt in proof construction.

The purpose of ITP courses is to teach logic rules, proof structures, and set theory (David & Zazkis, 2020). ITP courses in the US have been classified into three categories: standard only, standard + topic, and topic-based. The data for this study was gathered in a standard + topic. Standard + topic courses (40% of ITP courses surveyed) teach skills necessary for proof comprehension and production such as understanding symbolic logic, quantifiers, set theory, and truth tables. They also include an exploration of a new mathematical topic, in this case the topic was abstract algebra.

Zone of Proximal Development

Two theoretical frameworks underpin this study: the zone of proximal development (Vygotsky, 1987) and motivation theory (Dweck & Leggett, 1988). The zone of proximal development (ZPD) describes the interplay between intra-psychological and inter-psychological domains that enables the emergence of more advanced cognitive activity (Vygotsky, 1987). The traditional interpretation of ZPD is the interplay between what an individual can do on their own and what they can do with the help of a more knowledgeable other (p. 208-209). Vygotsky also described ZPD as the dynamic interplay between spontaneous concepts and scientific concepts (p. 214-222).

A *spontaneous concept*, often referred to as an everyday concept, develops through everyday experience, usually without the aid of formal instruction (Vygotsky, 1987). Ideas within a spontaneous concept are specific and often lack generalization. For example, a child learning a native language is developing a spontaneous concept because the child knows many specific words but may not be able to generalize about categories such as “noun” or “fruit.” Ideas within a spontaneous concept are specific and lack conscious awareness, volitional control, and generalization. A student entering an ITP course likely has a spontaneous conception of what it means to prove a statement, even if the student has never been introduced to formal proof. His spontaneous conception of proof may rely on the principles of proving things in familiar settings such as justifying an answer to a classmate, explaining a solution to a teacher, or convincing a

friend. While these spontaneous conceptions may proport the same purpose of proof, they are likely inadequate to equip students to comprehend or construct valid mathematical proofs. A student's spontaneous conception of proof provides important grounding to their emerging scientific conception of proof. That is, as students learn the nuanced rhetoric of mathematical proof, their spontaneous conception of proof grounds them in the purpose of the practice, which is to explain, justify, convince, etc. A *scientific concept* is one learned through mediated interaction with their formal meanings. Students develop a scientific conception of proof as they engage in formal instruction in an ITP course. This study will focus on students' spontaneous conceptions of proof and how the first 2-4 days of engagement in the ITP course support the emergence of a scientific conception.

Goal Orientation

The goals students set during a mathematics course influence the types of activities students engage in and, consequently, the conceptions of proof they develop. Thus, the proximal and distal goals students set at the beginning of an ITP course are of interest to mathematics education researchers. Dweck and Leggett (1988) proposed the nature of goals can be sorted into two categories: performance goals and learning goals. Individuals who adopt performance goals in a particular context are concerned with maintaining or gaining favorable judgements of ability from external sources. This may lead them to avoid challenging problems, which is typically seen as a maladaptive behavior since many worthwhile pursuits in both academic and non-academic life come only after confronting a challenge. Individuals who adopt learning goals in a particular context are concerned with increasing their ability. Individuals may adopt different types of goals when they are in different settings or learning different subjects. Selection of performance and learning goals are sensitive to outside factors such as task difficulty and task consistency (Steele-Johnson, et al, 2000). In this study we consider students goal orientation in the context of an ITP courses with task difficulty and content consistent with that required by the course. A student's goal orientation is influenced by motivation, personality, willingness to persist through challenges, and personal beliefs about intelligence (Dweck & Leggett, 1988). Students who believe intelligence to be a fixed entity (sometimes referred to as having a fixed mindset) are prone to adopt performance goals; students who view intelligence as malleable (sometimes referred to as having a growth mindset) are prone to adopt learning goals.

Methodology

The university where this data was gathered ran one section of their ITP course in Fall 2025 with 19 students enrolled. Seven students enrolled in the course participated in individual clinical interviews during the first week and a half of the course. Students had attended 2-5 class session at the time of the interview. Interview questions were clustered into three categories. First, students discussed their goals and expectations for the course. Second, students discussed their experience learning mathematics in prior mathematics classes. They described what has helped them be successful in past classes and what they planned to do in the ITP course to achieve success. Third, students were given five number theory claims and asked to determine whether they were true or false and explain what they though a math proof might look like for each claim. Follow up questions about these claims did not include words such as prove, justify, convince, or explain as these words may encourage the student to adopt a particular purpose of proof for the interview (Hanna, 2000). The purpose of this section of the interview was to make inferences about students' spontaneous conception of proof after minimal formal instruction. This section was concluded by asking students to share their current understanding of mathematical proof.

Upon completion of the interviews, a transcription was made and used to make preliminary inferences about student goals, beliefs, and conceptions of mathematical proof. The inferences were used to create narrative accounts for each student. Formal coding of the data will occur at the conclusion of the ITP course when most of the data for the larger project has been gathered.

Results

Conceptions of Proof

Most of the students were able to verbalize a description of mathematical proof compatible with proof descriptions frequently used in ITP courses. Their descriptions generally contained two parts: (1) a proof should show a statement is true or infallible and (2) a proof is made by piecing together correct mathematical statements to reach the conclusion. When asked to give a proof for number theory statements, some students were able to give arguments that were closely aligned with what may be acceptable in their course. For example, consider Max's written argument that the product of two perfect square integers is a perfect square.

"Given two perfect square integers m and n.
Let $m = k^2$ and let $n = c^2$.
Then $m \times n = k^2 \cdot c^2 = (kc)^2$.
Let $(kc)^2 = I$, integer. "

Note that Max has some issues with introducing variables (i.e. he does not give descriptors for k and l). Max felt the argument produced here was more akin to proof scratchwork than a proof. One thing he said was missing in his argument is stating the definition of perfect square. Max felt that the use of definitions was critical to a proof and even more preferrable if the definition could be given in symbols that could be manipulated. Other students had a hard time constructing an argument that resembled a proof but were able to recognize that what their arguments were far from being considered mathematical proof.

Two of the three statements given to the students were false statements. One statement was false for the entire domain of interest ("The product of two primes numbers is prime.") and one was false for part of the domain of interest ("A multiple of 3 is a multiple of 6."). With the exception of Luke, all students felt confident giving a singular counterexample to prove the falsity of a statement. Chase rewrote the false statements with explicit quantification (e.g. "All multiples of 3 are multiples of 6.") and then showed an example that showed the statement not true for all the domain. He said he was inclined to make the quantification explicit because he had heard statements of the form "for all, there is something." Rewording the statement helped Luke justify why a counterexample is sufficient evidence to prove a statement false.

Goal Orientations

While most of the students expressed a desire to earn a particular grade or pass the course, they each indicated their primary goal was the understand the complexities of proof at a deeper level by the end of the course. Max showed the most consistent evidence of have learning goal orientations. The first goal Max verbalized was to earn a high A in the course, but he rarely mentioned grades or course outcomes based on performance afterwards. He showed his eagerness to understand at a deeper level when he stated, "I just guess like a feeling of like satisfaction when it like makes sense, finally." He shared his plans to achieve his goal, including reading his textbook, attending office hours, and engaging in homework assignments and other practice opportunities. Many of these plans were based off practices he had established for success in previous mathematics class. He felt he would likely not be able to watch YouTube

videos as he had in the past because he felt there would be fewer videos available to support his learning.

Luke changed his goal orientation somewhat consciously based on his interest in the material and how important he esteemed the material to be. He expressed that he began the semester focused on getting a good grade, which is indicative of a performance goal orientation. After a few days in the class he seemed to be shifting to a learning goal orientation. He said, "I think approaching it initially it was more so just get an A because it's not relevant to my major, but I find it really interesting so far. So I think my my opinion on that's going to change, I'd rather understand the subject at the—at its level." In another part of the interview, Luke said that "however it goes, it goes," which, based on the surrounding text, we infer to mean that he is not concerned with achieving a certain letter grade in the course overall. This perceived shift in goal orientation is also supported by his statement that he hopes to do better communicating with his instructor via in-person interactions to deepen his understanding, something he has not prioritized in the past.

Discussion

After less than two weeks of instruction, students' proof construction abilities were varied. Max was fairly adept constructing proofs after only 2 class sessions while Luke was not confident producing an argument resembling a proof after 3 class sessions. Since this class serves as an introduction to proof, it may be tempting for instructors to assume that all students are starting at the same base level. The contrast among student abilities at the beginning of the class is evidence that students begin the course with very different skill sets. We suggest that these differences in skill sets can be attributed, at least in part, to students' differing spontaneous conceptions of proof. Students may use their spontaneous conceptions of proof as the foundation upon which to build a scientific conception of proof. Thus, if the spontaneous foundation differs among students, the resulting scientific conceptions and skill sets will differ.

At the time of the interview, students had seen one formal proof in class (a proof that the sum of two even integers is even). The rest of the class sessions were spent discussing logical principles and the nuances of using formal logic. For example, students spoke of the difference between their spontaneous understanding of the word "or" and the new, scientific meaning of the same word. These discussions spawned in students a belief that when writing proofs, careful attention must be given to grammar, definitions, and language. Some students became so wrapped up in the scientific conception of proof that they ignored their spontaneous conceptions. For example, when deciding if an argument was a proof, they focused on grammar, language, and introduction of variables rather than the convincing or explaining component of proof.

Luke's encounters with the material during the first week of class changed his goals for the course. He began the course with a desire to earn and A and after three class sessions he was prioritizing learning the material over earning a good grade. He attributes this shift to the material being interesting. Literature on goal orientation tells us that a learning goal orientation is preferrable (Dweck & Leggett, 1988). We note that students' goal orientations may be malleable at the beginning of a course. Future research could investigate what activities led to Luke's shift to a more productive goal orientation.

The results presented here provide insights into students' initial goals, beliefs, and conceptions of mathematical proof. As we continue to interview these same seven students throughout their ITP course we will monitor how their goals and beliefs evolve from this initial starting point. This data provides a snapshot of the students at the beginning of the semester, which will compare to other data gathered throughout the semester.

Values in Tension: Mathematics Teacher Educator's Decisions on Generative AI

Sarah D. Castle
University of Idaho

Marcus Wolfe
James Madison University

Hyunkyoung Yoon
California State Polytechnic University, Pomona

Shahabeddin Abbaspour Tazehkand
Missouri State University

This analytic autoethnography preliminary report examines how early-career mathematics teacher educators (MTEs) make decisions about if and how to use generative AI (GenAI) in alignment with their values. Using reflective journals and group discussions, with Value-Sensitive Design, our analysis highlights three themes in GenAI use: preserving autonomy and creativity, protecting human elements of our job while viewing GenAI as a supplemental tool, and managing institutional pressures. This work highlights values-based perspectives informing the broader understanding of MTE GenAI decision making.

Keywords: GenAI, Values, Professional Development, Ownership, MTEs

Emerging research focuses on how generative AI (GenAI) impacts student thinking and learning, ethical considerations surrounding the infrastructure needed for large language models (LLMs), and classroom practices. Critics in education have raised concerns over GenAI's impact on students' perception on mathematics, critical thinking skills, autonomy, and problem solving (Kosmyna, 2025; Lee et al., 2025; Schorcht et al., 2024; Wang et al., 2024). Further, researchers found that students need support in determining how to critically engage with these tools and not passively accept their outputs (Yoon et al., 2024), and teacher educators specifically support preservice teachers' developing critical dispositions (Sawyer & Aga, 2024). However, far less is known about how teacher educators navigate GenAI, especially for those early in their career who are still finding their professional identity. Their choices not only inform their practice but set norms for preservice teachers about how to integrate, or resist, GenAI in their classrooms.

Understanding how teacher educators make choices about GenAI humanizes the broader conversation about its integration in education. During this period of sociocultural shifts in response to GenAI, we as educators should be transparent about when and if we use GenAI. This is particularly important for mathematics teacher educators (MTEs) as mathematics emphasizes reasoning, justification, and sensemaking which can be undermined if GenAI produces answers without engaging in mathematical practices. Given the lack of professional guidelines, early career MTEs are facing nebulous choices about GenAI in their teaching and professional development while navigating their induction into the profession. As a group of young MTEs, we ask the question: *How do we as mathematics teacher educators make decisions to align with our basic values about using GenAI in our teaching, scholarship, and service?* To answer this research question, we use analytic autoethnography methodology coupled with Value-Sensitive Design (VSD) to understand the different tensions that emerge when early career MTEs navigate GenAI use. By examining our own experiences and reflections, this preliminary study aims to uncover the core values MTEs draw on when making choices around the use of GenAI.

Positionality Statement

We are four early career mathematics teacher educators who share a commitment to preparing ambitious mathematics teachers, supporting in-service teachers, and contributing to

research-based interventions. We identify across a range of racial and gendered identities as we are composed of one Middle Eastern man, one Asian woman, one Black man, and one White woman. Professionally, we represent R1, R2, and Research Colleges and Universities. We are located across the US in education and mathematics departments. Collectively, we bring our different lived experiences to the research as we have nuanced dialogue that explores the similarities and differences in our approaches to GenAI in mathematics teacher education.

Theoretical Framing

We draw on Value-Sensitive Design (VSD), a theory and methodology used to provide a systematic process to account for human values in technology development within a multi-stakeholder system (Friendman et al., 2002). VSD positions technology as non-neutral since developed technology will always be intertwined with human values. These values manifest in layers, and within education technology we can understand values as basic values, learning values, or technology use values (Prieto et al., 2025) which should be iteratively coded. This allows us a lens for understanding the interaction between GenAI and our values, as well as to look across multiple layers of stakeholders in education, both direct and indirect (Shen et al., 2025) because as MTEs, we are in within a department that serves students within a university within academia. We can trace both how and why we make decisions about using GenAI by uncovering the personal and professional values that guide those choices. These choices are not simply pragmatic but are intertwined with our professional identities, institutional pressures, and underlying commitments as MTEs. For value categorization we used Schwartz's (2006) core-values. Under this theory of basic values, values are desirable goals that motivate action that often serve as standards or criteria. People's values dictate an ordered system of priorities and the relative importance of multiple values guide action. There are ten core values given: self-direction, stimulation, hedonism, achievement, power, security, conformity, tradition, benevolence, and universalism.

Methodology

We used analytic ethnography to investigate the personal and professional values that guide how we, as MTEs, chose to use (or not use) GenAI. This type of ethnography is where the researcher is "(1) a full member in the research group or setting, (2) visible as such a member in published texts, and (3) committed to developing theoretical understandings of broader social phenomena" (Anderson, 2006). This methodology focused on our roles as both researcher and participant, thereby allowing for reflexivity in the analysis process and situating our narratives in a broader theoretical and institutional context. Data collection consisted of iterative individual reflective journals as well as group discussions over a three-month period. The journal prompts focused on our feelings and choices surrounding GenAI in our own teaching, service, and research. After the initial journaling, we read each other's narratives and rejoined for a group discussion where we could ask follow-up questions and focus on what was shared among members and where our approaches diverged. All meetings were transcribed and then we engaged in an iterative coding process to engage in individual sense-making and collective meaning-making. We finally coded all data against Schwartz (2006) core-values for our preliminary VSD basic values and proceeded to group codes and look for themes.

Preliminary Results

Our analysis revealed three key themes, each reflecting core values, namely self-direction, security, and ownership, that shaped our decision about GenAI use: (1) Preserving autonomy and

creativity when deciding whether to use GenAI, (2) recognizing that GenAI cannot replace the fundamentally human parts of being an MTE, but could serve as a supplemental tool, and (3) GenAI is a way to negotiate institutional demands that we do not view at the core of teaching.

Self-Direction

A core value that we drew on when deciding whether or not to use GenAI was self-direction, which focuses on independent thought and action, as well as choosing, creating, and exploring. This value manifested within our data as our commitments to autonomy, critical thinking, and creativity in our teaching and research. Within the classroom, we positioned GenAI as a tool for exploration and problem-solving if used, rather than shortcutting mathematical reasoning. We chose to allow for the use of GenAI in this manner because we wanted to have students make choices about their learning and have the opportunity to critically engage with GenAI and discourage simply copying and pasting answers. This reflected our commitment to autonomy as students are encouraged to direct their own learning and think both critically and independently. Within our research, we chose not to have GenAI independently generate references or citations for our work as this was in violation of autonomy, and we value self-direction. By choosing our resources or engaging in a systematic review process that we designed, we maintained our self-directed inquiry and focused on how we actively shaped our research rather than outsourcing intellectual labor to a machine. This focus on research and intellectual labor centered a larger conversation on the humanization of research and what does knowledge and ownership look like when human and machine contributions overlap?

Ownership and ideas. Ownership emerged as a central theme and value that shaped how we chose to use, or not use, GenAI. As ownership of ideas focused on making decisions about what to create, explore, or think critically about, we viewed it as a basic value under self-direction as it fundamentally centers on our autonomy over thinking and contributions. There was concern about not only what was produced but who was responsible for creating knowledge. This value informed decisions across multiple aspects of our work. In teaching, many of us described clear boundaries around students' work. Entering student assignments and work into AI tools felt like a breach of ownership and trust, since students shared their work with us, but never consented to AI, and this work belongs to the student. This demonstrates that ownership is not simply an abstract principle, but a value that is operationalized in a lived ethical boundary embedded in daily pedagogical practice.

Within our professional writing and communication, the value of ownership was often in tension with the need for efficiency within the academic system. Many expressed concern that over relying on GenAI would weaken their professional voice, thereby hiding identity and authorship from their writing. This led to us heavily editing AI outputs when used, and to treat them as starting points, rather than the final product. This allowed us to make decisions aligned with our desire for self-direction while maintaining productivity. However, many expressed the concern on homogenization of ideas and writing tone when using GenAI and wanting to promote individual thought and diverse ideas and writing styles.

One of the clearest choices made around GenAI as MTEs was protecting the humanization of ideas and roles. We consistently drew lines around activities that we considered core to our professional role and identity. Teaching and research, in particular, were framed as fundamentally human endeavors. As one reflection noted, education must remain a “human endeavor” where feedback, instruction, and inquiry flow from authentic human engagement, not automated outputs. This manifested within research as many of us expressed reluctance to use AI tools within qualitative analyses, as having a weighted algorithm categorizing, coding, and

grouping thereby undermines the reflexive research process and may cause harm. However, for elements of research that were not necessarily viewed as essential or relational, like debugging code, checking grammar, or organizing references, we were much more inclined to use AI tools, so long as the central intellectual labor was still-human driven. These instances highlighted how our effort to preserve ownership and autonomy in thinking forces GenAI tools to be viewed as a supportive tool rather than replacement of work.

Our choice of whether to use GenAI tools was not solely confined to our own work, but also for students. We raised concerns that if students turned to GenAI too quickly for answers, they would "cheat themselves" out of the process of thinking. It was important to all of us to emphasize the importance of cultivating critical evaluation skills and perseverance, so students could use GenAI as a dialogue partner rather than a replacement for their own reasoning. Allowing students to co-construct classroom AI policies was seen as one way of reinforcing ownership, making explicit the terms under which GenAI would or would not be used.

Ultimately many of us discussed feelings of guilt surrounding the use of GenAI when tasks were within our professional capacity because there was a feeling of inauthenticity as well as lack of ownership. Further, we were deeply troubled with current research highlighting the psychological impact of ownership and GenAI (Kosmyna, 2025; Lee et al., 2025). The more secure individuals felt in their intellectual capacities, the less likely they were to outsource critical thinking to machines. On the other hand, lack of confidence could lead to over-reliance, undermining ownership of ideas and even memory of the work produced. We had greater concerns of our GenAI use as early career MTEs, as this stage of academic work is often associated with imposter syndrome and developing our own professional identity.

Conformity and Security

Our values were not in isolation, rather our values of conformity and security interacted with the universities' institutional values, such as achievement and power. As early career MTEs thinking about their professional identity, we often focused on our belonging within professional communities and stability within our job and research; however, this was in competition with the expectations that are placed upon 'measurable' achievements and productivity. Within our context, we operationalized conformity as making decisions to not violate expectations of us as MTEs. These social expectations came from our universities, professional communities, and students. As mentioned, this was often tied with security, which focused on our safety within our job and the research community. Simultaneously, the university values of power and achievement impacted our decisions around GenAI as universities wanted to maintain a rigorous professional image, in alignment with power, and many times used physical measures that are social standards to determine achievement.

Due to the focus on measurable outcomes and the social norms imparted on us, and out of a sense of wanting stability in our profession, this created a context in which GenAI was a pragmatic strategy that was used to reconcile competing value demands. Often GenAI is what allowed us to meet the needs of the university and conform to expectations while being able to preserve what we viewed as the heart of teaching. When our commitment to our students, our research, or other job elements did not align with the universities' measures of achievement, this led to a greater likelihood of using AI. AI was not simply a technological tool but rather was a way to try and protect our core teaching and research values while meeting social norms and keeping our jobs. Even if using AI was not consistent with personal values like self-direction or universalism, including environmental concerns, some resulted to AI to meet these needs. For example, consider one of our experiences navigating AI use:

> "I struggle because it feels like I should be able to do all these things on my own and yet trying to do it all is not physically possible… I am trying to prioritize students… Many times, for generic things that I have to do as a faculty member that no one really reads, I will have ChatGPT do a first draft because if no one else is really caring about it, then why should I put my time and effort into it, especially if it is basically adult busywork. However, why should I make my life easier at the expense of others?"

Within this quote, it is evident that this MTE wants to focus on students; however, the university values of achievement and their desire for conformity created a situation where they felt they had to use GenAI. This choice was inconsistent with their value of universalism, but the value of security outweighed this concern.

The time pressure related to academic work and the change in communication expectations were expressed across participants and in these situations, our values combined with university values, created a space where GenAI allowed us to maintain our commitment to teaching while meeting the social expectations. A common situation was with regards to email and electronic communications. This practice was important to the university, but we did not feel was at the core of teaching. One member noted that "the need to communicate consistently, and keep the right tone, and the fact that I am not confident in this skill is the reason I have used AI to help me rephrase my email drafts." Another stated that "one of the things that I feel like that has changed, especially since COVID is the expectation of speed and time to reply to things. And so the only way for me sometimes to meet those deadlines with emails [which] to me it isn't at the core of teaching [is to use AI]". These are specifically tied to being "[measured] in number of articles or something like that or number of emails sent" which are norms set by the universities and professional communities. Further, despite the desire of universities to have achievement and power, one member, with agreement of others, expressed frustration in the university not willing to provide resources. Our reflections highlight that the use of GenAI in our work is more of a values-mediated coping tool as we respond to additional institutional and societal pressures related to tasks we do not highly value or view as innately human. It is not that we wanted to actively ignore GenAI, rather, to maintain the critical thinking desired in the classroom and to have time for mentoring students and conducting research, there are areas of our job that we were willing to compromise and use GenAI to complete. These areas are what the institution may deem necessary but are not at the core of our professional values.

Moving Forward

This preliminary report focuses on the first layer of basic value coding with our initial data. While we have identified some personal values and how they interact with institutional values over time, the application of VSD is still being worked on, particularly when we think of the interaction and creating a framing of the implications on GenAI use across all values. Further, we view this preliminary report and subsequent discussion with the larger community and stakeholders as part of the analytic autoethnography process. Questions that we plan to pose to the audience include (1) How could VSD be adapted to account for evolving professional expectations when core values are fixed? (2) Are there different values or tensions in the VSD framework that attendees feel we overlooked either in our analysis or based on their experience? (3) How can this analytic autoethnography serve a broader MTE audience for GenAI decision making? Feedback from attendees will further refine our framing and analysis while ensuring that this autoethnography is linking our experiences to the broader phenomena of MTE GenAI decision making. This feedback will help us explore the subsequent layers of VSD with learning and technology values.

HaLLMos: Constitutional AI for Feedback on Mathematical Proofs

Learning to construct and critique proofs is central to advanced mathematics but challenging for students. This paper reports on HaLLMos*, an AI model that helps students learn to write mathematical proofs. HaLLMos uses a constitutional approach along with expert-curated feedback exemplars to generate responses to students' proof efforts. Guided by Schoenfeld's Goals–Orientations–Resources framework and perspectives on proof as discourse, we investigate the tool's alignment with its constitutional principles and student perspectives on HaLLMos' value. Preliminary data from interviews and system logs suggest that HaLLMos supports students' independence while also preparing them to participate in mathematical conversations about proof. Preliminary findings suggest HaLLMos can expand resources for students and faculty while raising new questions about how AI-generated feedback can support students' mathematical interactions and their sense of belonging in mathematics.*

Keywords: Mathematical Proof, Feedback, Constitutional AI

Learning to construct proofs is one of the most significant challenges students face in the transition to postsecondary mathematics (Selden, 2012; Moore, 1994; Clark & Lovric, 2009). Proofs are not only logical structures, but also discourse practices, shaped by the norms of justification, explanation, and persuasion defined by the mathematical community (Stylianides, 2007, 2018; Weber, 2014). Many undergraduates struggle with both the technical and discursive demands of proof (e.g., Selden & Selden, 2008; Dreyfus, 1999) and how to participate in mathematical discourse (Sword et al., in press; Herbst & Chazan, 2010).

Mathematics and mathematics education faculty who seek to support students in learning to write proofs face the ongoing challenge of providing personalized (Pedemonte, 2018), immediate (Bokhove & Drijvers, 2012), iterative (Barker & Pinard, 2014), and well-framed (Alvidrez, Louie, & Tchoshanov, 2022) feedback on students' mathematical proofs. There remains a gap between what research suggests students need and what professors can provide, given the constraints of time and resources (Stylianides & Stylianides, 2018), a gap that widens where faculty are under-resourced, and for students who may be coming to college with less experience with proof methods (Fyfe & Rittle-Johnson, 2017).

To close this gap, HaLLMos, an AI tool, takes a *Constitutional AI* approach (Askell et al., 2021; Bai et al., 2022). To build HaLLMos, we convened a group of experts to create a *constitution* guiding the development and training of a Large Language Model specifically trained to give students feedback in line with constitutional principles. This tool is not intended to replace faculty as teachers and mentors but can offload some of the work of feedback on proofs so that faculty and students can focus on human aspects of mathematics (Jones & Herbst, 2012; Selden & Selden, 2008). HaLLMos.com is a prototype website for students to receive feedback on their proofs and a setting for research on how HaLLMos serves students and faculty.

Drawing on Schoenfeld's Goals–Orientations–Resources framework and perspectives on proof as discourse, we investigate the following questions: How does feedback from HaLLMos

align with its constitutional principles? How do students use HaLLMos, and how do they perceive its value in building their capacity to read, critique, and construct proofs? How does use of the tool affect students' preparation for mathematical discourse?

How HaLLMos Works

On HaLLMos.com, students enter a proof for a pre-loaded or custom-written exercise and receive feedback from the model. Unlike general-purpose chatbots, HaLLMos does not provide complete proofs or engage in open-ended conversation; it responds only to student proof attempts, encouraging revision rather than replacement.

To generate feedback, the model acts in two stages. In the first "critic" stage, the model analyzes each step of the proof for correctness, relevance, and support. This critique is not shared with the student but is fed into a second "coach" stage, in which the model, explicitly guided by constitutional principles and fine-tuned on over 350 expert-curated feedback exemplars, generates the feedback students receive. Sample constitutional principles include: the feedback should begin by identifying one or more correct elements of the proof, if any; feedback should always be connected to the content of the work, not about the person who wrote it; and feedback should not be overly prescriptive in how issues should be fixed, preferring instead to give the student enough information to fix problems on their own.

HaLLMos does not have "conversations" the way ChatGPT does. Students get iterative feedback by revising their proofs and resubmitting. Notably, unlike existing LLMs, HaLLMos does *not* provide correct proofs after giving feedback. Figure 1 illustrates this process, showing five iterations of a student proof with changes between iterations highlighted.

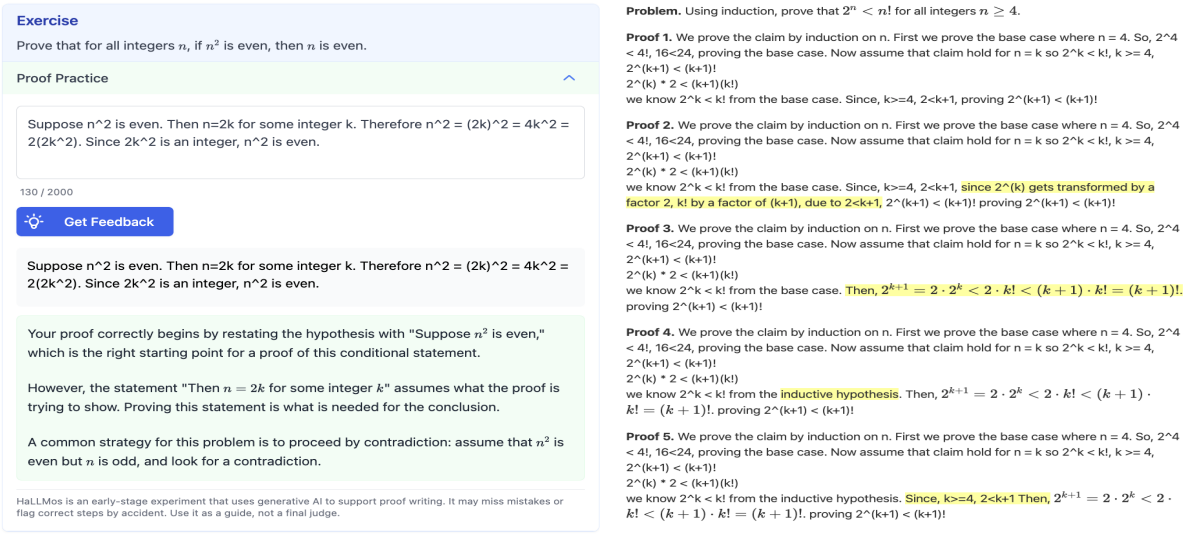

Figure 1. A screenshot from HaLLMos.com (left) and an example of a student iterating on a proof (right).

What Makes This Paper Preliminary

We are writing this paper at the end of a year of work largely dedicated to developing HaLLMos. At the time of writing, we have collected over 14,000 user-input proofs, surveyed students at four pilot sites, interviewed three self-selected students and one faculty member. In addition, we have had extensive informal conversations with pilot faculty, all of which have informed our interview protocol design. Multiple pilots of the tool are scheduled for spring 2026. We will conduct faculty interviews, as well as additional student surveys and interviews. While the

current size of the study limits the conclusions we can draw, we anticipate that the emerging themes will interest the mathematics education community as the field considers how to incorporate AI tools responsibly and productively into college mathematics.

As we continue this work, we pose the following questions for discussion with the RUME community: (1) What additional frameworks might illuminate the relationship between AI-mediated and human-mediated mathematical discourse? (2) How might we better assess alignment between AI feedback and constitutional principles at scale? (3) What safeguards should guide implementation of AI feedback tools in proof-based courses?

Conceptual Frameworks

This study is framed by Schoenfeld's theory of decision-making (2010, 2011) and the discourse perspective on proof (e.g., Stylianides, 2007, 2018; Weber, 2014; Herbst & Chazan, 2010). Together, these frameworks help us conceptualize HaLLMos as a pedagogical actor whose effectiveness lies not only in correctness but also in its capacity to realign decision-making resources and support students' proof discourse.

Schoenfeld (2010, 2011) describes teachers' instructional choices arising from the interaction of goals, orientations, and resources. We extend this framework to HaLLMos itself. HaLLMos' *goals* are to provide immediate, useful feedback and reduce faculty feedback load. Its *orientations* are encoded in the constitution, which emphasizes humanizing feedback that centers students' ideas. Its *resources* include extensive training exemplars. This framework allows us to evaluate HaLLMos' alignment with its constitution through its outputs to students.

Stylianides (2007, 2018) argues that learning proof requires appropriation of the sociomathematical norms governing acceptable justification. Herbst and Chazan (2010) demonstrate that classroom discourse norms determine who can participate and how, with students often excluded less by logical incapacity than by unfamiliarity with discourse expectations. Feedback thus functions as more than correction: it apprentices students into proof discourse by modeling the language, structure, and norms of mathematical argumentation.

Methods

HaLLMos was piloted in multiple Introduction to Proofs courses at R1 universities as an optional feedback tool for homework assignments. Data sources included website logs from student submissions, interviews with three self-selected students (majoring in engineering, statistics, and mathematics), and course materials. Interviews lasted approximately 30–45 minutes, were audio-recorded, and transcribed for analysis. Website logs captured student proof submissions, model feedback, and revision patterns. Interview protocols focused on students' experiences with HaLLMos, perceptions of feedback quality, and changes in mathematical interactions.

We employed template analysis (Brooks et al., 2015) informed by the GOR and proof-as-discourse frameworks. Initial codes were drawn deductively from both frameworks, with additional emergent codes identified through iterative analysis. Analysis focused on instances where students described their interactions with HaLLMos and how those interactions shaped subsequent mathematical activity.

Preliminary Findings

Our analysis of three focal student cases reveals themes illuminating how HaLLMos aligns with its constitutional principles, how students perceive its value, and how it reshapes their preparation for mathematical discourse.

Theme 1: Alignment with Constitutional Principles

Students consistently reported that HaLLMos feedback was useful in identifying errors and suggesting improvements: “My biggest complaint was that inputting my proofs took a while... But once I got all the way in there, the feedback was, for the most part—I never got any, like, *bad* feedback.” Another student compared HaLLMos to other AI tools: “The tone voice was always good... HaLLMos definitely gave me better answers compared to ChatGPT.”

These responses reflect alignment with key constitutional principles. Students did not report feeling personally criticized, consistent with the principle that feedback should address the work rather than the person. Descriptions of HaLLMos helping students “further develop the proof” rather than simply providing answers suggest feedback avoids being overly prescriptive.

However, students also identified areas where alignment could be strengthened: “It would help diagnose those problems. But when it had just one minor thing that really didn’t need to be changed, it would still tell me to change it... if it could differentiate between the major fundamental problems and the minor... that would be helpful.” Another noted, “Sometimes I would submit my proof... and maybe submit the same thing again, and I would get different feedback.” These observations point to opportunities for refining the model and highlight where human instructor judgment remains essential.

Theme 2: Building Confidence for Independent Work

Students described HaLLMos as an accessible “extra set of eyes” available outside office hours. One noted, “It definitely helped me with my homework, and the homework is where I learned.” Another began to think “more like a logician,” explaining, “As a mathematician, we have to basically explain and justify why our solutions work. Using HaLLMos helped me reinforce that understanding.”

One student pointed to the use of HaLLMos for getting started: “the biggest difference is when starting a proof by myself can be a little challenging... even if you start with a bare bones introduction to your proof in HaLLMos, it can provide feedback on how you can further develop the proof from there.” However, students consistently cautioned against over-reliance, emphasizing the importance of struggling through proofs. As one put it, “being stuck matters.”

Theme 3: Preparation for Human Interactions and Mathematical Discourse

One student pointed to the value of using HaLLMos before talking to a professor: “I didn’t want to just say, ‘I don’t know, I’m doing *anything!* Help me!’ So I wanted to have some understanding, and HaLLMos helped me with the first steps.” Another described the value of having a “peek behind the curtain” of mathematics that HaLLMos afforded him. Together, these findings point to HaLLMos as both a decision-making resource (in the Schoenfeld framework) and an apprenticeship tool for discourse, with potential to humanize students’ experience of learning to write proofs.

Faculty Perspectives

Faculty emphasized the pedagogical value of immediacy. As one instructor noted, "Anything with feedback that comes much later is not going to motivate students. But if the feedback is immediate, that helps students a lot." Another elaborated on HaLLMos' role in the iterative process of proof-writing: "Writing proofs—there's many ways you can go. A few right ways and many more wrong. Getting real-time feedback like 'don't go that way, try this'... that's absolutely beneficial." These observations align with the literature on feedback timing (Bokhove &

Drijvers, 2012) while suggesting that faculty see HaLLMos as addressing a gap they experience but cannot fill with existing resources.

Although our faculty data collection is ongoing, early interviews and informal communications from pilot instructors echo the student themes. One email exchange, while not part of our formal research data, has shaped our thinking on what kinds of things we can learn in a study like this one. The faculty member shared that a student "came to him after class and said she is so thankful for him sharing HaLLMos with her, because it doesn't judge her ideas." This unsolicited comment points to an affective dimension we had not fully anticipated: for some students, the non-evaluative nature of AI feedback may create space to take risks that feel too costly in human interactions.

We want to emphasize two important points about what the faculty member shared: he valued this student's experience of *feeling* not judged, not because he himself was judging her, but because she saw that aspect of HaLLMos as valuable. Second, as a team, we deeply value the human relationships that spring up around mathematics. We are not sharing that quotation because we believe HaLLMos could or should replace those human interactions. Our hope for HaLLMos is that it offer students and faculty more common ground for mathematical interactions, not less, lowering the barriers that keep some students from showing up to mathematical conversations at all. When routine feedback is offloaded to a non-judgmental machine, faculty and students can spend their time together on the aspects of mathematics that most require human presence: intuition, meaning, and community.

Implications

HaLLMos can relieve some of the burden on faculty by providing timely, principled feedback on proofs. This enables faculty to reallocate time towards activities often underemphasized in transition-to-proof courses, such as conjecturing, developing mathematical intuition, and cultivating mathematical habits of mind (Lin et al., 2012; Cuoco, Goldenberg, & Mark, 1996; Thurston, 1994). Furthermore, by modeling proof language and structure, HaLLMos lowers the threshold for students to participate in office hours and class discussions. Student reports that HaLLMos helped them know "what to ask" highlight the tool's role in apprenticing learners into proof discourse.

AI tools are proliferating quickly across education. There is a real need for research that informs the field about how to build and implement those tools responsibly, and for oversight about tools' effects on students. Such research should be situated in current literature rather than treated as "AI education research" independent of existing work.

Beyond studying the use of AI tools in undergraduate mathematics, this research offers a lens on proof learning. The constitutional process required us to work with our advisors to articulate criteria for high-quality feedback that often remain tacit in instructional practice. Website logs reveal the iterative, nonlinear nature of student proof development in ways that submitted homework cannot. And student responses, especially around students' perspectives on non-judgment and freedom to make mistakes, surface affective dimensions of proof learning that may be difficult to access through direct questioning about human instructors. AI tools, when designed and studied carefully, can function not only as interventions but also as instruments that make visible aspects of mathematical learning that are otherwise hard to see.

Investigating the Role of Various Conceptions of Subtraction in Calculus: A Textbook Analysis

Jude Shive, Rhodes College
Erika David Parr, Rhodes College
Morgan Sellers, Colorado Mesa University

The concept of difference, and its representation as distance within a graphical representation pervades Calculus. Indeed, difference expressions represent change, the very foundation of the subject. Yet, students may often default to a takeaway conception of subtraction, which may be incompatible with viewing subtraction as finding change. Other ways of conceiving of subtraction may support additional ideas in Calculus, related to translating functions, finding areas and volumes, or indexing terms of a sequence. In this preliminary report, we investigate the prevalence of various conceptions of subtraction in the study of Calculus through a textbook analysis of Stewart's Calculus: Early Transcendentals. We report our findings from our analysis and future directions for research.

Keywords: subtraction, difference, Calculus, representations, textbook analysis

The notion of difference, and its graphical representation as a distance between two points, is foundational in the study of Calculus, as it finds the change in values of a variable. Some instances include the limit definition of the derivative ($f(x+h)–f(x)$), the Mean Value Theorem ($f(b)–f(a)$), and the Fundamental Theorem of Calculus ($F(b)–F(a)$). To use a difference expression to model change in a quantity, one must conceive of subtraction as comparison, rather than as takeaway. Yet, the takeaway conception may be at the forefront of students' minds instead, possibly reinforced by concrete activities such as physically taking away objects or "going back" used to introduce subtraction (Selter et al., 2012). Though first teaching subtraction as takeaway at the elementary level is recommended, research has suggested that students need to hold multiple conceptions of subtraction for deep comprehension across the mathematics curricula (Bofferding & Wessman-Enzinger, 2017; Sievert, 2021). However, many undergraduate students may not readily use such a conception of subtraction to represent a horizontal distance between two functions in the Cartesian plane (Sinojia et al., 2023). Other ways of conceiving of subtraction may also be beneficial in Calculus, such as interpreting subtraction as translating a function down some number of units. To better understand the ways in which subtraction conceptions are embedded in the study of Calculus, we decided to conduct a textbook analysis. We chose Stewart's (2021) *Calculus: Early Transcendentals, 9th edition* because of its ubiquity in undergraduate courses. We follow Weinberg (2010) in adopting the lens of the *implied reader of a Calculus textbook* to consider the various conceptions of subtraction needed to meaningfully respond to the text. With this framing, we ask the following questions:

1. How do readers of *Calculus: Early Transcendentals* need to conceive of subtraction to meaningfully and accurately engage with the text?
2. What is the prevalence of various conceptions of subtraction in the text and by topic?

Theoretical Perspective

We adopt the framing of reader-oriented theory for mathematics textbooks, as explicated by Weinberg and Wiesner (2011), in which the text can be viewed as a site of interaction between the author and reader. The authors of a textbook may envision the reader of their text and address them as their target audience, referred to as the *intended reader*. In contrast, the *implied reader*

describes the capacities required of the reader to "respond to the text in a way that is both meaningful and accurate" (Weinberg & Wisener, 2011, p. 52). We take up the idea of the implied reader to examine the ways in which subtraction is required to be conceived of in order to meaningfully and accurately engage with Stewart's *Calculus: Early Transcendentals*.

To consider various conceptions of subtraction, we adopt the four models of subtraction identified by Parr et al. (2025) which they observed with undergraduate students on difference tasks designed for Calculus. These four models are: (1) magnitude, (2) takeaway values, (3) takeaway segments, and (4) translation. Table 1 contains the description of each model of subtraction as observed on a number line task or single axis.

Table 1. Four Models of Subtraction adapted from Parr et al. (2025)

	Models $b–a$ as
Magnitude	The distance between positions a and b
Takeaway values	The resulting position starting at position b and moving left a units
Translation	The distance between $b–a$ and 0
Takeaway segments	The resulting segment from removing a segment of length a from a segment of length b

Methods

We performed an initial textbook analysis of James Stewart's *Calculus: Early Transcendentals* in search of each representation of subtraction, led by the first author. We used each representation's description from Table 1. In order to begin to investigate our research questions, the first author identified whether various conceptions of subtraction occurred in each of the 116 subsection of the text (e.g., 4.7). The decision to document the presence of a particular conception, rather than code each individual expression or figure allowed us to avoid double counting repeated properties, definitions, or equations within each chapter. Preliminary coding was only done by the first author, with input as needed from the co-authors. Thus, the current findings remain exclusive to one perspective until others also code more extensively for reliability.

A subchapter would be coded with an "M" if it included any indication of a magnitude representation of subtraction. Mentions of "distance" or "length" were identified as such, as well as any graphical representation containing the length between two points. These concepts require a magnitude representation because this particular form conceives of subtraction as a representation of distance and change between points.

A subchapter would be coded with a "TV" if it contained any instances of a takeaway values form of subtraction. Language including "go back" or "shift down" were considered. The typical visual cue was any subtraction where the result was an independent value similar to the initial point before subtraction. Such instances demonstrate subtraction as a means of producing a new value rather than moving between two existing positions.

Subchapters would be coded with a "T" if they demonstrated a translation form of subtraction. The primary requirement for this representation to be identified was the translation of a segment representing length. If the endpoints of the visual subtraction on display did not match with the minuend and subtrahend, then some form of translation was involved. Otherwise, the subtraction was just considered an instance of the magnitude representation.

Subchapters would be coded with a "TS" if they involved the takeaway segments form at least once. Similar to translation, takeaway segments uses the same minuend and subtrahend as the magnitude form. This fourth model was considered when language involving "pieces" or "segments" was involved, which appeared in visual models as the comparison of smaller and larger lines that overlapped.

As these are visual representations of subtraction, we considered excluding coding to the explicitly graphical applications within the textbook. However, it became apparent early on that not all graphical concepts, such as the representation of the difference between two functions, were given a visual aid (Stewart et al., 2021, p. 40). Because of the space constraint of the textbook, we decided to code all applications of subtraction rather than exclusively graphical representations. Even if subtraction was not written out as an expression in a subchapter, we would still code for representations of subtraction if concepts applying the subtraction forms were referenced to get to these higher-level concepts. The most notable example of this was the expression Δx, which is used to represent the magnitude of the change in x over a particular interval. This symbol is used in later subchapters to represent this change in x while introducing higher concepts like rates of change (p. 146), double integrals in polar coordinates (p. 1063), and surface area (p. 1177). As a subject that builds upon its smaller concepts, we chose to code for references to earlier subchapters requiring subtraction.

Results

All four representations of subtraction were present within Stewart et al.'s *Calculus* textbook. The magnitude form of subtraction was the most prominent, occurring in 100 of the 116 subchapters (86.96%). Most observed instances can be divided between representations of distance/length and value comparison. Subtraction as length was applied in subchapters exploring rates of change, the precise definition of a limit, polar coordinates, series limits, and vectors. Each of these concepts build off of the basic concept of distance between two points. The distance between an initial and final x value is used in both the creation of derivatives as well as the defining of an integral's interval. These two central Calculus concepts were much of the reason for the magnitude form of subtraction being so prominent across the textbook. Value comparison appeared in additional concepts like the difference of limits, function value differences ($f - g$), rate comparisons, and the difference between two series. Real world examples using this representation of subtraction often involved physical positioning or distance.

Graphing general functions demonstrates how frequently concepts of distance are applied in Calculus. Rather than label the output of a function itself, the textbook would frequently label the length between the x-axis and the output with the function (Table 2). The expression of function outputs as distances from zero puts an emphasis on magnitude and the space between an initial and final value. The epsilon-delta definition of a limit is another interesting representation of distance through the magnitude form of subtraction. The distance between the limit $f(x)$ and $f(x) - \varepsilon$, for some $\varepsilon > 0$, is used as a reference for output value proximity to $f(x)$.

The takeaway values representation was the second most frequent model, and it appeared in 44 of the subchapters (38.26%). There was a greater variety in the applications of the model here, including function transformations, the creation of new functions, sequence notation, value reduction, and repeated subtraction. Function transformations were indicated by the "shifting" of a function around a graph. This became more prominent in later chapters when adding different values of c to an antiderivative. Value reduction occurred in scattered chapters, including the placing of epsilon ball boundaries, subtracting angles to get a third angle, and modeling

radioactive decay. Repeated subtraction demonstrated an instance of the operation unique to the takeaway values model, and it was best demonstrated with the concept of an alternating series.

Table 2. Four conceptions of subtraction identified in Stewart's Calculus: Early Transcendentals

Magnitude	Takeaway Values	Translation	Takeaway Segments
			Mapping a function output. The distance from 0 to f(x,y) is labeled f(x,y). Emphasis on distance.	*The (i-1)th term is one term before the ith term. Moving between values performed by counting down.*	*h(x) is the difference between f(x) and the bottom equation. It is then translated onto the x-axis so that Rolle's Theorem can be used to prove the MVT.*	*Subtraction of areas used to find "net area." Introduces integrals with subtraction.*

Sequence notation was the most frequent application of the takeaway values representation of subtraction, even if it is in a more abstract form. Working with the $(n-1)$th term requires students to "count back" one term from the nth value. The $(n-1)$th term was frequently depicted in graphs as an independent point directly preceding to the nth term. Table 2 presents a visual instance of this more abstract subtraction. When explaining the division of a shape into volume cross-sections, the textbook used the subscript of sequence notation to generalize the visual partitioning beyond any fixed number of segments. Across the chapters, more complicated concepts often employed index notation like this to generalize processes and demonstrate concept application beyond any limiting context. Integral subintervals used subscript subtraction most frequently.

The translation representation of subtraction was the least present within the textbook. There were only 13 subchapters, making up 11.3% of the textbook's sections. The most common occurrence of this representation of subtraction was within settings where the initial point was constant. The greatest example of this is the subtraction of two functions to create a new function. No matter what the result of subtracting two outputs is, the new function's output must be a magnitude relative to zero. The best visual depiction of this was in the proof of the Mean Value Theorem (Table 2). Function subtraction was used to produce a new function $h(x)$, which would have root values for the use of Rolle's Theorem. In a similar manner, subtracting vectors creates a new vector that can share the same initial value as the first two vectors. Problems involving centers of mass also applied this model, visualizing all points with a distance relative to the center. Other real-world problems such as the concept of displacement from a starting point can use this form of subtraction.

The takeaway segments representation of subtraction appeared in 29 of the subchapters (25.22%). Instances of a takeaway segments form being used include the comparison of lengths or quantities as well as area or volume subtraction. Length comparison is helpful when trying to visualize concepts like change over time, differences in rate, or radius subtraction. Displacement and position functions demonstrate subtraction as a tool for finding the remaining or added

length when comparing two different points or positions. Area and volume subtraction use the takeaway segments model more consistently because they represent the comparison of established "spaces," which are closer in concept to a "segment" than an individual point on a graph. Subtracting inner volumes from outer volumes, calculating the area of a portion of a shape, depicting change in area, and representing segments of polar rectangles are all examples of Calculus concepts that applied the takeaway segments form of subtraction in this way. Even integrals were introduced with help from this representation of subtraction, referring to an integral as "net area" (Table 2). Though the positive and negative areas are not overlapping in the same way that the position function's segments did, their subtraction still represents the comparison of spaces instead of points.

In this study's current state, the subtraction of two functions to produce a third function was the only Calculus concept where three or more representations of subtraction are applied. If $h(x) = f(x) - g(x)$, then $h(x)$ is the magnitude between the points $f(x)$ and $g(x)$. As a function of its own, all values of h are graphically represented as a distance from zero. This means that the magnitude of $f(x) - g(x)$ is translated to be a distance in relation to the x-axis. This distance can be understood as the difference between the distance from zero to $f(x)$ and the distance from zero to $g(x)$, alluding to the takeaway segments model. The best instance of this is in the proof of the Mean Value Theorem.

After determining the function for the secant line between the two endpoints of the designated interval, function subtraction is used to determine the magnitude of the distance between the secant line and the original function. This new function has two zeros at the endpoints of the interval, as the outputs on the secant line and in the initial function are equivalent. This allows for the use of the previously proven Rolle's Theorem to complete the remainder of the proof.

Discussion & Future Development

These findings assert that a magnitude representation of subtraction is the most essential for students to understand in Calculus. Graphical interpretations of both derivatives and integrals rely on expressing or representing the distance between points, making the magnitude model of subtraction a necessary resource for Calculus. Yet, this does not mean that the other representations of subtraction should be considered as nonessential. Each of the representations appeared within their own contexts, and thus, students can benefit from each of them to varying degrees. Rather than teach only a magnitude representation of subtraction, it would be beneficial for students to learn how to identify the situations where each form can be helpful.

We pose the following questions for discussion with the audience as we consider our next round of coding of the data:

1. Multiple representations of subtraction can be considered for our data. What is the audience's perception of the primary (and secondary) representations for the "net area" example?
2. Are there any other examples from the Stewart text that you do not think can be described by one of the models?
3. Are there any limitations of this framework as we consider examples in higher dimensions?

Community College Students' Definitions of and Experiences With Equity in College Algebra Classrooms

Camden Collins
Oregon State University

Irene Duranczyk
University of Minnesota

Mary Beisiegel
Oregon State University

In mathematics classrooms, equity has been researched, defined, and reported by those who have the ability and authority (professional organizations, instructors, state and federal educational agencies, local administrators, universities, and teaching faculty). However, the students who are susceptible to these definitions have not been asked for their perspectives of what equity would look like or what would remove the inequities they experience in their mathematics classes. Our goal is to center community college students' experiences with and definitions of equity as they reflect on their mathematics' learning journey, significant moments that shaped their engagement in mathematics, how they thought about equity, and whether and how they had experienced equity or inequities specifically in College Algebra. We found that participants' understandings and definitions of equity varied significantly, as did their experiences in mathematics classes. Additionally, we found that participants situated their understanding of equity in features of their identities.

Keywords: Equity, college algebra, student experiences, classroom practices

Introduction

In 2000, the National Council for Teachers of Mathematics published the *Principles and Standards for Teaching Mathematics*. One of the five key principles was equity. Since that time, researchers have argued for more robust understandings of equity in the context of mathematics teaching and learning (e.g., Cobb & Hodge, 2002; Gutiérrez, 2002) and many studies have been published about equity in the context of mathematics education. In conjunction with this movement, more professional organizations also began to focus on equity as a critical component of mathematics instruction and mathematics communities (e.g., American Mathematical Association of Two-Year Colleges, the Mathematical Association of America *Instructional Practices Guide*, 2018), noting that equity and equitable teaching practices have the ability to diversify the field of mathematics, create more inclusive spaces, and, as a result, enrich the field of mathematics.

For our work, we aimed to understand how equity was conceptualized in mathematics education research. In a review of 177 papers (Boeck et al., 2024) that focused on equity in mathematics teaching and learning, we found that only 21 explicitly defined and/or operationalized equity. Some of the earliest definitions of equity included Gutiérrez: "develop proficiency in dominant mathematics, contribute towards and develop critical stance and new perspectives on relationship between mathematics and society" (2002, p. 174) and Esmonde: "Fair distribution of opportunities to learn or opportunities to participate" (2009, p. 249). We observed in our literature review that many researchers relied heavily on Esmonde (2009) and Gutiérrez (2002) as the basis for their studies. However, we found that the definitions in the 21 articles were mostly created out of the researchers' understandings and interpretations of educational contexts and that student voices appeared to be absent in the literature.

The goal of our research is to add student voices to the mathematics education research literature focused on equity. Our focus is on community college students because they play an important role in the preparation of the next generation of STEM majors, the rise in the

percentage of students taking courses at community college to complete requirements for their undergraduate majors, and community colleges are well positioned to contribute to the diversification of the STEM workforce. In this preliminary research report, we share findings from the first of four interviews exploring community college students' experiences with mathematics generally and College Algebra specifically. Our inquiry focuses on students' definitions of and experiences of equity in College Algebra classes. We aim to answer the questions: (1) What are community college students' definitions and understandings of equity? (2) What do students' voices add to our understanding of equity?

Methods

We recruited participants from community colleges across four diverse states by announcing the study to classes of students, posting flyers in public spaces on community college campuses, and asking community college mathematics faculty to share the recruitment flyer through an announcement on the learning management system for the course. If students expressed interest in participating, we asked them to first answer survey questions about: the amount of time and the number of mathematics classes they had taken in community college; their work and family obligations; their past experiences with mathematics courses; and their definitions and experiences of equity. We chose students based on the survey responses, using a few criteria: age 18+, experiences with College Algebra, prioritizing those who intended to continue their academic studies after community college – looking for diverse backgrounds across the participants. This process resulted in a total of 37 participants across the four states. We then conducted interviews with the participants on zoom, asking questions about their current mathematics classes, including: How do the students in your class interact with each other?; Please describe a moment when you feel supported or motivated (or not supported or motivated); Have you had an experience in a college math class in which you or a classmate were either highlighted/singled out/ignored based on race, ethnicity, religion, gender, accent, or other identity? Based on their answers to the intake survey, we asked more questions about equity.

Questions based on intake survey about equity (question a, b, c and/or d were chosen depending on participants' survey responses)

(a) In the intake survey you said that you have **heard** the term equity used. How and where have you heard it being used?

(b) In the intake survey you said that you have **used** the term equity. How have you used it?

(c) In the intake survey you said that you have **defined** the word equity before. What is your definition for equity?

(d) In the intake survey you said that you have **explained** to others what the term equity means. Can you please share the explanation you used?

Questions about equity in mathematics classrooms

What would equity look like in a college math class?

- Can you describe specific examples of how your math instructors supported equity (e.g., representation, topics, perspectives)?
- Can you describe specific examples of how your math instructors do not support equity (e.g., representation, topics, perspectives)?
- What specific actions or approaches would support equity in your math classroom? (either by instructors or peers)

Based on our literature review (Boeck et al., 2024), we created an analytic codebook using the definitions and operationalizations described in the 21 articles, which we then used for deductive coding of the interviews. For example, one of our codes relied on Esmonde's definition of equity as the "fair distribution of opportunities to learn" (2009, p. 249). Another code was based on Gutiérrez's (2002) notion that students should develop proficiency in dominant mathematics. Other codes included: relational equity among students (Sengupta-Irving, 2014), agency (Gutiérrez, 2002), and opportunity to learn quality mathematics (Gregson, 2013), among others. For many of the codes, we created more nuanced categories; for example, for "fair distribution of opportunities to learn" we added the categories *unfair* and *occurred*, for "students' sense of agency," we added *lack of*, *exhibits*, and *struggling with agency*. Cleaned transcripts were uploaded to Dedoose qualitative software program and we independently applied the codes to the transcripts. We then reconciled the students' statements that we had captured with the different codes, refined our descriptions of each code, found examples for each of the codes to assist with future coding, and coded additional transcripts. For the purpose of this preliminary report, we focus on our analysis of students' definitions of equity and how they described what equity would look like in mathematics classrooms, providing examples from a diverse group of five participants.

Findings

From the codes that centered around equity, we analyzed students' statements to further understand the contexts in which students use the word equity in a college mathematics classroom and their functional definitions. Findings are derived from analyzing interviews with a team of three researchers. We first share different ways the participants defined equity, confounding equity and equality, and how they described equity in a mathematics class. Finally, we explore how the participants situated equity in their identities and their experiences.

Defining Equity Was Difficult for Some and Students' Definitions of Equity Varied

There were significant differences across participants' definition of equity. Below we provide examples for the different types of thinking and definitions.

- *Defining equity was difficult for some*: Will stated "I struggle with it, I think. Maybe more than either diversity or inclusion. And I struggle with all of them" while Elena was very unsure and asked if she could look up the definition of equity during the interview.
- *Some students thought of equity in a financial context*: George said equity is "the amount of money you possibly gain like an income like for a house", and Althea said "I think I would define it as, like, equal or, like, money wise, like a part of a business, but, or like the value you have issued in a business."
- *Some confounded equity and equality*: Will acknowledged that he "struggles to parse out equity, equality, and fairness," and Elena stated "equality, I mean is, we're all treated the same. We're all treated with the same, you know, we don't, you know, look at anyone different, treat in that sense as far as equality," while Althea remarked "sometimes equity and equality kind of, like, combine in my head." Althea suggested that teachers should give each student the same attention and further implied the teacher was unfair as they "sectioned us out, like there was, like, like, the smart people that, like, don't really need help. I don't really need to focus on them too much. I have to focus on the people who don't understand that much or like it.

- *Some participants provided more concrete definitions of equity*: As one example, Ayami said "I think equity is having the tools there to make it possible for all of us to work together [...] deep equity looks like, is that those tools aren't uh… aren't either forced on us or like and uh… an intrusive presence. Like, they're just part of the way things are."

Students' Descriptions of What Equity Looks Like in a Mathematics Classroom

We also heard a variety of responses to the question "what would equity look like in a mathematics classroom?" Below are some examples of their responses:

- *Varied understanding of equity in the classroom*: George answered "In the math classroom. I don't really know. I don't really know the word equity yet. I'm equity enough to say that," while Will stated "equity in a college classroom focuses on student needs and accommodations for academic success, over comparative treatment for all students." Althea defined equity as "everyone gets the same opportunity to understand the coursework and the way, like the teacher is teaching."
- *Personal and social identities are taken into consideration when considering what equity in the classroom*: Ayami provided a very in-depth conception of equity in the classroom that incorporated how both students and teachers could promote equity: "I think for classmates it'd just be more so, kinda being willing to help versus like being very closed off. Not really like, you know, just being willing to help someone if they ask, and then, in the sense and like kind of kind of fostering a non-judgmental zone… because, you know, when it comes to like things like neurodivergency, or like struggles it can be embarrassing to kind of like, talk about it, or like reach out for help, so kind of providing and creating a nonjudgmental zone."
- *Students identified meaningful interactions with their peers surrounding mathematics as a form of equity*: When asking for specific actions or approaches that would support equity in each participant's mathematics classrooms, there was a high frequency of students desiring meaningful interactions with their peers surrounding mathematics. For example, Ayami described her experiences in study groups as negative: "It wasn't really like the study group conversation of trying to learn math together." This implies that social interactions with teachers and students help define whether or not a space is equitable. Other examples of specific actions or approaches that would support equity that were provided included giving extra time to students, providing multiple resources to learn from, and adjusting for different learning styles. Ayami explained that the role of a teacher is to "guide the way. Not really dictating [...] I feel like also kind of exploring different kinds of learning styles, cause I feel like it's very rigid."

Situating Equity in Identities, Experiences, and Broader Viewpoints

Lastly, using the participants' examples of equity in a mathematics classroom, we observed participants provided some insight into their personal and social identities when considering equitable outcomes. Compiling a list from all participants, they expressed that race, neurodivergence, social classes, immigration status, physical health, and mental health are factors that equity should address in a college mathematics classroom. In addition, Ayami stated that "home life" itself may be enough to create inequities. It is important to note that no two participants had the same set of identities and this leads to a difference in beliefs as to what

impacts a student's experience in a mathematics classroom. Here we provide two different situations for understanding and describing equity through their identities:

- Will noted his identity as a white, middle-aged man and said: "And obviously, that's a certain amount of privilege, right? Because places aren't built to make me uncomfortable. It's very easy for me to make myself comfortable in them."
- Ayami noted her identity as a young, West Asian woman with caregiving responsibilities and part-time employment, who had recently been diagnosed as neurodivergent. Her definition of equity was rooted in her positionality: **"**I usually describe it. I'm trying to think of, like, a specific time that we use the word equity. I usually describe it more in a racial sense or neuro, like, in a sense that uses neurodivergency or social classes. I typically use examples to describe equity versus, like, giving like a definite, like a strict definition, because equity in general is kind of, because in order to use equity, it's like a social. It's a social construct. So, we have to like, you know, kind of give it context in order for it to seem. So, yeah, I kind of use more examples when I talk with them."

Discussion

We focused our *first research question* on hearing how students defined equity. Unsurprisingly, we found significant variation across the participants in this preliminary analysis, that equity can be conflated with equality or sameness, and a definition of equity that might suit all students does not, and likely never will, exist. That said, we found that student definitions centered around the three main ideas identified above and that these ideas varied by their ability to conceptualize equity in education vs. finance and their ability to concretize that conceptualization based on their classroom experience or their identity. With our *second research question*, our goal was to answer the question "What do students' voices add to our understanding of equity?" Our preliminary data from students highlights a number of important facets of the definitions of equity reported in the literature. Some of the terms used more frequently by the students, such as descriptions of what they would like to see in their mathematics classroom that would demonstrate equity, were related to *relational equity* as described by Sengupta-Irving (2014), which means learning to effectively communicate with one another and appreciate other perspectives. However, there were more instances of students not experiencing relational equity than reporting its occurrence, and the participants reported that their college algebra classrooms should focus more on collaborative work rather than "just a relationship between one student and the teacher." The second most coded definition of equity was Esmonde's fair distribution of opportunities to learn or opportunities to participate (2009). The occurrence of this element was almost evenly distributed between noticing that it had occurred in the classroom and noticing that it had not occurred, but would be an important element to promote equity in the classroom.

Discussion Prompts for the Audience at RUME

We have two prompts for the audience at RUME: (1) We have coded primarily looking for instances of students' reflections and utterances that resonate with definitions of equity that we found in the literature as well as what they say directly when we ask them what is equity and how would you see it in a mathematics classroom. Is there another approach for coding that comes to mind that we might consider as we move forward? (2) How might our findings inform equity frameworks as well as research studies that center student voices in mathematics?

The Nature of a Community of Practice: Social Expectations at an Informal Summer Mathematics Program

Grace Morrell
Texas State University

Cody Patterson
Texas State University

We present results from a pilot study conducted to inform possible directions for further investigation focused on a specific community of practice: an informal summer mathematics program for mathematically talented students. While the program is attended by high school students, they take undergraduate level proof-based courses and engage in research at a level comparable to a research experience for undergraduates. Journals and interviews were used to investigate aspects of the program using Wenger's Communities of Practice theoretical framework, which describes social characteristics of a community of practice in terms of mutual engagement, joint enterprise, and shared repertoire. Suggestions for feedback from the reader and audience are included.

Keywords: Communities of Practice, Informal Educational Context, Undergraduate Research

A plethora of communities exist around mathematics, both educational and professional, and it is worthwhile as researchers to describe the diversity of these communities. Wenger (1999) describes the importance of Communities of Practice (CoP): "Communities of practice are the basic building blocks of a social learning system because they are the social "containers" of the competences that make up such a system." (p. 4). The CoP framework is a useful analytic tool to study how knowledge is created and competency is assigned within a community. From a situated learning perspective, Lave and Wenger (1991) describe legitimate peripheral participation as a tool to study learning within CoPs. The purpose of this work is to explore the way knowledge is generated within an informal summer mathematics program (ISMP) by describing essential aspects of the community and observing the legitimate peripheral participation of its members. The purpose of this paper specifically is to overview the early stages of the project including the initial round of data collection and preliminary observations about the community of practice.

Components of a Community of Practice

Wenger (1998) establishes that CoPs combine three elements: mutual engagement, a joint enterprise, and a shared repertoire. The first component, mutual engagement, refers to when members interact and establish norms for how they will engage in their practice. Mutual engagement creates relationships among members of a CoP. However, Wenger notes that engagement may not always be positive. It is possible for conflict or tension to characterize the engagement of a community. The second component, a joint enterprise, refers to agreement among members of the community about what they're doing, what their goals are, and they hold each other accountable to those expectations. Wenger describes how the joint enterprise is established, "It is defined by the participants in the very process of pursing it." (Wenger, 1998, p. 77). Finally, shared repertoire refers to resources that are shared with all members such as specific vocabulary, artifacts, and experiences. Wenger points out that a shared repertoire reflects a history of mutual engagement and remains inherently ambiguous meaning it can be reused or applied in novel ways. Biza et al. (2014) describe transforming the CoP framework into *Communities of Inquiry* (CoI) (Goodchild et al., 2013), which they explain to be, "… a CoP in

which inquiry is a fundamental way of being in practice." (p. 164). In a CoI, inquiry manifests itself in all three components of a CoP. Members engage in inquiry-based processes, their goals are aligned with better understanding of concepts, and they share inquiry-based tasks and approaches (Biza et al., 2014).

A range of empirical work has been done using the CoP theoretical framework to study undergraduate participation in mathematics and related fields. Solomon (2007) reports on a study examining undergraduate students' relationship to mathematics within the context of specific communities. Solomon observed a lack of students who identify as Legitimate Peripheral Participants and attributed this scarcity to the dominant discourses present in the community. The continuation of the project in this paper may provide further insight into barriers to legitimate peripheral participation undergraduate students face.

The following sections describe an ISMP using the CoP theoretical framework by giving examples of a joint enterprise, mutual engagement, and shared repertoire within the program. Specifically, we address the following research questions:

1. What social values or expectations do the students hold for themselves and their classmates regarding the way in which the ISMP community engages with mathematics?
2. What is the nature of mutual engagement, joint enterprise, and shared repertoire in the context of informal mathematics communities?

Methods

Context

The data used in this analysis was collected from students participating in a six-week ISMP in the southwestern United States. The program invites students who demonstrate excellence in mathematics to participate for up to three summers during their high school years. Students take the following undergraduate level mathematics courses taught by faculty at the host institution: number theory and Python programming (first year), abstract algebra and real analysis (second year), and topology and combinatorics (third year). Second- and third-year students also undertake research projects supervised by faculty at the host institution. Students spend their afternoons and weekends engaging in a variety of recreational activities and field trips.

After graduating from high school, students may return to join a group of undergraduate and graduate mentors. The mentors are responsible for holding daily problem sessions with eight students to review material from class as well as nightly study groups with four students to work on problem sets. In addition to their academic responsibilities, the mentors, particularly those who were previously students in the program, also uphold the camp culture by organizing activities and honoring traditions.

Data and Participants

Students submit two journal entries reflecting on their ongoing experiences. The first journal entry is after the second week, and the second journal entry is after the fourth week. The journal prompts were written by the program faculty with the purpose of ensuring all students are supported mathematically and socially throughout the summer. For example, some questions inquire about the pacing of the courses, some about the dynamics of their study group, and some about recreational activities. While the prompts were not written specifically for this project, the questions the students are asked to reflect upon are still aligned with the goals of the research.

Journals written by fifteen first-year students, thirteen second-year students, and four third-year students were collected for this project.

In addition to the journals, nine students were chosen to participate in semi-structured interviews. The students were chosen based on availability out of the group of second- and third-year students. This allowed for questions about research, which we know from prior experience to be a treasured component of the experience for returning students. A common interview protocol was used for all participating students; however, for several students, questions were added based on their journal entries to give the students the opportunity to elaborate on their written responses. The interviews were conducted during the fifth and sixth weeks of the program. Each interview lasted approximately 30 minutes. Zoom was used to record the audio and generate transcripts. The interviews were conducted by the first author, who was familiar to the participants as a mentor and staff member at the program. The study was supervised by the second author, who is on the program faculty. It is important to note that the students were aware that their journal entries would be read by the two authors and by other faculty in the program.

Results

In this section we provide examples of themes in the data regarding the students' values and expectations, which point to possible directions for future analysis. The themes reported below were selected when several students shared the same or similar sentiments in response to the journal or interview prompts. The first theme is related to mutual engagement, the second is related to the students' joint enterprise, and the third is related to their shared repertoire.

Mutual Engagement: During the Program, Students Expect to Work Collaboratively.

During the interviews, a conversation contrasting the way students do math at the program versus the way they do math at school often came up. We did not include an interview question specifically aimed at this; this theme emerged in response to different prompts depending on the participant. The majority of participants noted the collaborative nature of mathematics at the summer program compared to school. The following are two illustrative examples.

One student, Eugene, described why he returned for a second summer:

> "I thought like being in a study group with other people and like working on problems together, instead of just like being at home and doing all the problems myself, it's a lot more interesting. And I think it's like a lot more enjoyable, so that's why I came back."

Eugene returned to camp with the expectation that his study group would be collaborative. Later in the interview, Eugene compared his first-year study group to his second-year study group. He described how the first-year group would work together to solve all the problems, use the chalkboards, and bounce ideas off each other. Sounding somewhat disappointed, he shared that his second-year study group was often quiet, and students in the group worked on their own. Eugene's disappointment in his second-year group indicated that his expectation to collaborate with his study group was not met, and their dynamic was abnormal.

Another student, Miles, shared that the summer program allowed him to find friends who shared his interest in math. When asked why it is nice to have friends with the common interest, he shared,

> "…math can definitely get bland at some point if you're working on the same problem for like hours on end. So, like just having another person, even if they're not like helping

doing the same problem as you, just having another person doing something similar and like able to help or talk to about the problem is nice."

Miles came to camp with the expectation that others there would share his interest in math and provide collaborative support that he did not have at home.

The students' shared expectation that they will work together with their peers suggests that collaborating mathematically is a social norm at the summer program. They come to the program expecting that their classmates will engage with them in problem solving. Further investigation into and analysis of the types of socially expected collaboration will help inform the characterization of mutual engagement at the program.

Joint Enterprise: CoP Members are Committed to Supporting Each Other's Learning.

Many of the students wrote in their journals or shared in their interviews about the techniques they used to support their own learning and the learning of others. As above, this was not an explicit question; it came up in a variety of contexts depending on the student.

One expectation set by the faculty at the program is that mentors provide students with written feedback on their proofs (often referred to as "grading" even though no numerical grades are assigned) and assign several proofs per problem set for the student to rewrite and resubmit. One student, James, created his own strategy for responding to feedback. When prompted in the second journal about the feedback he received from his mentor, James described how, rather than just rewriting the proofs on his own, he preferred to think about the feedback he received and have a discussion with his mentor about it during study group. He wrote, "This turns out to be a very productive strategy for me, as rather than 'doing corrections,' we can instead have constructive conversations in person during study group." James' reflection is notable for two reasons. First, his motivation for adopting this new strategy of responding to feedback was his own desire to be more productive and engage with the ideas in a more meaningful way. Second, his mentor willingly adopted the new way to engage James with feedback, going against the faculty's expectations, but honoring the fact that it supported James' learning.

Another example of the joint enterprise is from the perspectives of two students, Kaitlyn and Aaron, who were in a study group together. Kaitlyn wrote in her second journal that their study group was very collaborative, often solving all the problems together on the board. However, she claimed that Aaron was the most "advanced" out of all of them, so his contributions were often diagrams or hints to help the others arrive at the solution on their own. Aaron also wrote about this dynamic in his first journal. He says, "I usually tend to guide the discussion, but when I realize I am being too overbearing, I often decide to let the others figure out the problem without me." Both Kaitlyn and Aaron were asked follow-up questions about this dynamic. Kaitlyn expressed her appreciation of Aaron's approach, and Aaron shared that he used it because he thought it created a better learning opportunity for his group mates. These examples suggest that the students in the program have a shared purpose to engage deeply with mathematical ideas and support one another's endeavors to do so. More investigation into this shared value and its manifestation across contexts will be useful in describing the joint enterprise of the students in the program.

Shared Repertoire: The Program Provides Students With Shared Artifacts and Experiences.

During this program, students participate in intense mathematical exploration together as well as build memories through recreational activities and free time. During their courses and

research, they receive and create shared artifacts including their problem sets, proofs, and past research projects. An illustrative example of a shared artifact comes from the interviews with Eugene and Miles. When asked how their research groups chose their respective topics, they both explained that their groups built upon the research of groups from previous summers. Both referenced a shared document listing past projects, and future directions students could go. Eugene explained that his group was working on extending a result by a previous group, who showed a property is true for primes, to now be true for all natural numbers. The shared artifact in this case is the previous result and proof, which was available to Eugene's research group. Further investigation is warranted into other shared artifacts of the community, as well as the shared stories which live on in the community members' memories.

Discussion and Future Work

The examples above are the result of the early stages of an investigation into the community of practice at the summer mathematics program. From the journals and interviews, there are clear examples of the three aspects of a community of practice: mutual engagement, joint enterprise, and shared repertoire. This investigation is also practically useful for future study design. For example, the summer 2025 data collection provided an estimate of how many participants to expect in the future and what logistic challenges may arise. Guiding feedback on the direction for future data analysis would be appreciated from the readers and audience, as well as feedback on the theoretical framing of CoPs.

Future work will continue to build descriptions of the three aspects of the community of practice for this ISMP, examine how they influence each other, and ultimately lead to a useful way of understanding the way learning takes place in the context of the program. The results from future work will inform disciplinary knowledge about summer programs as well as other non-traditional communities within undergraduate mathematics such as REUs, clubs, and cohorts of mathematics majors. Intended future steps of this work include collecting more journal and interview data as well as observational data during the summer 2026 program and develop a coherent analytic approach to triangulate themes in the journals, interviews, and observations.

Students' Embodied Reinvention of the Bijectivity of Invertible Functions

Rosaura Uscanga, Mercy University
Kaitlyn Stephens Serbin, University of Texas Rio Grande Valley
Jessi Lajos, Utah State University

We present a preliminary local instructional theory of students' embodied guided reinvention of the bijectivity theorem of invertible functions. We leveraged the design principles of Realistic Mathematics Education (Freudenthal, 1991) and Embodied Design (Abrahamson et al., 2020). We present our task sequence, describe implementation in a classroom, and provide an analysis of student reasoning. We discuss our plans for reimplementation and implications for teaching.

Keywords: Realistic Mathematics Education, Embodied Cognition, Invertible Functions

Introduction and Literature Background

It is essential for students to understand properties of functions and inverse functions. The extensive literature on functions documents various student difficulties such as inattention to defining properties (e.g., Markovits et al., 1986) and issues with domain and codomain (e.g., Even, 1990; Hitt, 1998). Recent work has identified productive techniques for approaching defining properties of functions (e.g., Uscanga et al., 2024). Even when students attend to defining properties, they may conflate well-defined and one-to-one (e.g., Clement, 2001; Even 1993), and everywhere-defined and onto (e.g., Melhuish et al., 2020; Vinner & Dreyfus, 1989).

Reasoning about inverse functions is multifaceted. It may entail conceptualizing an inverse function as an "undoing" (Cook et al., 2023, p. 6), "manipulated element" (p. 7), or "coordination of the binary operation, identity, and set" (p. 8). This may involve recognizing the composition of a function and its inverse as the identity function, which acts as a "do-nothing function" (Bagley et al., 2015; Serbin, 2023). Reasoning about inverse functions may involve using analytic, graphical, or covariational approaches (e.g., Oehrtman et al., 2008; Paoletti et al., 2018; Paoletti, 2020). Students must also make sense of why a function needs to be bijective (i.e., one-to-one and onto) for its inverse relation to be a function (i.e., well-and everywhere-defined) (Bansilal et al., 2017), which is challenging for them.

Here, we explicate our local instructional theory (LIT; Gravemeijer, 2004) to engage students in reasoning about the properties of well- and everywhere-defined, one-to-one, and onto to reinvent a direction of this target theorem: *Let* $f: A \to B$ *be a function. An inverse relation* $f^{-1}: B \to A$ *is everywhere- and well-defined iff* f *is onto and one-to-one.* An LIT is "the description of and rationale for the envisioned learning route as it relates to a set of instructional activities for a specific topic" (Gravemeijer, 2004, p. 107). We provide the rationale for our preliminary instructional task sequence and evidence of students' progress. We merge the design principles from Realistic Mathematics Education (RME; Gravemeijer, 1999) and embodied cognition (Abrahamson et al., 2020) to inform the design of our task sequence. We address the research question: *What learning route can students follow to reinvent the target theorem?*

Theoretical Background: RME × Embodied Design Principles

Design research (Gravemeijer et al., 2003) involves a cycle of designing instructional task sequences, implementing them with students, analyzing students' reasoning, and revising the task sequences accordingly. We leveraged RME (Freudenthal, 1973; 1991), an instructional design theory in which, "students are expected to develop formal mathematics by way of mathematizing their own informal activities" (Gravemeijer, 1999, p. 160). RME has three

heuristics that guide researchers' design of an LIT. The first is using problems with "contexts that are *experientially real* for the students and can be used as starting points for progressive mathematization" (p. 158). The second is *guided reinvention*, by which instructors leverage students' ways of reasoning to guide them to reinvent formal mathematics. The third is the opportunity for students to develop an *emergent model*, an object or representation that students project meaning onto as they model the mathematics in play. We also use embodied design principles (Abrahamson et al., 2020; Nathan, 2021) to frame students' emergent models as *multiparty* enactments (Kelton & Ma, 2018) in which students use their bodies, physical materials/props, and space to carry their personal meanings for the mathematics (e.g., Soto, 2022; Lajos & Katz, 2025). Embodied design principles suggest the instructor should leverage a variety of students' embodiments (e.g., Soto et al., 2024) to support their guided reinvention.

As students reinvent mathematical concepts and transition from using their emergent model as a "model of" to a "model for," they engage in *horizontal* and *vertical mathematizing* (Rasmussen et al., 2005; Treffers, 1987). *Horizontal mathematizing* refers to "formulating a problem situation in such a way that it is amenable to further mathematical analysis" (p. 54) and entails a shift towards symbolizing via inscriptions and taking stock of what is noticed across a variety of emergent models. *Vertical mathematizing* is defined as performing mathematical activities that are built on and are grounded in one's own horizontal mathematical activities. For our context, this entails the act of moving from an embodied model to a formal definition, conjecturing, and arriving at classroom generated theorems using refined language.

Methods

We conducted a teaching experiment (Cobb, 2012) in a Fundamentals of Algebraic Structures course at a public university in the southern US. The course was taught by a teacher researcher (TR) who is a coauthor. The students were junior and senior prospective secondary math teachers. The task sequence implementation took place in one 75-minute class. Before this lesson, the course had addressed the definitions of relations, well- and everywhere-definedness of functions, and inverse relations, but not one-to-one and onto, which were focal properties in this LIT. We note that one group of students used "one-to-one" language as they worked on the tasks, but they did not recall the term or meaning of onto. We video-recorded two groups of four students each to capture their multiparty embodied models and class discussions. Each author watched the class videos and wrote content logs (Lesh & Lehrer, 2012) on students' reasoning, evidence of mathematization, embodied models used, and how the TR leveraged the students' embodiments to guide their reinvention. The authors compared and discussed content logs.

Results

In Activity 1 of our LIT, students embodied the functions in Figure 1 and their inverse relations. Students leveraged their embodiments (e.g., multi-party enactments, inscriptions) to make sense of everywhere- and well-definedness issues of the inverse relations. In Activity 2, students used their embodied models to formulate definitions for one-to-one and onto, make conjectures relating properties of functions and inverse relations, and arrive at the target theorem.

Activity 1: Enacting Puddle Diagrams of Functions and Their Inverse Relations

Activity 1 prompts students to physically act out puddle diagrams for functions and their inverse relations and determine whether each inverse relation is a function. Students played the role of elements in the domain and codomain for various functions (Figure 1). TR provided element name tags labeled 1, 2, 3, 4, 5, and 6, strings, and domain and codomain labels. We

present Group 2's (G2) embodied models for inverse relations. Next, students symbolized their embodied models using sets of ordered pairs and puddle diagram inscriptions. They leveraged their body formations to discuss whether their inverse relations were functions. This task was designed to give students an opportunity to model functions' inverse relations, which they could later use to make conjectures about the relationships between function properties.

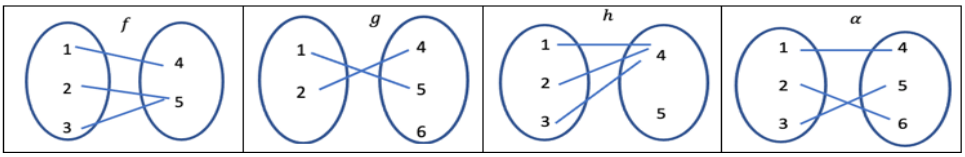

Figure 1. Parent functions given to students in Activity 1.

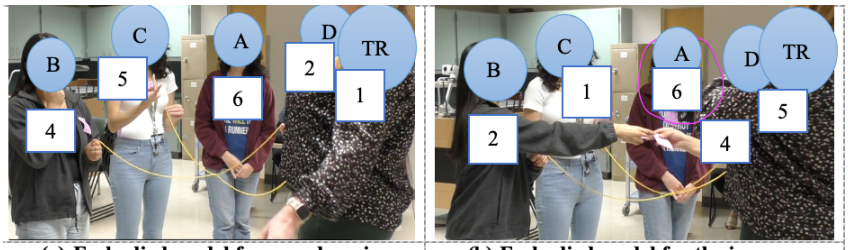
G2's embodied model for the inverse relation of g: "Switching (element) name tags." G2 made an embodied formation for the puddle diagram of g, and student C playing element 5 gestured a swap with her fingers (Figure 2a). To embody the inverse relation of g, the students playing elements 2 and 4 switched element name tags, and the students playing elements 1 and 5 switched tags (Figure 2). They were perturbed when the student playing 6 had no one to switch tags with, and their "swapping x and y" procedure was abrupted. The instructor remarked, "That's weird [glanced at 6 who was still standing in codomain area], should 6 be in the domain or codomain?" (Figure 2b). B questioned, "if 6 doesn't have a partner, can it still switch? No, right? because there is no one there." TR probed further: "What do we do with 6?" The students' strategy of switching name tags among paired elements in the domain and codomain did not work. They recognized that this embodied breakdown occurred because student A (6) did not have someone to switch tags with. The group next began to mix features of their embodied model (e.g., no one to swap with, kick her out, no partner) with formal property language.



(a) Embodied model for g; codomain left; domain right

(b) Embodied model for the inverse relation; codomain left; domain right

Figure 2. Embodied model for function g and its inverse relation "switching element name tags."

G2's adjustment and symbolization of their embodied model: "Kicking out" a peer in the codomain of g^{-1}. The group continued to focus on A (6) questioning where A belonged, the codomain or domain side. B (1) and C (2) suggested, "kick her [6] out." TR leveraged A's eviction and body location to invite her to stand on the domain side. She asked, "Why do we not want her in our domain set?" B replied, "Because she didn't have a connection in the first place." TR asked what function property was violated. B replied "Every x has to have a y," and D said, "Everywhere-defined." The group concluded g^{-1} is not a function, unless they restrict its domain. G2 confirmed g^{-1} was well-defined and concluded it was not a function because it was not everywhere-defined. Following their multi-body enaction, B symbolized g and g^{-1} as the sets, $\{(1,5), (2,4)\}$ and $\{(5,1), (4,2)\}$. Student B claimed to not know how to symbolize that "6 did not have a partner," so she wrote "Either remove or switch to domain without partner."

G2's embodied model for the inverse relation of h: "Holding onto strings and rotating." G2 embodied h as B (4 in the codomain) held three strings, TR (5 in the codomain) held no strings, and students C (1), A (2), and D (3) (in the domain) each held one string emanating from B (4) (Figure 3a). After looking at her peers across from her, student B exclaimed, "I only have one heart guys. I can't split it." G2 then decided their prior tag switching model would not work. At best, B (4) could only switch tags with one peer on the other side. This foreshadowed an issue that h^{-1} is not well-defined because h is not one-to-one. G1 suggested that they "just switch the [domain and codomain] papers on the table." G2 seemed puzzled and fell silent when TR asked, "is this [h^{-1}] a function?" TR offered a change in embodied perspective and motioned for them to rotate their entire embodied model for h (Figure 3b). After arriving at their new locations, C (1), A (2), and D (3) looked down at the codomain label on their side (Figure 3c). D stated, "It would be the same situation as [g] where it's well-defined but not everywhere-defined" and pointed to TR (5) in the domain who was not holding a string. TR noted D's partial meaning of "not everywhere-defined" and revisited issues of "well-definedness" during the class discussion.

Activity 2: Mathematizing Embodied Models to Inform Definition and Conjecture Drafts

Activity 2 was designed for students take stock of their embodied models. The first part prompted students to "make conjectures about what properties f must have for f^{-1} to be a function." This task was intended to engage students in horizontal mathematizing by explicating their informal ways of reasoning about one-to-one and onto grounded in their embodied models. TR could then leverage their embodied reasoning and introduce formal mathematical language to refer to their ideas. Next, students had to "fill in the blanks" in these definitions with either one-to-one or onto: (1) Let $f: X \to Y$ be a function. We say f is ___ when we have if $f(x_1) = f(x_2)$, then $x_1 = x_2$; (2) Let $f: X \to Y$ be a function. We say f is ___ if and only if for all $y \in Y$, there exists $x \in X$ such that $f(x) = y$. This encouraged students to further mathematize their embodied models as they identified mathematical symbols to represent their enacted properties. The last prompt asked students to formalize their conjectures as theorems. This engaged students in vertical mathematizing as they explicated relationships between a function's properties of one-to-one and onto and the inverse relation's properties of well- and everywhere-definedness. The class's negotiation of the theorem drafts concluded the guided reinvention of the target theorem.

Horizontal mathematizing: Taking stock of prior embodied models. During class discussion, TR asked about issues with the inverse relations. G1 explained that f^{-1} is not a function because "5 had two outputs" which violates well-definedness. G2 stated "our 6 doesn't have a partner [for g]," so g^{-1} is not a function. For h, G2 explained, "When we did the inverse to it, we got it was not well- or everywhere-defined, which meant the inverse relation was not a function." For α, TR mentioned that α^{-1} was a function, and G2 described this as "everyone has a partner and only one partner." TR encouraged more explicit language, "that's what well-

defined and everywhere-defined means, but now it's more special than that." Students drew from their embodied formations to formalize their language. They had a spatial sense for one-to-one and onto but were not familiar with the formal definitions. As they attempted to formalize their language, TR revoiced students' contributions: "We cannot have repeated partners." She posed the question, "What about the issue of everybody having a partner?" Revoicing again TR stated, "Everyone has a partner, and it's a unique partner" and introduced the term, one-to-one.

Vertical mathematizing: Defining, conjecturing, and reinventing target theorem. TR shared G1's conjecture that a function being one-to-one is sufficient for the inverse relation to be a function. Student E in G1 shared that g is a counterexample because it is one-to-one, but g^{-1} is not everywhere-defined. Drawing on their embodied model [gestured three fingers on each hand], E revised the conjecture and added that there "has to be the same amount of inputs as there are outputs." TR rephrased their contribution, "everything in the codomain needs to have a buddy." TR then introduced the term onto. To encourage symbolizing and formalizing, TR provided a fill-in-the-blank definition box. Students matched their notions of one-to-one and onto to the formal symbolic definition to fill in the boxes. Student F in G1 explained, "if it's one-to-one, there would be one input for an output and if it's onto, everything in the codomain has to have a partner, so that would be everywhere-defined." TR asked students what the "it" referred to. She wrote templates of students' conjectures and asked them to fill in the blanks: *If _ is one-to-one, then _ is well-defined. If _ is onto, then _ is everywhere-defined. If _ is one-to-one and onto, then _ is a function.* Student B said the first blank "has to be the function." TR followed with, "if f is one-to-one, then what is well-defined?" Student D replied "f inverse." TR then transitioned to the onto conjecture. She wrote student G's conjecture that *If f^{-1} is onto, then f is everywhere-defined*, and asked for input. Student B said, "I think he's okay, but the last one, would it be *If f is one-to-one and onto, then the f inverse is a function.*" TR validated this theorem draft and asked about the puddle diagram of f, "is that onto? [Students: "yes"] and is f inverse everywhere-defined?" [Students: "yes"]. She validated G's conjecture, "We could have f inverse or f, but from what we noticed in our little diagrams if f is onto, f inverse is everywhere-defined." TR wrote the class's target theorem: *If f is one-to-one and onto, then f^{-1} is a function.* This concluded the class's reinvention of the target theorem.

Discussion of Preliminary Findings and Conclusion

We shared our preliminary LIT on students' guided reinvention of the target theorem (refer to intro). Students' progressive mathematization of their embodied models supported them to reinvent the target theorem. Thus, we recommend the use of embodied enactments of puddle mapping diagrams to reason about function properties. Transitioning from horizontal to vertical mathematizing seemed difficult for students in this study. We suggest that more research should identify how tasks and instructors can scaffold that transition for students. A contribution is crossing design principles (RME and embodied cognition) to arrive at an instructional design framework for embodied reinvention. By leveraging this hybrid framework, our LIT contributes to the literature on instructional design and the teaching and learning of (invertible) functions. Future research could test the efficacy of this intersection in other design research studies. This is a preliminary task sequence which we plan to implement again as a new iteration of the design cycle to refine the tasks. Our revisions involve incorporating examples of functions with infinite domains/codomains and having students refine their conjectures to capture the bidirectional implication the target theorem could have. We seek advice from the audience on the task sequence and our merging of RME and embodied cognition.

Constructive or Procedural? Student Engagement With an AI Tutor in Multivariable Calculus

Eva Politou
Harvard University

Megan Selbach-Allen
Harvard University

Large language models (LLMs) such as ChatGPT are increasingly used in higher education, raising questions about how they influence student learning. While unstructured use often leads to shallow engagement, carefully designed AI tutors may foster deeper reasoning. This study examines student engagement with an AI tutor in a multivariable calculus course, drawing on the ICAP framework. The focal task asked students to use dot products and vector reasoning to estimate storm velocity from radar data. Preliminary results suggest that while the AI tutor frequently posed prompts aligned with constructive engagement, student responses were most often active, reflecting a "completionist" approach to problem solving. Constructive reasoning was difficult to sustain, and tutor follow-up was sometimes limited. These findings highlight both the promise and the complexity of designing AI tutors to elicit and maintain constructive mathematical engagement.

Keywords: Large Language Models, AI Tutoring, Student Engagement, ICAP Framework, Multivariable Calculus

Literature Review

Large language models (LLMs) such as ChatGPT have quickly become part of higher education, with students and instructors experimenting with their use for studying, writing, and problem solving. Stakeholders describe LLMs as convenient, confidence-building, and accessible, but also express concerns about over-reliance, inequity of access, and diminished opportunities for peer or instructor interaction (Govender, 2023; Hasanein & Sobaih, 2023; Kasneci et al., 2023). Systematic reviews in mathematics education confirm that AI tools, especially chatbots, are increasingly common across secondary and higher education, though most work is exploratory or tool-focused rather than analyzing learning processes in detail (Awang et al., 2025; Almarashdi et al., 2024; Walkington, 2025).

Empirical studies present mixed evidence on the effectiveness of LLMs. On one hand, research suggests that unstructured use of ChatGPT may reduce cognitive engagement and lead to shallow learning. For example, MIT researchers found that students relying on ChatGPT for essay writing showed reduced neural engagement and poorer recall compared to those using search engines or working unaided (Kosmyna et al., 2024). Similar results emerged in inquiry-based tasks: students using ChatGPT reported lower cognitive load but also produced weaker justifications (Stadler et al., 2024). In physics education, students frequently accepted incorrect ChatGPT solutions uncritically and performed worse than peers using a search engine (Krupp et al., 2023). These findings underscore the risk that LLMs may encourage passive or procedural engagement unless structured to promote deeper reasoning.

On the other hand, carefully designed AI tutors show promise. In a recent randomized controlled trial, Kestin and colleagues (2025) demonstrated that students working with a custom AI tutor, TeachGPT, achieved significantly greater learning gains in less time than students in active-learning classrooms. Similarly, Bastani et al. (2024) found that while unstructured ChatGPT use could hinder later exam performance, a safeguarded "GPT Tutor" version, engineered to provide incremental hints and anticipate misconceptions, avoided these negative effects. A meta-analysis of 51 experimental studies similarly concluded that ChatGPT can

substantially improve student performance and moderately support higher-order thinking, particularly when embedded in problem-based learning (Wang & Fan, 2025). In mathematics, ChatGPT-generated hints have produced learning gains comparable to those authored by human tutors, although accuracy concerns remain (Pardos & Bhandari, 2024). These findings suggest that the context and design of AI use are critical determinants of effectiveness.

One useful lens for understanding this contrast is tutoring research. Decades of work on human tutoring demonstrates that learning gains are often attributable not to tutor expertise but to the ways tutors elicit student thinking. Graesser et al. (1999) found that even untrained tutors often engaged students through feedback, hints, pumps, and elaborations, and that these discourse moves, not tutor expertise, were key features of effective tutoring. Chi et al. (2001) likewise found that tutoring effectiveness was driven by students' constructive responses, not tutor explanations. More recent innovations with AI tutors build on these insights, leveraging scaffolding strategies such as flipped dialogic approaches (Pavlova, 2024) or structured prompting frameworks (Tassoti, 2024) to push students beyond copying answers toward reflection and justification. Together, this body of work positions AI tutors not as replacements for human instructors but as systems that can be designed to elicit particular kinds of engagement.

Theoretical Framework

To analyze engagement systematically, this study draws on the ICAP framework (Chi, 2009; Chi & Wylie, 2014). ICAP proposes a hierarchy of engagement modes: Passive (receiving information), Active (manipulating or applying given information), Constructive (generating new inferences or explanations), and Interactive (co-constructing knowledge with peers). Research consistently shows that constructive and interactive activities lead to deeper learning than active or passive ones. In tutoring contexts, the constructive level is particularly salient: Chi et al. (2001) found that students' constructive responses predicted gains regardless of tutor expertise. Applications of ICAP to AI use likewise suggest that generative tools can promote deeper learning when designed to elicit constructive contributions (Gao et al., 2024).

We determined that in our context, interactive engagement is not feasible, since AI-tutor sessions involve a single student. We therefore adapt ICAP into three categories, Passive, Active, and Constructive, to code both AI prompts and student responses. Passive responses include minimal or off-task engagement (e.g., "idk," blank entries, or repeating AI text). Active responses recall facts, carry out straightforward operations, or follow procedures without interpretation. Constructive responses involve inference, justification, or proposing new ideas, such as setting up equations or reasoning about vector direction. We applied the same categories to AI prompts, distinguishing between explanatory (Passive), recall/procedural (Active), and generative/reflective (Constructive) tutor moves. This adaptation allows us to investigate how the design of AI prompts relates to the depth of student engagement.

Finally, while there is growing research on AI in mathematics education, most studies remain focused on procedural domains. ChatGPT explanations of multiplication, for instance, often reduce to repeated addition rather than deeper conceptual models (Hankeln, 2024). Studies on proof assistance emphasize correctness and formal revision rather than conceptual reasoning (Park & Manley, 2024). In calculus, student surveys report benefits of ChatGPT as a supplementary explainer but also concerns about accuracy and over-reliance (Serhan & Welcome, 2024). Reviews of AI in mathematics education confirm that most studies emphasize procedural problem solving, tool adoption, or broad perceptions (Almarashdi et al., 2024; Awang

et al., 2025; Walkington, 2025). In contrast, very few investigate how AI tutors can foster conceptual reasoning in advanced mathematics.

This study fits in that gap by analyzing AI tutor logs from a multivariable calculus course to investigate how the phrasing of AI prompts shapes the depth of student engagement on a conceptual vector problem. Using an ICAP-based coding scheme, we classified both AI prompts and student responses as Passive, Active, or Constructive, allowing us to examine the relationship between tutor design and student engagement. In doing so, our work extends prior research that highlights both the promise and pitfalls of LLMs: when carefully designed, they can foster individualized learning and constructive reasoning, but in unstructured use they often default to procedural explanations and promote shallow engagement. At the same time, most studies of AI in mathematics education emphasize procedural tasks such as algebraic manipulation or proof revision, leaving open the question of how AI tutors might support conceptual reasoning in advanced courses.

Guided by this framework, we investigate two research questions:

1. What types of AI prompts lead to the most constructive student-generated responses?
2. To what extent do students demonstrate active or constructive engagement in AI-tutor sessions?

Methods

In this section, we describe the course context, participants, focal task, data collection procedures, and analytic approach.

Course Context

Data were collected during a multivariable calculus course offered at a selective private university in the US. The course enrolled approximately 400 students across multiple coordinated sections, each meeting three times per week with 25–30 students per section. In this course, "workshops" are weekly applied problem sets designed to highlight conceptual applications of multivariable calculus and real-world data. Traditionally, these workshops were completed in small groups with support from undergraduate course assistants. In Spring 2025, the course offered an AI tutor as an optional support, revised from an earlier Fall pilot to encourage shorter, more guiding prompts, delayed solution suggestions, and more frequent checks for understanding.

AI Tutor

The AI tutor platform used in this study, TeachGPT, was created by Dr. Greg Kestin at Harvard University. Prior to the course, the tutor was configured to be supportive and encouraging but not to provide direct answers. Instead, it was designed to elicit students' thinking and ideas by offering prompts, hints, and checks for understanding.

Participants

This study was approved by the Institutional Research Board (IRB). Students were invited to participate via a survey distributed at the end of class, which asked about their experiences with the AI tutor and whether they consented to have their chat logs included in research. Of the total course enrollment, 123 students consented (approximately 31%).

Mathematical Task

The focal problem required students to use dot product calculations to build a system of equations for estimating the velocity of a storm using radar data from two different stations. Students worked with graphics and real data from a published research paper. Rather than providing exact numerical values, the task asked students to approximate storm speed and direction by interpreting vector arrows and color-coded visualizations. Evaluation emphasized conceptual application and reasoning processes, not exact numeric answers.

Data Collection

TeachGPT logs all student interactions, which can be downloaded by the instructor. The 123 consenting students produced over 1,500 turns of dialogue with the AI tutor. Each interaction turn (one uninterrupted chat entry) was recorded in the log. For this analysis, we focus on Spring 2025 logs, though the platform was also used in Fall 2024.

Data Analysis

Using the ICAP framework (Chi, 2009; Chi & Wylie, 2014), each turn of dialogue was coded as Passive, Active, or Constructive. Both AI prompts and student responses were coded, and turns could receive multiple codes. Two authors independently coded all responses and then met to reconcile disagreements. Agreement was generally high; precise interrater reliability will be reported in future analyses. At the time of this preliminary report, approximately 50% of the data has been coded. Codes are described in Table 1 below.

Table 1. Adapted ICAP-based coding scheme for student and AI tutor utterances.

Code	Student Responses	AI Prompts
P (Passive)	Minimal or off-task response; no meaningful engagement	Provides explanation without asking for a response
A (Active)	Recalls a fact, performs a basic operation, or follows a known procedure without interpretation	Prompts for recall or straightforward use of given information
C (Constructive)	Makes inferences, proposes ideas, sets up equations, estimates, or justifies choices	Prompts student to generate, infer, reflect, or justify

In what follows, we report descriptive patterns from the coded sample, focusing on the distribution of student and AI codes and illustrating how different types of AI prompts were associated with varying levels of student engagement.

Results and Discussion

Of the 564 turns coded so far roughly equally split between the student (n = 275) and the AI-tutor (n = 289) we found that the Active code occurred relatively equally between the students (n = 144) and the AI-tutor (n = 136). The passive code was actually more commonly applied to the AI tutor (n = 148) than the students (n = 98). However the form this code took was distinctly different. In the case of the students this code most often represented some amount of disengagement from the work as they said they just “didn’t understand” or asked the AI to give

them the answer. The AI tutor got a passive tag when it provided substantial information to the student such as laying out a procedure for how to solve a portion of the problem. The passive code was often applied alone for the student but for the AI it often was coded alongside Active or Constructive. The largest difference was seen in the constructive code with the AI tutor (n = 146) receiving the code much more frequently than the student interactions (n = 35).

The preliminary analysis provides insight into the depth and character of student engagement in AI-tutor sessions. Constructive responses were relatively rare, with most turns coded as active and oriented toward carrying out procedures or recalling information. When constructive responses did occur, they were often followed by active turns rather than sustained elaboration, suggesting that constructive reasoning was more difficult to maintain over the course of an interaction. Many students appeared to approach the task with a "completionist mindset," focusing on moving efficiently through the problem rather than pausing to reflect or justify their ideas.

At the same time, the AI tutor frequently generated prompts that were well targeted to the mathematical content and designed to elicit reasoning. These prompts often invited inference, justification, or reflection, aligning with the constructive category of ICAP. However, constructive prompts did not always yield constructive responses. More often, students replied at the active level, providing correct but concise procedural steps rather than extended explanations.

Some challenges also emerged in the tutor's interactional pattern. The AI occasionally asked several questions in succession without fully engaging with student input, which may have limited opportunities for extended dialogue. In certain cases, it appeared to misinterpret student responses, resulting in exchanges that did not progress as productively as intended. These patterns would then constrain the tutor's ability to sustain constructive engagement, even when its questions were well designed.

Taken together, these findings suggest both the promise and the complexity of fostering constructive engagement through AI tutoring. The AI posed strong and targeted questions, yet students' responses did not consistently rise to the constructive level, and the tutor's responsiveness at times made it difficult to deepen reasoning. As a result, interactions often emphasized procedural progress more than conceptual exploration, highlighting opportunities to refine tutor design in ways that better support sustained constructive engagement.

Preliminary Nature of Report

Because this analysis is drawn from an ongoing project, the findings should be considered preliminary. We focus here on a single conceptual vector problem from one workshop, which generated over 1,500 turns of dialogue, of which 564 have been coded to date. This problem was selected because it emphasizes the kind of conceptual reasoning central to the course, provides a strong context for examining constructive engagement and we have film of students engaging with the problem during in-person workshops. As coding continues, our next steps include completing analysis of this problem and extending the comparison to video data from in-person workshop sessions, allowing us to contrast AI-facilitated and human-facilitated interactions. We invite feedback from the audience and engagement with the following question: what additional coding categories or analytic lenses could help capture engagement not fully addressed by ICAP?

Elizabeth Roan
Texas State University

We report on an extension of previous findings from a project aimed at improving equitable groupwork in the context of undergraduate proof-based courses through designing and implementing group-worthy tasks. This quantitative study reports on three group-worthy tasks implemented in two topology courses. We investigated how student interactions in small groups reflect participatory equity when relating to perceived academic status along with differences in participation patterns between the two classes. Results are indicative of the tasks having the effect of balancing talk turns regardless of status, disrupting status hierarchy, or neither; similar to what has been reported previously. These findings suggest that implementation of group-worthy tasks is not sufficient to ensure equitable participation in small groups and that normalized groupwork has no impact on the effectiveness of the utilized tasks.

Keywords: Status, Equity, Group-Worthy Tasks, Proof, Groupwork

There is a growing consensus that students in undergraduate math courses can benefit from active learning approaches (Freeman et al., 2014). Evidence shows that active learning techniques can lead to more equitable outcomes (see Laursen et al., 2014; Theobald et al., 2020), but these outcomes are not guaranteed. Research shows that inequities can persist in settings including proof-based courses where groupwork is central to the classroom culture (Brown, 2018; Ernest et al., 2019; Johnson et al., 2020). One possible source for these inequities may be how students are perceiving each other's status, that is, student assumptions about who is "smarter" or "better" at math influences participation during groupwork (Esmonde, 2009b).

Research has shown that the nature of groupwork tasks themselves can magnify or depress inequitable participation (Shah & Lewis, 2019). The structure and content of the task can create or hinder access to students contributing and engaging mathematically. A well-designed group-worthy task can help manage status-related dynamics that would otherwise worsen participation for some students (Cohen et al., 1999; Esmonde, 2009a). We are far from understanding the complex interactions between status dynamics, group-worthy tasks, and equity in undergraduate courses that incorporate active learning strategies (Adiredja & Andrews-Larson, 2017); this lack of understanding is exacerbated in upper-level math courses. This particular setting shifts students' center of attention to formal proof, which may consequently trigger status issues (Weber & Melhuish, 2022).

In this report we share an analysis of a subset of data from the STructuring Equitable Participation in Undergraduate Proof (STEP UP) project whose aim is to assist instructors in the design and implementation of group-worthy tasks in proof-based courses. Previously, we shared results from a single class leading to the development of conjectures about how different types of tasks structures may disrupt or amplify status issues (Ellis et al., 2025). In this preliminary report, we provide a comparison between the original results and an analysis of a different topology course implementing the same structures. We sought to answer the following research question: How does groupwork, participation, and status interact in group-worthy tasks in two

topology courses? Do we find differences in these participation patterns in a course that regularly engaged students in groupwork and one that was typically lecture?

Background and Framing

We conceptualize equity as when an individual in a group has the requisite resources to support their learning (Shah & Lewis, 2019). On the other hand, inequity is when power dynamics are structured in such a way that halts students' access to these requisite resources. These resources can come in many different mediums such as physical access to a shared workspace like a whiteboard or worksheet, the opportunity to contribute to groupwork whether written or verbal, or accessing another group member's ideas. While equity is multifaceted, for this study we are particularly interested in participatory equity. Participatory equity refers to the fair distribution of opportunities to participate, and the realized participation shared amongst all individuals in a learning situation (Shah & Lewis, 2019).

These inequities in group settings may emerge because of imbalanced power dynamics that are rooted in the difference in status among group members. Status characteristics are defined as a "social ranking that everyone agrees is preferable to have a higher rank rather than a lower one" (Cohen et al., 1999, p. 84). Academic status characteristics, like perceived mathematical ability, have been found to be particularly influential inside the classroom (Cohen & Lotan, 2014). These academic status characteristics can be influenced by much broader status characteristics such as gender, race, and ethnicity (Cohen et al., 1999; Ridgeway, 2018). Evidence points towards students with higher status having more opportunities to contribute and participate (Cohen & Lotan, 2014). Increased opportunities to participate leads to greater learning opportunities (Cohen & Lotan, 2014; Esmonde, 2009a).

In addition to the dynamics between students, the nature of the task can influence the extent that participation can be inequitable in a group setting (Chizhik, 1999, 2001). Borrowing from Complex Instruction, the use of group-worthy tasks has been shown as one possible strategy to balance status and participation (Cohen et al., 1999; Featherstone et al., 2011). A task is considered "group-worthy" if it meets the following criteria: mechanisms are put into place that ensure every individual in the group is learning and engaged, the task affords multiple approaches, and the task endorses a sense of interdependence between group members in a positive fashion (Cohen & Lotan, 2014). These tasks may potentially disrupt imbalanced participation brought on by status differences by affording more opportunities for students to engage in mathematically meaningful ways.

Methods

Participants and Procedures

This study draws data from a larger NSF-supported partnership between mathematics educators and mathematicians aimed at developing and testing group-worthy tasks in proof-based settings. The three task types focused on proof comprehension, proof comparison, and proof construction, respectively. For this paper, we are focused on the set of tasks developed for Topology. The comprehension task (Universal Property of Quotient Spaces Theorem) involved students exploring examples with specific responsibilities and then engaging in discussion of the proof. In the discussion, each group member took turns leading the discussion by asking questions to probe for meaning in the provided proof. The proof construction task involved groups of four students. First, they examined two examples and then constructed a proof of the claim that "The diagonal is closed if and only if X is Hausdorff." Every group member was given

a distinct role[1] and the details they needed to finish the assignment. The proof comparison task involved students working in pairs. Each student was given the opportunity to become an expert on a different version of a proof for the focal theorem (homeomorphism preserves connectedness). They then engaged in asking questions, comparing and contrasting, and analyzing the proofs and theorem.

The set of tasks were implemented in an undergraduate introductory topology course in Fall 2023 (Instructor A) and in Fall 2024 (Instructor B). The tasks were spaced throughout the courses. Both were taught at the same large research university in the United States. Instructor A used groupwork throughout their course. Instructor B typically lectured. We note that the proof comparison task was taught by a mathematician on the research team in Fall 2024, as they were substituting for Instructor B. As a result, this task may be influenced by confounding variables related to the change of the instructor.

Data collected included video and audio recordings of the students working in groups on the tasks. The audio was transcribed and cleaned to ensure accuracy and all statements were attributed to the correct student. We also collected data regarding demographics and students' perceived status towards the end of the course. Replicated from Cohen and Lotan (1995), students were provided with a list of students in their class and asked to circle any students perceived as "best at math." An overview of student level data can be found in Table 1.

Table 1. Participant's Student Demographics and Perceived Status

Fall 2023			Fall 2024		
Name (Status)	Gender	Race/Ethnicity	Name (Status)	Gender	Race/Ethnicity
Ariella (low)	Woman*	Hispanic*	Ashley (low)	Woman	White
Lily (low)	Woman	Hispanic	Ben (low)	Man	White
Samantha (low)	Woman*	White*	Carson (low)	Man	White
Zahir (low)	Man*	Hispanic*	Kassandra (low)	Woman	White
Brandon (mid)	Man	White	Olivia (low)	Woman	White
Joe (mid)	Man	Spanish	Aaron (mid)	Man	White
Kieran (mid)	N/A	South Asian	Adrian (mid)	Man*	Hispanic*
Luke (mid)	Man	White	Arturo (mid)	Man	Hispanic
N (mid)	Woman	Mexican	Joseph (mid)	Man	Asian
Pink (mid)	Woman	White, Hispanic	Pepe (mid)	Man*	Hispanic*
Alexis (high)	Woman	White	Alan (high)	Man	White
Julie (high)	Woman	White	Elaine (high)	Nonbinary	White
Kendra (high)	Woman*	Black*	James (high)	Man	White
Xander (high)	Man*	White*	Jane (high)	Nonbinary	White

*Indicates researcher assumption; all other data is student self-identified.

Data Analysis

The transcript data were analyzed to create two ratios related to participatory equity for each student, adapted from Reinholz and Shah (2018). The first ratio is the "Words Spoken Ratio." This ratio compares the total words spoken by a student compared to how many words they would have spoken if each member of the group spoke exactly equally. The "Talk Turn Ratio" was computed similarly, but this time was based on how many times a student spoke. One talk turn reflects a contribution until a new speaker contributes. A ratio greater than one indicates a student is participating more than expected if everyone contributed equally (e.g., a student is expected to contribute a quarter of the time in a group of four) and less than one indicates a student is contributing less than expected. The status survey data was analyzed by grouping students into quartiles based on how many peers identified them as "best at math." Due to little differences in the first two quartiles, they were combined into a single group. This resulted in three categories in which the lower third is classified as "low" status, the middle third as "mid", and the upper third as "high."

We then created a series of graphs with Words Spoken Ratio on the vertical axis and Talk Turn Ratio on the horizontal axis and data points colored by status (see Figure 1 below). We provide a descriptive analysis of these graphs to consider the degree that participation patterns from the Fall 23 implementation were consistent (or not) in the repeated Fall 24 implementation.

Results

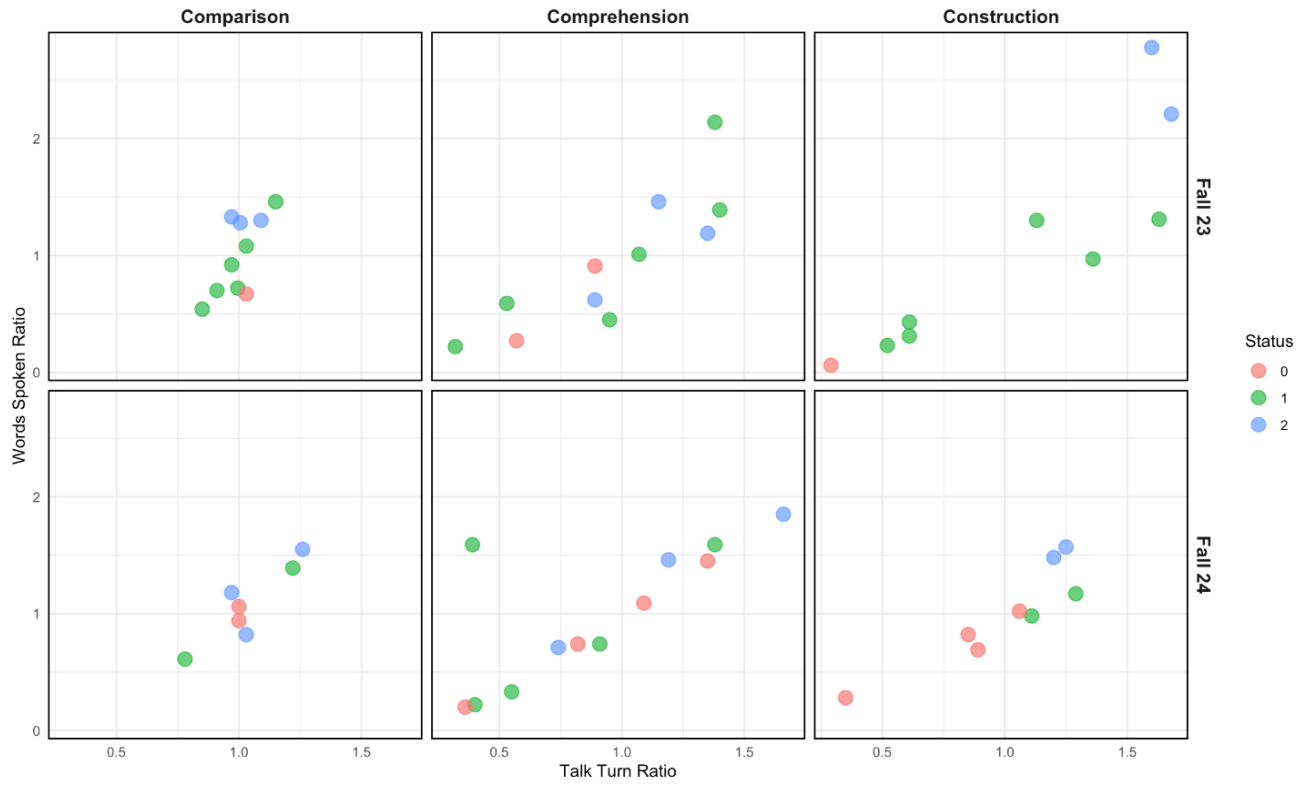

Figure 1. Correlations between Words Spoken Ratios and Talk Turn Ratios parsed by perceived status for each task for both classes.

When looking at these graphs, we want to attend to two features related to participatory equity. First, the closer all the ratios are to 1, the less differences there are in contribution ratios by student. Second, we want to see if there are clear orderings of status vertically and horizontally. There should be no pattern in a task that disrupts status hierarchy's relationship to status. In Figure 1, a task is said to not disrupt status if there is a hierarchical order from low to high status students along the vertical and horizontal coordinates. For example, the construction task in Fall 23 shows no disruption of status since the graph has high status students participating more and trickles down to the low status students.

In Ellis et al. (2025), we discussed the fact that the construction tasks seemed to maintain status hierarchy in participation both in terms of words spoken and number of contributions with the high-status students having the highest ratio of both. For the comprehension task, we noted that the status hierarchy was disrupted across both dimensions. Surprisingly, despite the substantial class differences for Instructor A and B, we see roughly the same outcome in both cases. The comprehension task with discussion prompts seems to be operating as intended. The construction task with group roles does not.

The comparison task was not as clear cut. This was a task with partner exchanges and comparisons across proof approaches. We claimed the implementation in Fall 23 did a good job balancing turns in talk, but not number of words. That is, the higher status students appeared to talk more than lower status students. In the Fall 24 implementation, we see the low status students are clumped right at 1. At this point, we can say that the structure of the task led to even turn taking in both classes, but the relationship with words spoken and status is less clear.

Discussion and Preliminary Nature of This Report

For this preliminary report, we expand upon our findings in the prior report by keeping the tasks and subject area constant with the instructor differing. We wanted to explore the degree to which we would see the same type of pattern across classes despite substantial deviation in the standard pedagogical approach to the class. We were surprised to find the degree to which the patterns in participation seemed to be replicated. This finding leads us to conjecture that the task features themselves may be the dominant variable for status disruption in a task. It seems that exploration and proof discussion prompts might disrupt status more than group roles in this context. This implies that a productive avenue of inquiry could be to test whether these patterns are consistent in other contexts. Additionally, we are interested in which task features contribute to these participation patterns. At this point, we have additional data gathered from abstract algebra, discrete mathematics, and real analysis. If we can demonstrate that it is simple changes to the task features that are disrupting status, then this may lighten the instructor's cognitive load when planning and creating classrooms that are more inclusive for students. Overall, we see promising implications for the teaching and learning of undergraduate proof-based courses.

We welcome feedback on ways we might account for the mathematical nature of student's contributions within our measures for participatory equity. Additionally, the current report was focused solely on participatory equity, but our team would benefit from feedback on how we can measure and quantify relational equity.

Mapping the Demands of Thinking: Spatial Reasoning and Cognitive Demand in an Undergraduate Discrete Mathematics Textbook

Laurie Short
North Carolina State University

Spatial reasoning and cognitive demand are critical for mathematical learning, yet they are rarely examined together. This study analyzes 178 tasks from the graph theory chapter of Discrete Mathematics: An Open Introduction to explore how these dimensions present themselves and how they interact. Most tasks were of high cognitive demand and required spatial reasoning, especially spatial relations and visualization. Notably, spatial reasoning did not consistently appear as cognitive demand increased in tasks. These findings suggest no clear correlation between the cognitive demand of tasks and the spatial reasoning required.

Keywords: spatial reasoning, cognitive demand, task analysis

Introduction

Strong spatial skills demonstrate advantages for future STEM performance, and notably, there is extensive correlation linking spatial skill to mathematics performance (Gilligan-Lee, Hawes, and Mix, 2022). Spatial reasoning is often overlooked in mathematics curricula at all levels (Gilligan-Lee, Hawes, and Mix, 2022), despite the high demand for STEM skills and the proven malleability of spatial reasoning (Uttal et al., 2013).

Equally important are problem-solving and reasoning skills for STEM success (NRC, 2012). When tasks actively engage students at a high level, they help develop these essential skills. This study examines exercises in the widely used open-source textbook, *Discrete Mathematics: An Open Introduction,* to explore how spatial reasoning and cognitive demand are represented in tasks, aiming to identify patterns in how graph theory problems encourage different types of thinking. This research seeks to determine which spatial skills occur most often and whether their presence aligns with patterns of cognitive demand. This analysis contributes to ongoing discussions about the importance of task design in undergraduate mathematics education and highlights spatial reasoning as a valuable component of mathematical learning.

Literature Review

Spatial Reasoning and STEM Outcomes

Spatial reasoning is the ability to understand, visualize, and manipulate objects and their relationships in space. Spatial reasoning is often thought of in terms of three connected parts: spatial visualization, spatial relations, and spatial orientation (Lohman, 1979). *Spatial visualization* is the ability to mentally construct or interpret a visual representation from a diagram or description. *Spatial relations* refer to understanding how elements are arranged and connected within a visual structure. *Spatial orientation* requires mentally changing your point of view to see an object from a different angle. Research has shown that spatial skills are highly malleable, and small amounts of training can improve spatial reasoning in children and adults (Uttal et al., 2013). Despite its importance in STEM fields (Wheatley & Abshire, 2002; Newcombe, 2010), spatial reasoning remains underemphasized in classroom practice.

Cognitive Demand and Task Complexity

Mathematics education researchers often examine how task design affects the depth of students' thinking (Arbaugh & Brown, 2005). Stein and Lane (1996) emphasize the importance of "starting with high-level, cognitively complex tasks if the ultimate goal is to have students develop the capacity to think, reason, and problem solve" (p.344). Building on this, Stein and Smith (1998) introduced a four-level taxonomy for classifying mathematical tasks based on cognitive demand. In this taxonomy, tasks are categorized as either lower-level demands or higher-level demands. Stein and Smith argue that although choosing a high-level task does not guarantee student engagement at a high level, it is a necessary prerequisite for it (1998).

Intersecting Spatial and Cognitive Demands

Although both cognitive demand and spatial reasoning are recognized as critical, few studies examine their overlap. Cognitive demand of math tasks has often been categorized using Smith and Stein's framework (1998) (Jones & Tarr, 2007; Sapkota and Bondurant, 2024) while spatial reasoning research has focused primarily in K–12 settings (Battista, 2007; Younger, 2018; Hawes, Gilligan-Lee, & Mix, 2023). Few, if any, studies have examined their overlap, and none have systematically addressed this in undergraduate mathematics. Given this gap, undergraduate discrete mathematics provides a useful setting to explore how spatial reasoning and cognitive demand intersect.

The Case of Undergraduate Discrete Mathematics

Discrete mathematics courses often ask students to construct and navigate graphs, networks, and combinatorial structures, activities that are inherently spatial. Graph theory is a core component in discrete math curricula and is a spatially rich domain. Unlike geometric contexts, spatial reasoning in graph theory often involves abstract structures that require students to reason about connectivity, adjacency, and relational structure. An analysis of the graph theory chapter of Levin's *Discrete Mathematics: An Open Introduction* explores which visual-spatial skills appear most frequently, how they align with levels of cognitive challenge.

Research Questions

This study of spatial reasoning and cognitive demand of tasks in *Discrete Mathematics: An Open Introduction* was guided by the following research question: *How are levels of cognitive demand distributed across tasks requiring different types of spatial reasoning and task types in Discrete Mathematics: An Open Introduction?* To address this, the study focused on three sub-questions:

1. How are levels of cognitive demand distributed across task types (e.g., preview activities, in-text exercises, end-of-section problems, etc.)?
2. How does the nature of spatial reasoning vary across these task types?
3. Are there patterns that link levels of cognitive demand with specific types of spatial reasoning required in these tasks?

By investigating these questions, the aim is to understand how spatial reasoning, task type, and cognitive demand interact in this text. These goals shape the study design and analysis outlined in the following methods section.

Methods

This study focused on a chapter introducing one core discrete topic, graph theory, to identify opportunities for students to engage in high cognitive demand tasks and spatial reasoning. *Discrete Mathematics: An Open Introduction* was chosen because it's a free, open-source

resource that's "especially well-suited for courses that incorporate inquiry-based learning" (Levin, n.d.) and is widely used as a primary or supplemental text in colleges and universities. The graph theory chapter was selected for this analysis because it appears early in the textbook (Chapter 2), making it easier to determine what topics students know when approaching each task. Additionally, given that spatial processing plays a key role in understanding complex graphs (Trickett & Trafton, 2007), this section provided a fitting context for this study.

All tasks in Chapter 2, except the summary, were analyzed. After examining results holistically, results were disaggregated by the type of problem: investigate, preview activities, in-text examples, reading questions, end-of-text exercises, and additional exercises. Initial coding assigned each task to the type of problem, and tasks were left out if they did not contain a question or ask students to do something. Tasks were the unit of analysis, and overall, n=178 tasks were examined. Grouping by task type, two frameworks were adapted into deductive coding schemes to measure the level of cognitive demand and type of spatial reasoning required for each task.

To identify cognitive demand, each task was coded based on Smith and Stein's Levels of Demand framework (1998). Tasks were identified as lower-level demands or higher-level demands. Lower-level demand tasks were broken into the categories of *memorization* and *procedures without connections*, while higher-level demand tasks were broken into the categories of *procedures with connections* and *doing mathematics*.

Next, a coding scheme was developed to identify the spatial reasoning required for each task. Each task was coded for the type(s) of spatial reasoning required, if any, using Lohman's (1979) framework, resulting in the following codes: *spatial visualization, spatial relations*, *spatial orientation,* and *no spatial reasoning*.

As many tasks contained more than one type of spatial reasoning, codes were treated as mutually exclusive combinations. For example, 'SV' refers to tasks requiring only spatial visualization, while 'SV & SR' includes tasks requiring both spatial visualization and relations. This led to eight mutually exclusive codes, clarifying both which types of spatial reasoning were most frequently used and how often students would need to integrate multiple forms of spatial thinking to complete a task. Figure 1 shows the classic Königsberg bridge problem. This task was coded as *doing mathematics*, since students must explore and reason to solve this task. This task was also coded as *spatial relations and visualization*, as students must understand how the islands and riverbanks (nodes) are connected by bridges (edges) while also mentally tracing and manipulating paths.

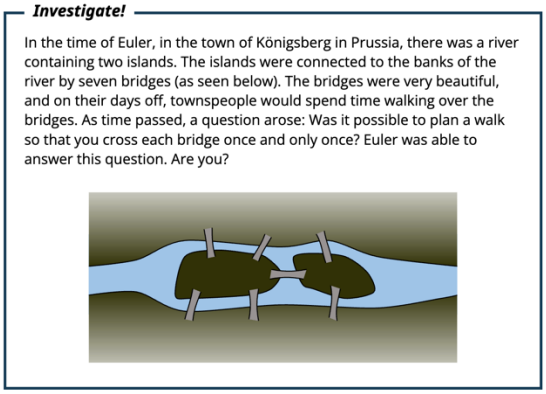

Figure 1. Task coded as doing mathematics and requiring spatial relations and orientation

Findings

Research Question 1: Cognitive Demand of Tasks

This study examined the cognitive demand of 178 tasks in Chapter 2. About 85% were of high cognitive demand (54% *procedures with connections*, 32% *doing mathematics*). The remaining 15% were *procedures without connections*; none were *memorization.*

Disaggregated by task type, most tasks were additional exercises (47%), and nearly all of these were of high cognitive demand, with a roughly even split *of doing mathematics* and *procedures with connections* tasks. End-of-text and reading questions leaned toward *procedures with connections,* while investigate tasks were exclusively high-level, mostly coded as *doing mathematics*.

Research Question 2: Spatial Reasoning Required of Tasks

Of the tasks examined, 67.4% required spatial relations (SR), 64% required spatial visualization (SV), 15.2% required spatial orientation (SO), and 28.7% required no spatial reasoning (NS). Note, that this does not add up to 100%, as some tasks were coded as requiring more than one type of spatial reasoning. Most tasks required some type of spatial reasoning (71.3%), with SR and SV showing up most frequently. Almost half of the tasks that required no spatial reasoning occurred in Section 2.6: Relations and Graphs. Tasks requiring SV and SR together occurred most frequently, with this pair present in 46.6% of all tasks (Table 1). Across task types, spatial reasoning appeared most in investigate and preview tasks (over 85%), somewhat less in additional exercises (76%), and least in end-of-text problems (63%).

Table 1. Mutually exclusive spatial reasoning codes with counts

Spatial Reasoning Only (SR)	Spatial Orientation Only (SO)	Spatial Visualization Only (SV)	SR & SV Only	SR & SO Only	SV & SO Only	SR, SV, & SO	No Spatial Reasoning (NS)
n=13	n=0	n=4	n=83	n=0	n=3	n=24	n=51

Research Question 3: Relationship Between Cognitive Demand and Spatial Reasoning

Spatial reasoning appeared across all cognitive demand levels but was most frequent in *procedures with connections* tasks (77%). *Doing mathematics* tasks required it less (63.2%), and *procedures without connections* the least (46.2%). Again, SV & SR were the most common combination across levels.

By task type, investigate tasks were all high-level, with almost all of these high-level tasks requiring spatial reasoning. Preview tasks also required spatial reasoning, while in-text examples and reading questions had many tasks without spatial reasoning. End-of-text exercises mixed cognitive demand and spatial reasoning. Interestingly, additional exercises showed higher spatial reasoning in *procedures with connections* tasks than in *doing mathematics* tasks.

Discussion and Future Work

Rather than evaluating the quality of tasks or making claims about student learning, this analysis documents how spatial reasoning and cognitive demand co-occur in graph theory tasks, positioning the textbook as a resource for understanding how mathematicians structure opportunities for spatial thinking. Across all task types, a clear pattern emerges in the data: **s**patial reasoning and high cognitive demand are both emphasized, but they are not always

coupled. Further, moving from *procedures with connections* to *doing mathematics* does not indicate that there will be more spatial reasoning required.

Overall, most tasks analyzed were of high cognitive demand, which was expected as this book is inquiry-based. Notably, tasks that appeared at the beginning of each section, investigate and preview activities, were almost all high cognitive demand, aligning with Smith and Stein's recommendation of "beginning with a task that has the potential to engage students at a high level if your goal is to increase students' ability to think and reason" (1998, p. 347). There was a difference in the breakdown of cognitive demand for end-of-text and additional exercises, both of which appear at the end of each section. Additional exercises included a significantly higher proportion of *doing mathematics* tasks, suggesting that assignments drawn from either the initial end-of-text exercises or the additional exercises could vary substantially in cognitive demand.

Spatial reasoning was present in many tasks (71.3% overall), but its distribution among tasks was uneven. Overall, spatial visualization and relations appeared most frequently, and were often grouped, as tasks that required students to think about how aspects of graphs related also required them to visualize the graph. Notably, almost all tasks that appeared at the beginning of each section, investigate and preview activities, required spatial reasoning, and additional exercises showed a slightly higher percentage of tasks that required spatial reasoning than end-of-text exercises.

Regarding the relationship between cognitive demand and spatial reasoning, spatial reasoning did not consistently increase with higher levels of cognitive demand. While many tasks coded as *procedures with connections* involved spatial thinking, spatial reasoning was less frequently seen in tasks categorized as *doing mathematics*. Many of these were focused on proof-based reasoning, where the cognitive demand was of the highest level, but spatial reasoning may not have been necessary. Though there was no clear relationship between cognitive demand and spatial reasoning, the data suggest that there may be a relationship between spatial reasoning and the type of task.

The data show two important findings: (1) spatial reasoning is not automatically embedded in mathematically rich textbook tasks, and (2) spatial relations and visualization are especially prominent forms of spatial reasoning in graph theory tasks. As spatial reasoning is highly malleable (Uttal et al., 2013), these findings can inform pre-college preparation or in-class scaffolding to equip students with the spatial skills necessary for success. These patterns also raise questions about whether selecting high-level tasks alone is sufficient to ensure consistent opportunities for students to engage in spatial reasoning, a hypothesis that warrants further study with student data.

Preliminary Nature of This Report

This report represents an early stage of analysis and is limited to a single textbook chapter with coding conducted by one researcher. Because this study analyzes textbook tasks rather than student work or classroom enactment, claims about how students engage in or develop spatial reasoning are necessarily inferential. Future directions could include expanding the analysis to additional chapters, additional textbooks, additional math content areas, and incorporating interrater reliability. I am especially seeking feedback on two areas still in development: (1) how the coding frameworks for spatial reasoning might be refined to capture nuances in undergraduate mathematics tasks, and (2) how the implications could be framed to best support both pre-college preparation and in-college scaffolding.

Mathematical Content in Physics for Life Sciences Homework

Yana Hubyak
University of Glasgow

Megan Selbach-Allen
Harvard University

This study presents a task-based content analysis of homework problems from a year-long, calculus-based physics sequence designed for life science students. Using a codebook created by adapting ideas from the Calculus Content Framework (CCF), we coded each homework task for the types of mathematical reasoning required, including derivatives, integrals, manipulating algebraic expressions, geometric reasoning, arithmetic calculation, and graph interpretation. Across the year, we found that manipulating algebraic expressions, arithmetic calculation, and geometric concepts appeared more frequently than calculus procedures such as derivatives or integrals. These findings align with prior work suggesting that algebraic skills and modeling are more central than calculus topics like derivatives or integrals in many physics tasks. As a preliminary study, this work invites feedback on how to build toward broader analyses, such as alignment with modeling-first calculus courses, with the long-term goal of better supporting students in navigating mathematics across disciplinary boundaries.

Keywords: Calculus; Physics for Life Sciences; Task-Based Content Analysis

The overwhelming majority of students who take a calculus class in college are doing so as a prerequisite to other courses they are required to take to pursue their major. These chemistry, biological science, physics or engineering courses require the knowledge of calculus as a foundation of their discipline and courses. However, students' ability to transfer knowledge learned in their math courses to other subjects has long been a challenge.

We also see challenges in the mismatch of requirements for certain majors and career trajectories, such as toward medical school which generally encourage students to take a full year of physics, but only one semester of calculus (Ceder & Harrington, 2024; Columbia University – School of General Studies, n.d.; Rutgers University Health Professions Office, n.d.; University of Connecticut Pre-Medical and Pre-Dental Advising, n.d.). While these students do not usually continue taking calculus past the required courses, many of their other courses do require knowledge of calculus. To prepare students for medical school, universities might create versions of calculus or physics courses to specifically serve a population of students such as biology or pre-med majors which are tailored to that student population. These classes are especially important because research has shown that students' comfort with and interest in using mathematics to understand biology varies widely and is lower for women and first-generation students (Andrews & Airens, 2018). This project was motivated by a desire to understand the math present in a physics series specifically targeting biology or premed majors to assess how well prerequisite math courses prepare life science students for their subsequent coursework.

We hypothesize that misalignment between different courses might impede students' understanding and success (Ayene et al., 2010; Redish & Kuo, 2015). In particular, Bowers et al. (2023) emphasize the distinction between mathematical and scientific mastery, noting that students may successfully learn the necessary mathematics without achieving conceptual understanding in physics. Building on Redish and Kuo's (2015) work, we draw on their argument that success in physics depends not just on mastering mathematics, but on blending it meaningfully with physics reasoning. Their framework points to the need to consider how supporting students' use of math in a physics context may require reframing or extending what is

typically taught in mathematics courses. While this report shares our analysis of homework problems we intend to use it as a foundation to examine student understanding more directly in future work.

Generally the strength of students' mathematical background appeared to correlate with their success in these classes (Ayene, 2010; Morán-Soto, et al. 2023; Quimson, 2021). To begin the work of determining how to better prepare students for subsequent courses such as physics we conducted a systematic content analysis of the math skills required for the completion of homework problems in the physics classroom. By classifying each task by the type of math skills it required, we aimed to show the specific mathematical emphases in these physics courses and how they relate to the math classes that preceded them.

We see this work as contributing to the understanding of the alignment or misalignment of math content in follow-on courses. We also see the need to consider how to support students to succeed in both their math courses and the courses they will go on to take later that make use of the math they learned. At the 27th RUME conference Robles and colleagues (2025) presented what they called the first study of math content in introductory physics using the calculus concept framework. We desire to build on their work with this examination of math content in an introductory physics course specifically targeting biological science majors. These desires led us to the research question for this preliminary proposal: What math content is present in a year long general physics class directed toward life sciences majors?

Literature Review

While there have been research studies targeting the different ways math is taught in physics courses, not many have targeted the physics courses for life sciences. Much of the research has provided insights into how math in physics courses might differ from math in math courses. González-Martín (2021) and Hitier and González-Martín (2022) found that there is a difference between the way integrals and derivatives are taught and used in physics and math courses. Some authors even go as far as to say that the math taught in math courses is inherently different from the math in physics courses but can be bridged if math courses emphasized the ways to apply the tools math provides (Rabin, et al. 2025; Redish, 2006; Redish & Kuo, 2015).

There have also been studies that compare students' performance in STEM classes and how it correlates with their performance in math courses. In fact, three in particular concluded that it seems that students who have higher performance in math courses also perform better in their subsequent STEM courses (Ayene, 2010; Morán-Soto, et al. 2023; Quimson, 2021). In a different study of how math background correlated with results in Physics 1 and 2 Burkholder and colleagues (2021) found that while math background was not a predictor of Physics 1 final exam scores, having completed vector calculus was a predictor of success in Physics 2. They found this appeared to be primarily due to better reasoning about vectors and geometry, not specifically vector calculus skills.

Projects that analyze the math content in STEM courses find few uses of the math learned in prerequisite calculus courses (Faulkner, et al. 2020, Robles, et al. 2025). Ayene (2010) puts this in a greater context by comparing the math content in physics courses throughout a physics program and whether they align with content from each prerequisite math course and determines that there is in fact misalignment in math content within this sequence of courses. There appear to be few studies that look at the broad use of math in introductory physics courses specifically. Our project continues the research seen in these papers such as that completed by Robles and colleagues (2025) through our analysis of the mathematical content in a physics sequence designed for life sciences.

Analytic Framework

To analyze the mathematical content in subsequent physics courses we adopted a task-based content-analysis approach. We wanted to evaluate the math content to see how well calculus courses are preparing life science students for these calculus-based physics courses. We treated each subpart of a homework problem as a task that a student had to accomplish and used instructor solutions to determine which techniques were used in each task.

To determine the math content present in each problem we considered the definition of calculus from the Calculus Content Framework (CCF) (Sofronas et a., 2011). The framework breaks out a number of concepts and skills that calculus experts deemed part of first year calculus. Perhaps unsurprisingly the first few skills that showed up in their study were derivative computations, techniques of integration and limit calculations. After this is a longer list of items identified by 1-4 participants, these included: sequences/series, manipulating algebraic expressions, area/volume, parametric equations, polar coordinates, trigonometric manipulations, facility with logs and exponentials, epsilon delta proofs, listening/reading comprehension and facility with definitions and notations. After consideration of this list and initial review of the problems we were coding we decided to keep the first couple of categories but to bucket together, adjust or leave out several of the categories that came up among fewer of their participants and that did not appear relevant to the calculus problems. We also wanted to include a code specifically for arithmetic calculation which we saw show up a number of times in problems. In the next paragraph we define each of the codes we used to understand the math present in the physics homework.

For the concepts of *derivatives* and *integrals* we used Sofronas' and colleagues' (2011) discussion to develop short descriptions. We also included a code for *manipulating algebraic expressions* which encompassed solving for unknowns, rearranging equations, and symbolic manipulation (Puig & Rojano, 2004) and included the expression of physical relationships. This code also included two sub codes, *summation notation* and *delta notation*, which appeared frequently in the problems although generally used differently than is typical in calculus classrooms. The final bucket we considered was *geometry*, which included area/volume, spatial reasoning, diagrams, coordinate systems, and shape-based interpretation (Jablonski & Ludwig, 2023). This bucket also included *vectors* and *trigonometry* as specific child codes.

Finally, we added an emergent code, *graph interpretation*, for problems requiring students to extract quantitative relationships from visual representations, a skill recognized as distinct in both mathematics and science education research (Roth & Bowen, 2001). This skill also came up in the CCF in connection with derivatives, but many of the problems that appeared to involve graphical interpretation in this set did not necessarily involve derivatives.

Methods

To analyze the mathematics present in the physics sequence, we obtained the complete written homework problem sets and instructor-provided solutions for each semester. These solutions offered insight into the instructor's expectations and represented the problem-solving techniques students were likely expected to use. We conducted a task-based content analysis of the homework sets to identify the mathematical skills required to complete each problem. We also analyzed online homework sets that did not include instructor solutions. These questions were multiple choice or short numerical responses. While these tasks still provided some information, the absence of solutions and limited response options led us to question exactly what mathematical skills were required for the problems and to what degree they were required.

Each homework problem and its subparts were categorized as either requiring mathematics or not. In cases where mathematical work appeared in the instructor's solution but was not necessary to solve the problem, we applied an additional tag, “math in soln.” To code the math content in each problem we devised a codebook in line with the calculus concept framework, but adjusted as described in the theoretical framework above.

The codebook was implemented in Microsoft Excel, with problem numbers, brief descriptions, and math tags documented to ensure consistency in analysis. Each problem was independently coded by both authors, and disagreements were discussed and resolved through consensus. Initial agreement rates were high, and once coding was complete, we conducted an informal member check by sharing our coding with the physics instructor, who confirmed that our characterizations aligned with the intentions for the problems.

Findings

In classifying the homework problems, we found that the majority of problems required math skills with 63% of problems across the sequence coded as involving math content in some way (n=240 of 379). Similarly, in the online homework 74% of the problems were coded involving math content (n=221 of 297). We found that the majority of math content required of students as represented by the homework problems involved manipulating algebraic expressions but only a minority included calculus specific skills such as calculating derivatives or integrating.

The skill most commonly appearing in the written problems was manipulating algebraic expressions with it showing up in 77% of the problems that involved math skills (n=185). The second most commonly appearing code was arithmetic calculation which appeared in 50% of the math problems (n=121). Geometry was the third most common code occurring in 43% of problems (n=103) with its subcodes of vectors (n=54) and trigonometry (n=54) each appearing in 22% of problems. Derivatives came up in 8% of problems (n=19) and integrals in 4% of problems (n=9). The most common skill in the online homework problems was arithmetic calculation showing up in 76% of problems (n=167) and manipulating algebraic expressions was the second most common code showing up in 25% of the problems (n=62). Considering the format and intent of the online problems, these skills being most common makes sense; these questions are intended to check basic, often conceptual, physics skills newly introduced in the class sessions. Derivatives were only coded in 2% of the online problems (n=4).

Beyond the frequency of the problems we also noted in coding that summation notation (n=11) and delta notation (n=32) were used in ways not generally seen in calculus curriculum. In the physics curriculum summation notation was often used as a stand-in for writing “sum” when a problem asked for summing up a number of different forces for example. This use is distinct from how students usually see summation notation in calculus courses in the context of series. Although we only did a formal review for the homework assignments, we performed an informal review for the in-class session activity handouts and found more calculus there. The calculus involved derivatives, chain rule, integration, differential equations, and calculus in 3 dimensions. No analysis was done of section activities, exam study materials, or supplementary resources.

Discussion

Different Emphases

Our analysis of these homework problems demonstrates that the math skills students use most frequently in an introductory physics series like this one differ from what calculus experts deem the emphasis of their classes. This difference is not necessarily surprising as the focus of a

calculus class is the understanding and implementation of the mathematics content itself. Math teachers need to support math understanding for students with broad aspirations while in physics the math provides tools for understanding the content of that discipline. While not surprising, we think this finding is important because when a course is a prerequisite then students would expect that completing that course means they are prepared for subsequent courses that require it.

This work reveals however that for success with the mathematics present in a course like this a solid foundation in algebraic and geometric knowledge and skills may be more important than skills related to manipulating derivatives and integrals. Many students likely enter their calculus courses already with strong algebra and geometry skills. However, for the subset of students that do not have a strong background in algebraic manipulation there is no guarantee that their calculus course will address these skills. As the CCF shows, many calculus educators emphasize new content like manipulating derivatives and integrals, but not the previously mentioned skills.

This disconnect between the emphasis of calculus topics and possibility that students get through without addressing gaps in their algebraic manipulation skills is especially salient in courses targeting life sciences majors. Students in these majors, especially those selecting these targeted courses, may have a more negative relationship to mathematics than other STEM majors (Wachsmuth et al., 2017). With this population that may be interested in being veterinarians or doctors, we need to consider the best options to serve them mathematically. This work shows that within the context of a physics class specifically designed for this population, the most commonly used skills aligned more to the modeling aspect of calculus rather than advanced differentiation and integration techniques.

Directions for Future Research

Our findings align with prior research and show that a lot of mathematics work is required of students in physics classes and confirm why prior studies have shown alignment between students' math skills and success in physics coursework, even if content does not necessarily align (Ayene, 2010; Morán-Soto, et al. 2023; Quimson, 2021). We consider this work preliminary because our true interest is in how to better support students' transition and transfer from calculus to physics, a well known and complex challenge.

This study provided insight into the skills that are most commonly required for students to succeed in a physics course targeting life sciences majors. These results align with Robles and colleagues' prior study that showed that in introductory physics the most prevalent skill required is algebraic manipulation with trigonometry, vectors, and graphs coming up more frequently than integrals or derivatives even in a calculus based physics course.

Others have recognized this disconnect and created alternative forms of calculus such as modeling-first approaches to calculus for life sciences students which have shown some success (Garfinkel et al., 2022; O'Leary et al., 2021). In future work we would like to analyze problem sets from these courses and more traditional calculus courses to see how they compare. We also want to analyze more physics for life sciences classes to see trends in mathematical content. Furthermore, we would like to look at student outcomes or consider conducting cognitive interviews with students to look at what they know and how it translates.

Questions

As a preliminary report, audience engagement is much appreciated, and we offer questions. Would further content analysis likely bring new insight into knowledge requirements, or should additional methods, like interviews, be used? What suggestions would you have for us to deepen this study further and make it more relevant to how we can better support students?

Women's Experiences Within the Communities of Practice of a Doctoral Mathematics Program: Insights Into Persistence

Brandi Whiteman
Oregon State University

For decades, women have consistently earned fewer than 30% of PhDs in mathematics in the United States each year. Advancement through a doctoral mathematics program can be viewed as a process of integration into the communities of practice within the department, and a student's persistence (or attrition) is influenced by experiences that enhance or inhibit their participation in the activities of each community. In this preliminary report, I discuss the experiences of six women in a doctoral program and their participation in the coursework, research, and graduate teaching communities of practice in their departments. In contrast to past studies that propose that these communities of practice are mutually exclusive, my participants' accounts illustrate some overlap between them.

Keywords: women, communities of practice, doctoral mathematics

Women have been underrepresented in the discipline of mathematics for decades, particularly in higher education settings. Data from the Survey of Earned Doctorates, conducted by the National Center for Science and Engineering Statistics (NCSES), shows that women consistently earned between 27%-29% of doctorates in mathematics and statistics each year between 2010 and 2020 (NCSES, 2024). Further, in the year 2020, non-white women accounted for only 8% of doctorate recipients in mathematics and statistics (NCSES, 2024). Since at least the 1970s, research dedicated to understanding the underrepresentation of women in mathematics and other STEM fields has revealed several cultural, institutional, and structural barriers to obtaining a graduate degree (Ceci et al., 2011; Roby, 1973). Research that focused specifically on the experiences of non-white women has highlighted additional layers of inequity that further pushes them to the margins (Malcom et al., 1976).

Background

Though much of the conversation has been focused on identifying barriers and highlighting inequities in higher education, some studies have also investigated factors that contribute to the persistence and success of women and women of color in graduate mathematics programs. For example, Borum and Walker (2012) found that among Black women who held PhDs in mathematics, early exposure to mathematics and participation in REUs prior to graduate school contributed to their interest and confidence, which helped them succeed. Among women who earned their PhDs in mathematics and secured positions at research institutions as tenure or tenure-track faculty, Miller (2015) found that two of the most important factors related to their success were strong undergraduate preparation in mathematics, and positive relationships with their graduate advisors.

Research addressing the persistence of women, and particularly women of color, in doctoral mathematics has several limitations. One is that many of these studies focus on women who have already completed their doctorates (e.g., Borum & Walker, 2012; Miller, 2015) which provides only retroactive accounts of their experiences. These women also attended different graduate institutions at different times, which makes it difficult to identify any political, structural, or institutional factors influencing their persistence. Additionally, differences in identity have

generally not been incorporated into the analysis of findings, which may unintentionally produce results that center the majority experience (in this case, that of cisgender white women) and erase or invalidate the experiences of minorities. In fact, the incorporation of multiple intersecting identities has often been limited to just race and gender. My study aims to fill this gap by focusing on womxn[1] currently enrolled in a doctoral program in the United States which graduates women at a rate higher than the national average, and by investigating their experiences through an intersectional lens (Crenshaw, 1989).

Theoretical Framework

Herzig's (2002, 2004) persistence framework for students in doctoral mathematics combines Lave and Wenger's (1991) theory of learning through participation in a community of practice with Tinto's (1993) model for doctoral persistence to describe the process through which mathematics doctoral students become academically and socially integrated into their departments and ultimately persist through completion of their graduate program (and thus become full participants in the community of practice of mathematicians). Herzig (2002, 2004) proposed that mathematics doctoral students encounter two sequential but disjoint communities of practice within their departments which they must participate in and become integrated into. These are the *course-taking community of practice* and the *research community of practice*, respectively. As these students become full participants in each, their likelihood of persisting through their doctoral program should increase. However, Herzig (2004) argued that this may not be as simple as moving through one community of practice and into the next.

> If students are to become full participants in the community of practice of mathematicians, they need access to all of the means of membership. … Instead, they are participating in a distinct course-taking community of practice, and their persistence at this stage depends on the degree to which they become integrated into this community. It is not clear to what extent this participation prepares them to participate in the community of practice of mathematics research they will encounter later (Herzig, 2004, p. 181).

In developing this framework, Herzig (2004) was particularly concerned with identifying factors that enhance or inhibit diverse students' access to the community of practice of mathematicians in order to understand how they become integrated into that community. She found that "while there are obstacles to participation and integration that all graduate students face, women and students of color face additional obstacles that limit their opportunities to participate fully and effectively in mathematics practice" (Herzig, 2004, p. 182).

At this juncture, it is worth noting that Herzig (2004) briefly acknowledged the existence of a third community of practice, that of graduate teaching assistants, though discussion of its relationship within the persistence model is absent. Perhaps this is because teaching assistantships aren't a requirement for obtaining a doctorate. However, many mathematics doctoral students, including all of the participants in my study, hold teaching assistantships for at least some portion of their program. Further, mathematics faculty are a large part of the community of mathematicians that doctoral students interact with during graduate school, so teaching is integral to the graduate students' overall practice as mathematicians. Therefore, I will incorporate the *graduate teaching community of practice* into my analysis.

[1] For the purposes of my study, I am choosing to adopt the definition of womxn from the Empowering Womxn of Color Conference, which "uses womxn to describe all who experience life through the lens of womxn in body, spirit, identity past, present, future and fluid." For more information, visit https://ewocc-berkeley.com/history/

While my study design and analysis incorporate intersectionality theory (Crenshaw, 1989), I want to note that this preliminary report focuses the discussion on communities of practice in doctoral mathematics. Intersectional analysis of the findings is in progress but lies outside the scope of the current paper.

Methods

I am conducting a thematic narrative inquiry (Riessman, 2008) to investigate the experiences of womxn currently enrolled in the same doctoral program in mathematics in the United States. The program was chosen because it shows a relatively high rate of women persisting through the doctorate, with over 30% of PhDs in mathematics awarded to women each year for several years (NCSES, 2024). Six womxn initially joined my study, but one discontinued her participation after completing the first set of tasks. Data collected from each individual includes three separate one-on-one interviews (conducted via Zoom), two personal artifacts, five reflective journal entries, and one focus group interview (to be conducted in person). Preliminary findings and discussion will draw from the first interview, the first artifact, and the first two journal entries.

The purpose of the first interview was to understand the participants' mathematical histories up to their decision to pursue a doctorate, and to get a glimpse into what their world as a doctoral student currently looks like. To accomplish the latter, each participant created a map of their doctoral world (their first artifact) that could include anything in their environment that has been meaningful to them during their time in the graduate program. The map was shared prior to the first interview so that questions about the map could be addressed. The interview protocol was largely open ended, beginning with the prompt, "Tell me the story of how you decided to pursue a doctorate in mathematics." Follow up questions inquired about influential people and inspiration, and their engagement with mathematics through time (coursework, research, conference participation, etc.). After obtaining the participant's mathematical history, we reviewed their map artifact together guided by the prompt, "Tell me about the places you included in your map." Follow up questions inquired more specifically about where their mathematical activity happens and where they choose to spend time. Each of the six interviews lasted between 60 and 90 minutes.

The five remaining participants completed their first journal entries within two weeks of their first interviews, and their second journal entries within two to four weeks of the first. Journal entries were structured, guided by prompts which asked about how they engaged in mathematics over the last couple of weeks, including questions such as "How did you share your own mathematical ideas? How did you feel they were received by others? Did your contributions become part of the mathematical conversation?" These journals are intended to capture the continuity of participants' experiences (Clandinin & Connelley, 2000; Riessman, 2008) with respect to their engagement with mathematics in the program over the course of a few months.

To analyze the data, I used a deductive coding scheme using the three communities of practice as broad category codes. Subcodes for each community of practice included "activities" which identified instances of activity or participation in the community, "factors enhance" which identified instances where a participant's experience facilitated integration into the community, and "factors inhibit" which identified instances where a participant's experience disrupted integration into the community.

Preliminary Findings

I found evidence of each of the communities of practice, described by Herzig (2002, 2004), that mathematics doctoral students are expected to encounter during their graduate program.

Each participant provided accounts in varying degrees of detail of their engagement with graduate coursework at their institution, research-related activities, and teaching activities.

Within the *course-taking community of practice*, important activities discussed by all participants, regardless of their current stage in the program, included taking a variety of courses, doing homework, and solving problems. One major factor that enhanced their participation in these activities was collaborating with their peers. Professors encouraged students to work together on their assignments, and the mathematics building provided ample space for doing so. Many participants spoke about their use of shared graduate student offices and openly accessible spaces in the hallways which had seating and whiteboards. During our discussion of her map, Sofya described one such space.

> *Sofya:* Our cohort stays very close to each other, so that – we do this on purpose – so we can like, work a lot together, and mine was the leftmost [office] in some sense. That's [the common table outside of the offices] where we sometimes just go out to all sit there and work, or they like to come to my office a lot. I realized that, like, we usually just end up with sharing one office. Because that's how - we were encouraged to have that. … Every professor will put like, 'You're encouraged to work together.' … I honestly think maybe we spend time together more in 1st year cause we were all in intro classes, and you know how frequent those homework came out. You need to work with each other in order to actually like, survive, sort of.

Having space to collaborate on homework, being encouraged to do so by her professors, and having easy access to others in her cohort all enhanced Sofya's experience and facilitated her integration into the course-taking community of practice in the department.

Though Herzig (2002, 2004) described the *course-taking* and *research communities of practice* as sequential and disjoint, I found that participants in their second and third years have all been able to access the research community of practice despite not having been fully integrated into the course-taking community of practice. For example, Anne was given her first research opportunity the summer before the start of her second year. In her first journal entry, she described working with a group of collaborators on specific tasks with the goal of writing a paper. In her second journal entry, she followed up by saying that she authored one paper and co-authored another by the end of the summer. This indicates that she was able to begin developing several skills needed to become integrated into the research community of practice of mathematicians.

Other forms of participation and activity in the *research community of practice* within the department are through seminars, colloquiums, and reading courses. Many of my participants mentioned attending seminars early on in their program, and the positive impacts this had on their trajectory.

> *Moose:* So I actually joined the seminar for my research group in my 1st year. It's the groups and topology seminar, and I found that to be a really helpful group. The professor, well, the professors behind that, two of which are my co-advisors, really wonderful at accepting people.

Moose was able to gain access to the research community in the area that she was interested in pursuing despite having just entered the program. Feeling accepted in that group further enhanced her experience and facilitated her integration into the research community of practice.

Interestingly, I also found some interaction between the *graduate teaching community of practice* and the *course-taking community of practice*. For example, when Maxine struggled in her first year with coursework despite having a collaborative relationship with peers.

Maxine: I started grad school during the pandemic, so I had, I think, like 2 or 3 friends that we had a little bubble with, and one of them was super high achieving – like, super duper fast, high achieving - and then the other one was also high achieving but did things a different way. And so, I was often just stuck in the middle, like 'I don't know what to do,' so definitely learning to ask for help. And, you know, you say this to our students so much, being like, 'Go to office hours.' *Going* to office hours [laughs].

Maxine described an isolating experience where she felt "stuck" between her two peers, who she positioned above herself as "high achieving" and who approached things differently, but the negative effects of this experience were mitigated by "learning to ask for help" during professors' office hours. In this case, her experience as a teacher who urges her students to attend office hours was reflected onto her own experience as a student struggling in a course and highlighted a path forward.

Discussion

Herzig (2004) argued that "the persistence of a doctoral student in mathematics, and the quality of her experience in graduate school, is a function of how well integrated she is in the academic communities of her department and discipline" (p. 201). My preliminary analysis investigated the experiences of womxn in different stages of their doctoral program to identify opportunities they had to participate in the mathematics community of the department, and factors that enhanced their engagement and integration into the *course-taking* and *research communities of practice*.

Previous research has found that competitive and individualistic environments isolate women from the communities of their departments (Herzig, 2002; Hollenshead et al., 1994; Stage & Maple, 1996). My analysis showed that peer collaboration was both encouraged and facilitated by aspects of the program environment, which promoted integration into the course-taking community of practice. One potential implication of this is that mathematics graduate programs which make concerted and intentional efforts to promote collaborative relationships among its graduate students will increase the likelihood of graduating their diverse students

During the first few years of graduate study, mathematics doctoral students are sequestered away from authentic practices of mathematicians while they focus on completing coursework and preparing for qualifying exams (Herzig, 2002). Herzig (2004) found that this structure denies students access to the *research community of practice* while also forcing them to spend significant time and energy developing skills which may not necessarily enhance their ability to perform mathematics research. However, my preliminary analysis suggests that the course-taking and research communities of practice overlap in this department. Students are offered summer research opportunities at the early stages of their program (even if they haven't yet passed qualifying exams), and they are also encouraged to attend research seminars and take reading courses in the department. I conjecture that this feature of the program plays a key role in the persistence of womxn pursuing PhDs.

Finally, my preliminary analysis suggests that participation in the *graduate teaching community of practice* may influence a student's ability to become integrated into the coursework community of practice. Attending to their students who are struggling may provide a mirror through which graduate students find ways to alleviate their own challenges and persist through their coursework. Further investigation is needed to determine whether and to what extent this is the case. I have the following questions for the audience: (a) Have you encountered graduate programs that offer students early research opportunities? (b) What other ways can graduate students be invited to the research community in their departments?

The Alignment of Student Conceptions With Course Learning Outcomes: A Case Study on the Definite Integral

Amelia Stone-Johnstone
CSU Fullerton

Samuel Pacheco
CSU Fullerton

Terisa Harlow
CSU Fullerton

Students pursuing science, technology, engineering, and mathematics (STEM) degrees require some proficiency in Calculus. The Fundamental Theorem of Calculus is arguably the most important theorem taught in a Calculus I course, yet it is not covered until the last weeks of the semester in a traditional three-part Calculus sequence. As a result, students tend not to hold deep conceptual understandings around integration, and the conceptions that they do hold are procedurally based. This paper illustrates the disconnection between student conceptions around integration (primarily area-based) and the general emphasis (from mathematics education literature) on accumulation. In addition, our work highlights how course learning objectives may drive a primarily area-based interpretation of integration. Our preliminary findings from interview data with Calculus III students confirm prior research, suggesting that students hold strong procedural and area-based conceptions, rather than accumulation conceptions.

Keywords: accumulation, definite integral, course learning objectives

Background

Extensive research has examined the diversity of student conceptions and challenges in understanding integration in introductory calculus (Jones et al., 2017; Serhan, 2015; Thompson & Silverman, 2008). As Thompson (1994) highlighted, "the realization that the accumulation of a quantity and the rate of change of its accumulation are tightly related - is one of the intellectual hallmarks in the development of the calculus." Some researchers have pushed for teaching integration with a pedagogical focus on "adding up pieces" to support productive conceptual development among learners (Jones & Ely, 2023). Even with this emphasis on accumulation, students often leave Calculus courses with a conception of integration as an antiderivative or a process for computing areas under or between curves (Jones, 2015; Nguyen & Rebello, 2011; Serhan, 2015; Wagner, 2017). In fact, students often learn about the Riemann sum as a means for calculating the definite integral, and later forget this procedure once they have learned the Evaluation Theorem (Jones et al., 2017).

It is not until the Calculus II course, at our institution, that students are exposed to applications of integral calculus. It is in these applications where having a conception about accumulation is more productive than simply holding an area conception. In Calculus III, students have opportunities to explore accumulation across multiple dimensions, though they may not always recognize it explicitly. Building on prior literature that documents this phenomenon, our research team aims to explore whether similar patterns emerge among students at our institution. We pose the following question:

1. What conceptions do Calculus III students hold on the definite integral?

Preliminary Work

The first research question was the primary subject of an undergraduate's (third author) summer research project. Upon completion of the data analysis for this work, the research team wondered about the relationship between the findings and the actual content that students learned

in their previous Calculus I and II courses at our institution. Thus, we pose the following question:

2. Based on the stated course learning objectives (CLOs) in Calculus I and II, what conceptions do we expect students to develop around integration after completing the first two courses in the three-part Calculus sequence?

In this preliminary report, we share findings from both research questions and pose further questions to explore. We intend to continue this work by systematically reviewing CLOs from various Calculus programs across the United States to observe how CLOs align with established perspectives around accumulation.

Methods

Author 1 and Author 3 participated in an independent study project where we set out to explore student conceptions around integration. During the first phase of the project, the research team performed a literature review and constructed an a priori codebook. The codebook was based on the work of Grundmeier et al. (2006) and Jones (2013), highlighting student conceptions that we anticipated students to hold around integration (see Table 1). Afterwards, the team developed a semi-structured interview protocol to engage with Calculus III students.

Table 1. A Priori Codebook of Student Conceptions of the Definite Integral.

Codes	Elaboration
Opposite	The student conceives the integral as the opposite of the derivative.
Area	The student conceives the integral as the area underneath a curve.
Infinite Sum	The student conceives the integral as an infinite sum of quantities.
Accumulation	The students discuss the idea of adding up, totaling, or accumulating areas. Without explicit reference to Riemann sums.
Procedure	The student only discusses procedures for evaluating a definite integral.

During the second phase of the project, Author 2 joined the research team. With IRB approval, the research team recruited ten students from our institution who were currently enrolled in Calculus III. Each participant participated in an hour-long video-recorded semi-structured interview, for which they were compensated with a $25 gift card to the campus bookstore. Each participant was asked eight Calculus I questions, where five were explicitly about integrals. Two questions were informal questions, posed as a means of capturing students' general ideas about integration (see Figure 1). Three traditional Calculus I questions that involved integrals were then posed to the participants (see Figure 2).

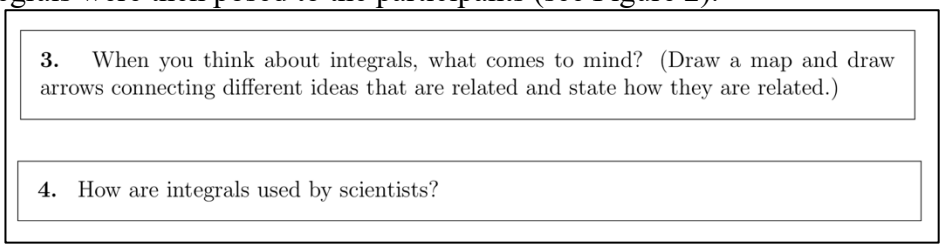

Figure 1. Informal questions about integrals posed to the participants.

The data from the semi-structured interviews were transcribed and coded using the a priori codebook. Each member of the research team coded the ten transcripts independently and met to discuss codes. Any disagreements around coding were discussed and resolved during research meetings.

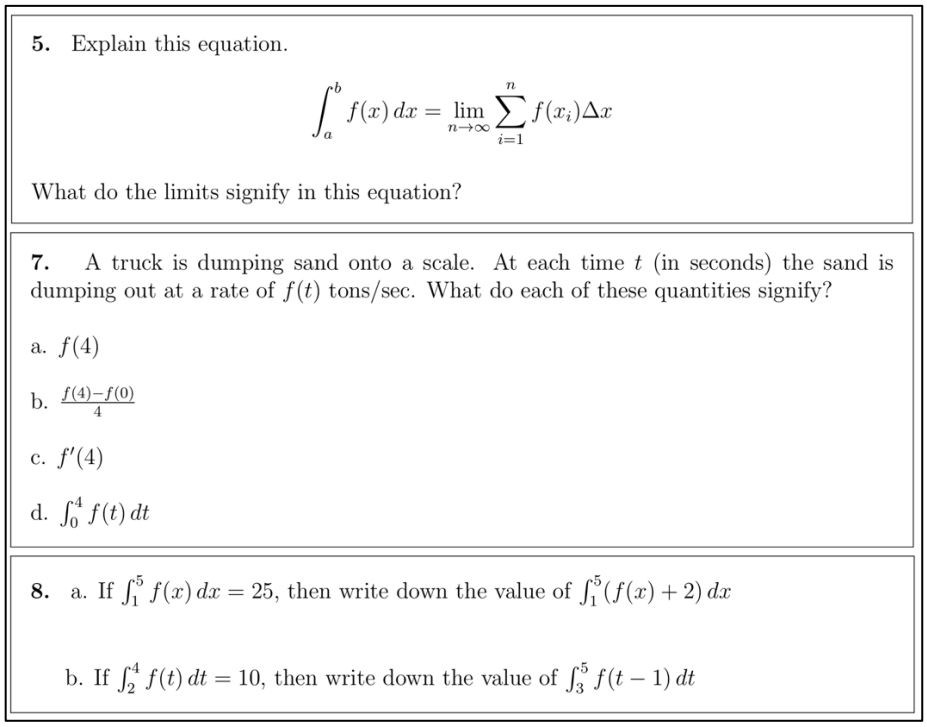

Figure 2. Formal questions involving integrals posed to the participants.

Considering preliminary findings from the student interviews, the research team decided to then explore and code the CLOs for the Calculus I and II courses that the student participants had taken in prior semesters. The CLOs were coded using the same codebook in order to make comparisons between the findings.

Preliminary Findings

In this section, we present findings in response to each research question.

Student Conceptions on the Definite Integral

We noticed several key observations from the student data. First, and consistent with the literature, all participants referenced the concept of area at least once during the interview. For instance, one participant sketched a picture of an arbitrary function $f(x)$ as they interpreted question 7d, "So because we have infinitely many rectangles, because that n approaches infinity… essentially it's like this whole area filled out." Second, all students demonstrated procedural understanding in solving at least one of the given problems (e.g., question 8).

Third, a majority of students articulated that integration is related to the notion of being the opposite of a derivative (7/10). One participant stated, "I think integrals are like antiderivatives…same thing as derivative just opposite." In addition, 7/10 students associated the integral with accumulation. Many students discussed an idea about totals. One student mentioned "total electric charge," and another mentioned "total work done" over some interval. In discussing question 7d, another student stated the following:

> If you're looking at the line, that's the output of the function. That's how much … sand got dumped. But, for an integral … it's kind of like saying, it's this much sand. It's this much sand. Like it's-it makes me think of saying like, that's all the sand ever between 0 seconds and 4 seconds.

This participant used gestures and repetition to emphasize the addition to a pile of sand as a representation of the integral in 7d.

Lastly, only 6/10 of the participants accurately discussed the idea of an infinite sum either within the definition of an integral or while explaining the process of integration. This was surprising given that each participant was presented with the Riemann sum in question 5.

Expected Learning as Outlined in CLOs

The Calculus I course at our institution covers the foundations of differential and integral calculus, with 12 CLOs. Six of these learning goals, as displayed in Table 2, pertain to student learning about integration. We noticed that the predominant emphasis in this Calculus I course was to facilitate the development of an area conception around integration. The Calculus II course covers techniques and applications of integration, sequences and series, and polar and parametric equations. There are 15 Calculus II CLOs, and only four were explicitly related to integration. All four of these CLOs were coded as Procedural. For instance, one CLO was, "to learn how to apply the definite integral and integration techniques to the problems of finding the arc length of a curve, the area of a surface of revolution, moments and centroids, and hydrostatic pressure and force." While it may occur in Calculus II, we do not speculate on whether an emphasis on an accumulation interpretation occurs during instruction.

Table 2. Six Relevant Calculus I learning goals Pertaining to Integration

CLO	Code
7. To study and understand the concept of an antiderivative of a function, and to find families of antiderivatives for some simple functions.	-
8. To grasp the meaning of the "area under the curve" problem, to be able to approximate such areas with left and right hand Riemann sums, and to evaluate the limit of these sums using summation formulas provided.	Area, Infinite Sum
9. To understand the meaning of the definite integral, to learn to use the notation correctly, and to be able to interpret its meaning in terms of areas.	Area
10. To learn how to use the Fundamental Theorem of Calculus to evaluate definite integrals and to find derivatives of definite integrals as a function of the upper limit.	Procedural
11. To learn how and when to apply the method of substitution to evaluate a definite integral, and to be able to interpret a definite integral using the Net Change Theorem.	Procedural
12. To understand how to apply the definite integral to find the area between two curves.	Area

Discussion and Conclusion

Though the sample size was small, when compared to the CLOs, these findings provide insight into potential conceptions students may develop about integration following their coursework in Calculus I and II at our institution. Findings indicated that students' conceptions of integration encompassed expected procedural methods, as well as connections to area under a curve and, in some cases, volume. Notably, students referenced accumulation (including "totaling" and "adding up") more frequently than anticipated. Overall, their conceptions were consistent with the stated CLOs.

To foster an understanding of accumulation, it is essential to identify concrete ways to *integrate* it into the course learning objectives. With that said, we pose the following questions for the audience to consider:

1. What CLOs would need to change if we want students to develop a robust conception of accumulation?
2. What barriers exist to shifting from a primarily area and procedural focus to an accumulation focus on integration? And, in what ways could we better leverage the introduction of the Riemann sum to cultivate an accumulation conception?

How Proofs Are Organized: A Systemic Functional Linguistics Theme Analysis

Valentin A. B. Küchle
Auburn University

Paul Christian Dawkins
Texas State University

Elizabeth Wrightsman
University of Nebraska Omaha

Joshua M. Balboa
Texas State University

We present a preliminary linguistic analysis of how proofs are organized. In particular, we performed a Theme analysis—an analysis from systemic functional linguistics (SFL) that identifies the starting points of messages at the level of independent clauses—on proofs from undergraduate textbooks. Theme analysis is one of the ways in which SFL studies the textual metafunction, that is, how texts are organized to relate to their context. Our preliminary results show that the main marked (i.e., unusual) Theme constructions in our dataset are: (a) beginning clauses with Adjuncts, and (b) beginning clause complexes with dependent clauses. Further, we found that textual elements (e.g., thus, so, since, if) were common as part of multiple Theme constructions.

Keywords: discourse, proof, systemic functional linguistics, textual metafunction

We expect that the reader will find the following proof (of the theorem that every finite integral domain R is a field) to be written in a frustratingly opaque manner:

> We need only show that for each $a \neq 0_R$, the equation $ax = 1_R$ has a solution since R is a commutative ring with identity. You let a_1, a_2, …, a_n be the distinct elements of R. Also, suppose $a_t \neq 0_R$. Consider the products $a_t a_1$, $a_t a_2$, $a_t a_3$, …, $a_t a_n$ to show that $a_t x = 1_R$ has a solution. We must have $a_t a_i \neq a_t a_j$ if $a_i \neq a_j$ (because by cancelation $a_t a_i = a_t a_j$ would imply that $a_i = a_j$). $a_t a_1$, $a_t a_2$, …, $a_t a_n$ are, therefore, n distinct elements of R. Although, R has exactly n elements all together, and so all the elements of R in some order these must be. In particular, $a_t a_j = 1_R$ for some j. A solution, consequently, the equation $a_t x = 1_R$ has, and a field R is.

This proof is a rewritten version of a proof by Hungerford (2014). We created it by changing the order of clauses within sentences, the order of clause constituents (e.g., subjects, objects), and conjunctions. With this rewritten proof, we wish to emphasize that authors of proofs make choices to ensure that they "relate[] [their] messages to the prior and following text and context" (Schleppegrell, 2012, p. 21). This relating process is what systemic functional linguists refer to as the textual metafunction, and this preliminary report's goal is to study how this textual metafunction is realized in proof texts. Although we eventually intend to perform several of the textual metafunction analyses SFL offers, this report focuses on one textual metafunction analysis: a Theme analysis. We capitalize Theme, which is roughly the first constituent of a clause (more on this below), to distinguish it from its everyday meaning. Thus, we seek to address: How are Themes realized in proofs from undergraduate mathematics textbooks?

Literature Review

Systemic functional linguistics (SFL) originates with linguist Michael Halliday. It studies the grammatical choices humans make within linguistic systems and the functionality of these choices (Schleppegrell, 2012), and for over 50 years, SFL has crossed paths with mathematics education. In 1974, Halliday attended the "Symposium on Interactions Between Linguistics and

Mathematical Education," after which he published a chapter about the mathematics register (Herbel-Eisenmann et al., 2017)—a register being "the constellation of lexical and grammatical features that realizes a particular situational context" (Schleppegrell, 2004, p. 18). Key to understanding registers and SFL are the three metafunctions—ideational, interpersonal, and textual—which are three types of meanings realized in every clause "to talk about the world [...] to interact with other people [...] [and to] organiz[e] language to fit in its context" (Thompson, 2014, p. 30). Below, we describe the metafunction most relevant to our work: the textual.

The Textual Metafunction (in Mathematics)

Two types of features realize the textual metafunction, that is, how messages are organized: structural features (i.e., thematic structure, information structure and focus) and cohesive features (i.e., reference, ellipsis and substitution, conjunction, lexical cohesion) (Halliday, 1994). Whereas the structural features are internal to a clause (or clause complex), the cohesive features focus on how clauses (or clause complexes) relate to one another (Halliday, 1994). (A *clause* is "(potentially) any stretch of language centred around a verbal group," Thompson, 2014, p. 17; a *clause complex* is "a combination of two or more clauses into a larger unit," Thompson, 2014, p. 186). Important for this report is the thematic structure, particularly the concept of *Theme*. Theme, which we discuss in greater depth in our Conceptual Framework, refers to "the element that serves as the point of departure of the message" (Halliday & Matthiessen, 2014, p. 89).

In mathematics education, several scholars have studied aspects of the textual metafunction. For example, O'Halloran (2005) observed that in mathematics texts: (a) marked (i.e., nontypical, not the default) Theme constructions are used to emphasize important content (e.g., "From Equation 3", "When the derivative is small"); (b) dependent clauses as marked Themes are common (e.g., "If $x = 4$"), and (c) conjunctions and conjunctive Adjuncts as textual elements of (multiple) Themes are common (e.g., if, then, therefore). Morgan (1998) postulated that in deductive texts, it is likely that textual elements (e.g., hence, therefore) and reason-providing Adjuncts (e.g., "By Theorem 1") appear in the Theme. (*Adjuncts* are those clause constituents that provide information about the circumstances of a situation, for example, why something happens, Thompson, 2014.) Further, Morgan (1998) suspected that unlike scientific explanations, mathematical deductive texts may favor leading with the cause and then providing the result. On the other end of the textual metafunction spectrum, González and Herbst (2013) and González (2015) have focused on cohesive features by studying conjunctions, and conjunctions and lexical cohesion, respectively.

Last, we wish to acknowledge that there are also studies in mathematics education that focus on the other two metafunctions or combinations of the three metafunctions. For instance, there is work focused on the ideational metafunction (e.g., DeJarnette & González, 2016; Herbel-Eisenmann & Otten, 2011), the interpersonal metafunction (e.g., DeJarnette, 2018; Herbel-Eisenmann & Wagner, 2010; Mesa & Chang, 2010; Zolkower & Shreyar, 2007), both of these (e.g., Burton & Morgan, 2000), or all three metafunctions (e.g., Herbel-Eisenmann, 2007; Morgan, 1998; O'Halloran, 2005). Finally, not all SFL-related work foregrounds the metafunctions. For example, there is also work that draws on SFL's writing on genre (e.g., Marks & Mousley, 1990; Solomon & O'Neill, 1998).

Conceptual Framework

This report focuses on the realization of the textual metafunction in proofs, and SFL offers multiple analytic tools for analyzing the textual metafunction (e.g., Theme analysis, conjunction analysis). The guiding concept for this report is the concept of *Theme*: "the element that serves as

the point of departure of the message; it is that which locates and orients the clause within its context" (Halliday & Matthiessen, 2014, p. 89). In English, placing something at the start signals that it is the Theme. The Theme typically contains given (i.e., already present) information, and the remainder of the clause, the *Rheme*, typically contains new information (Eggins, 2004; Fries, 1994). For each of the three basic grammatical moods in English—which SFL terms *declarative* (e.g., "Danielle watches TV."), *imperative* ("Danielle, watch TV!"), and *interrogative* ("Is Danielle watching TV?")—SFL proposes that there are *unmarked* (i.e., usual) and *marked* (i.e., less usual) Themes. For example, it is natural to start a declarative clause with a Subject (e.g., "I can do without grading") but less common to start with a Complement (e.g., "Grading I can do without"). (A *Complement* is a "nominal or adjectival group that refers to the same entity as the Subject, or describes the Subject," Thompson, 2014, p. 20). So, for declarative clauses, a Subject as Theme is referred to as an unmarked Theme, whereas other thematic choices are referred to as marked Themes. Note that it is SFL tradition to capitalize functional labels like Subject.

In our analysis of Theme, we follow Thompson's (2014) approach, and there are a few key points about his conceptualization of Theme that merit mention:

1. When a clause complex starts with a dependent clause, Thompson (2014) suggests treating the entire dependent clause as the Theme (e.g., "**If it rains**, I'll stay home").
2. Textual and interpersonal elements that precede the first experiential (or topical) element are part of the Theme, which is then called a *multiple Theme* (e.g., "**Thus, surely, you** agree"). Note that a multiple Theme is not multiple Themes, but one Theme consisting of multiple elements that correspond to different metafunctions.
3. Clauses with "there" plus the existential process (usually realized by "be") include the existential process in the Theme (e.g., "**There is/was** a bird outside").

Methods

Data Collection

Thus far, our dataset consists of ten proofs from five popular undergraduate textbooks (i.e., Abbott, 2015; Axler, 2024; Dummit & Foote, 2004; Fraleigh, 2003; Rudin, 1976) that cover typical undergraduate mathematics content: real analysis, abstract algebra, and linear algebra. Within each textbook, two proofs were randomly selected with a random number generator.

Data Analysis

First, the proof texts were separated into T-units: "independent clause[s] together with all the clauses that are dependent on it" (Thompson, 2014, p. 161). T-unit boundaries that occurred within sentences were indicated with a double slash (//). Next, the Theme (and Rheme) of each T-unit were identified, following Thompson (2014). Third, the Theme was studied to: (a) determine whether it was marked, and (b) identify any textual and interpersonal elements part of a multiple Theme. (Textual elements were highlighted in orange and underlined. Interpersonal elements were highlighted in blue and underlined with dots.) For an example of the T-unit separation and coding of a sentence from a proof by Abbott (2015), please see Table 1.

Table 1. Example Theme Analysis of a Sentence

Theme	Rheme	Marked?
If $a = b$,	then $\|a–b\| = 0$ //	marked (dependent clause)
and so certainly $\|a–b\|$	$<\varepsilon$ no matter what $\varepsilon>0$ is chosen.	unmarked (declarative)

The first author coded all ten proofs (i.e., 151 T-units), and, at the time of writing, we are in the process of having each proof coded by at least two authors. We are also currently studying the marked Themes to identify patterns. Our preliminary results are described below.

Preliminary Results

Theme Status

Theme status describes whether a Theme is marked or unmarked, and in our coding, marked constructions appeared roughly a third of the time (49 out of 151 T-units). In particular, we found two marked constructions: (a) beginning a clause complex with a dependent clause instead of the independent clause (33 times), and (b) beginning a declarative or imperative clause with an Adjunct (16 times). We note that among the possible marked options in declarative clauses, Adjuncts fall "somewhere in the middle on the scale of markedness" (Thompson, 2014, p. 150). As this breakdown shows, other marked options, like beginning a declarative clause with a Complement, did not appear at all. Artificial examples thereof (e.g., "To show that x is even is our goal", "A subset of Y the set X is") suggest that such Complement-as-Theme constructions sound strange and may be less functional for the flow and organization of proofs than their unmarked counterparts (i.e., "Our goal is to show that x is even", "X is a subset of Y").

Dependent clauses. For this subsection and the next, let P and Q refer to mathematical statements (e.g., "f is differentiable"). Among clause complexes beginning with dependent clauses, if–then constructions were most common, with "then" sometimes omitted (e.g., "If P, [then] Q"). There were also implicit conditional statements, such as "Assuming that P, [we get] Q", and "pseudo-conditional" statements that described depersonalized mathematical actions in the antecedent (e.g., "Renumbering [...], [we get] Q"). (We use the term "pseudo-conditional" to describe that although these clause complexes can be phrased in if–then terms [e.g., "If we renumber […], then we get Q"], they do not introduce a mathematical assumption.)

Another construction we observed was Thematizing mathematical warrants in dependent clauses (e.g., "Because P, [we get] Q"; "Since P, [we get] Q"). Lastly, we observed constructions that directed the reader toward a goal or direction (e.g., "To prove P, [...]", "Turning to multiplication, [...]"). We note that these uses of dependent clauses as Theme allow authors to adhere to the flow of logic—with data and warrants preceding claims—and, in the last case, orient the reader by framing the argument.

Adjuncts. As aforementioned, Adjuncts provide information about the circumstances of a situation (e.g., when, how, why) (Thompson, 2014). In our dataset, a majority of the Adjuncts appearing as Themes provided justification and typically took the form "By [*warrant*], P" (11 out of 16 times). Initial Adjuncts were also used (5 out of 16 times) to orient the reader and frame the Rheme (e.g., "In the forward direction", "For the [proof of the] first statement", "As regards (a')"). Initial Adjuncts almost exclusively appeared in declarative clauses (15 out of 16 times). The only example of an imperative clause beginning with a (framing-)Adjunct was: "In the general case, let [...]").

Theme Composition

Theme composition describes whether a Theme is simple (i.e., contains only an experiential element) or multiple (i.e., also contains textual and/or interpersonal elements).

Textual elements. There were many textual elements that initiated multiple Themes. To truly do these textual elements justice, a conjunction analysis (Martin & Rose, 2007) would be required. But even without such an analysis, there are several takeaways. Many textual elements

introduced (warranted) claims (e.g., "Hence", "So", "Therefore", "Then, "Thus") or antecedents (e.g., "If"). There were also textual elements that set a (new) stage (e.g., "Now", "First"), created contrast (e.g., "But", "However"), and were used to add (e.g., "and", "also", "again"). At times, multiple textual elements were combined, mostly to organize the text *and* do mathematical work (e.g., "Now if", "Again by", "And hence", "But then").

Interpersonal elements. There was only one interpersonal element in a multiple Theme: "certainly" in "**and so certainly** $|\mathbf{a}-\mathbf{b}|<\varepsilon$", which adjusts the force of the message (s. SFL's system of Graduation) (Derewianka, 2011). Since statements in mathematics are either true or false, there may be little need for resources like Graduation that intensify or weaken claims.

Experiential elements. The experiential elements of Themes were: Subjects in unmarked declarative clauses (e.g., "**The *i,j* entry of AB** is [SUM]") (80 times), dependent clauses in marked clause complex constructions (s. the "Dependent clauses" section) (33 times), Predicators (i.e., the verb that the Subject "does") in unmarked imperative clauses (e.g., "**Let** n = dim V") (22 times), and Adjuncts in marked declarative (and, rarely, imperative) clauses (s. the "Adjuncts" section) (16 times). Other than the markedness patterns, we noted that unmarked Subject-Themes often included Pre- and Postmodifiers. For example: "**The very definition of φ_a applied to a constant polynomial $a \in F[x]$, where $a \in F$** gives $\varphi_a(a)=a$", where the Pre- and Postmodifier are underlined with dashes. Thompson (2014) calls such Subjects *'heavy' Subjects*.

Other observations. Linguists disagree about the best way to perform a Theme analysis, particularly around where to draw the Theme boundaries (Thompson, 2014). We experienced this challenge and wish to highlight three structures we observed that were not captured by our Theme analysis but could have been captured if we had drawn different Theme boundaries: (a) leading with projected clauses of the form "We (+ *modal verb*) + *verb* + that + *mathematical statement*" (e.g., "We (must) show that […]", "We observe that […]", "We assume that […]"); (b) leading with projected imperative structures (e.g., "Assume that […]", "Note that […]", "Observe that"); and (c) leading with depersonalized versions of the previous two structures beginning with anticipatory "it" (e.g., "It follows that […]", "It needs to be shown that […]", "It may be noted that […]"). These constructions Thematize comments *on* the subsequent mathematical message instead of the message itself. We posit that this is a functional choice that allows authors to manage the flow of the argument and the links between claims.

Discussion

Although preliminary, our results align with O'Halloran's (2005) observations and Morgan's (1998) conjectures about Themes in (deductive) mathematics texts. Our next steps are to increase the number of proofs in our dataset and have all proofs coded by at least two authors. Since we are ultimately interested in what makes a proof flow for (student) readers, we want to also conduct a cohesion analysis. We believe that attending to cohesive features and making observations about how clauses (and clause complexes) are related to one another will complement our current results about how clauses (or clause complexes) are (internally) organized. We have several questions for the audience. First, we have thus far drawn on well-regarded mathematical texts, which appear to be making similar grammatical choices. How could we increase or diversify our dataset to better emphasize that choices are being made and to understand which choices are possibly more functional for communicating proofs in which contexts? Further, since our goal is to eventually understand the effects of these choices on the reading of proof, what methods could we draw on to study how Theme and cohesion choices influence the reading (and comprehending) of proof? Relatedly, how might our current clause-level observations inform the writing of proofs?

"There's Nothing Abstract About This Math": Abstract Algebra Students' Interpretations of Abstraction

Alice Mehalek
Colorado State University

Abstract Algebra is often cited as being a difficult course for undergraduate students because it is more abstract than computationally based courses such as Calculus. But what does it mean for something to be "abstract"? I conducted a grounded theory analysis of student survey data from an Introduction to Abstract Algebra course to explore how students define abstraction. The data show that students' personal definitions of abstraction go beyond conceptions of abstraction discussed in the literature, and the concept of abstraction acts as a mathematical artifact that influences the way students view abstract algebra concepts. Preliminary analysis also suggest that students' definitions of abstraction differed depending on their major area of study, indicating that abstraction is a boundary object whose definitions and uses vary depending on context.

Keywords: abstraction, abstract algebra, artifact, boundary object

As one of the first proof-based courses in the undergraduate math sequence, abstract algebra is often cited as being a difficult course for undergraduate students because of its abstraction level. The purpose of this study is to investigate how students conceptualize mathematical abstraction in an introductory abstract algebra class.

"Abstract" is used as both an adjective and a verb in various contexts in math education. The most well-known treatment of "abstract" as an adjective in Abstract Algebra is found in Hazzan's (1999) framing of Reducing Abstraction, which identified three interpretations of abstraction. Hazzan writes of "levels" of abstraction of abstract algebra concepts, defining this not as distinct enumerated stages but relative comparisons of how abstract a concept seems to a student.

In the first interpretation, Hazzan states that the level of abstraction of a concept or topic is not a property inherent to that concept, but a "reflection of the relationship between the object of thought and the thinking person" (1999, p. 76). Thus, a person's opinion of the abstraction level of a concept is influenced by their level of familiarity and prior experience with it.

According to Hazzan, the level of abstraction of a concept can also be described as a reflection of the process-object duality. Students working at a low level of abstraction are often focused on a process involving carrying out an algorithm or procedure, while students at a higher level of abstraction can view a computational process as a generalized object without referring to a specific example.

Hazzan's third interpretation of abstract is of complexity; "the more compound an entity is, the more abstract it is" (1999, p. 82). For example, a set is more abstract than one element in the set. Finally, Melhuish et al. (2018) expanded the framework and defined a fourth interpretation of abstraction level as the degree of formality or precision of mathematical objects. For example, a formal definition is more abstract than a metaphor or an informal definition.

The interpretations of abstraction identified by both Hazzan (1999) and Melhuish et al. (2018) were based on observations of student work and the strategies students use to make sense of abstract concepts. To date, no studies have directly addressed how students define what it means for a concept to be "abstract" in abstract algebra.

A limitation of Hazzan's study is the student population, which consisted of computer science students taking an abstract algebra class, after having previously taken a linear algebra class. However, some students take abstract algebra as their first introduction to abstract, proof-based mathematics, including students majoring in a variety of subjects. Thus, in this study I investigate how students with a variety of majors (including math, computer science, physics, chemistry, engineering, and economics) and differing levels of mathematical experience interpret abstraction in abstract algebra.

Theoretical Perspective

My theoretical perspective draws from sociocultural theory and the idea of mathematical artifacts as boundary objects. In the sociocultural view, learning occurs through social interaction and is mediated by artifacts, which includes language and symbols as well as physical or conceptual objects, tools, and concepts (Lerman, 2001). Mathematical artifacts are products of history and culture, and their meanings are "long-lasting but potentially changeable" (Lerman, 1996, p. 146).

An often-overlooked artifact encountered in abstract algebra is in the name, "abstract." While the definition of "abstract" is often taken to be self-evident, the concept of abstraction contains multiple meanings, each with their own culture and history. Students from differing backgrounds may have vastly different assumptions of what abstraction is, and these assumptions may influence the way they approach and interpret the subject.

Abstraction as an artifact is a boundary object, an artifact at the boundary between different communities of practice that are used differently by each community (Hoyles & Noss, 2004). Abstraction has long been at the boundary of mathematicians, math educators, and laypeople, who each have different conceptions and uses of abstraction (e.g., Thorndike et al., 1923; Corry, 2003). Students majoring in disciplines such as physics and engineering have different experiences with abstraction compared to math majors. As Hoyles and Noss observe when it comes to boundary objects, "communication of meaning and 'transfer' can be problematic unless and until the different conceptualizations—and the language in which they are expressed—are brought into alignment" (p. 3).

Methodology

Data were collected from students in an Introduction to Abstract Algebra course taught using a rings-first curriculum sequence. The course had an enrollment of 44 students with varied academic majors, including math, computer science, economics, physics, and others.

Halfway through the semester, I administered a written survey to students in the course, to which 33 students responded. For this paper, I analyzed student responses to the following questions:

1. This course is called Abstract Algebra. What does "abstract" mean to you?
2. What concepts in this course so far have seemed the most abstract to you?
3. What concepts in this course so far have seemed the least abstract to you?

I conducted a Grounded Theory analysis (Charmaz, 2014) of all 33 student responses to the survey question. Initial line-by-line coding resulted in 135 codes related to students' experiences with abstraction in this course. After several rounds of coding, I grouped these codes into three major categories representing students' definitions of abstraction, which will be described in the Results section. Following the survey, I conducted one-on-one, semi-structured interviews with 14 students. I used my coding results and memos to select six of the 14 interviewed students

representing all major codes. I coded portions of these interview transcripts and selected excerpts to represent each category.

Results

I identified three main categories that students consider in their definitions of abstraction: Structure, Purpose, and Beyond Sensory Experience. Each category was interpreted in two different ways by students. Three of these categories are further split into subcategories (Table 1).

Table 1. Student Interpretations of Abstraction

Category	Interpretation	Subcategory	Examples
Structure	Presence of Structure	Underlying reasons	Abstract algebra "breaks down" math to its fundamentals and explains the underlying reasons behind familiar procedures
		Simplicity	Abstract algebra concepts have simple definitions and axioms which require less justification than contextualized concepts
	Absence of Structure	Arbitrary	Abstract algebra changes familiar algebra rules and definitions without justification
		Indirect	Abstract algebra uses words and "math tricks" instead of numbers
Purpose	Widely Applicable		Abstract begins in applied concepts but moves away from applications Generalizing across dissimilar contexts Able to represent multiple things
	No Applications		Not relevant to student's major or future career

Beyond Sensory Experience	Basis of reality		Abstract math is a "sixth sense" that helps us learn about the world beyond the five senses
	Not Real	Outside the Real World	Things that are beyond perception by the senses are difficult to grasp
		Too strange to believe	Students have difficulty believing concepts are valid, even with proof

Structure

In the first category, Structure, some students interpreted abstraction as the presence of structure. One student, James (all participant names used are pseudonyms), described Underlying Reasons as a "broader view" of algebra:

> We are taking a look at algebra in a broader view. In simple algebra classes you learn the mechanics of algebra and how to apply it. In this class we are looking at things one level higher and proving why the mechanisms we previously used work.

Other students described abstraction as a lack of structure, marked by chaos and uncertainty. Hanna, a math and art double major, described frustration with the seemingly arbitrary nature of rules in abstract algebra, and couldn't see any underlying reasoning behind it. Hanna defined abstraction as "unstructured, random, chaotic… [groups and rings] seem like random 'things' with very specific conditions that someone decided randomly one day."

Purpose

A common theme involved how abstraction related to the purpose or applications of math. Some students said that abstract math is widely applicable to many different areas, seeing it as a generalization of more specific math. Travis described abstraction in terms of the number of applications: "Abstract means abstracting away from applications… groups feel the most abstract to me because they can represent so many things because of how simple the axioms for them are."

On the other hand, Rye, an electrical engineering major, expressed frustration with the lack of practical applications to her major:

> I am a very practical person. And my degree is very practical stuff. And so abstract just feels like, I don't feel like I'm ever going to use this material…it feels like we just chose different conditions, and we are like, 'this is now a ring' and 'this is now a group'. But what is it doing for us? …I actually don't see any importance. Like it just feels like someone's made it up.

The fact that Rye didn't "see any importance" to rings and groups indicates how necessary it is for her to have practical applications when learning a new concept. However, some students enjoyed the fact that there were no practical applications for the course material. Abraham, a biochemistry major, said about the course, "It all seems not very applicable to the real world, which I love. I love that. It's just like exercising the mind for the sake of knowing more things about numbers rather than for, you know, building a skyscraper or something."

Outside the Five Senses

Some students described abstraction in terms of the senses, contrasting abstract math with math that is visual or tangible. Chuck, a math major, suggested that abstraction goes beyond the five senses to learn more than we can normally perceive:

> Maybe math is another human sense. I think that the abstract can go beyond observations and make predictions… actually figuring out what's going on with the universe, sometimes we just can't see or hear or feel it. And I think that's where the abstract and mathematics comes into play and is super useful.

To other students, math that is not tangible and perceivable by the five senses is "not real math," which is how Taylor, a chemistry major, described abstraction. Ian, a physics major, described abstract math as "math that will never be used," "intangible," and "not actually proven." However, he found that a lot of concepts he learned in the course were connected to concepts he had learned in previous courses, leading him to conclude that "there's nothing abstract" about abstract algebra.

Discussion

Much of the literature on abstract algebra assumes that abstraction is inherently difficult for students. However, the students in my study did not consider "abstract" to mean the same as "difficult." There were several students who responded that nothing in the course was difficult for them, but everything in the course was abstract.

The categories of abstraction I found are different from Hazzan (1999) and Melhuish et al. (2018), which were the only previous literature that broadly addressed student perceptions of abstraction in abstract algebra. One possible reason for this is the student population. All of the students in Hazzan's study were computer science majors in an abstract algebra class, while my study included students majoring in math, computer science, and a variety of other STEM fields.

There were notable differences in how students with different academic majors viewed abstraction. A student's major constitutes a community of practice to which they belong, with each community holding different perspectives on and uses for abstraction. The majority of math and computer science majors in this study shared a similar view of abstraction as the presence of structure and purpose. Other majors, the majority holding opposing views, were likely not familiar with the conventions of abstraction in the mathematics community, and instead viewed abstraction through the lens of their primary area of study. In their interviews, several students described how abstraction is used in their major fields like chemistry and economics, and how that influenced their views of abstraction in abstract algebra. Future analyses will explore in depth the relationship between students' major and their understanding of abstraction.

I am in the process of analyzing further data from this same group of students, including a subsequent survey administered at the end of the semester, in which I ask students to rate their agreement with each interpretation of abstraction identified here. These data will reveal whether students' definitions of abstraction changed over the course of the semester. In addition, future analysis of task-based data from this same group of students will shed light on whether students' views on abstraction influenced the way they solved abstract algebra problems and constructed proofs.

From Noticing to Reflection: Graduate Teaching Assistants' Experiences With Written Classroom Accounts

Rasha Issa
University of California, Riverside

Sara Lapan
University of California, Riverside

Noticing is the first step to reflective teaching. Mathematics graduate teachers used 'brief-but-vivid' classroom accounts to reflect on teaching, documenting weekly moments and discussing them in facilitated groups. Two major themes emerged: (1) Capturing Fleeting Moments, emphasizing subtle classroom dynamics, student behavior, and practical strategies, and (2) Camaraderie and Learning Through Shared Accounts, where peer interaction fostered camaraderie, accountability, and co-construction of professional knowledge. Participants focused more on pedagogy than content, highlighting early instructors' priorities. Findings demonstrate that socially mediated reflection shapes teaching identity, informs instructional decisions, and links individual noticing to collective learning, with implications for designing more effective teaching professional development.

Keywords: Reflective practice, professional development, collaborative learning, teaching assistants, mathematics graduate instructor

Introduction

Overburdened with attending classes, reading, research, teaching, preparing, and grading, Mathematics Graduate Teaching Assistants (MGTAs) seldom have time to reflect on their teaching practices. The result? Many MGTAs exit their doctoral programs having missed opportunities to reflect on and improve their teaching.

Math graduate students juggle multiple roles in graduate school—student, researcher, and teacher. In research universities across the U.S., mathematics classes are often large, frequently exceeding 50 to 100 students (Cuseo, 2007). MGTAs are typically appointed to lead recitation or discussion sessions that support these large classes. Despite their minimal prior teaching experience, MGTAs often begin teaching early in their programs, sometimes on the very first day (Nyquist et al., 1991). Although a significant number may later pursue teaching faculty positions, teaching might be viewed as secondary to research in research-intensive universities (Fairweather, 2002). Especially when time is scarce and more emphasis is placed on research than on teaching, the instructional habits they form during this period can have a lasting impact on their careers.

The purpose of this pilot study is to explore how MGTAs, particularly Mathematics Graduate Teachers (MGTs), experience using "brief-but-vivid" accounts of classroom incidents to reflect on their teaching experience with peers and faculty. These accounts are intentionally descriptive rather than emotive, asking participants to focus on observable events and actions while omitting explanations, justifications, or personal interpretations. In doing so, the accounts functioned as entry points into discussions, enabling peers to engage with the teaching moments without being overly influenced by the writer's subjective stance. Also, respecting and valuing their time as they navigate the many roles they have. The research questions guiding this study are:

1. How do novice instructors experience and evaluate the process of using writing accounts as a tool for reflection within teaching professional development?

2. What do these accounts focus on? Specifically, what aspects of teaching do novices notice and choose to capture?

Literature Review

Teaching professional development (TPD) trajectories that begin early and continue throughout the teaching experiences of graduate teaching assistants (GTAs) are essential for fostering their growth as educators (Deshler et al., 2015). Continuous PD equips GTAs with the skills, knowledge, and experiences needed to succeed in their teaching roles. Lortie (1975) emphasizes that early teaching experiences play a pivotal role in shaping an individual's instructional identity. For GTAs, these initial teaching roles act as a bridge between their immediate responsibilities as graduate students and their potential long-term academic careers. Consequently, early TPD, combined with opportunities to reflect on teaching practice, can significantly impact not only the quality of MGTAs' instruction but also the broader departmental educational ecosystem and undergraduate learning outcomes (Åkerlind, 2008).

Recent scholarship has highlighted the importance of sustainable TPD programs that support long-term retention and growth for MGTAs as educators (Sadera et al., 2024). While many TPD initiatives provide opportunities for professional growth, these programs often feel short, sporadic, and disconnected from the realities of classroom teaching (Herrmann & Grossman, 2021). Without sufficient support and contextually grounded reflection, GTAs may default to replicating their prior educational experiences or rely on limited personal beliefs about teaching—patterns that can persist into their future faculty roles (Lee, 2019). One way to address this gap is through communities of practice, where novice instructors can share experiences and co-construct professional knowledge with peers and mentors (Wenger, 1998).

Reflection in teacher education is a complex process that involves negotiating values, attitudes, and beliefs, alongside developing cognitive skills (Calderhead & Gates, 1993). For MGTAs and novice MGTs, reflection could allow them to cognitively and introspectively transform their teaching experiences, consistent with Dewey's (1933) view that reflective thought emerges from actively examining one's experiences. Similarly, Schön's (1983) concept of the reflective practitioner highlights the importance of learning through critical reflection on action, both during and after practice. Engaging in reflective practice helps MGTAs and MGTs make sense of challenges in discussion sessions and classrooms, refine instructional strategies, and develop a stronger professional teaching identity, underscoring reflection as a central component of professional growth (Brookfield, 1995; Korthagen, 2017).

Schön (1983) describes the expert practitioner as someone who is awake to and aware of their practice, rather than simply immersed in it (Mason, 2002). Mason (2002) extends this idea, emphasizing that reflection requires *noticing* incidents before one can act upon them. To facilitate this noticing, Mason advocates the use of written 'brief-but-vivid' accounts, which capture key classroom events and provide a starting point for reflection. He explains that brevity is achieved by omitting distracting details, while vividness focuses on observable behaviors that others could independently verify. Furthermore, he distinguishes between giving an "account-of" an event versus an "account-for," highlighting that the former encourages an inner split between actor and observer, fostering reflective awareness (Breen et al., 2014). These accounts can also function as entry points, connecting individual noticing to collaborative reflection in group discussions, which is consistent with the idea of boundary objects in professional learning (Akkerman & Bakker, 2011).

Building on this work, our research team seeks to create conditions in which MGTAs bring their own expertise into reflection, discussion, and critique. By crafting stories that are

meaningful and valuable to them, MGTAs can engage in reflective practices that not only deepen their understanding of teaching but also contribute to the collective professional knowledge of the departmental community.

Theoretical Frameworks & Methodology

This study is framed through a multi-faceted lens of reflection and sociocultural learning theory, emphasizing the lived experiences of MGTs. Schön (1983) explained that *reflection-in-action* occurs during teaching, as instructors respond in real-time to students' needs, confusion, or questions, while *reflection-on-action* takes place afterward, when instructors review classroom events and analyze what happened. Writing 'brief-but-vivid' accounts facilitates this reflective process, providing a concrete means for MGTs to capture and examine their teaching experiences.

Thompson and Thompson (2018) emphasize that reflection should not only help practitioners make sense of past experiences but also inform their future actions, a process they refer to as *reflection-for-action*. This type of reflection serves as a complementary perspective, highlighting how insights gained from writing and discussion inform subsequent teaching and guide future classroom decisions.

Sociocultural learning theory situates these reflective practices within a hands-off facilitated community of practice, emphasizing that professional development is socially constructed through interaction with peers and faculty. In the context of this study, the 'brief-but-vivid' accounts function as objects to enter the discussion, connecting individual noticing to collaborative reflection. Through discussion, MGTs compare experiences, propose strategies, generalize from specific incidents, and co-construct professional knowledge, thereby integrating individual reflection with collective learning in a hands-off facilitated community of practice.

Context and Methods

This pilot study was conducted at a PhD-granting HSI in the southwest. The structure of the mathematics graduate program is that graduate students dedicate their first and second years to coursework, preparing for two written qualifying exams. MGTA starts teaching four discussion sessions on the first day of the program and is expected to teach every quarter if they are offered a TAship as a source of funding. After meeting specific departmental requirements, these MGTAs are encouraged to serve as the primary teachers of undergraduate courses over the summer, when classes are typically smaller, with approximately 30 students per class. We then refer to them as mathematics graduate teachers (MGT).

Study Participants

Study participants included four MGTs who are the primary teachers for summer undergraduate math classes ranging from pre-calculus to calculus II for life science majors and business calculus. Participants were all in the 4th or 5th year of the PhD program. Their teaching experience varied from their second to third time being the primary teacher at that institution. All study participants had been teaching assistants during their time in this program.

Methods

The data collected for this qualitative study included written 'brief-but-vivid' accounts, semi-structured group meetings, and an individual exit interview. Participants were asked to write three 'brief-but-vivid' accounts of their teaching each week and share those accounts via Google Docs, which all participants could access. These accounts were prompted as follows: Think of a

moment or experience from your class that stood out to you. Describe it as simply and directly as possible—focus on the facts, omitting unnecessary details and emotions. Don't explain why it happened or try to justify the actions involved. Instead, aim to give an account of what happened as if you were an outside observer, just as you would if you were telling someone about the moment without adding your interpretation.

The group meetings served as a space we thought of as a hands-off, facilitated community of practice. Participants met once each week for an hour and a half over a period of five weeks, during which they were teaching. The first author, a peer math graduate student, and the second author, a faculty member who serves as one of the TPD providers in the department, facilitated the group discussions in order to maintain a fruitful, continuous conversation. These group meetings were semi-structured and audio-recorded throughout the 5-week summer term. There was one participant who could not make the group meetings but wrote the 'brief-but-vivid' accounts.

All participants participated in an exit interview, which helped us capture the meta-reflections on the whole process of writing the accounts and the subsequent group discussions.

Preliminary Findings and Discussion

In examining how MGTs described their experiences using the 'brief-but-vivid' accounts in this study, two major themes emerged. These themes highlight both the social and cognitive dimensions of reflective practice, illustrating how the accounts functioned as tools for noticing, processing, and sharing classroom experiences. The first theme, Capturing Fleeting Moments, underscores how documenting subtle, often overlooked classroom events enabled MGTs to engage in reflection-in-action, reflection-on-action, and reflection-for-action, ultimately informing future teaching practices. The second theme, Camaraderie and Learning Through Shared Accounts, emphasizes the ways in which peer interaction, discussion, and mutual support fostered professional growth and a sense of camaraderie. Together, these findings illustrate that reflective practice among MGTs is both individually meaningful and socially mediated, aligning with sociocultural learning theory and concepts of communities of practice.

Capturing Fleeting Moments

A key theme was the accounts' ability to capture fleeting, often-overlooked moments in teaching. Participants noted that documenting small but significant classroom interactions—such as unexpected questions or subtle changes in student behavior—enabled them to reflect on real-time classroom dynamics and their responses. By writing these incidents shortly after they occurred, MGTAs engaged in reflection-in-action (Schön, 1983) while also generating material for reflection-on-action. One participant reflected on how a small observation sparked practical reflection:

> *But some other things. Like, another interesting one that I had written about was the fact that, like, that one time I left to get water, yeah, like, one minute, you know, and I come back and everyone's just much more bubbly, much more social. This sort of prompted something within me to at least consider maybe I don't have a great answer yet, but like, How can I simulate this without me having to physically leave the classroom for XYZ reason, whatever. So it affected me, I suppose, in these ways, most mostly practical.*

This quote illustrates that fleeting classroom moments, when captured and reflected upon, can lead to practical insights and potential strategies for future teaching. The act of writing accounts not only promotes noticing but also supports reflection-for-action (Thompson & Thompson, 2018), helping MGTs anticipate and plan responses to similar situations in the future.

Camaraderie and Learning Through Shared Accounts

A significant theme that emerged was the social dimension of reflection—participants emphasized learning from their peers and experiencing a sense of camaraderie. One participant remarked, "It doesn't only happen to me," highlighting that challenges and successes in teaching were shared across the group rather than experienced in isolation. Another participant reflected on the supportive yet accountable nature of the group:

> *Like more intention about, like, how we're teaching, or like how we're dealing with situations…in a group that's like an accountability group as well…we do reflect on it, and I share what we did…Sure, it's like a judge-free environment, but like, to some extent…*

Participants described how reading and discussing peers' accounts provided opportunities to compare experiences, share strategies, and learn from one another. One participant noted:

> *Yeah, I definitely learned a lot from other people's accounts. I also felt like I got to share some experience…you're not alone in those experiences…you hear somebody else has something similar going on in their classroom…And then there were some new ones for me…so now I feel like I would think about them now, like, how am I going to address that if it ever happened to me?*

Therefore, engaging with peers positions reflection as a collective rather than individual practice, allowing participants to recognize their teaching experiences as shared and socially situated. Through this process, the group functioned not only as a supportive, judgment-free space but also as an informal accountability structure in which participants exchanged strategies, surfaced common challenges, and jointly made sense of their instructional decisions.

What Aspects of Teaching Do MGTs Capture & Discuss?

Analysis of the accounts revealed that MGTs primarily focused on pedagogical and classroom management aspects rather than on mathematical content itself. Common observations included students not answering questions, minimal student interaction, writing more visibly on the board, use of technology, and other practical classroom strategies. These findings suggest that novice instructors are especially attuned to the flow and dynamics of teaching—how students engage, respond, and interact—rather than the technical content being delivered.

Interestingly, the research team noted that there was minimal attention to mathematics itself in the accounts, which was surprising given that the participants were teaching math courses. This highlights that early-career instructors may be more focused on how to teach effectively, rather than on content mastery, particularly when balancing multiple teaching, research, and student roles.

Through capturing these observations, MGTs engaged in reflection-in-action and reflection-on-action, attending to observable behaviors and classroom interactions that directly impacted the teaching and learning environment. The accounts provided a space for noticing both challenges and small successes, creating opportunities to improve instructional strategies and develop pedagogical awareness.

These findings raise several questions for future research. One particularly compelling question is: How might TPD programs better integrate content-focused reflection with pedagogical reflection, so that novice instructors attend both to what they teach and how they teach it? Addressing this question could provide insights into designing professional development that more fully supports the dual goals of content mastery and effective pedagogy.

Poster Reports

Designing a Study to Explore the Quantitative Literacy Practices of U.S. Undergraduates

Samuel Luke Tunstall
Trinity University

Keywords: numeracy, quantitative literacy, social practices

In this document and accompanying poster, I share motivating literature and the outline of a study that started in Fall 2025 and that will continue through Spring 2026.

Over the last three decades, coursework centered on quantitative literacy (QL) has become increasingly common at postsecondary institutions across the U.S. (Madison, 2019). A common definition of QL accompanying such courses is that QL is a skill set and disposition to engage with quantitative information in various arenas of life (e.g., work, school, daily life) (Boersma & Klyve, 2013). Given this framework for QL, the logic of such courses is that there are certain skills students need to thrive in the modern world, and that if we can teach students those skills, as well as instill in them the habit of mind to engage with quantitative information, students will be prepared for a modern world "awash in numbers" (Steen et al., 2001, p. 1). That logic is flawed, as research in anthropology (Lave et al., 1984; Street et al., 2005), psychology (Carraher et al., 1985), and numeracy studies (Yasukawa et al., 2018) suggests that the ways in which individuals reason and engage with quantitative information in daily life is not well aligned with how related mathematics might have been presented in formal schooling. An alternative to the ability/disposition framework for QL is to view QL as a social practice (Graig & Guzmán, 2018). A social practices approach to QL focuses on what people do with quantitative information—their QL practices—rather than what people can or cannot do, which is a common focus that follows from viewing QL as an ability.

Understanding the QL practices of a group is a critical part of designing a QL curriculum for such a group (Baker, 1998). While there is work in the area of QL practices among children (Anderson & Gold, 2006; Street et al. 2005), adults in India (Rampal, 2018), vocation-school students (Boistrup et al., 2018), and among workers in select professions (e.g., Kalman & Solares, 2018), to date there are no studies in relation to college students (of any age) in the U.S. This year-long multiple case study aims to address that gap by providing insights into the numeracy practices of eight undergraduate students at a small liberal arts college in the Southeastern U.S. The overarching research question that drives the project is: What are the numeracy practices of the students I am working with? The theoretical framework of numeracy as a social practice necessitates the use of ethnographic methods (Yasukawa et al., 2018). In this study, I engage in in-depth interviews with the eight participants several times per semester over the course of an academic year; while interviews from month to month have a similar structure, they evolve based on the student and their interests. During both the interviews and the focus groups, students share artifacts (e.g., course slides, homework, photos) that relate to the topics discussed. The purpose of working with students over the course of a full years is not to examine change over time—though that is likely to occur—but instead to capture information that a one-time interview simply cannot (Barton & Hamilton, 1998).

Analysis of data from the project is ongoing and informs the questions used in the interviews and focus groups. By the time of the conference, I will have early results to share.

The Impact of Near-Peer Mentors' Interactions Within Lower-Division Mathematics Classrooms

Jackson Drown
Boise State University

Brinley Stringer
Boise State University

Keywords: Near-Peer Mentors, Positioning Theory, Bloom's Taxonomy, Developmental Math

A near-peer mentor (NPM) is a general term for an undergraduate student who supports other undergraduate students' learning, typically in STEM courses. NPMs are associated with increased student performance and retention in STEM courses (Alzen et al., 2018; Barrasso & Spilios, 2021) and additionally help promote active learning techniques, reduce barriers to student help-seeking, and foster community within the classroom and throughout campus (Bronstein, 2008; Knight et al., 2015; Sellami et al., 2017) . However, there is a gap in the literature regarding exactly *how* NPMs have these impacts in classes. This study aims to address that gap – using positioning theory (Harré et al., 2009) as a theoretical framework – by examining the *positions*, *acts*, and *storylines* that structure NPM-student interactions. Additionally, the framework of Bloom's taxonomy (Bloom, 1956), which categorizes a hierarchy of cognitive learning (ranging from recalling to innovating), will inform the ways that NPMs encourage student learning through their interactions. This study is guided by the research question: "**How do NPMs impact both students and themselves through their in-class practices in lower-division mathematics classrooms?**"

This study will take place at Sageview University (SU), which is a mid-sized public university in the Mountain West region of the United States that serves roughly 27,000 undergraduate and graduate students. This study focuses on two developmental math course sections supported by NPMs: MATH 101 - Elementary Algebra and MATH 110 - Intermediate Algebra. MATH 101 focuses on academic success and self-efficacy in mathematics and is designed to prepare students for all other future math courses at SU. MATH 110 is intended to support students in their transition to college algebra as well as fulfill general education requirements. Both of these courses incorporate small-group activities and individualized work time during class, which provide opportunities for NPMs to interact with students. Data sources for this study include classroom observations of NPM-supported and non-supported sections, focus group interviews with NPMs and students, and student success metrics (grades, test scores, and pass rates). All titles used are pseudonyms to maintain anonymity.

In-class interactions between NPMs and students will be analyzed by identifying how questions that NPMs ask align with the six categories in Bloom's taxonomy, which will help identify how the NPMs are guiding students through their learning processes. Focus group data will be analyzed using positioning theory to identify themes that arise from student and NPM perspectives about their interactions in class. Their shared perspectives in conjunction with the classroom observation data will reveal patterns (*storylines*) that emerge from the *acts* and *positions* observed in class and discussed in focus group interviews.

Data collection for this study is ongoing during the Fall 2025 semester, but we anticipate that findings will highlight how NPM roles shape classroom culture and engagement. This research will additionally contribute to understanding how peer mentorship structures can strengthen student success in introductory mathematics and inform training for NPM programs.

The Impact of AI Tools on Metacognition and Study Skills

Emma Eastman
Boise State University

Brinley Stringer
Boise State university

Keywords: Artificial Intelligence, Metacognition, Study Skills, Introductory Math

The growing use of Artificial Intelligence (AI) tools by students in mathematics education presents both opportunities and concerns related to student learning. AI tools provide students with personalized learning experiences and instant feedback, but overreliance on these tools can undermine critical thinking skills and create opportunities for academic misconduct (Alasadi & Baiz, 2023; Lo, 2023; Yoon et al., 2024). Essential for addressing the concerns posed by AI tools are students' metacognitive skills and their adherence to academic integrity, both of which play critical roles in effective and ethical learning. Metacognition refers to one's knowledge of and ability to monitor, control, and regulate one's own thinking and learning processes and allows students to understand and regulate their thinking processes, leading to improved problem-solving skills and deeper learning (Desoete & De Craene, 2019; Flavell, 1979; Velzen & H, 2016). Academic integrity entails acting honestly, transparently, and responsibly in all academic activities, which is essential for fostering genuine learning (Riedesel et al., 2012; Seaton, 2019). The central question guiding this study is: **How do AI tools impact students' metacognitive awareness and study skills in introductory mathematics courses?**

Methods

This study will take place at Timberline University (TU), a mid-sized public university located in an urban area in the Mountain West region of the United States, serving approximately 27,000 undergraduate and graduate students. It focuses on students and faculty from six introductory mathematics courses, ranging from developmental math to precalculus. These courses are part of an award-winning program within TU's Mathematics Department, known for its innovative practices and strong student success rates. As part of the initial intervention efforts, instructors will have weekly discussions with their students about how to effectively and responsibly use AI tools.

Data sources for this research include pre- and post-semester student surveys assessing AI tool use and learning behaviors and student focus groups exploring study habits and AI usage. A qualitative survey will be sent to math instructors teaching these courses to explore their perspectives on AI's impact on student learning and academic practices. The data will be analyzed using a mixed methods approach to explore trends in AI use, metacognitive development, learning behaviors, and academic integrity. The pre- and post-semester surveys will be compared to assess changes in students' AI tool use, metacognitive awareness, and study behaviors following the initial interventions. The qualitative survey and focus group data will undergo thematic analysis to identify recurring patterns in students' AI use, learning strategies, metacognitive reflections, and perceptions of academic responsibility. Additionally institutional data will be used to contextualize the self-reported behaviors within broader academic trends.

Data collection for this study is ongoing during the Fall 2025 semester. We anticipate findings will reveal trends in how students engage with AI tools in relation to their metacognitive development and adherence to academic integrity. In addition, this study will contribute to the development of practices and guidelines regarding AI tools that enable both faculty and students to foster metacognitive awareness and support academic integrity.

Unpacking Students' Intuitive Limit Views Using Graphical Representational Approach

Kingsley Y. Adamoah
Arkansas State University

Keywords: Graphical, Intuitive, Limits, Object, Tool

Students' intuitive reasonings of the limit of a function at a point play a role in their overall conceptual understanding of the limit concept. Some researchers have defined intuitive limit views as students' understanding of the limit concept based on their everyday experiences (e.g., Adiredja, 2014; Adiredja et al., 2020; Rathnayake & Jayakody, 2023). In this study, I characterize limit views that are based primarily on reasonings with less emphasis on *mathematizing* those ideas as *intuitive.* Research shows that intuitive views are closely linked to students' graphical reasoning (Adamoah & Strayer, 2025). Building on the findings of Adamoah and Strayer (2025), this study explored how students' intuitive understandings of limits are connected with graphical representations. The results of this study highlight an instructional approach to help overcome what past research identified as students' misconceptions about the difference between $lim_{x\to a} f(x)$ and $f(a)$ (Bezuidenhout, 2001; Denbel, 2014; Fernández, 2004). Specifically, I addressed the research question: *How do students' intuitive limit views influence their **reasoning with** and **use of** graphical representations in calculus?*

This poster presentation shares a portion of the results of a larger study that framed students' limit views as *intuitive*, *informal*, and *formal* and their representational approaches as *graphical*, *numerical*, and *algebraic* to understanding the limit of a function at a point. This study was conducted at a large public university in the southeastern United States in Fall 2024 with 63 Calculus II students. First, all the 63 participants completed a pre-assessment survey that focused on the three limit views and three representational approaches. Afterwards, I chose four participants for each limit view type (intuitive, informal, and formal), and that resulted in 12 participants purposively selected for the structured task-based interviews where they explained more fully how they reason about limits with each of the three representational approaches.

In this study, I found that students' *intuitive* limit views were linked with the graphical representational approach in two ways: (1) viewing limits with graphical representation as an *object* and (2) viewing limits with graphical representation as a *tool.* Graphical representation as an object implies students' belief that "*it shows me*" and graphical representation as a tool implies students' belief that "*I'm using it to show*". Below was Jake's explanation of how the graph with removable discontinuity showed and helped him to distinguish $lim_{x\to 2} f(x)$ and $f(2)$.

> *The graph helps me understand that the limit isn't going to just be like a point* [referring to the (2, 5) on the graph]*. We're going to get to, so it's not going to be the value of F of 2 is 5. This helps me understand* [referring to the graph] *we're getting closer and closer to a number, just as like we're evaluating a function as it gets closer and closer to a point.*

Jake's explanation above characterizes students' reasoning with graphical representation as an *object*. On the other hand, students' view of graphical representation as a *tool* was seen as they used it intuitively to prove the formal conventional $\varepsilon - \delta$ definition as well as using graphs to visualize and validate analytic properties of limits. The results of this study offer calculus instructors ways to integrate and effectively use graphical representations either as an *object* or as a *tool* to help deepen students' understanding of limits including the formal limit definition.

"I'm Making This Math, Not Only Taking This Math": Poetic Transcription of a Trans Student's IO Calculus Experience

Mal McCall
Michigan State University

Kristen Vroom
Michigan State University

José Saúl Barbosa
Michigan State University

Catherine Davis
Michigan State University

Ayesha Maliwal Bundy
Michigan State University

Keywords: Poetic transcription, Inquiry-oriented instruction, Student experience

Inquiry-oriented (IO) mathematics instruction holds promise for engaging undergraduate students in meaningful mathematics. Yet, recent research shows that this promise may not be realized equitably without careful attention to classroom norms and participation structures. IO instruction can reproduce existing hierarchies, privileging dominant voices and marginalizing others (Ellis & Alzaga Elizondo, 2023; Ernest et al., 2019; Reinholz et al., 2022). Our project explores what IO instruction can feel like when it creates a more affirming space, especially for students from historically excluded groups.

We use poetic transcription to share the experience of Mal (first author), a trans undergraduate student in an IO Calculus 2 course. Mal was a student in Kristen's class, which used research-based IO materials on sequences and series (Vroom et al., 2025; Vroom & Davis, 2024; Vroom & Alzaga Elizondo, 2025). To address potential inequities, Kristen drew on Universal Design for Learning (Lambert, 2021, 2024; Vroom & Alzaga Elizondo, this issue). Mal participated in a reflective interview with Saúl, where they discussed both classroom experiences and research findings. Mal's reflections felt especially resonant, offering insight into the IO experiences that engage students in meaningful mathematics *and* affirm their identities.

We chose poetic transcription to center Mal's voice and emotional experience (Prendergast, 2009). Our work aligns with trans* methodology, attempting to "disrupt, disorder, and rupture" narratives of collegiate mathematics classrooms and cishegemonic research through a mix-gender research team including gender-nonconforming members (Jourian, 2017, p. 431). Like Rios et al. (2024), each team member created an individual poem by re-listening to the interview, selecting emotionally significant quotes, and juxtaposing them (Tremaine, 2022). Since each author created a poem, Mal's voice transcended from transcript data into personal connections for each of us (Lather, 1991; Richardson & St. Pierre, 2005). We shared drafts, provided feedback, and created a line bank from excerpts. Prioritizing Mal's preferences, we grouped lines by emergent themes and iteratively rearranged them to shape a cohesive emotional arc.

The final poem tells a hopeful story. It begins with Mal's previous view of math: "Math is a more straightforward thing // It's either right or wrong / No / You're wrong // It just ends there / People shutting down." It traces how their questions were dismissed and how identity shaped their experiences: "I would ask a question and I wouldn't really get an answer // I am a visibly queer person / Is this why this is happening...?" But in the IO course, something shifted: "The environment very much set the tone that it is absolutely okay to ask questions // I have never doubted that I am not being heard." Mal reflects on collaboration ("Working together, Not forced together"), how instruction recognized their whole self ("I am more than just the question I asked"), and growing mathematical agency ("I'm making this math / Not only taking this math"). The full poem illustrates that IO instruction can support belonging and joy in mathematics.

An Analytic Perspective Expanding the Construct of Practice-Linked Identities for Undergraduate Mathematics Students

Brandi Rygaard Gaspard
Texas State University

Kristen Lew
Texas State University

Keywords: mathematical identity, analytic procedures, theoretical perspective, calculus

Mathematical identity is broadly defined as the dynamically negotiated self-understandings students develop in the context of mathematics (Martin, 2006). With growing interest in mathematical identity among researchers and emerging conceptualizations continuing to appear, Darragh (2016) critiqued that mathematical identity has been thought of inconsistently, in terms of studies not clearly aligning choices such as the definition employed, theories, or methods. As distinct studies have different purposes that will inform their choices, authors using varying conceptualizations would be less problematic if there was more "theoretical coherence" in individual studies, avoiding "defining identity in a contradictory manner to the methods used and conclusions drawn" (pp. 24, 28). In this poster, we will propose a clarified analytic expansion of Nasir's (2011) "practice-linked identities", which has been used in cultural community settings such as high school basketball, mathematics, and track (Nasir & Hand, 2008; Nasir & Cooks, 2009) but not yet explored further in terms of analytic considerations or undergraduate settings. We offer ways to explicitly analyze practice-linked identities of undergraduate students as they develop a personal perspective towards themselves linked to practices they engage with in mathematics classrooms. We will also outline empirical examples from our work with Calculus I students to illustrate the analytic perspective. We are guided by the research question, "How can analyzing undergraduate students' development of practice-linked identities be clarified?"

Expansion of Practice-Linked Identities

Our perspective meets Nasir's practice-linked identities that individuals develop as they build a connection to local practices with Ernest's (2009) social constructivist view towards learning in that there is a reflexive relationship between individuals' understandings and the social world they encounter. This reflexive relationship includes students' understandings towards who they see themselves as within contextual classroom practices. In that realm, we emphasize the weight of the student perspective in developing their sense of self and how that perspective impacts how they define and take on practices. We expand Nasir and Hand's (2008) insights that practices become salient when students achieve access to the domain (the discipline of the community, i.e., undergraduate mathematics), access to self-expression (the ability to enact personal meanings), or integral roles (making valued contributions) for the purposes of analytic considerations in two ways. First, we clarify that this access occurs from the student point of view, and next, we introduce that there also must be evidence of personal importance. That is, it is not enough to consider a student to have developed a practice-linked identity by one of the three access criteria alone; students should express personal connections by either citing why the practice personally matters, such as aligning with their values (Seah & Andersson, 2015), using first-person active voice (Morgan, 2006), or expressing emotion (Kaasila, 2007; Tannen, 1979).

In the poster presentation, we will detail our analysis from a study of six Calculus I students' accounts via interview data to illustrate considerations for what evidence should exist to classify units of analysis as part of a student's developing practice-linked identities. We will provide several examples and non-examples while connecting to the perspective discussed above.

That's My Job!: A Preliminary Analysis of How Mathematicians View Teaching

Holly Zolt
Middle Tennessee State University

Elizabeth Roan
Texas State University

Keywords: Pedagogy, Abstract Algebra

As a person engages in the act of teaching, they make numerous decisions before, during, and after the instructional period. In making these decisions, teachers (mathematicians in our case) justify their decisions based on their perceptions of their obligations. For example, Fukawa-Connelly, et al. (2016) found that most mathematicians choose to lecture. Others, such as Woods and Weber (2020) corroborated these findings and suggested that lecture best served various goals such as the goal to cover certain content. While mathematicians engage in large scale decision making (such as lecturing), they also engage in smaller scale curricular decisions such as content ordering (e.g., Mirin and Rupnow, 2022). While research has started addressing why mathematicians make specific decisions, we began to ask the question, how do mathematicians conceptualize teaching and their role in the process– specifically which aspects of teaching and learning do mathematicians view as their responsibility and which aspects of teaching and learning are put on the student?

In this poster, we report on our initial steps towards addressing this question. Specifically, we report on our preliminary analysis of 14 mathematicians' answer to the questions: *What do you view as your role in teaching [abstract algebra]? What do you view as the students' role in learning [abstract algebra]?* The data originated from a larger dissertation study focused on pedagogical decision making in Abstract Algebra. Of these mathematicians, 4 self-identified as taking an inquiry-oriented approach, while 10 self-identified as taking a lecture-based approach. Each author independently conducted thematic analysis on the instructor role and student role questions. We then compared our themes and came to a consensus through discussion. We noticed six themes across how mathematicians conceptualized their role and four themes in how they viewed the role of students. From the instructors' view, the role of the instructor is: to spend time outside of class preparing for class and grading, to ensure that content moves forward within the class time frame, to inform overall trajectory of course content, to steward the discipline of mathematics - that entails providing correct information and fostering disciplinary norms, to spark students' interest in mathematics in order to motivate them to learn the math, to adhere to institutional guidelines. From the instructors' view, the role of the student is: to engage with the materials that I provide, engage with materials that I provide outside of class, to engage in self-exploration of the content, to positively interact with their peers.

We noticed that given information about how the instructor viewed their role, we could see who did or who did not identify as inquiry-oriented, with some exception. However, we noticed that there was no clear pattern in the relationship between instructional choice and how the instructor viewed the role of the student. This result is intriguing considering students tend to engage in different activities in IO classes compared to lecture based classes. This leads us to wonder if those patterns would hold true with more data. For this poster, we will report the results of our pilot analysis and present a study design which seeks to further address our research question.

Empowering Undergraduates Through Community-Engaged Mathematics Outreach: A Model for Undergraduate-Led AMC Workshops

Tanya Huffman
Florida Gulf Coast University

Daniel Kern
Florida Gulf Coast University

Kayla Kerr
Florida Gulf Coast University

Mason Huffman
Florida Gulf Coast University

Keywords: community engagement, STEM outreach, experiential learning

This study investigates the impact of undergraduate-led mathematics workshops on both undergraduate instructors and middle school participants. The workshops are built around topics from the American Mathematics Competition (AMC), providing a rich context for exploring problem-solving and conceptual understanding beyond the standard K-12 mathematics curriculum. Specifically, the study examines how designing and teaching these AMC-based workshops influence undergraduate students' communication, leadership, and research skills. It explores whether participation in these teaching experiences enhances undergraduates' confidence in explaining mathematical concepts, strengthens their collaboration and pedagogical abilities, and deepens their understanding of the broader societal impact of mathematics education. In parallel, the study investigates the extent to which middle school students demonstrate measurable knowledge gains after participating in the workshops. It assesses improvements in their problem-solving abilities and conceptual understanding through pre- and post-assessments, providing insight into how undergraduate-led initiatives can effectively support K–12 learning in mathematics.

This project builds on existing research highlighting the dual benefits of STEM outreach for both undergraduate instructors and K–12 learners. Studies consistently show that undergraduates who engage in teaching or outreach develop stronger communication, leadership, and content knowledge skills (Felege et al., 2022; Schalk et al., 2009). Feldon et al. (2011) found that graduate students with teaching experience demonstrated stronger research design and hypothesis development than peers focused solely on research.

STEM outreach further promotes confidence, collaboration, and public engagement skills essential for future educators and researchers (Curtis, 2017; Pickering et al., 2004; Philipp et al., 2016). Beyond undergraduate benefits, outreach programs have been shown to enhance younger students' engagement and conceptual understanding in science and mathematics (Volbrecht et al., 2019). Embedding such experiences within the undergraduate curriculum strengthens students' preparedness for professional STEM careers while fostering community connections and mentoring relationships (Caldwell et al., 2007; Pfund et al., 2012).

Overall, the research demonstrates that structured outreach creates reciprocal learning benefits—advancing STEM education through meaningful engagement between college and pre-college students.

Addressing the Need for an Undergraduate Statistics Teaching Observation Protocol

Caitlin Ireland
University of North Carolina at Charlotte

Keywords: introductory statistics, teacher practices, observation protocol, statistical knowledge for teaching

Historically, teacher knowledge has been categorized by the work of Shulman (1987): general pedagogical knowledge, knowledge of learners and their characteristics, knowledge of educational contexts, content knowledge, curriculum knowledge, and pedagogical content knowledge (Shulman, 1987). Ball, Thames, and Phelps (2008) expanded on these ideas by identifying mathematical tasks of teaching and tying them to Ball et al.'s (2008) adapted domains for mathematical knowledge for teaching (MKT).

The work of Gleason, Livers, and Zelkowski (2017) led to the Mathematical Classroom Observation Protocol for Practices ($MCOP^2$). The instrument "examines teaching mathematics for conceptual understanding through lenses examining teacher facilitation and student engagement" (p. 113). This research has served as the basis for continued observation protocol work, such as that conducted by the CoMInDS program (Lauren & Haberler, 2017). Another instrument that has been developed around the concept of observing teacher practices is the Mathematical Quality of Instruction (MQI) (Hill, Schilling, and Ball, 2004) which was used to measure Mathematical Knowledge for Teaching (Hill, Blunk, Charalambous, Lewis, Phelps, Sleep, & Ball, 2008).

However, there are few resources that pertain to observing practices in statistics education. Cobb and Moore (1997) argue that statistics' inherent focus on variability lends itself to a need for contextualization. They point out that "design, exploration, and interpretation [which] are core elements of statistical thinking" (p. 805) do not fall under traditional mathematical skills. Likewise, content in statistics differs from typical mathematics content. Thus, it is necessary to teach statistics differently than mathematics.

Groth's (2013) statistical knowledge for teaching (SKT) framework adds to Hill et al.'s (2004) domains with key developmental understandings (Simon, 2006, as cited in Groth, 2013), and pedagogically powerful ideas (Silverman and Thompson, 2008, as cited in Groth, 2013). Callingham and Watson (2011) published research on levels of SKT: aware, emerging, competent, and accomplished. In a hypothesized model of SKT, Batur (2021) embedded Callingham and Watson's (2011) levels with Groth's (2013) framework to develop a five domain framework that can be assessed at four levels, all with the aim of centralizing statistical literacy.

It is using this model that I believe I could create items for the development of a new instrument to observe a teachers' current abilities in statistical teaching, and potentially assess or evaluate their SKT. Therefore, my current questions for this study are 1) How are teachers currently enacting SKT in the classroom? And 2) How can we observe and evaluate SKT in the classroom? My plan to answer these questions would be to 1) observe for qualitative data collection what is currently happening in statistics classrooms, and 2) use the extant literature and my observations to find or write items for a new observation protocol. The target population for this instrument would be AP Statistics high school teachers or introductory statistics college course instructors. Further development of the instrument would require a validation study.

Understanding Strategies of Multiplication and Division Through Worked-Out Examples Using an Inquiry-Based Approach

Emmanuel Onyegu
Utah State University

Michelle Frierson
Utah State University

Keywords: worked-out examples, multiplication, division, inquiry-based approach

Aim and Literature

The study aimed to enhance prospective elementary teachers' conceptual understanding of multiplication and division strategies. This project examined whether combining worked-out examples with an inquiry-based approach could improve comprehension, confidence, and instructional readiness.

Cognitive science shows that worked-out examples with step-by-step reasoning build procedural and conceptual understanding when paired with self-explanation and peer discussion (Atkinson et al., 2000; Renkl, 2002; Chiu & Chi, 2014). Inquiry-based learning fosters exploration but can overwhelm learners without scaffolding (Kirschner et al., 2006). Integrating both provides structure, guided inquiry, and collaborative meaning-making in mathematics.

Methods

Pre-service elementary teachers were randomly placed in groups of four and given worksheets with fully solved examples. Each group studied two different multiplication or division strategies (e.g., area model, lattice, box method, repeated subtraction, grid, and traditional algorithms). For 15–20 minutes, groups discussed the correctness of each solution and compared methods, leading to rich inquiry about how multiplication strategies relate to identifying divisors in division. After the initial discussions, a carousel activity began: two members from each group rotated to teach their strategies to another group while learning two new ones from the remaining pair. Each rotation lasted 20 minutes, and after four rotations all teachers had learned all eight strategies before returning to their original groups. Throughout the activity, students engaged actively, communicated clearly, identified patterns, and explained their reasoning, showing deeper inquiry than in previous semesters.

Discussion

Students exhibited greater mastery and confidence in explaining and applying all multiplication and division strategies. Students expressed satisfaction and reported that teaching peers enhanced their confidence and understanding. Combining worked-out examples with inquiry-based instruction created an engaging and supportive learning environment where all students participated meaningfully. The approach promoted mathematical discourse, peer collaboration, and self-explanation, key components of conceptual understanding. Integrating worked-out examples within an inquiry-based framework effectively supported preservice teachers' conceptual and procedural fluency in multiplication and division. This approach empowers future teachers to confidently teach diverse mathematical strategies and foster conceptual understanding among their own students.

Mathematics Self-Efficacy in Collegiate Calculus

Christine M. Phelps-Gregory
Central Michigan University

Keywords: beliefs, calculus, mathematics self-efficacy

Mathematics self-efficacy (MSE) refers to students' beliefs in their ability to successfully perform mathematics (Bandura, 1997). MSE is an important construct because it has been shown to impact students' perseverance, college major choice, likelihood of remaining in college, and success or failure in mathematics (Gill, 2019; Grigg et al., 2018; Hackett, 1985; Street et al., 2017). Generally high MSE has been linked to more beneficial outcomes, such as higher grades or choosing a STEM major. MSE can be measured globally, for an overall subject like mathematics, or locally, for specific topics or problems (Bandura, 1997).

A review of self-efficacy in higher education found that students' self-efficacy can change in higher education and that interventions designed around social cognitive theory or practical experiences that allow students to feel successful can improve self-efficacy (van Dinther et al., 2011). For MSE and MSE in calculus specifically, less research has been conducted though Nicolescu (2015) found that calculus at a community college generally raised students' MSE.

Research Design

This study examined the global and local MSE of students enrolled in collegiate calculus, with the goal of identifying and qualitatively describing cases of participants who reported changing MSE. Participants were 14 students enrolled in a first collegiate calculus class. A semi-structured interview was used to explore participants' mathematics experiences prior to calculus, their experiences in calculus, and their global self-efficacy beliefs before calculus and in calculus. Participants were also asked to rate their local MSE for three calculus problems (one on evaluating a limit graphically, one on finding a derivative that required the product rule and knowledge of the derivative of trigonometric functions, and one on using the first derivative test to find local extrema). Participants were asked to describe why they felt that confidence level and what solution strategy they would use to solve the problem.

Findings and Implications

Results show that some participants reported changed global MSE because of calculus, with 7 reporting lower MSE in calculus than previous mathematics courses, 4 reporting higher MSE in calculus than held previously, and 3 reporting the same MSE in calculus as other mathematics classes. Participants reported reasons for changes to their MSE included difficulty of the exams, pace of the courses, and differences in teaching style. For local MSE, participants were generally confident on the problems, reporting the highest confidence in finding the procedural derivative using the product rule (mean confidence 4.5 out of 5) and the lowest confidence on using the first derivative test (mean confidence 3.71 out of 5). Results have implications for our knowledge of MSE, a relatively stable belief that can still change under certain conditions (Bandura, 1997; Byars-Winston, et al., 2017; Friedel et al., 2010). Results also have implications for collegiate calculus instructors who wish to better support their students.

Relationships Between Pre-Service Teachers' Decentering Actions and Quantitative Reasoning

Kevin C. Moore
University of Georgia

Luke Jiawei Zhuang
University of Georgia

Cun Ma
University of Georgia

Geon Lee
University of Georgia

Keywords: Quantitative Reasoning, Decentering, Pre-Service Teachers

The emergence of quantitative reasoning—conceiving situations in terms of measurable attributes and relationships between those attributes (Carlson et al., 2002; Karagöz Akar et al., 2022; Thompson, 2011; Thompson & Carlson, 2017)—as critical for K-16 students' mathematical development has generated a need for exploring its role in preparing future teachers. Also related to supporting K-16 students' mathematical development is the act of decentering, which involves a teacher putting aside their own ways of thinking for the purpose of discerning and building a model of their students' thinking (Baş-Ader & Carlson, 2022; Carlson et al., 2022; Ellis, 2022; Hackenberg et al., 2024; Silverman & Thompson, 2008; Teuscher et al., 2016). Notably, researchers have recently illustrated an important link between teachers' decentering and quantitative reasoning capacities (Tallman & Frank, 2020; Tallman et al., 2024).

In this poster, we explore secondary mathematic pre-service teachers' (PSTs') decentering actions and their quantitative reasoning. Specifically, we draw on clinical interview data to illustrate relationships between the PSTs' enacted meanings and the ways in which they appraise secondary students' solutions and reasoning. The PSTs' enacted two primary types of meanings. As one type, they drew on meanings that consisted of declarative facts and indexical associations. For example, some PSTs drew on a learned fact that involved a type of function (e.g., a quadratic function) necessarily being associated with a shape (e.g., curving up). As a second type, they drew on meanings that involved enacting quantitative operations to make sense of the posed solutions and reasoning. These PSTs made sense of a graph by considering how it might have emerged via the covariation of the two quantities along the axes (e.g., y changes by three times the amount x changes). We noted that in some cases, PSTs drew on both types of meanings to make sense of the posed student solutions and reasoning.

With respect to the PSTs' decentering actions, their dispositions varied depending on the enacted meanings. When PSTs enacted meanings foregrounding declarative facts and indexical associations, they typically focused on the extent the posed solutions and reasoning either violated or maintained those learned facts and associations. For instance, if a given graph had a learned shape they associated with a function the secondary student intended to graph, they deemed it correct. If it did not have the learned shape they associated with the function, they deemed the student incorrect regardless of the student reasoning presented. When PSTs enacted meanings foregrounding quantitative reasoning, they predominantly searched for various ways posed student solutions and reasoning can be considered a viable and correct solution to the posed task. For instance, regardless of the familiarity of a given graph's shape, these PSTs considered conventional and unconventional ways in which the graph might convey the quantitative relationships the graph was to convey. This enabled them to account for unfamiliar student reasoning that was viable. In general, we illustrate that PSTs' quantitative reasoning provided a flexible grounding for considering students' diverse ways of reasoning as compared to instances in which PSTs enacted declarative facts or indexical associations.

Readiness for the Next Disruption: Lessons From Instructors' Struggles During COVID-19

Modiu Olaguro
Virginia Tech

Estrella Johnson
Virginia Tech

Naneh Akparian
San Diego State University

Keywords: Crisis-readiness; Pandemic pedagogy, Emergency remote teaching, STEM instruction, Resilience theory

When higher education rapidly shifted online in 2020, instructors across STEM disciplines faced fundamental challenges. They include academic integrity concerns, inequitable access to technology, insufficient institutional training, unclear communication, and significant emotional strain (Daniel, 2020; Pokhrel & Chhetri, 2021). Using a national dataset of 934 chemistry, mathematics, and physics instructors' open-ended survey responses, this study investigates which pandemic-era challenges instructors faced during pandemic response teaching.

This poster is theoretically grounded in resilience theory (Hoiling, 1973; Norris et al., 2008). While it can be argued that undergraduate education has survived the pandemic, the disruption it ushered suggests that a strategy of survival is insufficient. To better prepare for the potential disruptions in the future, it is helpful to adopt a strategy of "community resilience" that integrates robustness, redundancy, resource mobilization, rapidity, communication, and social capital into a web of "adaptive capacities" (Norris et al., 2008, p. 127). Applying these frameworks to instructional systems, resilience is not simply the readiness to make the in-person-online transition on the outset of the next disruption. Rather, it is the extent to which such a move does not compromise academic integrity, dismantle professional communities, widen inequity, or encroach on student learning.

This study draws on text responses in a large-scale survey of STEM instructors across U.S. institutions. We conduct a qualitative thematic analysis focused on two research questions:

1. What pandemic-era instructional challenges did instructors face?
2. What capacities or structures did they identify as lacking?

Preliminary review reveals recurring themes: (a) insufficient technological preparation and emergency training; (b) academic integrity and assessment validity concerns; (c) lack of communication and unclear expectations; (d) inequitable access to devices, software, or stable internet; (e) emotional exhaustion and social isolation for both faculty and students; and (f) the need for departmental and institutional infrastructure that is proactive rather than reactive. These findings indicate that in addition to asking whether instructors can teach wholly online again, more focus should be on how they define readiness—technologically, pedagogically, institutionally, and psychologically. Findings can inform a framework that explicates fundamental criteria for emergency response teaching preparedness needed in STEM departments: rapid development of online assessments resistant to cheating, proactive instructor training, better communication systems, equitable access to digital tools, and structures that preserve community and belonging.

This poster contributes to the growing scholarship on lessons learned from COVID-19 by: (1) shifting the conversation toward future-focused resilience; (2) documenting instructors' own reflections on challenges; and (3) identifying the kinds of instructional, technological, and institutional capacities STEM that we can be investing in now.

Leveraging Open Educational Resources and Interactive Technologies to Enhance Learning in Undergraduate Mathematics: A SoTL Approach

Kim Johnson
West Chester University of Pennsylvania

This study investigates the impact of Open Educational Resource (OER) modules on student learning and perceptions in a mathematics content course for elementary education majors. Rising textbook costs have created significant barriers to student access and learning (Perry, 2022; Osterman, 2021). Research demonstrates that interactive technologies, such as H5P and GeoGebra, can increase student engagement, motivation, conceptual clarity, and self-managed learning (Shadaan & Eu, 2013). Additionally, OER initiatives have been associated with both academic and economic benefits for students (Thurman, 2020).

Keywords: Open Educational Resources, Teacher Education, Elementary Content Courses

Methods

Fifteen weekly OER modules were developed using H5P and GeoGebra and embedded in the university Learning Management System, replacing a $45 publisher inclusive access homework platform. Student outcomes were assessed via final exams and surveys measuring engagement, perceptions of learning, self-paced learning, and feedback utilization. Using he Scholarship of Teaching and Learning (SoTL) provides a research-based framework for systematically examining how teaching practices affect student learning outcomes. Additionally, the study explores whether interactive OER activities enhance engagement, understanding, and self-directed learning of undergraduate education majors, and considers how this approach can be applied to other mathematics courses.

Results and Discussion

Initial analysis comparing final exam scores across semesters prior to the OER modules and those using the OER modules indicated no statistically significant difference ($P = 0.1151$), suggesting that students using the OER modules performed comparably to those using the publisher platform. Despite similar performance outcomes, student survey responses revealed strong positive perceptions of the OER activities. Approximately 79% of students reported that the interactive modules helped them learn the course content, 88% valued the ability to work at their own pace, and 94% indicated that immediate feedback encouraged continued engagement. Qualitative feedback reinforced these findings, with students noting that the weekly OER activities were more engaging and beneficial than the traditional platform, increasing motivation and enjoyment in learning.

While OER modules did not significantly alter final exam performance, they positively influenced student engagement, motivation, and perceptions of learning. The ability to work independently and receive immediate feedback fostered self-directed learning and a more meaningful learning experience. Framed through the SoTL perspective, this study illustrates how systematically investigating teaching innovations can provide actionable insights to improve instructional practices and support student success. This model can be applied to other undergraduate mathematics courses, promoting affordable, interactive, and evidence-based teaching approaches that enhance both learning outcomes and student confidence, particularly for prospective teachers.

Examining the Nature of Participation in NREUPs: Narratives of Racially Minoritized Students

Christopher C. Jett
Georgia State University

Gulden Karakok
University of Northern Colorado

Keywords: Mentoring, racially minoritized students, REUs, undergraduate research experience

The Mathematical Association of America's (MAA) National Research Experience for Undergraduates Program (NREUP) provides opportunities for racially minoritized students to collaborate with faculty in the mathematical sciences on summer research projects at a diverse range of institutions. Through a rigorous and accessible research experience, NREUP's goals are to increase undergraduate degree completion rates and ignite students' interest in obtaining graduate degrees and embarking upon careers in the mathematical sciences.

Since 2003, the NREUP has supported approximately 100 faculty members and 768 students, with about half of them identifying as Black/African American and about 35% as Latinx/Hispanic. In this poster presentation, we will share results of the analysis of follow-up interview data from students who participated in the NREUPs during the summers of 2019-2024. This work focused on this time frame as part of evaluative efforts examining the grant project's five-year period. Of the 151 former NREUP students, one third did not provide information about their post-undergraduate whereabouts, and the remaining students were placed into two distinct categories — (1) those who were attending graduate school in the mathematical sciences and (2) those who were pursuing careers in the mathematical sciences.

We randomly selected 10 students from each category to capture the longitudinal impact of the program. Ten students from category 1 participated in the study; however, only eight students from category 2 did so. The reason why we did not reach our target number of participants from category 2 during the given time frame (until August 31, 2025) was because we did not have access to the working professionals' email addresses. As a result, our total sample size consisted of 18 former NREUP students from racially minoritized groups. Our research question was: What is the nature of NREUP participants' experiences from diverse institutions?

This qualitative study was evaluative in nature (Patton, 2015). We conducted online, semi-structured interviews that lasted about 50 minutes. Sample interview questions included: In what ways did the program shape your decision about whether or not to attend graduate school? In what ways did the program shape your decision about your future career? Each researcher read through the individual transcripts to engage in preliminary analysis and highlight the positive aspects and areas of improvement for NREUPs. Then, we used open coding to perform data analysis and to extract overarching themes (Saldaña, 2021). Next, we explored math identity work and mapped our findings onto this theoretical frame (McGee, 2015; Voigt et al., 2023).

Across both categories, students consistently reported gains in knowledge about the research process, the benefits of having formal and informal mentors to learn more about discipline-based opportunities, and the advantages of collaborating with undergraduate and graduate student peers. Students also praised the structure of the program and expressed that it led to increased confidence as emerging scholars within the mathematical sciences. Given this, we highlight potential avenues for future RUME work that considers different programmatic structures and mentoring approaches associated with NREUPs. In all, our study extends prior work regarding undergraduate research experiences (Castillo-Garsow & Castillo-Chavez, 2016; Sturner et al., 2017) by following up with participants from racially minoritized groups who participated in NREUPs.

Exploring the Relationship Between Language and two Problem Types

Molly Stern
Teachers College, Columbia U.

Anthony Zhang
Teachers College, Columbia U.

Esther Issever
Teachers College, Columbia U.

Nicholas Wasserman
Teachers College, Columbia University

Paul Christian Dawkins
Texas State University

Keywords: Problem types, Language, Mathematics register, Mathematical domains

Much of the study of mathematics is reducible to the problems students are asked to complete. We are thus motivated to explore the language within problems – which would be part of the mathematics register (Halliday, 1975; Pimm, 1987) or even its own genre (Bakken & Andersson-Bakken, 2021). Yet, whereas mathematical terms are often both well-defined and consistently used, the language used for posing mathematical problems – our interest – is neither.

In a previous RUME report, Wasserman and Dawkins (2025) elaborated 8 problem types. In that preliminary theoretical paper, two common problem types across K-16 mathematics were noted as distinct, yet at times difficult to differentiate. SOLVE problems were about producing "the complete solution set of mathematical objects that satisfies a given set of properties" and EVALUATE problems were "the outcome of a procedure or operation" (p. 1023). The first might be understood as a search for particular elements in set builder notation, e.g., $\{x \mid +(5,x)=12\}$; the latter as the output of a function, e.g., +(5,7). This proposal reports on work that further explored these two categories of problems in relation to the language used to pose them.

Methodology

Specifically, our work was guided by the following research question: "What, if any, linguistic features mark and distinguish prototypical SOLVE and EVALUATE problems across K-16 mathematics textbooks?" Five coders worked on the project. After discussing the two problem types, each selected a different elementary, middle, high school, and college textbook; and each added about 75 problems per book, from its breadth, that they felt could be unambiguously categorized as either SOLVE or EVALUATE. Coding then included the "problem stem" – often an imperative verb (e.g., Find), though sometimes an interrogative (What is) – and the problem type, along with some other basic information (e.g., grade level). Next, the research team coded each other's problems, with disagreements being adjudicated or problems being removed as ambiguous. The result was a collection of (n=915) problems across K-16 that the five coders could unambiguously code as either SOLVE or EVALUATE.

Findings and Implications

From this work, we briefly share three claims (data supporting them, and others, will be shared on the poster): i) Some verb stems were distinctly associated with a problem type, e.g., "Add" and "Compute" were EVALUATE whereas "List" and "What are" were SOLVE, and other common verb stems like "Find" and (interestingly) "Solve" may have been either type of problem; ii) Two-verb structures (e.g., Use… to determine…) were primarily EVALUATE; and iii) Grade level impacted the distribution of problem types as well as particular verb stems.

We see this work as valuable because it informs how we might clarify to students the nature of a mathematical problem – either as SOLVE or EVALUATE – by incorporating specific linguistic choices into how we pose it.

Keywords: Conference, Motivation, Career Development

Academic disciplinary conferences are believed to be critical sites in academic trajectories (Henderson, 2015), yet the people who attend them likely have many different reasons for doing so. These roles and motivations remain under-researched. In this study, we examine both the intellectual and social community of the SIGMAA on RUME Annual Conference as part of people's decision to attend (or not), including barriers and issues of access to the community.

We developed a survey based on the work of (Fukawa-Connelly et al., 2025). The survey included demographic questions (about participants' conference attendance, home department, career stage, and research expectations), questions about their current and first reasons for attending the SIGMAA-RUME conference, and questions about the participants' experienced barriers to participation. Links to the survey were posted in various locations at the 2025 SIGMAA-RUME conference and via the RUME Google Group listserv. In total, 165 people completed all survey items, and five more completed at least two-thirds of the survey.

RUME participants reported a wide range of reasons as "most" or "very" important for attending the conference. The three reasons with the largest share rated as "most" important were "being part of a warm/welcoming community" (41%), feeling like the conference is their academic or intellectual home (38%) and networking (34%). When including ratings of "very important," the most commonly reported reason is learning about other people's work because it's interesting (72%), although many other reasons were close behind. The two reasons participants were most likely to rate as either "somewhat" or not important were participation as a job expectation (84%) and advancing their career (54%). These reasons differed slightly depending on the career stage of the participant. For example, graduate students and new faculty members were much more likely to assign increased importance to "advancing their career," while experienced faculty members were much less likely to do so. However, within each career stage, the relative importance of the various reasons stayed roughly consistent. Comparing participants' reasons for attending the conference to their reasons for *first* attending suggests modest shifts as participants become more experienced.

A total of 91 participants identified at least one barrier to their recent participation in the SIGMAA-RUME conference. These barriers included (in decreasing frequency) the feeling of a lack of belonging, financial barriers, the perceived relevance of conference topics, the feeling of "imposter syndrome," scheduling and workload conflicts, accessibility, and the political climate.

These findings suggest that community—both intellectual and social—matters when people decide whether to attend the conference. These aspects bring people to the conference initially and lead them to return. The disciplinary focus, tightly connected research groups, and personal relationships mean that people can feel "at home" both as scholars and as people, but these same aspects can also pose barriers to participation.

From Belief to Practice: Investigating Growth Mindset as a Bridge Between Teacher Cognition and Student Experience in Mathematics

Chukwuemeka Metu
The University of Alabama

Ifeoma Metu
Nnamdi Azikiwe University, Awka

Nigar Altindis
The University of Alabama

Keywords: growth mindset, motivation, confidence, mathematics, beliefs

Teacher beliefs are integral in shaping classroom culture as they affect the teacher-student relationship, students' learning-related processes, and learning outcomes (Wolf & Brown, 2023). Yeager et al. (2019) believes that embracing a growth mindset can enhance students' academic outcomes and teachers can cultivate growth mindset cultures in mathematics classrooms through specific practices and interactions (Murphy et al., 2021). Many students experience negative attitudes in math-related contexts, and these responses result from lack of confidence in solving mathematical problems, which has an impact on the student's motivation and learning (Aguilar, 2021; Metu et al., 2023; 2025). These negative responses could be impacted by the teacher's belief found to be associated with an educational system's overall efficacy (Li & Ma, 2025). Teachers with growth mindset are able to influence their pedagogical decisions and their classroom conduct (Laine & Tirri, 2023; Zhang & He, 2025). However, previous studies focused primarily on student-centered beliefs, while giving little attention to the teacher's role in shaping classroom behavior, especially in mathematics classrooms. Despite growing literature on the importance of growth mindset in classroom settings, there is limited literature on how undergraduate mathematics teachers' growth mindset influences students' belief, motivation and confidence. This study examined: (i) the beliefs teachers hold about the nature of mathematical ability and learning; (ii) the extent the teachers' growth mindset predicts students' beliefs, motivation, and mathematics confidence.

This study adopted a descriptive correlational research design, which allowed for both understanding the teacher's perception of growth mindset and determining the strength of the relationships between the teacher variable and the students' variables. The sample size included Seven (7) teachers and 181 first year students from the mathematics education unit, University of Nigeria, Nsukka. The instruments "Implicit Theory of Intelligence Scale (Dwerk et al., 1995)" for teachers and students growth mindset; "Student Opinion Scale (Sundre, 2000)" for motivation; and "General Self-Efficacy Scale (Schwarzer & Jerusalem, 1995)" for students' confidence were all adapted. These surveys (with likert scale 1-5) were distributed and collected through the face-to-face approach. The collected data were analyzed using descriptive statistics and regression analysis.

Result showed that $Mean = 3.73; SD = 1.04$ was obtained about the teachers' belief. While the scores were moderately dispersed, the majority of the teachers leaned towards the growth mindset belief. This implies that the teachers support the principles of growth mindset that with practice and strategies, an individual's ability in mathematics can be developed. Regression analysis revealed that teachers' belief accounted for 14.4% of variation in students' growth mindset($r = 0.38$), 21.2% of motivation($r = 0.46$), and 2.9% of confidence($r = 0.17$). Therefore, students are encouraged to seek out faculty with growth mindset attributes as they are more inclined to creating a supportive learning environment. This result will also encourage students to form peer groups that share a growth mindset, thus increasing their motivation and participation.

Keywords: Incoming Math Students, Graphing, Integrated STEM, Design Experiment

We report on our analysis of student reasoning during the first iteration of a design experiment (Cobb et al., 2003) in which we implemented a lesson that integrates mathematics and biology content through graph interpretation activities. Montclair State University (MSU) has seen an increase in the number of first-year STEM majors who fail college Precalculus, contributing to lower retention and graduation rates. In response, the MSU math department developed a course called Approaches to College Mathematics (ACM) to prepare these students for Precalculus. Research shows that integrating graphing with other STEM content can lead to improved learning across the integrated content areas (e.g., Basu & Panorkou, 2019; Gültepe, 2016; Panorkou et al., 2022). We conjectured that activities we designed for ACM with an integrated STEM context might support students in reasoning emergently about graphs and their covariational meanings. Moore and Thompson (2015) define emergent (in contrast to static) shape thinking as reasoning about a graph as a meaningful trace of the relationship between two covarying quantities. Therefore, we explored the following research question: What kinds of reasoning do ACM students engage in as they work with the integrated lesson we designed?

The lesson consisted of a whole-group graph comparison task, an in-depth analysis of graphs in student pairs, and a concluding presentation by students to showcase their learning. Our analysis was based upon multiple data sources: student handouts, group digital posters, and instructor (second author) field notes. Two researchers, neither of whom were the instructor, independently coded the student data, employing a qualitative coding process that began with deductive analysis and then moved into inductive analysis (Hammersley, 2004; Patton, 2015). After discussion and comparison of codes, there was 100% intercoder agreement.

We noted three major categories to classify students' static versus emergent thinking, as well as integrated versus unintegrated reasoning: unintegrated (biology only) with no shape thinking, unintegrated (math only) with static shape thinking, and integrated thinking (both biology and math) with emergent shape thinking. We found that these students engaged in reasoning about integrated math and biology content only when they were engaging in emergent shape thinking. When their shape thinking was static, their reasoning was unintegrated. We argue that this shows the potential for lessons with an integrated design to foster deeper mathematical understanding in ACM students. At the same time, we noted that students struggled with details of mathematical terminology and notation, such as the origin, domain and range, scale, and the labeling of points. We also noted a significant amount of interval-point confusion, a long-known graphing difficulty (Leinhardt et al., 1990). These difficulties are typical of the struggles ACM students face and may be exacerbated by the differences between graphs that appear in biology and math texts.

Our poster will include the research design, graphs and interpretation tasks, students' written responses, and a discussion of how we make sense of their integrated reasoning through a static-emergent shape thinking framework. Student data will be showcased, organized according to major themes from our findings.

Acknowledgements

We thank the ACM team as well as Chris Langner and Elena Petroff, our colleagues in the MSU Biology Department who helped us access their introductory textbook.

Reimagining Calculus Through Team-Based Course Redesign

Samara Chamoun
University of Notre Dame

Kathy Quardokus Fisher
University of Notre Dame

Neil Nicholson
University of Notre Dame

Kathryn Mulholland
University of Notre Dame

Anne Pilkington
University of Notre Dame

Richard Hind
University of Notre Dame

Kuangchen Hsu
University of Notre Dame

Keywords: Transformational change, Calculus redesign, Value-based vision, Team efforts

Change guided by a shared vision and aligned with a department's cultural norms can be transformative. With a charge from administrative leadership, Notre Dame (ND) Learning has established the Foundational Course Transformation Academy (FCTA) as a team-based process grounded in literature to facilitate sustainable change. Currently, ND Learning is partnering with the Department of Mathematics to redesign the Calculus I course with an eye toward building learning-centered environments that are better for students and instructors.

According to Henderson et al. (2011), effective change strategies must align with the beliefs of those involved, avoid uniform policies that deter individualized solutions, and be compatible with the complex ecosystems of the university. Reinholz & Apkarian (2018) emphasize that sustainable changes require attending to the structures, symbols, people, and powers that define a department. Quardokus Fisher & Henderson (2018) and Quardokus Fisher & Koretsky (2021) further argue that change is impactful when it grows from faculty's concrete visions, aligns with their aspirations, and provides them with autonomy and resources.

In Phase 1 of the process, informed by this literature, the FCTA team created community norms, reviewed literature on course redesign and effective mathematical practices, and created a shared value-based vision. They also engaged with stakeholders within and beyond the Department of Mathematics, benchmarked with peer institutions, and acquired data from the Office of Institutional Research. Aligning their individual proposals with the data, stakeholder feedback, and relevant literature, the team crafted the following transformational goals: a) implementing a learning cycle of exploration, sense-making, formalization, and application (Schoenfeld, 2016); b) redesigning content to include targeted precalculus review; c) redesigning assessments to align with the five strands of mathematical proficiency (National Research Council, 2001); d) embedding holistic students' support structures (Johnson & Hanson, 2015); e) restructuring course coordination and formalizing ongoing training and support for graduate student instructors and postdocs (Rasmussen & Ellis, 2015); and f) designing 1-credit support courses (one for pre-calculus review, and others connecting calculus to disciplinary contexts).

Currently, the team is in Phase 2, applying the backward design framework (Wiggins & McTighe, 2005) to define course competencies and learning outcomes aligned with the transformational goals crafted in Phase 1. Next, the team plans on creating instructional material (syllabus, modules, assessments) informed by the learning outcomes, while continuously sharing progress and receiving feedback from stakeholders. In Phase 3, the team will implement the redesigned course, meet regularly with instructors, revise and assess the course redesign, develop a sustainability process, and conduct further research. In this poster, we share our redesign process, along with how we plan to assess it for faculty, administrators, and students involved.

Acknowledgments

We would like to thank Ron Metoyer (Vice President and Associate Provost for Teaching and Learning), all members of the Kaneb Center for Teaching and Learning, Office of Digital Learning, OIT's Teaching & Learning Technologies, and the Department of Mathematics at the University of Notre Dame.

Navigating Calculus: Challenges and Assets of First-Generation STEM Students

Carlos Acevedo
Texas State University

Keywords: Assets, Calculus, First-generation students, Persistence

Students tend to encounter challenges when facing gateway courses, such as calculus. For example, calculus courses tend to have high failure rates (Bressoud et al., 2013), discourage students from persisting because of certain classroom experiences (Rasmussen & Ellis, 2013), and have an implicit mechanism that pushes students away from STEM (Olson & Riordan, 2012). There is little research on how first-generation college students navigate calculus. However, there is research that has shown these students often face challenges throughout their college journey, such as financial hardship, work and have caregiving responsibilities, gaps in academic preparation, and feelings of isolation (Chen & Carroll, 2005; Ardoin, 2017; Covarrubias et al., 2019).

Nevertheless, Gutiérrez (2008) warns that research on the achievement gap overshadows the advancement of marginalized groups and "suggest[s] a research agenda that focuses on advancement, on excellence, and on gains within marginalized communities" (p. 362). Therefore, this poster will also present findings on the assets first-generation college students activated while navigating through calculus. That is, I will present what specific challenges they encountered throughout their calculus journey and the assets that they employed that supported their persistence. To stay consistent with literature, I define first-generation college students as those whose parents or guardians have not earned a four-year degree. My specific research questions are:

1. What obstacles do first-generation STEM students encounter as they transition into and navigate their calculus journey?
2. What assets do first-generation STEM students draw on to support their persistence in their calculus journey?

I will note that when I refer to their calculus journey, I am including what they experienced within the university and outside the university. Sometimes these obstacles get intertwined with their experience taking their semester long course, which participants still need to navigate with challenges that happen outside the classroom. Moreover, all participants passed their calculus course and took the course within the same university.

This study uses interpretative phenomenological analysis (IPA) to explore how participants understand and reflect on their lived experiences. Rather than stopping at description, IPA seeks to highlight participants' perspectives while also interpreting the significance of their accounts (Larkin et al., 2006). The approach combines three elements: phenomenology, hermeneutics, and idiography. Phenomenology guides the focus on participant's shared experiences, in this case, how they navigate and persist through calculus. Hermeneutics introduces a double layer of interpretation. That is, participants work to make sense of their own experiences, and the researcher then interprets those reflections. Idiography centers on detailed analysis of individual cases before drawing connections to broader patterns across participants.

My poster will present initial findings from eleven STEM, first-generation students who are reflecting on their calculus journey from their semi-structured interviews. I look forward to sharing my study with the RUME community and gathering feedback on how to conceptualize their calculus journey in relation to challenges and assets.

The Impact of Attending Mathematics Tutoring on STEM Retention

Joshua Pearcy
University of Oklahoma

Melissa Mills
Oklahoma State University

Keywords: explanatory sequential design, mixed methods, STEM retention, peer tutoring

University students who choose STEM majors often do not complete their degrees in STEM. A 2009 study found that 55% of STEM majors leave STEM fields altogether (Chen, 2009). Many STEM majors require a sequence of mathematics courses. The PCAST 2012 report found that engineering majors who were enrolled in math courses that utilized active learning strategies were more likely to persist in engineering majors (PCAST, 2012). Students have been shown to be more actively engaged during a peer tutoring session than in lecture, as measured by the number of questions asked by the student (Graesser & Person, 1994). This study examines how attending peer tutoring for mathematics courses impacts STEM retention.

Multiple studies have found that attending peer tutoring correlates to higher grades in mathematics classes (Byerley et.al, 2018; Rickard & Mills, 2018; Xu, et al., 2001). In fact, a study of ten mathematics tutoring centers in the USA found that five centers had a statistically significant positive correlation between course grades and number of visits, three had no significant correlation, and two had a negative correlation (Byerley et al., 2022). Clearly, passing required mathematics classes is necessary for a student to persist in their major, but there may be other social benefits to attending tutoring such as students' sense of belonging and formation of a positive mathematical identity (Bjorkman, 2019).

Our research questions are: What is the relationship between math tutoring center usage and STEM persistence? What do students identify as factors contributing to their STEM retention?

For this study, we employed an explanatory sequential mixed methods design. Our first quantitative phase examined the statistical correlation between tutoring visits and STEM persistence. These results informed the second qualitative phase which consisted of interviews with seven STEM majors who attended tutoring.

We gathered quantitative data for all STEM majors every semester for a two-year period. These measures included their major at the beginning of each semester, math course grades each semester, and the number of visits to the math learning center each semester. We utilized a logistic regression model to determine the likelihood of STEM retention over the two-year period based on the students' passing rate for their math courses and average tutoring attendance per course. We found a statistically significant positive correlation between tutoring visits and persistence, and that the odds of persisting in STEM increases by 10.92% for each additional visit to the MLSC per math course.

We then recruited STEM majors who passed 4 or more math courses to participate in an interview. Seven students agreed to participate, and six of these students utilized the math learning center. We utilized the constant comparative method (Glaser & Strauss, 1967) to identify themes in the interview data. All seven said that they had mostly positive experiences in their mathematics courses. They viewed the peer tutors as helpful and several mentioned that they met up with friends at the math learning center. Several of the students discussed how the tutors helped him understand the process but didn't give away answers, which implies that they were actively engaged in the tutoring session. They also mentioned other spaces where they connected with classmates to study, both virtually and in person.

The Role of Self-Efficacy in Student Personas for Redesigning a Calculus Recitation

Jen Crooks Monastra
University of South Carolina

Melinda Lanius
Auburn University

Keywords: Calculus, Self-Efficacy, Recitation, Personas

A common format for Calculus 1 at large universities across the United States is a large lecture with an accompanying recitation led by a graduate teaching assistant. A Merit recitation program, based on a model developed by Uri Treisman (1983) at the University of California, Berkeley, replaces the typical recitation with a Merit one that meets for twice as long. Merit recitations also have smaller class size and a specifically trained facilitator who guides students through tough problems and understanding the core concepts of calculus. Our design problem concerns building personas of students participating in Merit recitation to understand (1) their choice to enroll, (2) their in-recitation learning experience, and (3) self-efficacy. Personas, which are "life-like archetypes that stress users' diverse goals and motivations and embrace their corresponding needs and challenges" (Huynh et al., 2020) can help a Merit program director to predict how students will engage with the program and can guide program refinement to more fully support students in achieving their academic goals. Our Merit student personas address mathematical self-efficacy. Bandura argued that self-efficacy, an individual's belief that they can successfully execute a behavior to produce a desirable outcome, influences the effort and persistence a person puts into a task (Bandura, 1978). Further, he posits four sources of information that strengthen or hinder self-efficacy: performance accomplishments, vicarious experiences, verbal persuasion, and emotional arousal. Students can provide insight into how and why these sources of information change students' self-efficacy (White, 2025).

To generate our personas, we conducted two in-person focus groups with a total of 12 students. These were audio-recorded, transcribed by AI (Otter and Rev), and cleaned by the first author. Both authors independently coded the transcripts for sources of self-efficacy, then met and discussed codes to reach consensus on all codes. Code mapping was used with each source of information to form the basis for the development of each persona (Saldaña, 2016). From these results, we constructed 2 personas - Maddie and Jacob - who had distinct motivations for enrolling in a Merit-style recitation. Maddie had low mathematical self-efficacy coming in and just wanted to pass calculus. Maddie's parents strongly encouraged her to enroll, affirming that she needed the additional support outside of the large lecture. Jacob had at least modest mathematical self-efficacy in general, however had very low self-efficacy with respect to passing Calculus 2 at our institution, which they had heard was "apparently really hard." His parents were more neutral than Maddie's, telling their student to decide for himself if he wanted to take Merit. Being able to ask questions during their Merit recitation was extremely important to both student personas. Jacob just needed the time and space for questions, especially in contrast to lecture and regular-timed recitations. In addition to time and space, Maddie additionally needed to feel safe to ask "humbling" questions, particularly about prerequisite material.

With these newly developed personas, the Merit director better understands the role of parents in the enrollment process and can better market the program. Additionally, the director can stress particular aspects of the Merit graduate teaching assistant training, to better support students' comfort in asking questions during recitation. Thus, these personas guide structural adjustments that better support the wide variety of students who choose a Merit recitation.

Mathematicians' Views on Intuitive Concepts in Abstract Algebra

Jessi Lajos
Utah State University

Holly Zolt
Middle Tennessee State University

Keywords: Abstract Algebra, Intuitive Knowledge, Intuitive Concepts, Mathematicians' Beliefs

Developing an intuitive feel for mathematical objects (e.g., concepts, problems, principles, languages/representations, etc.) (Godino et al., 2022) and thinking intuitively is considered an important skill as students transition into more advanced university coursework (Burton, 1999; Davis et al., 2012). While developing an intuitive feel for the mathematics is important, many studies have documented that abstract algebra, a foundational undergraduate course for advancing math majors and pre-service teachers, continues to be difficult for students to grasp (e.g., Melhuish & Fasteen, 2016; Melhuish et al., 2020). Given these continued difficulties, a more clarified understanding of how to better support students in developing an intuitive feel for key abstract algebra concepts is needed. However, it seems that experts' views on what constitutes an intuitive or non-intuitive concept, the methods they used as learners to develop an intuitive feel for key abstract algebra concepts, and how they integrate such methods into their teaching practices has yet to be explored and compiled for specific undergraduate course contexts. Considering these gaps, we address the following research questions: 1) What criteria do mathematicians (who are also instructors of abstract algebra) use to characterize a concept as intuitive/non-intuitive? 2) Is the "intuitive" quality of an abstract algebra concept fixed, or can it change? If it can change, what methods or events do mathematicians credit with helping them shift an abstract algebra concept(s) from having a non-intuitive to intuitive quality?

While the goal of this work is to explicate what mathematicians mean by "intuitive", we are informed by prior work on intuition. Currently, there are various understandings of what it means for something to be intuitive. In light of this, we chose to draw on Semadeni's (2007) theorization of "deep intuition" (p. 3) as it relates to concepts and intuiting methods (e.g. Nathan et al., 2021).

The data comes from a completed pilot study aimed at investigating mathematicians' views of "intuitive'' versus "non-intuitive" qualifiers in connection with various abstract algebra concepts. These concepts were drawn from Melhuish's (2019) Delphi study that ranked abstract algebra concepts for difficulty and importance (e.g., first isomorphism theorem, quotient groups, group properties, etc.). We conducted hour long interviews with 7 mathematicians from various universities across the United States selected through convenience sampling. We note that all participants regularly teach abstract algebra at their respective universities. Mathematicians were initially asked a series of questions regarding their beliefs on what it means to them for a concept to be "intuitive". They then engaged in card sorting activities (Rugg & McGeorge, 2005) which further illuminated the criteria used to decide if a concept is intuitive. To analyze our data, we used Thematic Analysis (Braun & Clark, 2006).

Based on a compilation of our interview data, we found a multitude of themes or criteria that mathematicians used to characterize a concept as intuitive. One such criteria was being able to work with the concept in practice. We also found that they used varied approaches to develop an intuitive feel such as practice and teaching a course. We expand further on these results and provide future directions for research.

Students' Perturbations and Accommodations in the Context of Graphing

Audrey Gianelle
Towson University

Kristin Frank
Towson University

Keywords: Covariational Reasoning, Student Cognition, Graphing

Covariational reasoning can support students' thinking across mathematical domains including functions, graphing, calculus, and modeling. Researchers have developed several frameworks for classifying students' covariational reasoning. For example, Thompson and Carlson's (2017) levels of variational reasoning apply broadly across mathematical contexts and attend to the nature of the students' images of variation and the construction of a multiplicative object in students' reasoning. While researchers have documented the ways students' reason about and construct graphs of covarying quantities, it remains an open question how covariational reasoning develops in students' thinking and whether the levels articulated by Thompson and Carlson are developmental.

Our work seeks to provide empirical evidence for the extent to which Thompson and Carlson's levels of covariational reasoning might be developmental, and to understand the mechanisms and instructional decisions that might contribute to the development of students' covariational reasoning. To address these goals, we conducted one-on-one task-based clinical interviews (Hunting, 1997) with college Calculus I students to understand the extent to which task sequencing of non-normative graphing tasks might facilitate the development of students' covariational reasoning.

In this poster, we focus on one student, Meg, to explore how her engagement with a sequence of non-normative graphing tasks contributed to her demonstration of more propitious levels of covariational reasoning. Our analysis is grounded in Piaget's conceptualization of schemes where students' schemes to develop through processes of assimilation and accommodation (Piaget, 1985). We examine how Meg assimilated tasks into her existing graphing schemes, we document the perturbations Meg experienced when assimilating these tasks, and classify the nature of the accommodations she made to her graphing scheme to resolve her perturbations. Through this process, Meg's reasoning evolved from gross images of variation to chunky images of covariation in four distinct phases. We take this as preliminary evidence that there might be a developmental progression between the levels of covariational reasoning.

Additionally, our analysis revealed that the interplay between Meg's activity constructing graphs and then reasoning about her constructed graph resulted in Meg experiencing cognitive perturbations that ultimately led her to make accommodations to her graphing scheme. This finding builds on our previous work that students reason differently when constructing graphs and interpreting graphs and that students' graph interpretations more often align to their images of covarying quantities than their graph construction (Frank, 2018). Thus, as Meg interpreted her constructed graphs in ways that did not align with her images of covarying quantities, she experienced perturbations that challenged her graphing scheme.

This work provides empirical support that levels of covariational reasoning might be developmental and if a student has robust images of covarying quantities, then their work constructing and reasoning about their constructed graphs can serve as a productive mechanism for the development of their graphing scheme.

One Prospective Secondary Mathematics Teacher's Responsive Task Design Through a Locally-grounded Experience

Colin Crawford
Towson University

Nicholas E. Witt
Towson University

Keywords: pre-service teacher education, culturally responsive mathematics teaching, curriculum

Critical mathematics (Skovsmose, 1994) can promote critical thinking about the world through mathematics, leading to a rising *critical consciousness* (e.g., Ladson-Billings, 1995). However, critical mathematics curriculum intending to be meaningful or relevant to students may lead to tensions with respect to the authenticity of the tasks and their connection to societally-valued mathematics content (Brantlinger, 2022). One proposal for teaching mathematics that supports students' deep understanding and learning of mathematics through meaningful activities reflective of students' lived experiences is culturally responsive mathematics teaching (CRMT; del Rosario Zavala & Aguirre, 2024). However, what CRMT looks like in prospective secondary teacher (PST) education remains an under explored area of research.

In this poster presentation, we share the results of an exploration of PSTs' emerging critical consciousness as they engaged in an activity based on Zavala & Aguirre's (2024) "Mathematizing Your World" (p.39). During a variation of the activity, 13 PSTs were instructed to "*Take 15 minutes to walk with your partner. Go outside, return in 20 minutes (build in any personal breaks you may need). When you return, be ready to share about this experience."* and reflect upon the following, *"(1) What do you notice about the places you visit? (2) What feelings do you have about the things you see? (3) What questions come to mind as you do this? (4) What mathematical problems might you pose about what you observe?*" For homework, PSTs were instructed to design a task suitable for teaching content to students in grades 6-12 based on their partnered walk.

This poster will share one PST's (Colin, first author) reflections about the activity and a task that Colin developed through engaging in the *Mathematizing Your World* activity. The poster will provide examples of how Colin's critical consciousness with respect to the socio-ecological (e.g., Coles et al., 2024) was activated through the activity and how this informed his task design which centered an invasive species that he encountered during the walk. For example, he noted how the observation of several spotted lantern flies (an invasive species in the region) informed his decision to construct an exploratory activity for students where they would engage with their local environment and collect and analyze data regarding the number of lantern flies they encounter. This work serves as an example of how engaging PSTs with CRMT activities can creatively inform their curriculum design, promoting a responsiveness to locally-relevant issues.

Exploring Undergraduate Mathematics Instructors' Perspectives and Considerations About the Literature Related to the Teaching and Learning of Mathematics

Callista Skillings
Oklahoma State University

Michael A. Tallman
Oklahoma State University

Keywords: Documentational Approach to Didactics, College instructors' engagement with research, Research dissemination, Generative Study

Cobb (2007) characterized mathematics education as a design science, "the collective mission of which involves developing, testing, and revising conjectured designs for supporting envisioned learning processes" (p.3). Thompson (2008) similarly defined the discipline of mathematics education: "students' mathematical learning is the reason our profession exists. Everything we do as mathematics educators is, directly or indirectly, to improve the learning attained by anyone who studies mathematics" (p. 45). Mathematics educators' investigations into a multitude of social, cognitive, affective, and cultural phenomena serve to inform the development of innovative designs—pedagogical, curricular, social, political, and otherwise—to improve the quality of students' mathematics learning. The extent to which mathematics educators' contributions accomplish this aim depends on the effective dissemination of their scholarship to those who might be positioned to leverage its insights to improve students' learning. We argue that the effective dissemination of mathematics education research must be informed by an understanding of practitioners' motives for accessing the literature and the facilitations and hinderances they experience to implementing its findings.

To address this need, the research reported in this poster examines how and for what purpose college mathematics faculty and instructors apply insights from the mathematics education literature. Our study was guided by the following research questions: (*RQ 1*) What are the perspectives and considerations of instructors regarding the utility of literature related to the teaching and learning of mathematics? (*RQ 2*) What facilitates or hinders instructors in their efforts to access and utilize literature related to the teaching and learning of mathematics?

We applied survey and clinical interview methods (Clement, 2000; Goldin, 2000) in a manner informed by our literature review to explore instructors' perspectives about the utility of the mathematics education literature, including the facilitations and hindrances they experienced in accessing and applying its insights. Informed by the elements of schemes of usage from the Documentational Approach to Didactics (Trouche, Gueudet, & Pepin, 2018), our thematic analysis (Braun & Clarke, 2006) revealed several convergent themes related to instructors' engagement with the literature. We present these themes and discuss their implications for improving the content and dissemination practices of scholarly products to address the barriers practitioners experience in accessing, applying, and learning from the mathematics education literature.

Based on our thematic analysis of the survey data, we invited a subset of respondents to participate in a one-hour virtual interview. Our analysis of these interviews enabled us to further explore provisional hypotheses that emerged from our thematic analysis of the survey data and to elaborate our emergent themes. Our poster will present and exemplify these themes with sample interview responses. Additionally, we reflect on the implications of our research for the dissemination practices of mathematics education scholarship and ways of supporting practitioners' engagement with this literature that reduces the barriers abstracted from the survey and interview data.

Creation, Implementation, and Evaluation of a Training Program for Undergraduate Guided Study Group Leaders

Jaime Acre
Oklahoma State University

Melissa Mills
Oklahoma State University

Keywords: Communities of Practice, Peer-Assisted Learning, Group tutoring, Tutor training

Duah, Croft, and Inglis (2014) define peer-assisted learning (PAL) as "a formal scheme of assistance that is provided by one or more students to other students to enable them to develop their understanding of course content, and also to assist them [in developing] the study skills required to be successful [in] the course" (p. 554). Inspired by other PAL models such as *Supplemental Instruction* (Fayowski & MacMillan, 2008) and *Learning Assistants* (Barrasso & Spilios, 2021), we discuss a PAL model called a Guided Study Group (GSG). A GSG is a small group tutoring session focusing on a singular mathematics course and guided by an undergraduate GSG leader who is employed as a mathematics tutor specializing in the mathematical topics within the course. The overarching goal of each GSG session is to help establish students within a learning community specifically catered to their course, engage them in a collaborative learning environment, equip them with study skills specifically pertaining to their course, and encourage them to rely on and connect with their peers.

The purpose of this research project is to create, implement, and evaluate a training program for undergraduate GSG leaders at a mathematics learning success center. Through colloquial conversations with past GSG leaders, I was able to determine and design training sessions that I believed would be beneficial for GSG leaders. Fifteen GSG leaders engaged in a training session at the beginning of the Fall 2025 semester. The training lasted approx. 1 hour and involved a review of GSG policies, procedures, and expectations as well as two training activities: *Exploring Mathematical Identities* and *Mock-Tutoring Scenarios*. The creation and implementation of the training was informed by the theoretical perspective of *Communities of Practice* (Wenger, 1998). Specifically, the training sessions required the GSG leaders to be active participants in the training in hopes that the training topics being conveyed would be accepted as a *reified object* in the community of practice we hope the GSG leaders will form. We will evaluate the training according to the following research questions: *(1) What impact does the training have on the practice of guided study group leaders? (2) In what ways does the training facilitate a community of practice among the guided study group leaders? (3) In what ways does the training equip the leaders to support the development of a community of practice among students?*

The data collection methods being employed in this study consist of: Session Reflections, Observations, and Interviews. This poster will present a case study of one GSG leader in particular. This participant was chosen based on preliminary data from session reflections and observation field notes which seem to indicate that the GSG leader displays behaviors that point to a positive impact from the training. In particular, this GSG leader showed that they were focused on making the students active members of the problem-solving process, repeatedly encouraged students to work together, and noticed common misconceptions which were then addressed as a whole group.

Improvement in Undergraduate Student Survey Responses About Engaging and Belonging in ELITE PD MGTAs' Mathematics Courses

Kelsey Quaisley
Oregon State University

Mary Beisiegel
Oregon State University

Charalambos Charalambous
University of Cyprus

Keywords: Graduate Teaching Assistants, Professional Development, Student Experiences, Survey

Research on teaching practices in post-secondary mathematics classrooms consistently show that students benefit from engaging, active learning environments (Harper & Quaye, 2009; Laursen, 2013; Laursen et al., 2014; Laursen & Rasmussen, 2019; PCAST, 2012; Wieman, 2017). However, such benefits are not necessarily possible for all students unless those active learning environments also foster a sense of belonging (Brown, 2018; Ernest et al., 2019; Johnson et al., 2020; Voigt et al., 2023). Given that mathematics graduate teaching assistants (MGTAs) teach a significant number of undergraduate students over the course of their graduate studies (Selinski & Milbourne, 2015), it is important for MGTAs to develop teaching practices that engage students and increase their sense of belonging.

Our research team implemented a three-year PD program (ELITE PD) for MGTAs that is focused on teaching practices that support each and every student to meaningfully engage in learning mathematics, especially through group work. The goal of this poster is to share results from our analysis of undergraduate student survey responses from the mathematics classes of MGTAs enrolled in ELITE PD. Our research question is: *Do MGTAs receive improved student survey responses over time in the ELITE PD program, specifically from Winter to Spring during the 2023-24 and 2024-25 academic years?*

We focused our analysis on one cohort of 12 MGTAs who were new to teaching in 2023-24 and who completed two years of ELITE PD during their first two years of the mathematics graduate program. The MGTAs experienced a three-day, pre-fall term orientation and graduate teaching seminar in their first year. During fall and winter of their second year, they participated in seminars that emphasized active learning and student engagement through exploration and discussion of numerous evidence-based teaching practices. As part of our study, we surveyed the MGTAs' students during each term to see whether we saw improvement in students' responses to the MGTAs' teaching. We collected over 1000 responses for this cohort over this time period.

We conducted two statistical analyses by comparing means and standard deviations of survey responses for our cohort of 12 MGTAs from winter to spring: (1) in 2024 (2) and in 2025. Wilcoxon Signed Ranks Tests revealed significant differences (at $p=.05$ and $p=.10$) in means and standard deviations for a number of Likert-scale items (ranked from Strongly Disagree (1) to Strongly Agree (5)) in 2024 and 2025. For example, in 2024 the mean scores across all 15 items increased from 4.04 in winter to 4.15 in spring, and statistically significant differences in means (at $p=.05$) were found for four survey items. Two such items included: *I felt welcomed, comfortable, and a sense of belonging in this course*; *This course was structured so that I could work effectively with others who were different from me.* We also found statistically significant differences in means (at $p=.05$) for two survey items in 2025: *I felt safe contributing my ideas in class discussions*; *My TA presented examples that resonated with me or related to my interests.*

For our poster, we present our statistical results in more detail, discuss their implications, and future analyses. Primarily, these results demonstrate the promise of professional development for MGTAs to improve all students' engagement and sense of belonging in mathematics classrooms.

Prospective Teachers' Modeling of Student Thinking About Sampling Distributions

Ryan Gabriel Aniceto
San Diego State University

Victoria Delaney
San Diego State University

Ruo Ning (Nancy) Qiu
San Diego State University

Keywords: sampling distributions, prospective teachers, second-order modelling

Although prospective secondary teachers (PSTs) are expected to teach ideas involving sampling and sampling distributions, research shows there may be limitations in their understanding of these concepts (Begué et al., 2023; Valenzuela-Ruiz et al., 2023). Prior work suggests that analyzing student work can deepen knowledge for teaching (Crespo, 2000; Heritage, 2022), yet little is known about how PSTs' attention toward statistical ideas shapes their ways of engaging student thinking. This study addresses that gap by examining how PSTs make sense of and respond to hypothetical student statements about sampling distributions.

We adopt Steffe and Thompson's *first* and *second-order models* as the central theoretical construct guiding this work. A first-order model refers to a learner's own construction of knowledge, while a second-order model represents a teacher's conception of a learner's thinking based on observations of their reasoning and work. With this framework, we pose the following questions: *Which features of sampling distributions do prospective teachers attend to when interpreting hypothetical students' statements about sampling distribution? Also, how do PSTs construct second-order models in response to students' reasoning about sampling distributions, and how are these models shaped by the statistical features the PSTs attend to?*

This study was part of a teaching experiment (Brown, 1992) within a statistics unit in a curriculum course for PSTs at a large public university. After introductory discussions about sample and sampling distributions, 11 PSTs discussed two hypothetical student statements that reflected common misconceptions about sampling distributions (Chance et al., 2004): with one hypothetical student conflating the sampling and population distributions, and another overlooking how averaging reduces variability. Transcripts of recordings of group discussions were used for analysis. In our analysis, we used Wilson et al.'s (2011) and Didis et al.'s (2016) frameworks to deductively code PSTs' talk turns into increasingly elaborate categories of second-order model-building. We identified instances in the transcripts where PSTs showed evidence of *describing* the hypothetical students' work, *questioning* aspects of that work, *comparing* it to their own reasoning, *inferring* about the students' thinking, and *restructuring* their understanding or ideas of teaching the sampling distribution concept. We also inductively coded the transcripts to identify the features of the sampling distribution concept PSTs were attending to in their discussions. Through pattern coding (Miles et al., 2014), we examined how PSTs' focus on statistical ideas influenced their second-order models of the students' thinking.

The analysis revealed that the PSTs' discussions of the statements reflected productive engagement with statistical ideas and elaborate forms of second-order model-building, while also indicating opportunities to deepen their understanding of sampling distributions, particularly how averaging influences variability. Given that PSTs often receive limited preparation in statistics compared to mathematics (Lovett & Lee, 2017), their second-order models reflected this imbalance, showing emerging insights but somewhat limited attention to the full scope of sampling distribution concepts. In the poster session, we will share illustrative episodes from PSTs' discussions that exemplify these findings and hope to foster discussions about how teacher educators can help PSTs build models of student thinking while identifying and addressing overlooked aspects of the subject matter to deepen their own knowledge for teaching.

Creativity in Proving Through Individual, Small Group, and Whole Class Contexts

Amanda Lake Heath
University of Houston - Downtown

Keywords: group work, collaboration, proving, creativity

Calls to foster creativity and collaboration in undergraduate mathematics have grown in recent years (e.g., Conference Board of the Mathematical Sciences, 2016; Saxe & Braddy, 2015; Schumacher & Siegel, 2015). Yet, little is known about how students perceive collaboration or individual work as supporting their mathematical creativity. Prior studies have largely measured creativity before and after instructional interventions (e.g., Asahid & Lomibao, 2020; Gilat & Amit, 2014, Levav-Waynberg & Leikin, 2012, Yuan & Sriraman, 2011; Zazkis & Holton, 2009), with limited attention to students' lived experiences. Further, few have examined proof-based courses or explicitly explored how collaboration may shape mathematical creativity.

This study investigates students' perspectives on experiences of mathematical creativity in an introduction-to-proof (ITP) course. Specifically, after a semester-long introduction-to-proof course taught with collaborative, inquiry-based methods, how do students recall individual, small-group, and whole-class activities as fostering their mathematical creativity?

Theoretical Framing and Methods

I adopt a relative perspective on mathematical creativity, defining it as the process of generating or implementing mathematical ideas or strategies perceived by the individual as non-routine. Feeling creative is thus taken as evidence of being creative (Satyam et al., 2022).

Data were collected from undergraduate students (n = 7) enrolled in an ITP course at a large public university in the southeast United States. Primary data for this study were participant responses to an end-of course reflection asking, "Did you feel creative in your Introduction to Proof course? Provide as many details as possible in your response." Responses were first open coded (Saldaña, 2016) to highlight students' words describing the contexts in which they felt creative. Codes were refined through iterative analysis, and findings were triangulated with course artifacts and video data to contextualize students' perspectives.

Findings

Students described feeling mathematically creative across individual, small-group, and whole-class contexts. Students felt creative in **individual** work when they independently overcame proving impasses, often by revisiting class videos, applying learned strategies, or experimenting through scratch work. Participants reported working in **small groups** allowed them to be creative because collaboration fostered shared ownership of ideas, helped with moving past stuck points, and revealed multiple valid approaches to a proof. Lastly, **whole-class** work fostered long-term creativity by positioning students as responsible for gaining their own understanding and short-term creativity when the instructor provided specific guidance and questioning. Insights from this study can inform the design of instruction in proof-based courses to intentionally use collaboration to cultivate students' creativity in mathematics.

This poster presentation will communicate detailed findings, including participant quotation and secondary data such as course artifacts and invite feedback and conversation about how to continue this work for a more explicit comparison of individual, small group, and whole-class contexts in undergraduate mathematics courses.

Examining How Students Leverage Code as a Representational Tool in Combinatorics

Rebekah Kuss
Oregon State University

Elise Lockwood
Oregon State University

Keywords: combinatorics, discrete mathematics, computing, programming.

In order to have students use computational tools in exploring mathematical ideas (e.g., Papert, 1980) and to explore the role of computing in students' mathematical reasoning (e.g., Geraniou et al., 2024; Lockwood & Morken, 2020), we wanted to explore how students engage with coding modules while solving combinatorics problems. While analyzing student work, we noticed that students pointed out different aspects of their code in their explanation of how they solved the problems. In this poster, we seek to answer the following research question: *What aspects of the code did students attend to as they used code as a representation in solving combinatorial problems, and how did they leverage these aspects of code*?

Literature and Theoretical Perspectives

This poster will focus on connecting counting process and sets of outcomes from Lockwood's (2013) model, whose components are counting processes (the procedures used when solving counting problems, formulas/expressions (the number, variables, and operations used to get an answer to a counting problem), and sets of outcomes (the sets of objects that are being counted). We build upon prior work that has explored students' use of programming while solving counting problems (e.g., De Chenne & Lockwood, 2022; Lockwood & De Chenne, 2020). Here, we will expand on such prior work on students' use of code and aspects of the code as a representation. In this poster, we will also focus on *machine-based computing*: "the practice of developing and precisely articulating algorithms that may be run on a machine" (Lockwood & Morken, 2021, p. 405), which in this poster is programming (both for writing and editing code) (in alignment with Weintrop et al., 2016). The code itself is the counting process, and the output of the code is the set of outcomes.

Methods

A set of modules were designed that focused on students engaging with coding in Python and counting problems, and they were implemented in an upper-level mathematics classroom for pre-service teachers. The whole class worked through the modules, and we video- and audio-recorded pairs of students during six class sessions while they worked; the instructor and another researcher checked in and asked questions about their thinking and work. For data analysis, we reviewed the paired sessions and identified instances in which students referred to particular aspects of the code (including initialized sets and lists, lines of code, and output), and we examined, compared, and contrasted episodes where students focused on different parts of code.

Results

In this poster, we will show different ways that the students used various aspects of the code to represent different aspects of their combinatorics process. We found that some of the ways that the code was used to represent their listing process, to represent their counting process, and using the output of the code as a representation. In all, the code aligned with counting processes, sets of outcomes, and the connection between the two from Lockwood's (2013) model.

Telling Latina Stories

Marissa Martinez
The University of Texas at San Antonio

Keywords: identity, racism, sexism, Latina students

Today in the United States the rights of people of color, specifically Hispanic people, and women and transgender individuals are under fire with these populations being told to or made to stay silent and disappear. The focus of this poster, and the larger project behind it, is to highlight and amplify the voices of Latina STEM majors and explore their navigations of their own identities in the context of their math courses. This work brings students' own self-identifications to the forefront of the conversation and examines student experiences in undergraduate mathematics. Specifically, I focus on Latina women of various Latin American backgrounds, their identity co-constructions, and how if at all it affects their experiences as doers of mathematics (Oppland-Cordell, 2013; Leyva, 2022). For students with intersectional identities, the classroom environment and peer-to-peer interactions or instructor-to-student interactions can be incredibly difficult to navigate; when individuals identify in ways other than cisgender, straight, white, and male, these racialized and gendered themes emerge (Leyva et al., 2021). Works like Adiredja and Zandieh (2020) highlight the counter-stories of women in mathematics and STEM in order to accurately portray what these women go through and how they persist in mathematical spaces where it can be easy to disappear. This project stems from my effort to not only contribute to a body of work that tells the stories of people like me, but also to join my participants in their desire to be role models for young women who want to go into STEM fields despite experiencing discouragement and silence. This project explores the question: *how do Latina women in STEM majors feel in Calculus I courses and do those feelings affect the negotiation of their identities as math doers, STEM majors, and Hispanic women?*

Over the course of this study, I interviewed six women ages 18 and 19 from a variety of STEM majors who are currently taking Calculus I. The initial interviews focused on forming initial student profiles about each woman's background and how they perceive three main aspects of their identity: (a) their identities as Hispanic or Latina, (b) their identities as women, and (c) their identities as doers of mathematics. After being asked directly about their experience with racism or sexism in the math classroom, the majority of the women interviewed were able to either explicitly describe an instance of racism or sexism they saw or experienced in their schooling or mentioned taking note of racialized or gendered experiences. Furthermore, at least two women mentioned refusing to stay silent or make themselves smaller in the face of these experiences. For the women who identified explicit racist or sexist encounters, they expressed finding comfort in their support systems of family or roommates and friends who would hear them out and let them vent their frustration in the face of these aggressions. Preliminary results provide insights into what participants' responses are to discrimination inside and outside of the classroom and evidence of how they view themselves and the different intersections of their identities. Potential implications of this work in the research world encourage more lived experience storytelling for Latina STEM majors, the public will hear more voices of women in STEM, and Latina women and girls can see and hear the stories of women like them to show what is possible.

A Collaborative Rubic Development and Scoring Program

Bernadette Mullins
Florida Polytechnic University

Justin Hoffmeier
Florida Polytechnic University

Jared Bunn
Florida Polytechnic University

Satyajith Boyana
Florida Polytechnic University

Dipali Swain
Florida Polytechnic University

Keywords: coordinated courses, rubric scoring, inter-rater reliability

Research Aims and Relationship to the Research Literature

The literature speaks to the benefits of course coordination (Rasmussen et al., 2014) and the importance of consistency in grading across multi-section courses. Achieving grading consistency can be challenging (Reddy & Andrade, 2010) but can be enhanced by using task-specific rubrics and rater training (Jonsson & Svingby, 2007; Crisp, 2017; Schoepp, et al., 2018). It is well-documented in the literature that rubric training can be a time-consuming process and that faculty time constraints can be a barrier to implementation of assessment practices in general and rubric scoring in particular (Charlton & Newsham-West, 2024; Holmes & Oakleaf, 2013; Williams, 2024). However, the research literature does not seem to adequately address how, after an initial time investment, rubric use can become routine. We seek to investigate the following research question: after instructors invest time in rubric development and training, how does the time needed for rubric implementation change?

Preliminary Data Collection and Results

Our investigation of this research question has two phases. Phase one is the initial time investment in rubric development and training. Phase two is rubric utilization. For the first phase, we collected student responses ($n = 147$) on assessment items involving exponential growth, cooling, and trigonometry. Faculty members (two associate professors and two assistant professors in their first year of teaching post Ph.D.) teaching a coordinated precalculus course participated in a collaborative rubric development and training program: after selecting a task aligned with learning outcomes (e.g., problem-solving, communication, modeling exponential growth), we collaboratively developed a draft task-specific rubric specifying partial credit based on the demonstrated level of understanding, then refined it by anticipating potential student solutions, errors, and omissions. We scored a small sample of blinded student responses as a whole group to discuss how to apply the rubric and make necessary revisions. Next, we independently scored a sample of student work and discussed results to identify discrepancies and come to a consensus rating. After the training session, we independently scored the remaining student solutions, then reviewed discrepancies to identify lessons learned. In round one, the percent agreement across all raters was 50.3% and the percent adjacent agreement was 73.1%. In round four, the percent agreement was 84.7% and the percent adjacent agreement was 91.5%. Implementation of the second phase is forthcoming. Using already collected student work on different assessment items, each faculty participant will write a task-specific scoring rubric without additional training beyond the initial time investment in phase one. For each rubric, all faculty participants will independently score the student work and percent agreement will be computed. Faculty perceptions of changes in time required for rubric development and implementation will be captured through a survey and a structured interview process with each faculty participant.

A Corequisite College Algebra Support Program With Undergraduate Peer Facilitators

Natasha Speer
The University of Maine

Steven Kimball
The University of Maine

Keywords: co-requisite support, college algebra, calculus sequence placement practices

Many undergraduate science, technology, engineering and mathematics (STEM) degrees require one or more calculus courses. For some, the path to those courses includes one or more prior-to-calculus courses. Not all students who begin this journey end up succeeding, and the higher the number of pre-requisite courses students need, the less likely they are to eventually succeed in the course needed for their program (Jaggars & Stacey, 2014). Many factors influence student success, however, pre-requisite skill fluency and understanding of foundational ideas can impact learning in calculus sequence courses and are thus often the foci of placement tests.

We report on a student support program in college algebra, designed by combining principles of co-requisite support (Zaback et al., 2016) and Peer Led Team Learning (PLTL) (Willson & Varma-Nelson, 2016). Co-requisite support typically takes the form of a supplementary course taken concurrently with the target course and provided as an alternative to having students take a term-long course on the prerequisite material.

Our program is a variation on this model. The university does not offer a course as preparation for college algebra. Historically, students who did not place into college algebra were unable to begin their path towards calculus. Now, students whose placement scores are below the requirement for college algebra enroll in the combination of mainstream 3-credit college algebra and a 1-credit support course. The course coordinator developed groupwork materials and supervised undergraduate facilitators, overseeing hiring and preparation meetings. This approach was modeled after PLTL which had been implemented previously on campus (for other purposes), including in mathematics. Experienced undergraduates were student group facilitators and time was spent strengthening prerequisite skills needed for up-coming topics, reducing potential impediments to student learning.

We share findings from the first year of implementation at a research-intensive university in the northeastern U.S. Data included grades from the 63 participants for both the semester when they were in college algebra and for subsequent semesters. Findings confirmed our hypothesis: students who were under-prepared for college algebra (as measured by placement scores) could succeed (earn grade needed to move to the next course) with additional support. A chi-square test revealed that success rates of those in the course and those in the course plus support were statistically indistinguishable (at the $p<.05$ level). In addition, the vast majority who enrolled in a next course in the calculus sequence were successful in that course.

Our findings suggest that what was found in community college settings (i.e., Zaback et al., 2016) can also be true in university settings. In particular, findings suggest that co-requisite support enabled student success in college algebra and in subsequent calculus sequence courses. In addition, findings suggest that undergraduate peers can staff such programs which could help with wider-spread implementation. The poster includes additional details and we seek feedback on evaluation design and ideas for additional research questions to pursue. Of particular interest are the undergraduate peer facilitators since their involvement is a variation from the typical co-requisite support program model. In addition, we seek discussion about further research questions that might be possible to investigate if this program were expanded to other courses in the calculus sequence (e.g., pre-calculus and first-semester calculus).

Acknowledgments

The student success program described in this report was supported via an internal grant to the authors that was funded by the Alfond Foundation.

Using Provided Guided Notes in Coordinated First-year Mathematics Courses

Jennifer Huber
The University of Texas at Arlington

Theresa Jorgensen
The University of Texas at Arlington

Keywords: coordinated courses; guided notes; post-secondary mathematics

Course coordination has been successfully implemented at the mathematics departmental level at various universities (Regier et al., 2024; Jensen-Vallin, 2013; Golnabi et al., 2020; Rahman et al., 2021). Adeyemi et al. (2023) described "Course coordination implies coordination in the design, structure, and teaching of a course to the extent that multiple instructors within a multi-section course have come to a common agreement." Another path to improving student experience, explored by instructors, has been implementing guided notes in the classrooms. Feudal and Panse (2022) defined guided notes as "a modified version of the instructor's notes with certain blanks the students have to fill in during the lecture." The department in which this research study is being conducted has begun to use standardized guided notes as part of the provided curricular materials in course coordination. There has been little studied about the impact of course-wide standardized guided notes, created by someone other than the instructor, in post-secondary mathematics. The research question is: In what ways does the use of standardized guided notes in a coordinated classroom in first-year college mathematics affect student and instructor perceptions, expectations, and actions within their course?

This project focuses on first-year mathematics credit courses which have no prerequisites in which students are required to purchase student workbooks containing guided notes created by a former coordinator of the course. The study takes place at a large, public, research university in the Southern United States. Researchers utilized an inductive mixed methods approach.

To begin understanding the use of the guided notes, course coordinators were asked to provide basic course information to determine the intent of the guided notes and to determine the coordination structure, according to framework established by Couch et al. (2023). Next, the instructors completed an online Instructor Survey which asked about their experience teaching coordinated courses, their plan for using the workbook when teaching, and the survey included a Likert scale on Mathematics Teacher Self Efficacy, modified from Zuya et al. (2016). The instructors also participated in a focus group interview to provide qualitative context to their survey responses. Students enrolled in the course were asked to participate in a survey which included a Likert scale of student perception of guided notes (influenced by Feudal and Panse, 2022). Researchers observed a class meeting of two sections of the course, conducted by different instructors, covering the same topic of Systems of Linear Equations. A classroom observation rubric modified from Mustafa et al. (2014) was utilized to record instructor actions and the use of the workbook as well as student engagement. During the last five minutes of class, the researchers took pictures of student notes to determine the types of information recorded by students (Fukawa-Connelly et al., 2017).

Researchers piloted the study in Spring 2025, with the course sections of College Algebra for Economics and Business. The poster will feature preliminary results from the pilot study, highlighting instructor and student perspectives on guided notes. In Fall 2025, the researchers will expand the study to include two additional large multi-section first-year mathematics credit courses (Contemporary Mathematics and College Algebra). As the study is expanded to cover multiple courses, the researchers are also interested to learn how other universities utilize guided notes or student workbooks in their first-year mathematics courses.

Exploring Covariational Reasoning Pathways in Undergraduate Mathematical Modeling

Eva Fuentes-Lopez
UC San Diego/San Diego State University

Steve Bennoun
UCLA

Keywords: Covariational Reasoning, Mathematical Modeling, Differential Equations, Trajectories

Modeling plays a critical role in helping students make sense of and analyze complex biological systems, which is important for those pursuing life science or health professions (AAMC, 2009). Participants in this study previously completed a life science modeling course designed to improve their ability to use modeling as a tool for understanding the dynamics of biological systems. This work investigates students' covariational reasoning (CR) when engaging in tasks requiring movement across multiple representations, such as developing a trajectory from a time series and, conversely, generating a time series from a trajectory. A time series showcases how a single variable changes as a function of time, while a trajectory illustrates how two variables change in a space formed by the two variables that describe the system (Bennoun, 2024). Covariational reasoning refers to an understanding of how two quantities change with respect to one another (Carlson et al., 2002) and is foundational to understanding the concept of function, reasoning with multiple quantities, and modeling dynamic functional events (Thompson & Carlson, 2017), all critical skills for success in mathematics.

This work builds on Bennoun's (2024) work on examining the extent to which undergraduate students who completed a modeling course have learned how to sketch the trajectory associated with a time series and vice versa. Extending this line of work, we focus on how students reason through these representational shifts and how their covariational reasoning manifests across tasks. Our research question is: *How do students engage in covariational reasoning when working with time series and trajectory representations of mathematical models in biology?*

To investigate students' CR, we conducted 10 task-based think-aloud interviews (Zazkis & Hazzan, 1999) with students who had taken a mathematical modeling course at a research-intensive university in the southwestern United States. For the interviews, students were asked to sketch a time series associated with a given trajectory and compare their sketch to alternative solutions. To analyze the interview data, we deductively coded the data using Thompson and Carlson's (2017) six levels of covariational reasoning as a priori codes (Miles & Huberman, 1994), followed by reflexive thematic analysis (Braun & Clarke, 2006) to identify overarching themes that emerged from the data.

Our preliminary findings highlight CR's dynamic and flexible nature, as students shifted between reasoning levels across tasks, leveraging different levels depending on the demands of each task. We present three empirical cases that illustrate different CR pathways and discuss how classroom norms and teacher expectations may shape students' conceptions of what counts as "correct." For example, all students' responses for sketching task were categorized into the smooth, chunky, or coordination levels. When presented with solution comparison problems, they either remained at the same level across tasks or shifted to another level, sometimes moving from smooth to chunky, or from coordination to smooth, depending on the task. We then compare the three paths, noting that students often referenced classroom expectations, emphasizing the interplay between individual understandings and classroom norms.

How Education Within Social Networks Shape Perceived Barriers to Applying to Graduate Mathematics Programs

Amelia Hogan
College of Holy Cross

Tim McEldowney
College of the Holy Cross

Emma Tweed
College of Holy Cross

Quinn Salmon
College of the Holy Cross

Keywords: Social Network, Graduate School Applications, Social Capital

Students rely on information from their social networks to navigate decisions about college and career-related choices (Canché et al., 2014). Beyond undergraduate education, enrollment in graduate programs is heavily influenced by a student's parent's level of education (Bryer, 2025; Mullen et al., 2003; Seay et al., 2011). The theory of social capital suggests that students learn information, norms, values, standards, and expectations for education from their family, peers, and others with whom they may form inter-personal relationships (Coleman, 1988). We use this framework to discuss our results. The following data was collected from 519 survey responses to a 57-question survey investigating student knowledge about applying to graduate school in mathematics. The following table shows selected results from one survey item about application barriers compared to the survey item: "What is the highest level of education completed by someone in your network (friends/extended family)?" We use the term "First-Generation" to describe students whose social network contains less than a bachelor's degree. Using Kruskal-Wallis tests we found there was an association where students whose social networks had people with post-secondary degrees were less likely to view obtaining letters of recommendation and relocating as potential barriers to applying to graduate school. When navigating the college application process, student peer groups provide knowledge which ultimately makes applying to college more accessible (Tierney & Venegas, 2006). Students who know someone with a graduate degree, can rely on them and/or their social network to know how to obtain proper letters of recommendation or prepare to relocate for graduate school. Thus, these students may find it easier to apply to graduate school compared to their peers due to their social capital.

Table 1. Kruskal-Wallis test results for selected items for the question "To what extent are the following factors a potential barrier to your pursuit of graduate school?" using the level of education of social network variable.

Item	Group	*N*	Mean	Mean Rank	*H*	*Df*	*P*	η^2
Obtaining letters of recommendation	First-Gen	44	3.07	323.69				
	Bachelor's	122	2.56	265.92	12.508	2	.002	.024
	Graduate	346	2.36	243.07				
Possibly having to move to a new place	First-Gen	44	3.41	324.30				
	Bachelor's	122	2.93	277.22	17.401	2	<.001	.034
	Graduate	344	2.57	238.97

Preliminary Design for Pilot: Bridging Conceptual Gaps in Orthogonal Projection in Applied Linear Algebra Through Principal Component Analysis (PCA) Visualization

Zhen Zhang
Florida State University

Keywords: Principal Component Analysis, Orthogonal Projection, Applied Linear Algebra Instruction, Visualization-Supported Reasoning, Representational Coordination

Students often encounter orthogonal projection as a formula-driven procedure, leading to disconnects between geometric intuition, vector decomposition, and symbolic manipulation. (Córdova-Esparza & Piñon, 2025). Leveraging PCA as a visual means, this study aims to bridge students coordinate image, vector, and symbol for deeper conceptual understanding. Research Questions: RQ1. How do PCA-based visuals support undergraduates in developing a robust understanding of orthogonal projection? RQ2. Which instructional features foster stronger conceptual explanations and reduce misconception?

PCA technique offers a visual framework links geometric intuition with algebraic operations, making orthogonal projection more accessible (Konyalioglu et al., 2011; Pandit et al., 2020). In undergraduate linear algebra, PCA connects dimensionality reduction, visualization, and real-world applications (Gewers et al., 2018; Greenacre et al., 2022), Its foundation in orthogonal projection enables students to visualize high-dimensional data on lower-dimensional subspaces (Espadoto et al., 2021; Görtler et al., 2019). PCA visualization and interactive activities connect theory and practice, supporting conceptual reasoning (Glen & Zazkis, 2020; Trigueros, 2018). Conventional learning creates gaps between symbolic manipulation and conceptual understanding (Kontorovich, 2020; Zhang, 2024). Few studies address how PCA-based activities coordinate geometric, vector, symbolic reasoning, an explicit gap this project addresses.

This study draws on Multiple External Representations (MERs) theory, which strengthens conceptual understanding by coordinating visual, geometric, and symbolic forms (Hahn, L., & Klein, P.2023). PCA-based visualization, vector decomposition, and symbolic projection activities foster representational fluency (Fonger et al., 2018). Guided by constructivism theory (Greenfield & Bruner, 1966), the design uses hands-on tasks to bridge image ↔vector ↔symbol. A conjecture map as a design-based research approach (Oktaç, 2019), systematically links instructional features to student reasoning and evidence of conceptual change. These frameworks guide activities to bridge conceptual gaps in orthogonal projection.

This activity applies PCA as a data-driven context to make orthogonal projection visible and discussable. Students work with three figures: a 3D projection to the PC1-PC2 plane, a 2D view with perpendicular drops, and a PC1-PC2 scatter plot to anticipate PC1 direction, mark orthogonal drops, decompose vectors ($v = v_{\parallel} + v_{\perp}$), and compute projections using the dot product. The sequence threads one idea across image ↔vector ↔symbol, with pre/post concept checks and figure annotations scored by a 0-3 rubric. Targeted prompts address recurring confusions (e.g. "along" vs. "onto," PCA vs. regression, and centering.)

At the preliminary design and pre-pilot stage, this approach is expected to bridge gaps and strengthen students' conceptual understanding of orthogonal projection by coordinating geometric, vector, and symbolic reasoning. It aims to reduce misconception, common errors, deepen explanations, and provide instructors with a portable toolkit-conjecture maps, rubrics, and repair prompts to support representational coordination. Pilot results will inform further refinement and broader instructional adoption.

Can x Equal Zero? A Look at Two Calculus I Students' Reasoning About Variables

Rasha Abadir
Rutgers University

Keywords: Calculus; Algebraic Manipulation; Variables; Errors

Introduction

When solving calculus problems, undergraduate students rely on variables and algebraic manipulation. However, students frequently view variables as symbols to be manipulated rather than as quantities to be related (LaRue & Infante, 2015; White & Mitchelmore, 1996). While algebra education research (e.g., Booth, 1989; Küchemann, 1981; Lucariello et al., 2014) addressed students' interpretation and manipulation of variables, more research is needed to understand how these processes manifest specifically among calculus students. This poster will address several facets of this need.

Context

This work is part of a qualitative research study conducted at a large R1 university on the East Coast of the United States. The study involved students enrolled in Calculus I courses for life and social sciences during the Fall 2024 semester (Abadir, 2025). This poster will highlight a task-based episode from the larger study in which two undergraduate calculus students reasoned about algebraic manipulation and the use of variables while identifying points of local maxima and minima for a given function. In calculating critical numbers, students mistakenly treated the variable as a constant and divided both sides of the derivative equation by it, which led to the omission of a critical number. However, during a debriefing session with the researcher, the two students explained and reflected on their solution process, allowing them to identify their mistake and the conceptual implications of their algebraic manipulation. The students were able to connect algebraic ideas and properties, allowing them to engage with error in a way that facilitated a deeper understanding of the significance of variables as placeholders.

Methodology

Guided by Borasi's (1987) framework "errors as springboards for learning," this poster presentation aims to answer the research question, "In what ways do students' reflections on their algebraic manipulation and errors serve as an opportunity to reason about variables?" This analysis examines how students' engagement with their own errors fosters a deeper conceptual understanding of the role and significance of variables. The primary data sources include students' written work and a video recording capturing both the problem-solving process and the subsequent debriefing session.

Results and Significance

This poster will present detailed data and systematic analysis of the students' algebraic manipulation and error, along with their reflections as they articulated the significance of variables and how they relate to algebraic properties. These findings contribute to the body of research that frames errors as opportunities for deeper learning, specifically by using students' algebraic mistakes to enhance their understanding of the role of variables.

Grades, Learning, and Reattempts: How Students Experience Outcomes-Based Testing

Debra Carney
Colorado School of Mines

Naga Chandra Padmini Nukala
Colorado School of Mines

Carla M. Strickland-Hughes
Colorado School of Mines

Keywords: alternative grading, outcomes-based testing, linear algebra

Recent years have shown an uptick in faculty interest in alternative grading practices as they question the effectiveness and meaning of traditional grading practices and points-based systems (Blum, 2020; Nilson & Stanny, 2023). According to Clark and Talbert (2023), the four pillars of alternative grading are (1) clearly defined standards, (2) helpful feedback, (3) marks indicate progress, and (4) reattempts without penalty. An alternative grading practice built on these four pillars prioritizes learning, feedback, iteration, and transparency over point-earning and early mistakes. Shifting the focus from grades to learning intends to make grades more meaningful and to support the learning process We are interested in how alternative grading can provide a supportive learning experience for our students and how the experience of reattempts on outcomes specifically affects them.

In this poster, we will present findings from a study on outcomes-based testing (OBT), a form of alternative grading, in linear algebra at a medium-sized public engineering institution. This work replicates and extends the research by Swanson et al. (2025) which reported on the benefits and drawbacks of mastery-based testing in linear algebra, and student beliefs about final grades as compared to other courses. In the present study, using qualitative and quantitative data collected from students across four different sections taught by two different instructors, we examine three key questions: (1) What benefits and drawbacks did students perceive in the OBT system?, (2) Did students believe that OBT grades more accurately reflected their learning compared to grades in other courses?, and (3) How did students' experiences differ based on the number of attempts they made to complete course outcomes?

Data for this study were collected during the fall 2024 and spring 2025 semesters. Students answered multiple 5-point Likert-scale rating items and open-ended questions about the perceived benefits and drawbacks of OBT and the meaning of grades through online, optional surveys administered at the beginning and end of the semester. Thematic analysis (Braun & Clarke, 2022) was used in coding the open-ended questions. Together with qualitative analyses, our results support the findings of Swanson et al. (2025) regarding benefits, drawbacks, and grades (RQ1, RQ2) with notable differences in the student experience based on outcomes attempt frequency (RQ3). Namely, we found that students perceived OBT to support their learning (e.g., deeper understanding) and to support self-regulated learning (e.g., flexible), and we found that aspects of OBT both reduced and provoked stress. Students rated grades in OBT as fairer and more accurate than grades in other classes. Some benefits of OBT were more pronounced for students who had less frequently reattempted outcomes; for example, while students reported less exam anxiety in the OBT-graded course than other courses overall, this benefit was greater for those who used fewer reattempts.

In this poster, we will include a brief description of our OBT system together with our full results on student-reported benefits, and drawbacks which are organized around how OBT supports both learning and self-regulation. We will conclude the poster by including implications for improving our OBT implementation and addressing equity in student experience.

The Role of Context in Adult Undergraduates' Problem Solving

Olivia Bruner
Arizona State University

Michelle Zandieh
Arizona State University

Keywords: Problem-Solving, Role of Context, Adult Undergraduates

For this poster, we define adult learners as those who have had significant time away from school mathematics before returning to undergraduate mathematics learning. Based on the first author's prior work with adult learners, she became interested in how adult learners might leverage their experience in their adult professional and personal lives to better understand mathematical ideas. To pilot this type of exploration, she designed two tasks with similar mathematical structure but set in different real-world contexts. This design was informed by existing work, which shows students bring prior experiences to the undergraduate classroom, but often don't see their out-of-classroom experiences as relevant to their classroom work (Graham et al., 2000; Jameson & Fusco, 2014). Also, others have noted that the nature of the context can inform student reasoning in a task (diSessa, 2018; Thevenot, 2017). In light of this, our goal was to consider in what ways adult learners approached these similarly structured mathematical tasks, and in what ways the contexts of the scenarios influenced their problem-solving.

We conducted clinical interviews with two adult learners using missing value proportion tasks. We see these tasks as both mathematically fundamental, and likely to connect to adult learners' prior experiences, since proportional reasoning is one of the most common math applications in everyday life (Doyle et al., 2015; Hilton et al., 2016; Kontogianni & Tatsis, 2019).Our tasks were a Baking Task and a Traveling Task, which read, "Matthew is baking a cake. The recipe calls for 2 cups of flour and 3 teaspoons of vanilla. If a scaled-up version of the recipe calls for 7 cups of flour, how much vanilla should Matthew use?" and "As Buddy walks to school at a constant speed, he travels 8 feet in 3 seconds. How long will it take Buddy to walk 20 feet?" From an expert point of view, each task includes a given ratio and one value of another ratio, with the question asking for the missing value of the second ratio. We analyzed how two adult learners (1) solved each task, (2) thought about the similarities and differences across the two tasks, and (3) reflected on their solving processes.

For (1), we identified five different ways they solved the task. We characterized differences in terms of the main ratio the student leveraged and how they leveraged the ratio. By main ratio we mean whether (a) the student used the two unlike unit data (e.g., 8ft to 3 sec) as the main ratio and then tried to match that ratio or (b) the student used the two same unit data as the main ratio (e.g., 8ft to 20 ft) and then tried to match that ratio. Both participants had one solving method for the Traveling Task, with Travis leveraging a same unit ratio, and Jessica leveraging an unlike unit ratio. In contrast, on the Baking Task, both produced multiple solving paths and leveraged both unlike unit ratios and same unit ratios. With regards to (2) and (3), the students initially did not perceive the tasks as the same, primarily because they used different solving paths for the two tasks. However, upon reflection Travis noted that the same strategy would have applied to both saying, "I could have set them up the same way." With regards to the role of context, the Travel Task had similarities to problems in a math course both participants recently completed, and they both referenced school math solving methods in their reflections. In contrast, while solving the Baking Task, Jessica leveraged her prior cooking experience saying, "What if I was actually baking, what would I do?" We note that both the learner's solving approaches and their reflections seemed to be influenced by the context itself and their experience with the context.

Student Perspectives on Effective Recitation Design in an Active Learning Calculus I Course

Sophia Towle
University of New Hampshire

Karen Graham
University of New Hampshire

Keywords: Active Learning, Calculus, Student Perceptions

Active learning has become a central approach to student-centered learning in undergraduate mathematics courses (CBMS, 2016; Rasmussen et al., 2019) and has been shown to improve student engagement and outcomes (Altindis et al., 2025; Kurepa et al., 2019). While research on instructor practices in active learning environments is growing, less is known about how students experience these classrooms. This study addresses this gap by examining students' perceptions of an active-learning model implemented in Calculus I recitations at a medium-sized university. Recitations were taught by Graduate Teaching Assistants (TA) and aided by Undergraduate Learning Assistants (LA).

To capture students' experiences, we analyzed responses to two open-ended questions on an end-of-semester survey: *If you were an instructor or a TA designing recitation: (1) What are at least two things you would keep? Explain why these are strengths. (2) What are at least two things you would alter or remove? Explain why those changes would be an improvement.* Data were collected during Fall 2023 and Spring 2024, with 238 students (of a total of 404 enrolled) completing both prompts. Using inductive qualitative thematic analysis and the constant comparative method (Patton, 2002; Strauss & Corbin, 1998), the authors collaboratively developed and refined a codebook with 23 distinct themes organized into five overarching categories: *Student Work Structures & Group Dynamics*, *Instructional Practices*, *Recitation Environment*, *Assignment-Related Aspects* and *Assessment & Review.* Interrater reliability was established through independent coding and reconciliation discussions.

Overall, students mentioned more aspects to *keep* in recitation (429 total codes; ~2 per student) than to *alter or remove* (240 codes; ~1 per student), indicating generally positive perceptions of the active-learning format. The most frequent "keep" themes involved *Instructional Practices* (42.7% of codes) and *Student Work Structures & Group Dynamics* (30.8% of codes). Within these themes, specific strengths were noted by students, with percentages reflecting the proportion of students who mentioned each: *group work* (~50%), valued for fostering collaboration, comfort, and peer explanation; *worksheets* (27%); *teacher-led problem solving* (18%); *introductions* (18%); and *conclusions or wrap-ups* (16%). In contrast, for the "alter/remove" question, *Assignment-Related* themes were most common (31.7% of codes), though most suggestions focused on refinements rather than removals (full removal accounted for 11% of codes). Common refinements mentioned by students included revising *worksheets* to clarify instructions and adjust length or difficulty (21% of students) and improving *group work* implementation, such as having clearer facilitation roles (13% of students).

This study reinforces that collaborative active-learning structures support student engagement (Kurepa et al., 2019; Nji & Chinyelogo, 2025) and adds insight into *how* students want these structures implemented. A novel contribution of this study is eliciting student feedback from the perspective of a TA/instructor, yielding actionable recommendations for strengthening recitations, such as worksheet design and group work facilitation. Incorporating student feedback into active-learning recitation design has the potential to improve the effectiveness of active learning implemented in introductory mathematics courses.

Keywords: Student resources, exam readiness, math anxiety

The Midweek Math Training (MMT) program is designed to empower and prepare calculus students for exams via weekly peer-led practice exam sessions students can voluntarily attend. MMT draws inspiration from the well-documented positive effects of Supplemental Instruction (Skoglund, Wall, and Kiene, 2018) and repeated exposure to practice exams (Kulik, Kulik, and Bangert, 1984). In each session, students first individually attempt exam-level problems on recent course content. Trained peer facilitators then guide student discussion of appropriate strategies for these problems and test-taking strategies more generally.

In the spring semester of 2024, MMT was used by 61.84% of students in Calculus 1 & 2 before Midterm 1. Many students have expressed anxiety about the course. Math anxious students often avoid working practice problems, particularly practice exam problems (Jenifer, Levine, and Beilock, 2023). We want to know 1) What impact MMT has on student's math anxiety? 2) How do students believe MMT is impacting their understanding, behavior, and relationship with math? 3) Why do students come to MMT?

Methodology

Study participants were recruited through their Calculus classes and MMT. Each week student attendance is taken at MMT each week. Six times through the semester, study participants were sent the same select questions Abbreviated Math Anxiety Scale (AMAS) (Hopko et al, 2003). After each exam, study participant were sent the AMAS and a brief survey about MMT survey. Participants are invited to participate in a 30-minute interview to discuss their relationship with math and MMT. Data is currently in collection and will be ready for analysis spring 2025.

Acknowledgments

We would like to thank the Howard Hughes Medical Institute for their funding for MMT and this study through the Success in Science Initiative.

Chemistry Graduate Students' Problem Solving With Quantum Mechanical Models: "What Do I Plug in for Delta?"

Slade McAfee
University of Wisconsin – Milwaukee

Jon-Marc G. Rodriguez
University of Wisconsin – Milwaukee

In the chemistry curriculum, physical chemistry stands out as one of the most challenging given its reliance on calculus, particularly when using quantum mechanics to describe atomic and molecular structure. Though there is literature in chemistry education research that investigates students' conceptions of quantum chemistry, few of these studies focus on students' use of mathematics in this context. To this end, we interviewed graduate students (N = 23) about the "particle-in-a-box", one of the first quantum models discussed in physical chemistry. Preliminary analysis investigates phenomenographical categories of students' problem-solving strategies and their affective responses to the problem-solving task.

Keywords: chemistry, quantum mechanics, calculus, interdisciplinary

There are few studies in the chemistry education literature that specifically focus on students' conceptualizations of quantum mechanical models (McAfee et al., 2025), and though these articles provide a great foundation for further research, they do not explicitly investigate students' use of mathematics. This gap does not insinuate that quantum mechanics is taught in chemistry without mathematics, but rather that chemistry education research often borrows findings from physics education research to contextualize students' conceptualizations of quantum mechanics. To this end, the aim of our study is understanding how students apply quantum mechanical models when problem-solving. For our study, we conducted semi-structured interviews with chemistry graduate students (N = 23) who received $50 gift cards for participating in a two-hour-long, in-person interview.

Preliminary data analysis, guided by phenomenography, focused on two major components of the graduate students' problem-solving: (1) their performance on the problem, and (2) their affective responses to solving the problem in front of a peer. To better understand their treatment of the molecule in the problem, we generated a rubric with a normative application of the particle-in-a-box model in which points were assigned to the graduate students' work based on correct decision-making during the task. The variation in model application shone through in the students' treatment of variable *a*, in which they needed to calculate the length of the molecule. Notably, none of the students applied the model completely normatively which speaks to the immense challenge quantum mechanics poses to students.

During the interviews, we noticed many affective responses from the graduate students such as nervous laughter, screams, qualifiers, etc. Given this, we inductively coded these responses which we frame as observed indicators of stress. Taken together with their problem-solving, three groups of students have emerged: (1) high performers with low observed indicators of stress, (2) low performers with low observed indicators of stress, and (3) low performers with high observed indicators of stress.

For next steps, we are interested in expanding our analysis to further understand the affective responses we observed form the graduate students and further describe the emergent phenomenographical groups.

Applying Process Tracing to the Development of the Indigenous Math Courses and Secondary Math Education Program at Turtle Mountain College

Danny Luecke
Turtle Mountain College

Keywords: tribal college, indigenous math, process tracing, course development

Background and Motivation

Undergraduate math courses focused solely on Indigenous math are relatively new within tribal colleges/universities. Turtle Mountain College has developed a three-course sequence on Indigenous Math in conjunction with developing their bachelor's program in Secondary Math Education. The development process of the Indigenous Math courses led to the Indigenous Math Framework. The framework has four components situated within the medicine wheel. The four components are (1) Nature/Place/Land, (2) Community, (3) Heritage/Traditional Games, Arts, Engineering, etc., and (4) Language. The framework is not the only way to view Indigenous math but rather just a way that is used at Turtle Mountain College (Luecke 2023, 2025). The courses and framework build upon scholars who articulate the error and danger of Western perspectives of math being mythologized as pure, universal, culturally neutral, and culturally superior (Aikenhead, 2017; Bishop, 1990; Ernest, 2021; Kawagley, 1997; Medina et al., 2024; Stevens, 2021; Xu & Ball, 2024). Further, these courses stand on previous K-12 math education research demonstrating that math and local language/culture integration strengthens students' cultural identity and improves math exam scores (Lipka et al., 2007; Kisker et al., 2012).

Purpose of the Study

The development of the Indigenous math courses and the Secondary Math Education program focused on content and pedagogy (Luecke, 2023, 2025). This research will go beyond the end-product of what was developed and study the why and how of the development process. The expectation is that a greater understanding of how the Indigenous Math courses and the Secondary Math Education program were developed will afford opportunities to strengthen the courses and program as well as offer insights into supporting any math faculty interested in integrating more Indigenous ways of knowing and being into an undergraduate math class. The research question is "What strategies for developing math (and math education) programs with a greater emphasis on Indigenous STEM can be derived from a retrospective analysis on the development of the Indigenous Math courses?"

Methods

The research methods are situated within an Indigenous research paradigm with its emphasis on relationality, relational accountability, and storywork (Archibald, 2008; Kovach, 2009; Wilson, 2008; Windchief & San Pedro, 2019). Aligning with the research question, a process tracing method (Atcha, 2022; Beach, 2017; Montano et al, 2025) will be applied to the initial development of the Indigenous Math courses and Secondary Math Education bachelor's program to determine strategies in navigating tensions/decisions in development. A process tracing methodology affords a systematic, reflective analysis to see causal relationships on how the courses/program developed. Identifying moments of decision, struggle, and overcoming demonstrate one way to increase Indigenous Math content in all math courses/programs.

Course Coordination and Student Success: Evidence From the Literature

Sunday Stein
San Diego State University

Naneh Apkarian
San Diego State University

Chris Rasmussen
San Diego State University

Debra Carney

Keywords: course coordination; precalculus; calculus; student success

In the United States, Calculus I is extremely efficient at reducing student enjoyment and perseverance in mathematics (Bressoud et al., 2013). Coordinating gateway courses (e.g., precalculus, calculus) is a strategy that has been proposed as a way to improve students' experiences and outcomes (Bressoud & Rasmussen, 2015; Rasmussen et al., 2019). In an effort to assess that strategy, we conducted a literature review on course coordination to answer the question: *How is course coordination associated with changes in student success across institutions?* Our literature search consisted of peer-reviewed mathematics education journals and edited volumes that address coordination and institutional change efforts for student success. From this review, we identified 62 articles that explicitly mention or describe course coordination, with 23 discussing student success outcomes as a result of coordination.

Coordination is characterized as a system that synchronizes course content and instructor interaction under designated leadership, emphasizing collaborative design and ongoing instructor communication (Carney et al., 2025; Martinez et al., 2022; Rasmussen et al., 2019, 2021; Williams et al., 2021). Note that we define coordination beyond common syllabi, textbooks, and exams; it involves sustained structures that support the collaborative development of materials and pedagogy, with more robust coordination systems developing into *de facto* communities of practice (Apkarian & Rasmussen, 2020; Couch et al., 2023; Rasmussen & Ellis, 2015; Rasmussen et al., 2019; Williams et al., 2021).

Twenty of the 23 papers targeted passing rates as their measure of success and reported some level of improvement. These papers credited a variety of strategies, such as instructors forming a community to share in-class activities (Oliver et al., 2023) and addressing student concerns around grading transparency (Akin & Veil, 2020). Institutions that focused on research-based practices like active learning had larger improvements in their DFW rates, particularly when faculty were supported through learning assistants (LAs) or embedded peer tutors (e.g., Carney et al., 2020, Mingus & Koelling, 2021). Across these contexts, varied degrees of prescriptiveness had a similar pattern: shared infrastructure, ongoing instructor dialogue, and structured supports that align with improved pass rates and more equitable outcomes.

Eight of the 23 papers moved beyond pass rates to consider shifts in identity, belonging, and persistence in mathematics. Factors that contributed to students feeling a stronger sense of community within their classrooms included the integration of LAs (e.g., Chamberlain et al., Mingus et al., 2023), flipped classrooms that focused on student group discussion (e.g., Chamberlain et al., 2021; Diamond et al., 2021), and adoption of active learning activities (e.g. Hancock et al., 2021). Taken together, these student perceptions complement the achievement findings and align with broader accounts linking coordinated structures to enhanced confidence, interest, and persistence in STEM pathways. The poster will further elaborate on the benefits (and constraints) of different coordinated models for departments and mapping these design choices to student outcomes.

Exploring Conceptions of Smartness in Mathematics: Connecting Student and Instructor Perspectives at a Hispanic-Serving Community College

Gabriela M. Hernandez
San Diego State University

Charles E. Wilkes II
University of California, Davis

Mary E. Pilgrim
San Diego State University

Keywords: Smartness, Equity, Community Colleges, Mathematics, Teacher Beliefs

In this poster, we build upon the work of (Hernandez, Wilkes, Camacho, & Pilgrim, 2025), describing how community college students' conceptions of smartness in math class can be categorized based upon a framework that accounts for both dominant (Boaler & Staples, 2005) and counternarratives (Reinholz, 2021), which are important for how learners see themselves and how classrooms reinscribe and perpetuate inequities (Leonardo & Broderick, 2011; Hatt, 2012). To build on this work, we leveraged the perspectives of the students' instructors to explore potential alignment between student and teacher conceptualizations of smartness.

The study takes place at a Southern California Hispanic-Serving Institution (SCHSI) a comprehensive two-year community college. Participants were students enrolled in math classes taught by five instructors who participated in professional development (PD) sessions. The students were enrolled in gateway mathematics courses. The data collected consisted of 103 open-response answers to the question: “What do you think it means to be smart in math at SCHSI?” In the first phase of analysis, the student data were analyzed using thematic analysis (Braun & Clarke, 2012) across three coders, resulting in a two-axis coordinate system and a heat map to visualize the distribution of student responses. The coordinate system ranged from process to outcome and from dominant to counternarratives. (Hernandez et al., 2025)

The next phase of analysis looked at 10 interviews (2 interviews per instructor) that focused on instructors’ beliefs, experiences, and practices around equity in mathematics. While the interviews did not explicitly focus on smartness, we argue that instructors implicitly communicated their conceptions of smartness. The analysis was done in two parts: a) disaggregate students’ placement on the axis based upon their instructor, b) leverage the coding scheme developed in the first phase to gain a broadened understanding of where instructors’ conceptualizations fall in the aforementioned coordinate system.

One major finding is that one instructor, Paul, has prominent placements along the tension of counterprocess and dominant outcome, as well as numerous counter outcomes. Nhung has equal amounts of dominant outcome and counter process, also demonstrating a tension. The second finding is that the instructors seem to describe tensions in the interviews that describe their own experiences against their desired practices. Nhung described striving for conceptual understanding but often reverting to procedural practices, such as limited wait time, relying on frequent participants, and narrowly structured lessons. Similarly, Paul noted the tension between wanting to meet students’ needs through varied supports and the reality that time and content demands constrain his ability to do so.

After analyzing interviews by instructors to understand their conceptualizations of smartness, we found that instructors had tensions between their implicit conceptions and their students’ explicit conceptions of smartness. While we do not make claims about the instructors’ impact on students' placement in this study, we believe it’s important to consider instructors’ conceptualizations of smartness as opportunities to disrupt the conceptualizations of smartness that students may hold, which might be unproductive.

Development of the Undergraduate Mathematics Class Attributes Questionnaire

Jim Gleason
The University of Alabama

Martha Makowski
The University of Alabama

Keywords: class environment, questionnaire development, learning environment

Understanding instructional dynamics in post-secondary mathematics requires tools that capture both classroom complexity and students' lived experiences. Existing instruments such as EQUIP (Reinholz & Shah, 2018), WIHIC (Dorman, 2003), and X-PIPS-M (Creagar et al., 2022; Street et al., 2021; Walter et al., 2016) have advanced research on teaching environments by assessing discourse, engagement, and collaboration in the classroom environment. However, these tools often prioritize researcher-defined metrics over student perspectives, leaving critical gaps in equity-focused analysis. Melhuish et al. (2025) caution that observation-based measures risk reinforcing dominant cultural norms, framing "good teaching" through whiteness and middle-class values unless marginalized voices are centered. They advocate for QuantCrit-informed redesigns that embed cultural responsiveness and intersectionality to ensure validity.

Additionally, observation protocols like EQUIP provide insights into classroom discourse but fail to capture out-of-class learning spaces such as homework and study groups, creating blind spots in understanding student experiences. To address this, we are developing the Undergraduate Mathematics Class Attributes Questionnaire (UMCAQ), grounded in the Instruction as Interactions framework (Cohen, Raudenbush, & Ball, 2003) and informed by Hiebert and Grouws' (2007) definition of teaching as interactions around content. By integrating participatory equity (Reinholz & Shah, 2018; Shah & Lewis, 2019), UMCAQ shifts from measuring what happens to exploring how it feels and for whom, positioning equity as a guiding principle in instrument design.

Pilot Study – Item Selection

In spring 2025, we conducted a pilot study with 197 students enrolled in four undergraduate mathematics courses (Calculus I, $n = 39$; Calculus II, $n = 54$; Differential Equations, $n = 76$; and Intro to Proof, $n = 28$), with the intent of exploring item sensitivity to section-level differences related to instruction. At the section level, groups ranged from small (2–8 students) to large (up to 17 students), providing variability to examine section-level differences.

For each of the 37 items included in the pilot study, which were derived from both extant classroom surveys and investigator developed items, we looked for the response patterns to find items with low variance. To examine section-level sensitivity in student perceptions, we employed cumulative link mixed models (CLMM) using the ordinal package in R, which is well-suited for ordinal data such as Likert-scale responses. We fit two complementary models for each UMCAQ item. The first model specified the course section as a fixed effect and the course as a random intercept, allowing us to directly test whether differences between sections were statistically significant while controlling for course-level clustering. The second model treated the courses and sections as nested random intercepts, providing variance components for both levels and enabling computation of Intraclass Correlation Coefficients adapted for ordinal outcomes. This hierarchical specification captured the proportion of variance attributable to course and section differences without imposing fixed-effect assumptions. This poster invites attendees to explore opportunities for collaborative development and adaptation of UMCAQ, ensuring that diverse student voices shape the future of mathematics education research.

The Thinking Project: Supporting Metacognitive Growth in Calculus Students

Kathleen Guy
FIU

Hagit Kornreich Leshem
FIU

Richard Aguado Mesa
FIU

Keywords: Metacognition, Calculus, Higher Education Mathematics, Self-Regulated Learning

Despite extensive efforts to improve undergraduate mathematics instruction, many students continue to struggle, not only with mathematical content but also with the metacognitive skills necessary to monitor, regulate, and direct their own learning. Metacognition refers to individuals' awareness and control of their own cognitive processes (Flavell, 1979). Incorporating metacognitive strategies in mathematics classrooms can help students become more deliberate in planning, monitoring, and evaluating their learning, which can in turn positively influence affective outcomes such as confidence and anxiety (Roick & Ringeisen, 2018). Research consistently shows that students with higher metacognitive awareness tend to perform better in mathematics and problem-solving tasks than their less-aware peers (Schneider, 2010).

In this poster session, we will present *The Thinking Project* (TTP), a metacognitive support initiative implemented in multiple sections of an Applied Calculus course at a large R1 university. The project is designed to foster students' metacognitive awareness through structured, ongoing activities embedded throughout the course. These web-based activities promote self-reflection and help students become more aware of their understanding of course content, academic progress, and learning goals, while making the activities easily accessible and straightforward to complete. The activities were adapted from an educational intervention in which students identified self-reflective components as some of the most valuable aspects to their learning. Moreover, students who participated in that intervention had significantly lower mathematics anxiety and higher self-efficacy (Guy, 2024). TTP was first piloted in Summer 2025 in a single Applied Calculus course and expanded to additional sections in Fall 2025. The pilot highlighted the need to improve the technology used to administer the activities and to optimize the instructor feedback process.

The Metacognitive Awareness Inventory (MAI) was administered at both the beginning and end of the term to assess changes in students' metacognitive awareness (Schraw & Dennison, 1994). Additionally, qualitative feedback was collected at the end of the semester to further explore students' perceptions of the activities. During the poster session, we will share how the project was designed and facilitated, along with a QR code linking to the activity materials for instructors interested in adopting or adapting them. Preliminary findings will be presented, and we will discuss implications for future research and instructional practices.

This session highlights a practical, research-informed approach to fostering metacognition in undergraduate mathematics courses, an area that remains challenging for many students. By presenting TTP, participants will explore how structured, course-embedded activities can support students' self-reflection, awareness of their learning processes, and strategic engagement with mathematics content. This poster emphasizes both the instructional design and the theoretical rationale, offering educators and researchers a model for promoting metacognitive growth across diverse mathematics learning contexts while also showcasing the ongoing mixed methods study to investigate the project's effectiveness.

Building Bridges Through Mentoring: Graduate Student Instructors' Pedagogical Development

Kimberly C. Rogers
Bowling Green State University

Nicholas G. Long
Bowling Green State University

Salma Hasannejad
Bowling Green State University

Tanmoy Rudra
Bowling Green State University

Keywords: active learning, boundary crossing, community of practice, professional development

This action-research project examines how peer mentoring supports novice precalculus graduate student instructors (GSIs) in developing as reflective, collaborative teachers. Grounded in *communities of practice* (Wenger, 1998) and the notion of *boundary crossing* (Akkerman & Bakker, 2011), we explore how mentoring can help GSIs navigate between the communities of academic mathematics and mathematics education (see also Darragh, 2022; Fried, 2014). We conceptualize mentoring as a structured, dialogic process (Roberts, 2000) to promote reflection, pedagogical growth, and participation in professional learning communities. Our team, comprised mostly of graduate students serving as mentors, investigated the following: (1) what motivates GSIs to engage in mentoring, (2) how do GSIs perceive mentoring's purpose, and (3) how does participation shape GSIs' teaching reflection and active-learning (AL) strategy use.

At a Midwestern public university, five GSIs teaching precalculus for the first time were mentored by a third-year PhD student ("Morgan"), who had completed a mathematics education mentoring PD program (Yee et al., 2024). During a 15-week semester, Morgan facilitated seven bi-weekly small group meetings emphasizing reflection and active learning, and Morgan observed each novice teaching twice. After Week 5, GSIs completed a three-question survey identifying motivations for participation and desired supports. Their feedback guided revisions to subsequent sessions, including the addition of a collaborative AL activity design task. Data included survey responses, observation notes, and post-observation conversations. We analyzed these data thematically to identify patterns in motivation, reflection, and pedagogical change.

Survey results revealed novices primarily valued *sharing experiences* but less often identified *improving teaching* or *learning AL strategies* as motivators. Few novices articulated an explicit desire for pedagogical development. In response, mentoring sessions were restructured to foreground collaborative design and AL implementation. After this change, novices exhibited greater engagement and reflection: one novice transitioned from individual practice problems to structured group work with conceptual questioning; another novice displayed increased confidence in facilitating AL activities; and a previously disengaged novice remained for a full session to design lessons. Although overall engagement increased, inconsistent attendance across meetings also shaped participation patterns and represents a limitation in this study.

Individual post-observation conferences revealed novices' growing awareness of instructional challenges and their need for pedagogical support. These shifts suggest that intentional, practice-oriented mentoring can help GSIs cross boundaries between disciplinary and pedagogical communities, fostering deeper instructional reflection. In conclusion, peer mentoring, when explicitly framed as both community-building and pedagogical development, can motivate GSIs to engage more meaningfully in teaching reflection and AL design. The process also served as professional growth for mentors, who refined their facilitation and research practices. This project highlights the potential of peer mentoring as a means for theory-informed, sustainable professional development that bridges the math and math ed communities.

Keywords: differential equations, modeling, covariational reasoning, time series

Over the last thirty years there has been a trend in the teaching of differential equations to move away from analytic techniques and to focus on graphical and numerical methods (e.g., Rasmussen, 2001). In parallel to this movement, mathematical modeling has gained a lot of importance in biology and the life sciences. Leading professional organizations have called for a reform of the mathematics instruction of biology students in order to include the study of modeling and dynamical systems (e.g., American Association for the Advancement of Science, 2009). The notions of time series and phase plane trajectories are central to the study of modeling and dynamical systems. A pivotal skill is the ability to navigate between these two types of representation of solutions to differential equations.

Previous research has analyzed students' conceptions of solutions to differential equations as well as strategies used to sketch their representations (e.g., Rasmussen, 2001; Trigueros, 2001; Bennoun, 2024). In particular, Bennoun (2024) used the covariational reasoning framework developed by Thompson and Carlson (2017) to analyze students' reasoning when sketching time series and trajectories. Bennoun (2024) observed that students reasoned in majority at the smooth continuous or chunky continuous levels. An important open question is: How do students explain why they use either of these levels when working with time series and trajectories?

To investigate this question, we conducted ten think-aloud interviews with students who had completed a mathematics course focusing on modeling biological systems. Students were given a textbook exercise showing the (smooth) time series of an epidemiological model that depicted the evolution of healthy and infected populations. Then, they were presented with two possible solutions, one chunky continuous trajectory (i.e., with clear corners) and one smooth continuous trajectory. They were asked which one of the two trajectories best corresponded to the given time series and why. We conducted a reflexive thematic analysis (Braun & Clarke, 2006) of the interviews focusing on the reasons the students used to justify their choice as well as the level of covariational reasoning.

Our preliminary findings reveal that while all students picked the smooth trajectory as being the one that best corresponded to the given time series, their reasons varied. Several students reasoned that since the time series given was smooth, the associated trajectory should also be smooth. For example, one student explained that "because these [two functions on the time series] are curved graphs, […] the actual [trajectory] would also be a curved graph." He added that if the functions on the time series were chunky, then the trajectory would also be chunky. Other participants mentioned Euler's method, that they had learned to approximate trajectories, and how a smaller time step means that the trajectory is more accurate. They explained that as one decreases the time step the trajectories look more and more curvy and that therefore the smooth trajectory was more accurate. Some students used arguments relying on more superficial features such as the smooth graph having axes that are easier to read or the chunky graph feeling confusing to them. On the poster, we will describe these themes in more depth as well as discuss implications for practice.

This work is supported by the National Science Foundation grant DUE-2225258.

From the Polar to the Pole: The Enactive and Embodied Choreomathematics of the Polar Coordinate System

Steven Greenstein, PhD
Montclair State University

Asja Alic
Montclair State University

Ariel Bonneau-Rodriguez
Montclair State University

Bridget Looney, PhD

Keywords: Pre-calculus, Polar Coordinate System, Enactivism, Embodied Cognition

The polar coordinate system (PCS) is typically introduced in Pre-calculus, where it provides a foundation for undergraduate coursework in mathematics, physics, engineering, and other STEM fields. Regrettably, students' engagement with it is often limited to procedural tasks, such as plotting points, rote memorization of the relationship between the shapes of graphs and the parameters of their polar equations, and converting these equations between Cartesian and polar forms. And too little attention is paid to how radius and angle measure co-vary in the graphs of polar equations (e.g., Moore et al., 2014; Paoletti et al., 2013). This project seeks to remedy the anemia of this conventional approach by discerning the features of an enactive educational ecosystem for emergent learning that enables learners to graph and reason within the PCS.

The enactive theory of cognition (Maturana & Varela, 1987; Thompson, 2007) and the theory of inclusive materialism (de Freitas & Sinclair, 2014) frame our investigation of mathematical thinking as a complex and emergent phenomenon constituted in embodied and material engagement, and in the affect and aesthetics of relational interactions between learners and their environments. Owing to its attention to the essence of in-the-moment, lived experience, these theories take inspiration from the philosophy of phenomenology (Husserl, 1977; Merleau-Ponty, 1962). Prior research has demonstrated the viability of such an approach, which enabled young learners to make the sophisticated distinctions between qualitative and quantitative change (Greenstein et al., 2024a, 2024b).

At the onset of design-based research (Brown, 1992; Collins, 1992; DBRC, 2003) into what might be the preconceptual (Varela, 1992), enacted, and embodied groundings for understanding the PCS, we found ourselves in need of an actual "pole" as well as the use of gestures and other bodily movements to enact the roles of radius and angle measure through movement. This experimental and exploratory experience led to the decision that pole dance could situate our approach to emergent learning, and that we would seek to move in new ways (Abrahamson & Sánchez-García, 2016) that might enable us to predict the shapes of polar curves. As soon as we moved forward, though, an obstacle we encountered involved the reliance of the PCS on references to trigonometric functions in the Cartesian coordinate system (CCS; e.g., substituting $x = rcos\theta$ and $y = rsin\theta$ to move from Cartesian to polar). And as we recursively moved between the two worlds of the PCS and CCS in order to coordinate simultaneous changes in the covarying quantities, we got the sense-ation that these parametrized experiences (Dimmel et al., 2025) might illuminate the roles of radii and angle measures in dynamic traces of polar curves. This proved to be a surprisingly joyful aesthetic experience, the essence of which we hope to illuminate through phenomenological inquiry (e.g., van Manen, 2023). Our next step is to determine what pole-dance choreographies and other practices make this interworldly movement productive. We will share these and other findings, which lend credence to our emergent learning approach to teaching the polar coordinate system.

Self-Reported Student Experiences in a Combined Pre-Service Elementary Education Teacher and STEM Major Quantitative Reasoning Course

Tricia Phillips
University of Alabama at Birmingham

Anne Ho
University of Tennessee, Knoxville

Keywords: quantitative reasoning course, pre-service teachers, student experiences, self-regulated learning, reflective portfolio assignment

We are interested in the self-reported student learning experiences based on written reflections in end-of-semester portfolios. Previous work has looked at the effects of reflective notebooks (Salinas, 2004) or end-of-semester portfolios (Hanush, 2020) on perceptions of prospective elementary teachers in math, both of which had positive outcomes. Others showed increased performance in classes like precalculus (Burks, 2010) due to portfolios, or that portfolios were seen as valuable for pre-service teachers and for departments (Johnson & Koirala, 2013). Keith (1996) highlighted the ability to gain summative evaluation on assignments that involve self-reflection on student learning. Hauk (2005) and John et al. (2020) both analyze student writing to capture students' past math experiences. These studies lay the foundation that portfolios are helpful tools to gauge student perceptions and experiences. Other relevant work includes the mathematical experiences of pre-service teachers (Szydlik et al., 2003); and a look at mathematical beliefs of students (Ward et al., 2010), including comparing majors (Szydlik, 2013). Dias and Santos (2016) found promising self-regulated learning (SRL) in a mathematical portfolio of one high school student but SRL has not been investigated in college level math portfolios. We seek to answer the research question: how does a reflective portfolio assignment in a college level mathematics class reveal students' SRL?

The study context is a quantitative reasoning course that the first author teaches that is intended for elementary education and STEM majors with a focus on students being competent and confident in mathematics, learning not "what to see" but "how to see," and developing the skill of seeing patterns in multiple ways. In this course, students collaborate to build their own understanding, develop solutions using multiple representations of a function, and practice communicating their approaches to a diverse class of peers.

We use SRL (Zimmerman, 2002) as our theoretical framework to examine our research question. We collected data from the final reflective piece of 25 student portfolios, approximately half education majors and half STEM. We performed thematic analysis (Braun & Clarke, 2006) and categorized our codes into different phases of SRL. The Forethought phase (self-motivation beliefs) revealed in student work included codes related to enjoyment, renewed interest, and mindset shifts; the Performance phase of SRL (self-control processes) included codes about problem-solving creativity, approaches, and exploration; and the Self-Reflection phase (self-reaction processes) consisted of codes regarding perseverance, slowing down, and productive struggle. For our poster, we will share the comprehensive list of codes and representative student responses.

We believe this work is beneficial for instructors of similar quantitative reasoning courses at other institutions (e.g. mathematics for the liberal arts or for pre-service teachers) who may be able to implement course features (e.g. reflective portfolios, "menu"-style assignments) into their own courses in order to facilitate SRL processes for students, as well as for scholars who study student writing or SRL. Next steps include comparing student experiences from different majors.

Developmental Math Course for TCUs: Standardizing Pathways to College-Level Success

Dr. Heather A. Bleecker
Edutorium of Excellence

Keywords: Tribal Colleges and Universities, pathways, developmental math, online learning

Background and Motivation

At many Tribal Colleges and Universities (TCUs), students are seeking to achieve dreams rooted in community and cultural responsibility. Yet placement exams and prerequisite requirements often place them into multiple developmental math (DevEd Math) courses that delay degree progress, add tuition costs, and offer no credit toward graduation. In Montana, where TCUs largely serve Indigenous, first-generation, and non-traditional students, these barriers can lessen confidence and momentum, especially when courses are inconsistently offered due to low student enrollment or faculty availability.

This study builds on existing literature addressing developmental education redesign (Boatman, 2021; Ngo, 2019; Vandal, 2014) and culturally responsive frameworks such as Tsosie's (2022) Six Rs of Indigenous Research. It explores how Montana TCUs might implement a unified, online developmental math course that (1) strengthens academic readiness, (2) sustains Indigenous ways of knowing, and (3) promotes equity and access in higher education. This research seeks to answer the research question, What are the opportunities and challenges in developing a unified, online developmental math course accepted across TCU campuses?

Methods

A qualitative case study was used to examine current DevEd Math structures across the seven Montana TCUs. Data sources include faculty, staff, and administrator interviews, and a review of course syllabi, institutional placement practices, and success data collected in Fall 2025. Data were analyzed thematically using an inductive approach to identify recurring ideas and experiences across institutions. Coding and interpretation were guided by Tsosie's (2022) Six Rs of Indigenous Research, which provided a culturally grounded framework for understanding how the values of respect, reciprocity, and responsibility shape the design of developmental mathematics. The analysis attended to each institution's unique context while revealing common barriers and collective strengths across Montana's TCU network, centering the voices of faculty, staff, and administrators.

Preliminary Findings and Next Steps

Early findings reveal widespread recognition of the need for a consistent, culturally responsive DevEd Math pathway. Common themes emerging from participants include: access and equity, faculty capacity, cultural relevance, and collaborative potential. Participants described a unified course as a way to reduce redundancy, enhance TCU collaboration, and provide equitable opportunities for students to begin their college-level mathematics journey with confidence and belonging. Next steps will focus on: course logistics, instructional design, curriculum development, institutional agreements, and a pilot implementation at Montana TCUs. This ongoing collaboration represents an important step toward standardizing equitable math pathways, strengthening inter-institutional partnerships, and honoring Indigenous approaches to mathematics and learning.

Precalculus Students' Perceptions of Instructor Actions and Intentions via Stimulated Recall

Jason Guglielmo
Arizona State University

Keywords: participative math identity, stimulated recall

The results in this poster contribute to a larger dissertation study aiming to understand how students' perceptions of their interactions with their instructor relate to their math identity, or their view of themselves as a "doer of math." This is a participative approach to math identity, influenced by the figured worlds framework (Holland et al., 1998) and Wood's framework of micro-identities (2013), which both contest that the 'kind of person' one enacts within specific environments relates to the 'kind of person' they generally identify themselves as. Studies conducted in undergraduate STEM courses show how instructors can set classroom expectations that influence the STEM identities students are permitted to enact (Jackson & Seiler, 2017), and that students are aware of these different expectations that may be imposed on them (Lim et al., 2023). This poster will discuss results on students' varied interpretations of instructor actions and intentions in an undergraduate math context.

Data for this poster comes from observations of an interactive precalculus class in the southwestern U.S. during Fall 2025, and early- and late-semester interviews with seven focal students. Observations involved video-recording each class session, providing video clip data used for stimulated recall (Lyle, 2003) in both interviews. The interviews were designed to understand students' beliefs about their math ability and have them reflect on their roles while interacting with their instructor. Analysis for these results was completed via open coding (Strauss & Corbin, 1998) of interview transcripts, involving refining codes along three dimensions: (1) *emotions* and *beliefs* expressed by the student about the interaction; (2) perceptions of the *emotions* and *beliefs* of the *student in the video clip* (sometimes themselves); and (3) perceptions of *instructor actions* and their *intentions*. These codes have been organized into various categories of meaning and are still actively being explored. For this poster, two initial findings will be presented: (a) *variability of an interaction*, and (b) *the typical interaction*.

For (a), the students had variation in both the instructor actions they noticed in these clips and their interpretations of these actions (and their intentions). For a particular early-semester clip, some students noted a vocal inflection used by the instructor when responding to incorrect answers, while others noted the instructor's physical gesturing. With the vocal inflection, students also had varied interpretations for the instructor's intent, including to indirectly guide the students to the correct answer or to push back against student responses. For (b), the students overall described a typical student-instructor interaction as the instructor probing for student understanding and avoiding directly giving answers to students, which students typically interpreted as the instructor encouraging them to think deeply about the material.

These findings suggest that students may be consistent in interpreting the 'typical' interactions in their classroom, but may have varied perceptions of more unique interactions. Further work needs to be done to understand how these different perceptions might be impacting students' math identities. There are future plans to analyze the math identity items from the interviews to understand the students' relationship to math throughout the semester. In doing so, I will be able to better connect the different ways these students interpret instructor actions to the different math identities they enact (and believe they enact), which will lead to a deeper understanding of the complex ways instructors can influence student math identity development.

Needs, Success, Race, and Equality: A Q Methodology Study of Community College Algebra Students

Rabia Gul Kirikçilar
University of Michigan

Megan (Mack) McCormick
University of Utah

Vilma Mesa
University of Michigan

AI@CC 2.0 VMQI Research Team

Keywords: college algebra, community colleges, diversity, equity, inclusion, Q methodology

While prior studies have explored students' experiences in college algebra (Gardner, 2020) and examined undergraduate students' sense of inclusion and belonging in mathematics at predominantly white institutions (Leyva et al., 2021), there remains a gap in research focusing on how community college students understand diversity, equity, and inclusion or how these understandings develop over time. Our study seeks to address this gap by exploring the question: What are community college students' understandings of diversity, equity and inclusion in their college algebra classrooms?

We present preliminary findings from a Q methodology study exploring community college students' perspectives of equity in college algebra. This study is part of a grounded theory analysis (Charmaz, 2006) to build a conceptual framework of this construct from students' perspectives. Community colleges serve students from diverse local contexts, and thus, their interpretations of equity are shaped by both institutional and community factors. We collected data from 41 students from eight colleges located in four regions of the United States—Northwest, Southwest, Central, and Midwest. The participating colleges were selected for the demographic diversity of their student populations. Our recruitment efforts intentionally focused on including students representing varied racial, gender, ethnic, physical, and neurodiverse identities.

Each participant completed four semi-structured interviews over one year. During these interviews, students (1) discussed their personal and mathematical histories and how these shaped their current understanding of diversity, equity and inclusion; (2) provided commentary on short classroom videos, identifying moments they associated with equitable or inequitable practices; (3) engaged in a Q-sort activity (Rieber, 2020) using 33 statements derived from student interviews and literature to express their viewpoints on equity in mathematics classrooms; and (4) are currently completing interviews that allow participants to reflect on changes in their perspectives throughout the process.

In the Q-sort activity, 25 of the 41 participants placed statements on a scale ranging from most disagree to most agree. We used a scale in the shape of a normal distribution for the use of a forced sort structure allowed us access to individual students' unique perspectives and to directly compare student responses to identify common themes. Following the Q-sort activity, we asked the participants to explain how their unique perspectives were formed, focusing on the four statements they placed into "most agree" and "most disagree". The Q-sort data was analyzed using the KADE desktop application (Banasick, 2019), which identifies shared and divergent perspectives among participants. Our analysis yielded four distinct factors (Needs, Success, Race, Equality), each representing a different way community college algebra students conceptualize equity in mathematics classrooms. In this poster, we present findings from the Q-sort analysis, highlighting the themes and perspectives that emerged from these four factors.

Making Sense of Earth's Climate Using Iterative Algebra

Amber Armstrong
University of Minnesota

Anita Schuchardt
University of Minnesota

Keywords: Sensemaking, Iterative Algebra, Climate Model

Differential equations are fundamental to many models of dynamic systems. Earth's climate, for example, is a dynamic system often modeled using differential equations (Kaper & Engler, 2013). Differential equations thus provide a promising avenue to incorporate pressing topics such as Earth's shifting climate into the mathematics classroom; however, not all students study differential equations, which necessitates an alternative method to introduce students to mathematical relationships governing a complex system's evolution (Bressoud, 2015; Bressoud, 2021). One method proposed to teach students ideas similar to differential equations without the use of calculus is through *iterative algebra* (Coles, 2013). Using an iterative algebra approach, students are given an initial state and an equation that defines how the system changes for each future timestep. The change is always based on the system's current state and is repeated iteratively to model how a system changes over time.

Despite the potential of iterative algebra in mathematics classrooms, few studies have determined how students can understand dynamic systems using iterative algebra. Our study addresses this gap in research through investigating how students—who mostly do not have a calculus background—make sense of the mathematics and science behind a climate system using iterative algebra. In particular, we ask, *How do students make sense of the mathematics and science of equations modeling aspects of Earth's climate?* To answer this question, we studied students *sensemaking*—how individuals make meaning of new situations based on prior experience and knowledge (Odden & Russ, 2019). We used an even more specific framework, the Sci-Math sensemaking framework (Zhao & Schuchardt, 2021), as a tool to analyze the types of mathematics and science sensemaking students engaged in while working with a mathematical model of climate.

In a college algebra classroom in a large Midwestern university, students were tasked to develop and interpret recursive equations (i.e., engage with iterative algebra) representing the dynamics of the North Atlantic Current. The activity took place across three consecutive 75-minute class sessions of college algebra. We collected audio recordings and written responses from each participating group. Using the Sci-Math Sensemaking, the sensemaking processes of three different groups of students (each composed of 2-3 students) were studied as they worked on the mathematical climate model activity.

Students engaged in an array of mathematics and science sensemaking types. We found that students understood variables and rates of change as mathematical and scientific constructs. For example, students recognized that certain parts of their equations represented change, either by discussing the quantity or direction of change (mathematics sensemaking) or by describing the science context of the change (science sensemaking, e.g., "This part of the equation represents the temperature of the water decreasing over time"). Furthermore, when developing equations, students often began by making sense of the science context, completing a series of calculations, followed by generalizing their calculations in equation form. These results suggest that students, with primarily no calculus background, can engage in interdisciplinary sensemaking of a dynamic system. This provides promise for teaching more students dynamic systems through iterative algebra.

Class Size, Room Setup, and Use of Group Work: Undergraduate STEM 2019-2025

Michel Manrique
San Diego State University

Naneh Apkarian
San Diego State University

Keywords: instructional practice; class size; STEM; teaching change

Despite recommendations to engage in interactive pedagogy, didactic lecture remains the primary experience of most undergraduate students in introductory STEM courses (e.g., Apkarian et al., 2021; Stains et al., 2018). Often-cited barriers to adoption of alternatives, such as group work, include large class size and auditorium-style setup, though the empirical evidence is somewhat inconclusive across instructors' experience and contexts (e.g., Ake-Little et al., 2020, Apkarian et al., 2021; Yik et al., 2022ab). We endeavor to shed further light on how these factors impact instructors' pedagogical decisions, leveraging survey data from the same individuals at two points in time: Spring 2019 and Spring 2025. Specifically, we explore the research question: *to what extent do changes in course enrollment and classroom setup relate to changes in the percentage of class time instructors report spending in group work?* For brevity, this proposal discusses only the former.

Data come from two NSF-funded projects which surveyed postsecondary instructors of general chemistry, single-variable calculus, and introductory physics across the USA. The surveys deployed in each project used web-based surveys with many identical questions; the latter additionally included items related to instructors' experience during the pandemic response teaching period, although that is not the focus of this analysis. The same roster was contacted for both projects, with a smaller response to the follow-up: $N_{19} = 3769$; $N_{25} = 933$.

Our outcome variable is the reported percentage of in-class time, during a normal week, that students are expected to work on mathematics problems in small groups. We also considered their course enrollment (binned as: 0-19; 20-29; 30-39; 40-59; 60-99; 100+) and classroom setup (easily accommodates group work; does not). Instructors' responses to these items were paired across their 2019 and 2025 responses. In total, 551 instructors' responses were available for pairwise pre-/post-analysis of these items; we admit appropriate caution about generalization in light of response bias and the complexity of the intervening years. Instructors were assigned to one of three groups based on a comparison of their class size in 2019 and 2025: increase, decrease, or no change. Three paired *t*-tests, with Bonferroni-corrected *p*-values to account for repeated testing, were conducted for class time spent in group work between 2019 and 2025. The results are in Table 1. In short, we find no differences in the amount of time spent using groupwork, regardless of whether, and how, their class size changed. Our poster will include additional details of this analysis and a similar analysis related to changes in classroom setup.

Table 1. Results of paired t-tests on instructors' reports of percentage of class time spent in group work, 2019 compared to 2025, disaggregated by changes in their course enrollment.

	Percentage of class time spent in group work: M (SD)					
Enrollment Change	2019	2025	Δ	*df*	*t*	Adjusted *p*
Increase (N = 89)	20.51 (19.96)	17.98 (18.80)	-2.53	88	-1.736	0.258
No change (N = 324)	22.24 (20.82)	24.58 (21.51)	2.34	323	2.372	0.055
Decrease (N = 138)	20.83 (18.74)	21.48 (20.43)	0.65	137	0.479	1.000

Research Outline of Preparation of Potential STEM Majors for College Calculus

Karen C. Enderle
Clemson University

S. Megan Che, Ph.D.
Clemson University

The initial college mathematics placement of Science Technology Engineering and Mathematics (STEM) majors may influence the direction and duration of their college studies. This study aims to explore how secondary mathematics preparation of potential STEM majors may influence their initial mathematics placement. For this study, we consider mathematics preparation to consist of secondary mathematics courses and college preparation advice.

Literature Review

Secondary mathematics course sequences may be accelerated or hyper accelerated. These practices can be advantageous for some students yet push others too quickly through the mathematics curriculum (NCTM, 2012). Oftentimes, accelerating mathematics ensures the student has access to a high school calculus course. However, sometimes in a Rush to Calculus, students may complete the highest secondary mathematics course available to them before their senior year of high school; this can create a gap in rigorous mathematics coursework prior to beginning college mathematics.

First year college students who understand the expectations of college mathematics typically have a smoother transition from high school to college mathematics (Clark & Lovric, 2008). In high school, potential STEM majors may obtain advice from their secondary community about college preparation; however, the community may prioritize secondary calculus for its perceived role in college admissions.

Research Question and Theoretical Framework

Guiding this study is the following research question: How are undergraduate STEM majors' high school mathematics experiences and college preparation connected to their initial college mathematics placement?

The theoretical framework is The Theoretical Model of the Secondary to Tertiary Transition in Mathematics by Clark & Lovric (2008) where the researchers mapped the Rites of Passage from the field of anthropology onto the transition from high school to college mathematics. The theoretical model considers not only the time required to learn mathematics but also the community's role in preparing students for college mathematics.

Methodology

This observational study is a sequential mixed methods design. In the first phase, factors that may influence initial mathematics placement are analyzed quantitatively. The factors being the timing of participants' secondary mathematics courses including any gaps in rigorous mathematics learning prior to beginning college mathematics. After completion of the quantitative data analysis, a survey will be distributed to collect qualitative data in the second phase. The survey questions participants about their experiences transitioning from secondary to tertiary mathematics and the advice they received. Once the qualitative data is analyzed, the results will be compared with the quantitative findings to uncover any meta inferences.

Mathematical Dispositions of Pre-Service Elementary Teachers

Gulden Karakok
University of Northern Colorado

Samuel Waters
University of Delaware

Joanna E. Lewis
University of Northern Colorado

Katie Morrison
University of Northern Colorado

Caterina B. Azzarello
University of Northern Colorado

Molly M. Jameson
University of Strathclyde

Keywords: Eye tracking, math anxiety, mathematical dispositions, pre-service teachers

Dispositions include an individual's behavioral (i.e., things they say & do), cognitive (i.e., attention & memory), and affective (i.e., emotions & beliefs) tendencies (APA, 2020). In mathematics education, researchers discuss productive mathematical dispositions as a "...habitual inclination to see mathematics as sensible, useful, and worthwhile, coupled with a belief in diligence and one's own efficacy…" (NRC, 2001, p.116). In contrast, unproductive dispositions (e.g., anxiety, avoidance) do not reflect a lack of ability but rather behaviors that can hinder students' engagement with mathematics (Feldhaus, 2014). Supporting the development of productive dispositions is therefore critical for improving students' mathematical knowledge and achievement (Awofala et al., 2022; Cobb & Hodge, 2002).

Pre-service elementary teachers (PSETs) often exhibit unproductive mathematical dispositions (Cornell, 1999; Patkin & Greenstein, 2020), including low confidence and avoidance behaviors, which may negatively influence their learning of mathematics, their future teaching, and their students' attitudes toward math (Beilock et al., 2010; Phillipp et al., 2007). Addressing these mathematical dispositions early in teacher preparation is essential. This three-year study examines PSETs' mathematical dispositions during their first mathematics content course, focusing on four key constructs: mindset, self-efficacy, anxiety, and avoidance. Data were collected via pre- and post-semester surveys, including validated scales for math anxiety, self-efficacy, growth mindset, and content knowledge in all three years. During the second and third years, students completed targeted in-class interventions guided by their instructors. Additionally, a subset of students (volunteers) participated in an eye-tracking study at the beginning and end of each semester. Eye-tracking technology (Eyelink 1000+) was used to assess implicit visual behaviors during arithmetic tasks, offering insights into math-related anxiety and avoidance.

In the baseline year (Fall 2023), 58 students provided matched pre- and post-data; in the intervention year (Fall 2024) there were 59 matched ones. Quantitative results revealed that students in the intervention semester showed a significantly greater decrease in math anxiety (mean change = –2.62 vs. –0.57, $p = .048$) and significant gains in growth-oriented mindset (mean change = 1.58 vs. 0.21, $p = .027$) and math content knowledge (mean change = 1.42 vs. –0.07, $p = .0095$). Changes in self-efficacy and avoidance were not statistically significant. Preliminary eye-tracking data suggest that students with higher math anxiety exhibit lower fixation rates and durations during arithmetic tasks, indicating potential visual avoidance. These findings underscore the importance of targeted interventions to reduce math anxiety and foster productive dispositions among future educators. This research and its findings on interventions in mathematics content courses offer valuable contributions to the RUME community and to faculty teaching lower division mathematics courses for non-math majors. Moreover, it provides insights into the potential of multimodal data collection methods, such as eye tracking, for studying students' mathematical dispositions and learning processes.

Mathematical Modeling Experiences in Nonformal Learning Environments for Preservice K-8 Teachers

Abigail Cortez
Washington State University

Sarah Castle
University of Idaho

Keywords: Pre-service K-8 teachers, mathematical modeling, nature of mathematics

Because of the many purposes mathematical modeling serves, several organizations have called for the incorporation of modeling in K-8 mathematics education (AMTE, 2017; CCSSM, 2010; GAIMME 2nd edn., 2019; NCTM, 2000). Engaging in modeling as learners can help teachers more effectively implement modeling experiences in their own classrooms (Anhalt & Cortez, 2016; Burroughs, 2021; Wickstrom & Jung, 2024). This project seeks to explore the following questions:

1. How is mathematics used by a business owner in her work and how can her experiences be used to create tasks that make connections between elementary school mathematics and activities outside of school explicit for preservice K-8 teachers (PSTs)?
2. What are preservice PSTs' perceptions of the nature and purposes of mathematics?
3. How does an off-campus mathematical modeling experience in a nonformal learning environment impact PSTs' perceptions of mathematics?

Literature Review

Out-of-class environments can provide authentic contexts for students to engage in mathematical modeling (Boaler, 1993; Eshach, 2007; Martínez-Jiménez et al., 2022; Vale et al., 2019). Non-formal learning, which is usually structured, mediated with formal education, and teacher-led, has the potential to impact the affective domain of student engagement (Eshach, 2007), through positive, long-lasting memories of the experience (Falk, 1983).

Methodology

During Fall 2025, a business owner was interviewed regarding her use of mathematics in her work running a farm. This interview informed the design of out-of-school mathematics experiences for a math content course for PSTs. Students visited a farm to bake bread, estimate areas of fields, and engage in various profit estimation activities. Students engaged in tasks that required the application of arithmetic, proportions, percentages, fractions, estimation, and area. Interviews with students were collected focusing on their perceptions of the nature and contexts of mathematics.

Results

Data were analyzed using reflexive thematic analysis (Braun & Clarke, 2006) to identify themes regarding (a) connections between school mathematics and activities outside of school and (b) PSTs' perceptions of mathematics and its contexts and the purposes of learning mathematics. Themes identified from the businesswoman's interview include using elementary mathematics for profit estimation (including cost estimation and pricing goods), recipe development, and plant management (including diluting chemicals and estimating seed purchases). Results from this interview were used to create mathematical tasks for students during the field trip to the farm. Analysis of student interview data is still in progress at the time of writing. The results from this project will inform activity revisions and research design in future semesters.

Exploring Math Identity and Cultural Perspectives Through Narrative Math Games

Jeffrey Jones
Red Lake Nation College

Keywords: game-based learning, math identity, narratives in mathematics, cultural perspective

Students at a Tribal College or University (TCU) can be said to have a "home and family culture that does not fully resonate with that of school and the wider society (Bishop, 1991)." Frequently, attempts to improve math education for these students look at improving access to better math instruction in order to increase achievement. This is the "dominant axis of equity (Gutiérrez, 2012)." Is it possible that using the critical axis, identity to power, math instruction can help TCU students leverage their cultural identities?

Purpose of the Study

The purpose of the study is to examine the mathematical identities of students in a mathematics class at a Tribal College. The mathematics class employs a culturally relevant technology game based on the units of the mathematics reasoning course. The mathematical identities of college students shape their perspectives on their capacities as mathematics learners and persistence in STEM fields. (Cribbs, Mantone, & Piatek-Jimenez, 2015) These mathematical identities are tied to students' sense of belonging in the mathematics class, and to the field of mathematics itself. Researchers have found that mathematics instruction that is culturally relevant, in this case to indigenous culture, increases students' sense of belonging and positive mathematics identities. (Matthews, 2014)

The mathematics class under study aims to provide mathematics students with a culturally relevant experience in part through a technology game. The game is to provide students with mathematical experiences that are embedded in a narrative around activities that are specific to the Mi'kmaq tribal communities. The game is set in the historical period of the late 1500s, and the activities include building a birch bark canoe and learning navigation skills. (Bahar, 2019) As the students engage in the games, they interact with certain tasks along the way that include both mathematics and cultural content. They are also prompted to reflect on their experiences as they play the game, including their relationships with the mathematics and with the cultural activities.

Methods

This study is being conducted at a tribal college in the upper Midwest. The students are taking a math reasoning class and part of the curriculum is the game. The study employs a qualitative methodological approach to study the students' engagement in the mathematical games and the kinds of mathematical identities they are developing as a result. Students will be asked to complete a survey that asks about their attitudes and expectations in a math setting. We will also interview a sampling of the participants to get more open-ended responses.

Potential Impacts

The study aims to counter existing narratives about what math is and who can do it that tend to limit the participation of certain communities in mathematics. For the tribal college community, this research will reveal the importance of culturally relevant mathematics instruction. The resultant technology will be made available for other TCU's to review and potentially adopt.

Keywords: Lesson Study, Observation Protocols, 5Rs Framework, Noticing.

Our Lesson Study (Cerbin, 2011; Lewis et al, 2019) group of mathematicians and mathematics educators adapted and operationalized the 5Rs framework for promoting equitable norms and culture in mathematics (Sears, 2021) in the context of studying undergraduate geometry courses (Boyce et al, accepted). The 5Rs —Responsibility, Relationships, Relevance, Responsiveness, and Rigor (Sears, 2021)—refer to critical aspects of equitable mathematics teaching that instructors of prospective teachers should model to inform their future practice. This research aims to understand how instructors can adapt and use a 5Rs observation instrument to promote equitable norms and culture. In this poster, we describe our process of operationalizing the framework for observations of courses that serve a variety of audiences (e.g., PSTs and STEM majors) and instructor backgrounds.

The observation instrument includes two components for each R: a description of the construct and protocol questions to guide observations. The process of creating and revising these components consisted of three cycles, each consisting of (1) coming to shared understandings of individual Rs' meanings and relationships amongst Rs, and (2) posing and testing construct descriptions and observation protocol questions to determine the extent to which they align with our shared understandings of the 5 Rs. In the first cycle, we maintained the original descriptions of the Rs' meanings from Sears (2021) and developed a set of 20 questions, some of which attempted to simultaneously address multiple Rs. Upon testing that protocol with a lesson observation, we experienced multiple tensions, such as the degree to which we maintained fidelity with the original descriptions; we felt that it was necessary to allow for clarifications and ways to embrace common understandings associated with the terminology. For example, for "Rigor," we noted that the Dana Center (2019) has written about different interpretations of that word, and scholars have identified connections between Rigor and Relevance (Daggett, 2014). In the second cycle, we revised the descriptions of the Rs and created new questions to address only a single R at a time, attempting to resolve the tensions we experienced after the first round. In the third (ongoing) cycle, we have been more deliberate about group members' roles and responsibilities in the testing of the protocol and analysis. Pairs of group members asynchronously analyzed a single lesson, focused on a single R. Subsequently, other group members met synchronously to identify commonalities, themes, and learning opportunities from their peers' observations. The poster will present the current form of the protocol as well as highlights of our learning from creating it.

A Bustling Inquiry-Oriented Math Environment: Who is Present and What is Happening?

Eunice Tachie-Menson, Michigan State University
Kristen Vroom, Michigan State University
Tenchita Alzaga Elizondo, University of Texas Rio Grande Valley

Keywords: inquiry-oriented instruction, new materialism, post-representationalism

Inquiry-oriented (IO) instruction enables learners to discover and explore mathematics, actively engage in the classroom, ask questions, and construct their own knowledge (Kuster et al., 2018; Rasmussen & Kwon, 2007). Grounded in constructivist theories, inquiry-based mathematics education emphasizes the construction of knowledge through learners' interactions with their prior knowledge, peers, and instructor (Laursen & Rasmussen, 2019). These theoretical foundations are crucial for realizing IO's transformative potential for students' cognitive growth. However, we argue that these alone are insufficient given that IO environments and learners are dynamic and thus warrant careful consideration to inform thoughtful classroom design. In this poster, we explore a researcher's (Author 1) relationship with classroom data to consider how the material world participates in learning within an IO classroom. Drawing on new materialist and post-representational approaches, we aim to evoke new wonderings about IO instruction.

We drew on MacLure's (2013) proposal to encounter data that "glows," analyzing bodily responses and spontaneous interactions from two videotaped sessions of an undergraduate IO Calculus II course. By focusing on interactions among different agents in an IO class, we moved beyond traditional transcriptions and coding and instead identified significant material entanglements in the IO classroom that captured our interest. We decentered the teacher and students as the sole agents in the IO instruction, and acknowledged the agency of non-human entities that actively shout their presence in the classroom and contribute to facilitating learning (De Freitas & Sinclair, 2014). Kimmerer (2017) explained "…just because we don't think of them as humans doesn't mean they aren't beings" (p. 57). This idea, stemming from indigenous knowledges, prompts us to envision the possibilities of rich interactions that can exist between these "beings or becoming" (De Freitas & Sinclair, 2014) within the classroom environment.

We identified four "beings or becoming" that brought life into the IO classroom: (1) teaching and learning resources, (2) classroom practices, (3) students, and (4) teacher. Together, these emphasize that the bustling atmosphere is not only contributed to by the students and the teacher, but also by other non-human agents. As an example, a particular teaching and learning resource, Euler maps, served to engage students in conjecturing about sequences (Vroom et al., 2025). When observing the recording, we were struck by the unique invitation the maps extended to students, encouraging them to draw closer and approach learning with their own expressions, bodies, and physical movements. We saw some groups of students becoming more animated and using hand gestures on the Euler maps, while others maintained silence before interacting with their maps, and some students wrote on the adjacent blackboard. We could hear the bustling energy in the classroom through the intensity of the conversations happening around the maps. This leads us to wonder – in what ways can the IO classroom provide different opportunities for students' embodiments? In our poster, we will present our observations and corresponding wonderings, which could lead to reformulating theories for IO classrooms.

Development and Change in Motivational and Self-efficacy Beliefs in Calculus: Relations With STEM Retention

Kaitlyn Roxby
West Virginia University

Vicki Sealey
West Virginia University

Jake Follmer
West Virginia University

Jeffrey Carver
West Virginia University

Retention in science, technology, engineering, and mathematics (STEM) disciplines continues to be an important focus in higher education, with many institutions seeking to enhance student persistence in these disciplines. Previous studies have shown that a higher sense of belonging, self-efficacy, and perceptions of the usefulness course curriculum (e.g., utility value) relate to higher rates of persistence (Tinto, 2017). However, high rates of attrition among students who initially declare a STEM major still exist (e.g., Brewer et al., 2021; Cromley et al., 2016; Doerschuk et al., 2016; Sithole et al., 2017). Previous studies have noted that students' personal characteristics such as motivational and self-efficacy beliefs, academic backgrounds, and institutional factors such as policies related to course sequencing, registration, and grading are factors that play a part in STEM retention (Cromley et al., 2016; Green & Sanderson, 2018). Students who do leave STEM degrees often cite negative experiences in introductory level courses, such as calculus, as their primary reason for leaving (Ellis et al., 2014; Rasmussen & Ellis, 2013; Seymour & Hewitt, 1997). These early courses are often framed as being gateway or "weed-out" courses (Lee et al., 2024). Previous research has noted that students often experience declines in motivation in these courses (Perez et al., 2014), with students enrolled in calculus classes reporting significant declines in their confidence, enjoyment, and desire to take additional mathematics classes (Bressoud et al., 2013; Sonnert et al., 2015).

Given that calculus is a foundational course supporting many STEM majors, it is important to investigate the nature of students' experience in calculus, changes in motivational processes and beliefs in calculus, and the role of such changes in predicting students' intention to remain in STEM. The goal of the present study is to conduct such an investigation through a longitudinal analysis of the utility value, complexity, and general and task-based self-efficacy beliefs of students enrolled in a first-semester calculus course. A survey was implemented across four time-points consistently after completion of common course exams. Our research is framed by the following questions:

- How do students' motivational and self-efficacy beliefs change over time?
- How does the nature of students' change in motivational and self-efficacy beliefs relate to their intent to remain in a STEM degree?
- How do students' motivational and self-efficacy beliefs predict their academic achievement?

Data analysis is ongoing. However, the analyses will provide insight into several key areas addressing student retention and support in STEM. By understanding the nature of change in students' motivational and self-efficacy beliefs in a first semester calculus class along with the nature of students' experiences, we can gain insights into how best to support students. Pedagogical approaches that foster and bolster motivational and self-efficacy beliefs and promote positive learning experiences may be beneficial in promoting persistence.

Justification of Exponent and Logarithm Rules From an APOS Perspective

Matt F. Park
Virginia Tech

Investigations have been conducted into how students conceptualize exponents and logarithms, utilizing APOS theory, particularly regarding how students justify exponent rules. The thesis by Williams (2011) presents a list of codes to identify the conceptions that students hold regarding logarithms. However, a gap in the literature remains on how students justify the corresponding logarithm rules. In this poster, I compare the thinking of two students to extend her work.

Keywords: Algebra and Algebraic Thinking, Undergraduate Education, Precalculus

This poster draws on data from my dissertation regarding how students in a complex analysis course leverage their knowledge of real-valued exponents and logarithms to reason about the complex-valued analogs. Part of my dissertation aims to describe the conceptions that college students have for real and complex exponents and logarithms, and to compare the similarities and differences in terms of APOS theory (Dubinsky, 1991; Asiala et al., 1997; Dubinsky and McDonald, 2001). In my literature review, I have encountered studies that examine how students justify various logarithm rules, particularly the work of Williams (2011). Part of Williams' (2011) claims is that responses to questions about logarithm rules can be used to characterize their process or object conceptions about logarithms. However, her thesis does not report on responses to such questions. The findings in this poster contribute to a larger goal of extending Williams' (2011) framework on exponents and logarithms from an APOS perspective.

Discussion

There was evidence to indicate that both May and Jim's schemas for exponents and logarithms were unified under a broader schema due to the inverse relationship between the two operations. Another similarity between their two schemas was the combinatorial interpretation of exponential expressions, where a^b would be considered shorthand for the number a multiplied by itself b times when b was a natural number. There was more substantial evidence that their schemas diverged when operationalizing an interpretation of fractional exponents. While it is likely that both May and Jim would use roots when calculating fractional exponents, there was definite evidence that such interpretations were not operationalized in proof contexts.

The differences in proofs indicate some variations in their respective schemas. Jim relied solely on the interpretation of iterated multiplication to justify exponent rules. For example, he attempted to reduce the justification of fractional exponent rules to the case of integer exponent rules. He likely operationalizes definitions when justifying properties of exponents and logarithms. He will likely explain the properties of the complex exponent and logarithm by referring to the definition of the complex exponent and the inverse relationship between the exponent and logarithm. In contrast, May's use of logarithm rules to justify exponent rules suggests that in the complex setting, they are less likely to refer to exponents when justifying properties of the complex logarithm.

These phenomena suggest that a similar conception for exponents does not necessarily imply similar conceptions of logarithms. More broadly, among college students, it is likely that the schema for exponents and the schema for logarithms are unified. However, conceptions relating to exponents are likelier to be homogeneous compared to conceptions for logarithms.

Mentoring, Belonging, and Feedback Loops: A System Dynamics Model of Foundational Mathematics Course Coordination

Mitra Alizadeh, Bowling Green State University
Kimberly C. Rogers, Bowling Green State University
Nicholas G. Long, Bowling Green State University

Keywords: Course coordinators, system dynamics model, active learning, instructor belonging

Coordinated collegiate mathematics courses are complex systems wherein social dynamics, mentoring structures, and institutional factors shape how graduate student instructors (GSIs) approach teaching. We focus on eight faculty members who coordinate and teach foundational math courses (FMCs) taught by GSIs (Rogers & Long, 2025), including College Algebra, Precalc, Quantitative Reasoning, Intro Statistics, Math for Architecture & Construction, Math for Elem. Teachers, & Calculus. We hypothesize how implementing professional development (PD) focused on teaching math through active-learning (AL) strategies (Freeman et al., 2014; Laursen & Rasmussen, 2019) for FMC coordinators can enhance their sense of belonging and increase their use of AL in teaching and course coordination. We assess sense of belonging with a modified version of the survey developed by Sidney et al. (2025). Our study considers: (1) How do course coordinators' orientations toward humanistic growth (Martinez et al., 2022) shape their GSI mentoring and engagement with AL within PD contexts? (2) How does course coordinators' participation in PD influence their sense of belonging and relate to evolving approaches to mentoring and instructional change? Together, these RQs lead to: *What interrelated mechanisms among coordinators' humanistic orientations, mentoring structures, and experiences of belonging support emergence and maintenance of meaningful instructional change in FMCs?*

To explore these foci, we developed a qualitative system dynamics model using Vensim simulation software (Mohaghar et al., 2017). By thematically analyzing course coordinators' dialogue and surveys, we found 12 key constructs shaping the FMC coordination landscape; we list the six most prevalent: *Shared Time*, *Resource Accessibility*, *Communication Channels*, *Recognition Events*, *Workload Policy Support,* and *Barriers to AL*. We organized the 12 constructs into five key areas of influence, i.e., system stocks: *AL Use in Coordination*, *Humanistic Growth (HG) Coordinator Orientation*, *Mentoring Structure*, *Instructor Belonging*, and *Exclusion Among Instructors*. We then mapped feedback loops for how these areas interact:

- *Mentoring Loop*: how shared time, trust, and modeling reinforce effective mentoring
- *HG Orientation Loop*: how values and coordinator identity sustain reform
- *Exclusion Brake*: structural barriers that disrupt coherence and inclusion

Our model highlights how mentoring and coordination are not isolated interventions, but dynamic systems shaped by institutional conditions and relationships. When policies support HG mentoring goals and create a collaborative space, FMC instructors are more likely to use AL strategies and experience a stronger sense of community. Conversely, when access, time, or recognition are constrained, exclusionary pressures can dampen change efforts. Rather than presenting coordination as a fixed structure, this model conceptualizes it as a responsive system whose trajectories can shift depending on feedback dynamics, institutional levers, and interpersonal trust. By using system dynamics modeling, we visualize how instructional change emerges through interconnected loops of mentoring, belonging, and institutional structure. The framework makes visible both leverage points and tensions within departmental systems and offers a way to design mentoring structures that are equity-minded, sustainable, and context-sensitive; insights that can inform future PD programs and coordination policies.

Characterizing Generative AI Policies in a University Mathematics Department

Hannah Constantin
Harvard University

Megan Selbach-Allen
Harvard University

Keywords: Generative AI; Course Policy Analysis; GenAI in Math Education

Background and Literature Review

For the 2025–26 academic year, the university examined in this study required instructors to include a generative AI (GenAI) policy in their syllabus but provided only sample language, not specific directives. Prior research shows mixed effects of GenAI on student learning, enhancing engagement and confidence in some contexts (Serhan & Welcome, 2024; Kestin et al., 2025; Wang & Fan, 2025) but reducing cognitive effort and independent reasoning in others (Stadler et al., 2024; Krupp et al., 2024; Kosmyna et al., 2025). While a few studies have examined course-level policies directly (Ali et al., 2025; Kaufmann et al., 2025) none have focused specifically on mathematics courses. This study aims to provide information in this gap by answering the research question: how are math instructors framing policies about GenAI in their syllabi?

Methods

We conducted an inductive thematic analysis (Braun & Clarke, 2006) of 14 course-level GenAI policy statements from math classes at a single institution. This institution serves as a case study and allows us to see what variation exists while controlling for the culture and environment of the department and university. Each policy was authored by an individual instructor or coordinator, reflecting personal perspectives in the absence of established disciplinary norms. Seven policies came from the calculus–linear algebra sequence and seven from proof-based courses. We read and discussed the documents to identify recurring language, rationales, and contrasts in how instructors framed AI use (Bowen, 2009). The resulting descriptive themes capture emerging approaches to GenAI in a university math department.

Results and Discussion

Across the calculus sequence, all courses adopted a moderate approach to GenAI: allowing use for conceptual understanding but prohibiting it for completing homework. Most framed GenAI within broader discussions of learning resources; about half provided explicit examples, and five required students to acknowledge or document their use.

Policies in proof-based courses were more varied. One referred only to general academic integrity, two fully prohibited GenAI, one was completely open, and three mirrored the moderate stance of the calculus sequence. Learning-focused rationales were most common, though some also cited unreliability, integrity, or broader social concerns.

Overall, departmental policies reflected diverse individual perspectives but a shared trend toward moderation, acknowledging that GenAI use is likely and difficult to monitor while clarifying appropriate versus inappropriate use. Several emphasized metacognitive learning rather than unreliability alone, echoing calls to frame GenAI as a learning tool rather than solely a risk (Walkington, 2025). One open policy noted that grades were based mainly on closed-book exams, implicitly justifying limited concern about GenAI access. However, contradictory language, banning GenAI while requiring citation, suggests ongoing ambiguity. Clarifying such tensions and supporting students in ethical, informed use remain central challenges as disciplinary norms continue to develop.

Bridging Mathematics and Science: Task Design and Blended Sensemaking

Anita Schuchardt
University of Minnesota – Twin Cities

Desi
Sriwijaya University

Keywords: mathematics sensemaking, science sensemaking, task

Mathematical equations are a key part of undergraduate science instruction (Li & Schoenfeld, 2019). Students in science classes have both science and mathematical resources they can use to make sense of mathematical equations (Hammer, 2000). Students who make connections between these resources (engage in blended sensemaking) are better able to solve novel or more complex quantitative problems (Bing & Redish, 2009; Schuchardt & Schunn, 2016; Taasoobshirazi & Glynn, 2009). Little research has been done on affordances and constraints for blended sensemaking of different types of tasks involving mathematics in science classes. **RQ:** How do different tasks on mathematical equations in biology affect the types of blended sensemaking discussed by students?

Incoming biology students participating in a session on mathematical modeling of population growth were recorded as they worked in pairs on a sequence of two mathematical tasks. Varying by session, the first task consisted of one of four variants: DM) developing mathematical equations, CM) comparing two mathematical equations, VR) describing relationships between equation variables, and PS) solving problems following an example. The second task was always the same, modifying an equation from the first task. Recorded discussions for each task (4-6) were coded for types of mathematical and science sensemaking and for blended sensemaking using the Sci-Math sensemaking framework (Zhao & Schuchardt, 2021) by two independent coders (Krippendorf's alpha=.77). Counts were standardized for number of groups, time on task.

Across both tasks, the DM/DM-Modify sequence had the most instances of blended sensemaking (DM=100, DM-Modify=169) while the PS/PS-Modify sequence had the fewest (PS=22, PS-Modify=64). Blended sensemaking was categorized into levels based on the types of connected science and mathematics sensemaking (Kaldaras & Wieman, 2023). Lower level indicated connections between sensemaking about mathematical procedures and rules and identifying variables as components of the scientific system. Higher level indicated connections between sensemaking about the structure/syntax of the equation, the quantitative relationships between variables, or represented mathematical concepts and the scientific mechanisms or patterns of the system. Transitional represented connections between lower and higher levels of sensemaking (one from science and one from mathematics). The modify task in each sequence contained high levels of higher level sensemaking (DM=24, DM-Modify=113; CM=31, CM-Modify=76; VR=24, VR-Modify=67; PS=10, PS-Modify=35) mostly between mathematical structure/syntax and patterns students observed in the scientific system. The DM task had many instances of transitional sensemaking (64), most frequently between sensemaking about arrangement of the variables in the equation (mathematical structure/syntax) and what they represent in the scientific system.

These results indicate that different tasks elicit different levels of blended sensemaking indicating different affordances and constraints for helping students make connections between mathematical equations and the scientific system they represent. These findings have implications for which tasks instructors design to leverage student resources and meet learning objectives not only for science classes where students are working on mathematical tasks but also mathematics classes where students are working on modeling scientific phenomena.

Students' Positive and Negative Experiences in Proof Courses

Susmita Pathak
University of Texas Rio Grande Valley

Dr. Tenchita Alzaga Elizondo
University of Texas Rio Grande Valley

Keywords: Proof Courses, Student experience, Undergraduate mathematics courses

Existing research on students' experiences in proof-based courses has often focused on examining insights students gain from lectures (Krupnick et al., 2018; Lew et al., 2016) and their beliefs about the processes of reading, writing, and interpreting proofs (Guajardo & Lew, 2024; Lew & Mejia-Ramos, 2019; Weber & Mejia-Ramos, 2014), with much of this work highlighting students' struggles with proof. In their transition to proof-based mathematics, students are often required to conform more deeply than they would have previously towards linguistic, logical, and authoritative standards that trickle up from and symbolize larger mathematical cultures (Lew K. & Mejía-Ramos, 2019). Such standards can be alienating, especially when they suggest that individuals have struggled or made mistakes, or when they receive unclear or confusing responses (Dawkins & Weber, 2017). Therefore, it is important to understand, from the students' perspective, what students have found supportive or unsupportive throughout their experiences with proof courses. This poster aims to address the research question: What do students perceive as helping or hindering their experiences in proof-based courses?

This poster will use data from interviews with five undergraduates who all had taken at least three proof-based courses. These students were recruited after they had taken a survey regarding their experience with proof courses and had responded "yes" to an interview invitation. The interviews took place over Zoom with the second author and an additional researcher. Students reflected on their experiences in proof-based courses and proof culture. They shared experiences that shaped their views on what is valued in the proof community.

To answer our research question, we used a thematic analysis to identify themes related to what students noted as helpful or not in relation to their experience in their proof-based course.

From our initial analysis we saw a few things come up right away. Grading and expectations were huge issues for students. Some students couldn't figure out what their professors wanted. They lost points for writing too much, or for using shorthand. One student said, "I thought I did everything I needed to. But I didn't know what he wanted." Another said, "Proofs aren't supposed to be assignments… they're explanations for why something is true." Suggesting that disparities in grading expectations hindered their learning experience as it was unclear what was "right" and what was "wrong". This shows students wanted proving to feel more authentic and less rule-driven. The students also pushed back against the idea of blindly accepting answers just because they came from a textbook or a professor. "Most of the class would agree with a proof just because it came from the professor. But nobody's perfect. Anyone can have a small error." This suggests that providing a more authentic proving experience that allows mistakes and errors can help students' learning experience. Students also noted that they wanted more chances to work with classmates, more flexibility. In their eyes, proving did not have to be a solo job, it could feel more like a group puzzle or even a lab, suggesting collaborative work in their proof courses was helpful. This poster will share the themes that came out of these interviews. By identifying these themes, we will gain insight into small changes like better feedback or more chances for group work that can help students feel more supported in proof-based math.

Power Evasiveness in the Graduate Texts in Mathematics Series

José Saúl Barbosa
Michigan State University

Reagin Taylor McNeill
Michigan State University

Keywords: power, critical discourse analysis, graduate texts

Texts have an interpersonal function that establishes relationships between authors, readers, and the content of the texts (Morgan, 1996), and, thus, can be exclusionary. For example, examining the interpersonal function of middle school mathematics texts, Herbel-Eisenmann (2007) found readers are rarely positioned with mathematical authority despite the curriculum's intention. Similarly, texts can valorize masculinity (McBride, 1989), individualism (McBride, 1994), and passively maintain the status quo (Dowling, 1991). Despite the demographic homogeneity of postsecondary mathematics education (Blair et al., 2018), little research has critically analyzed postsecondary mathematics texts. We extend Herbel-Eisenmann's analysis to investigate the interpersonal function of the Graduate Texts in Mathematics (GTM) series with a particular focus on the use of pronouns by textbook authors. We pursue the research question: What do pronouns in the GTM series convey about interpersonal power?

Our analysis is grounded in theories of power evasiveness. Power evasiveness emerged from critical whiteness studies to characterize how racial power can be enacted in implicit or invisible ways (e.g., Frankenburg,1993; Haviland, 2008). For example, white people's common avoidance of racially direct language can be understood as power-evasive, as it deflects recognition of the roles of racism and white supremacy while still allowing them to benefit from their ongoing enactment. Although our analysis does not explicitly center race, we recognize whiteness operates by creating factions to suppress collective resistance (Tochluk, 2010) and structures oppression across many dimensions (e.g., gender; Robertson & Hairston, 2022). We use power evasiveness to describe any enactment of power that is shrouded by power-neutral framings.

We selected 40 books from the GTM series, prioritizing books currently used by graduate mathematics students. Leveraging critical discourse analysis (Fairclough, 2013), we analyzed the opening pages of these texts through the first proof. We used an open/axial/selective coding scheme (Straus & Corbin, 1998) with two sets of open codes: one for pronouns and another to characterize the reader's mathematical authority. In line with prior critical textbook analyses (Herbel-Eisenmann, 2007; Morgan, 1996), we then categorized coded excerpts as inclusive when the reader was an actor in the sentence and exclusive otherwise.

Authors tended to use pronouns that signify the readers' inclusion while simultaneously constraining their agency. For example, "There are topologies on X that do not respect the vector operations in this way, but they are of no interest to us" (Clarke, 2013, p. 4) uses inclusive language to refer to the author and the reader while imposing the authors' mathematical agenda. Similarly, "We agree to write $\mathrm{ord}_p 0 = \infty$" (Koblitz, 1984, p. 2) includes the reader as an actor but forces their agreement with the author. These excerpts demonstrate power evasiveness through their seeming inclusiveness while exerting power over the reader.

While the postsecondary mathematics community has made important strides towards inclusion, this analysis illustrates that inclusion is insufficient to reconstruct mathematics as a liberatory domain (Martin, 2019); power continues to constrain mathematical agency and epistemic diversity (Gutiérrez, 2017). Power evasiveness in pronoun use symbolizes a need to reconstruct the very ways we think, write, and talk mathematically.

Mathematics Support Structures for Calculus and Precalculus: What are the Impacts on Student Outcomes?

Sandy Spitzer
Towson University

Miriam Parnes
Towson University

Keywords: Undergraduate Education, Policy

A long-standing body of evidence (e.g., Bressoud, 2014; Whitcomb et al., 2020) suggests that Calculus I often serves as a gatekeeper course – meaning that a relatively high percentage of students are unsuccessful in Calculus I, and that a failure in the course often causes students to leave STEM degree programs. Some research suggests that Precalculus can play a similar role (e.g., Cooper & Woodward, 2011, Wang et al., 2017). Given the need to maintain a strong STEM pipeline and sustain student career aspirations, there is significant need for university interventions to support student success in courses such as Calculus I and Precalculus. Research indicates that peer-to-peer interactions and mentoring, paired with curricular support, can be effective structures to help students be successful in their early mathematics courses. For instance, co-requisite models have demonstrated success at the Developmental Mathematics level (e.g., Childers et al., 2021; Ngo & Melguizo, 2024), though there is less research on the role of co-requisite courses at the level of Precalculus and above.

This research aims to add to the body of knowledge about co-requisite and peer-led supports by evaluating the success of two mathematics support options for undergraduates at a large public university: an intensive summer "Bootcamp" immediately prior to the start of the Fall semester, and "Companion Courses" which run throughout the semester on a weekly basis. Both structures are supervised by faculty members and implemented by Undergraduate Learning Assistants and incorporate just-in-time mathematics practice, conceptually-oriented review, and study skills support. The Bootcamp was aimed at incoming first-year students who demonstrated readiness for Precalculus or Calculus I, while the Companion Courses are offered to all students enrolled in Calculus I. To understand the effects of these structures, we analyzed data related to student course outcomes (passing grades of ABC vs. repeating grades of DFW and course GPA) for students who participated in these two structures, compared to the general student population.

Results suggest that both structures promoted student success, though the impacts were different for the two programs. For instance, 83% of students who participated in the Bootcamp (N=54) earned passing grade in their first mathematics course, and they earned an average grade of 2.93 (on a four point scale). In comparison, for non-attending students in those same classes (N=431), only 65% earned a passing grade, with an average grade of 2.30 (these differences are statistically significant with $p < .05$). The Companion Course showed more limited evidence of impact, with 63% of enrolled students (N = 40) earning a passing grade in their Calculus class, compared with 62% of non-enrolled students (N = 402; not statistically significant). These results should be interpreted with caution, as selection bias is a significant complicating factor. Our poster will share additional data and explore implications for university policymakers.

An Examination of the Implementation of Inquiry-Based Learning in a Developmental Mathematics Course

Peter Sassman
Northern Illinois University

Keywords: inquiry-based learning, developmental, college algebra

In order to address the college-readiness of students entering colleges and universities, many universities have developmental mathematics courses to help prepare students for later mathematics courses. To help the students in these courses, active learning is often implemented in the classroom, where students are generally engaging in problem solving and using higher-order thinking skills (Bonwell & Eison, 1991), such as analyzing, evaluating, and creating (Krathwohl, 2002). Active learning has also shown generally positive results (e.g. Freeman et al., (2014), Theobald et al. (2020)). A specific type of active learning model is known as Inquiry-Based Learning (IBL), where students are given investigative tasks that promote the engagement of students in the creation of important mathematical concepts (Laursen & Rasmussen, 2019). Generally, this involves students creating and testing conjectures, making generalizations, providing justifications, and reflecting upon their conclusions and reasoning (Mesa et al., 2020). In addition, IBL often involves student collaboration, where students work together to build their knowledge, while the instructor facilitates the learning, in contrast to being the sole source of knowledge. IBL has generally seen positive effects on academic achievement, as well as reducing learning gaps between groups of underrepresented students (e.g. Kogan & Laursen, (2014); Laursen et al., (2014)). However, the use of IBL varies by practitioner, without a consistent definition, although it is consistent with and supported by education research (Laursen and Rasmussen 2019). Because of this, how IBL gets implemented in the classroom may differ across instructors or universities. My project focuses on how IBL is implemented in a developmental mathematics course by five different instructors.

This project uses classroom observations to see how IBL is being implemented in a developmental mathematics classroom covering college algebra. The classes were taught by five different instructors, who were given a few days of training in IBL as well as activities and worksheets they could implement in the classroom. To measure the level of inquiry, the Inquiry-Oriented Instructional Measure (IOIM; Kuster et al., 2019) is used, which is a well-defined measure of inquiry for Inquiry-Oriented Instruction. In addition, to measure how often the students and instructors were engaged with different activities, the Toolkit for Assessing Mathematics Instruction – Observation Protocol (TAMI-OP; Hayward et al., 2018) was used. I examine the IOIM scores as well as the TAMI-OP data, across four content units, to see any similarities and differences in the IBL implementation. This poster will present the data collected and the resulting analysis, to answer the questions: (1) What are the differences in the implementation of IBL by instructors? (1a) What is the frequency of activities and questions students and instructors engage in? (1b) What are the differences of the levels of inquiry in the classroom?

For five different sections, there was a wide variety of ways IBL was implemented. The percentage of groupwork and lecturing varied between the sections. In addition, the frequency and type of questions varied drastically across sections. The IOIM scores also showed differences across sections, both in terms of the mathematics being completed, as well as the ways the instructors elicited and utilized student contributions.

Beyond a Surface-Level Understanding: Developing a Conceptual Assessment of the Derivative

Billy Robertson
West Virginia University

Vicki Sealey
West Virginia University

Keywords: Calculus, Derivative, Assessment, Concept Inventory, Productive Understanding

Background and Literature

Many examinations in mathematics given to students often focus on the students being able to perform procedures such as calculating derivatives. Even when questions are not designed around students invoking specific procedures, problems are often routine enough that students can perform well in the examinations without necessarily having a good grasp of the concepts involved in why their responses are valid. (Tallman et al., 2016, 2021). In contrast, a *concept assessment* or *concept inventory* is an examination which is dedicated to determining how well students understand the concepts associated with a given subject area. Several concept inventories exist for branches of science and mathematics (Hestenes, Wells, & Swackhammer, 1992; Carlson, Oehrtman, & Engelke, 2010), and for calculus the first such concept assessment was Epstein's Calculus Concept Inventory (Epstein, 2013). However, this assessment has been criticized by being not research-based as well as not holding up to tests of validity (Gleason, 2019), leading to additional projects aiming to create improved concept assessments for calculus (Hall et al., 2023; Lee et al., 2025).

Research Aims

This research is part of a larger project, tentatively called Developing CALC, which aims to create a set of smaller, modular concept assessments focused on specific areas within calculus. The first section of the project focused on developing an assessment for definite integrals (Hall et al., 2023), whereas this portion focuses on developing a similar assessment for derivatives. This research is based around much of the literature surrounding student understanding of derivatives, and what makes such an understanding productive (e.g. Zandieh, 2000; Carlson, 2002; Jones, 2018; Reed et al., 2023). Our research question is: "What kinds of questions about derivatives assess whether students have a productive, conceptual understanding of the derivative as opposed to merely surface-level or procedural understandings?"

This second portion of the project is currently in its preliminary stages, with the current goal being the development of the questions themselves. The questions being developed are based on tasks found in previous research, questions in common calculus textbooks, as well as our own teaching experiences. Our aim is for these questions to require students to have good conceptual knowledge of the corresponding topic to be answered correctly, and then the questions will later be given to students to determine if the questions do in fact assess the students' conceptual understanding. The primary goal of this poster will be to serve as a space of discussion, where experienced researchers can critique the tasks we have chosen, come with their ideas for what kind of questions could best serve our aims, which additional topics may be important to ask in an assessment such as this, or to otherwise give feedback on the project at this early stage.

Acknowledgments

The authors would like to thank the rest of the Developing CALC team: Beth Cory, Taylor Martin, & Michael Oehrtman.

Keywords: college algebra, community colleges, mathematics, emotions, attitudes

Attitudes toward mathematics play a critical role in shaping students' learning experiences, academic performance, and long-term engagement with the subject. In the context of community college education, where students often face diverse academic and personal challenges, understanding these attitudes becomes especially important. College Algebra, a foundational course for many degree programs, frequently serves as both a gateway and a barrier to academic progress for STEM fields. For a significant number of community college students, this subject also evokes complex emotions - ranging from anxiety and frustration to curiosity and resilience. Research links positive attitudes to increased motivation and academic success, while negative attitudes, particularly math anxiety, can significantly hinder performance and persistence (Barroso et al., 2021). Students' beliefs about their ability to succeed in mathematics, often shaped by their mindset and goal orientation, influence both their engagement and achievement (Bostwick et al., 2017). As such, exploring how students perceive and emotionally respond to mathematics and the learning of it in college algebra classrooms can offer valuable insights for improving future instruction and support.

As part of a broader research project involving eight community colleges in four states, this study seeks to explore the following research question: What are college algebra students' general feelings and attitudes toward mathematics in community college? Participants engaged in a series of four interviews within a year. During the interviews, participants (1) discussed their personal and mathematical histories related to their current understanding of equity, diversity, and inclusion in the learning of mathematics and the learning environment; (2) provided commentary on short videos of classroom instruction noticing specific characteristics that can be associated with of equity, diversity, and inclusion in the learning of mathematics and the learning environment; (3) engaged in a Q-sort exercise of student statements from the first interview supplemented with statements from the literature that were geared to elicit their perspectives on equity in their learning of mathematics and their learning environment; and (4) reflected on how their understandings of equity, diversity, and inclusion in the learning of mathematics and the learning environment had evolved over time.

This poster will focus on the first interview, where questions were asked to get students' affective connection to mathematics, and gain insight into how their experiences in college algebra classes at community colleges impact their relationship with mathematics. We will share our preliminary findings on college algebra students' general feelings and attitudes about mathematics in community college classrooms around the themes of participants' (1) affective relationship with mathematics, (2) observations about learning mathematics, and (3) beliefs about the nature of mathematics.

Keeping Time: Utilizing Non-Normative Axes in Graphing Tasks to Support Covariational Reasoning

Claudine Margolis
Bolton, MA USA

Keywords: covariational reasoning, graphs, graphing, task design

Covariational reasoning—reasoning about the relationship between simultaneously varying quantities—can support students' sense-making about dynamic real-world or abstract mathematical phenomena. Covariational reasoning has been shown to be challenging for undergraduates (Carlson et al., 2002), preservice mathematics teachers (Moore et al., 2019), and in-service mathematics teachers (Thompson et al., 2017). However, there is also evidence that students as young as middle school can engage in covariational reasoning (Ellis et al., 2015; Paoletti et al., 2023). Tasks in which students are prompted to construct a graph representing the relationship between covarying quantities in an animation of motion can support students in reasoning covariationally (Johnson et al., 2020; Paoletti et al., 2023). However, researchers must pay careful attention to how particular features of the task support or constrain students' opportunities to engage in such reasoning (Stevens et al., 2017).

Covariational reasoning entails constructing quantities (i.e., identifying attributes of a situation that are measurable; Thompson, 1994), imagining those quantities changing in some way (Castillo-Garsow, 2012), and then coordinating those changes (Thompson & Carlson, 2017). When graphing tasks prompt students to coordinate changes in a non-temporal quantity with changes in the quantity of time, students often reason variationally by keeping elapsing time as implicit and something they sense passing by as the other quantity changes (Janvier, 1998; Johnson et al., 2020; Paoletti, 2015; Stevens et al., 2017). As a result, researchers have recommended avoiding using time as a quantity in graphing tasks that are intended to promote covariational reasoning (Paoletti et al., 2022; Stevens et al., 2017). However, many quantitatively rich dynamic situations are time-dependent, particularly in courses that are preparing students for future work in science and engineering fields. In those cases, adhering to the design recommendation would create other curricular tensions.

In this poster, I address the question: *How do students reason about the relationship between time and distance in a dynamic situation when engaged with a graphing task that utilizes non-normative axes?* I use data collected from a series of task-based interviews (Goldin, 2000) with undergraduate Calculus 1 students. Each student participated in two 90-minute interviews which consisted of a series of animation-based graphing tasks designed to elicit covariational reasoning. I coded for the level of covariational reasoning (Thompson & Carlson, 2017) that I inferred students drew on as they engaged with the graphing tasks. I compared students' covariational reasoning on distance-time graphing tasks that utilized normative and non-normative axes (i.e., time on the vertical axis). I found that students engaged in much more sophisticated levels of covariational reasoning when engaged with the non-normative graphing tasks. This finding indicates that designing graphing tasks with non-normative axes is a strategy for supporting students in reasoning covariationally even in contexts where time is one of the quantities. This has implications for curriculum design and research on covariational reasoning in the context of graphing tasks.

Collaborative Approaches for Developing Teaching, Learning, and Stewardship

Emily Braley
Johns Hopkins University

Natasha Speer
The University of Maine

Shandy Hauk
San Francisco State University

Keywords: teaching-focused professional development; leadership; collaboration-based learning

The research in undergraduate mathematics education (RUME) community has amassed insights into features of high-quality learning opportunities for students and what instructors need to know and do to create such opportunities. What does it look like if we leverage what is known from that literature to consider the question: How do we use RUME findings to design and study development of those who sustain and connect professional learning across roles, contexts, and time? Such leaders function as *Stewards* of a discipline, not just expert researchers; they are guardians, teachers, and innovators who ensure that the discipline thrives and remains meaningful for future generations (Bass, 2006).

Powerful classroom-level practices include student collaboration on group-worthy, authentic tasks. RUME has examined ways instructors build the knowledge, skills, and dispositions to support such teaching and learning of mathematics. RUME has also explored how those who are Providers of teaching-focused professional learning create opportunities for instructional growth through purposeful design (e.g., Akin et al., 2023; Braley et al., 2023; Deshler, et al., 2015; Smith et al., 2021; Yee et al., 2023). Together these contributions reveal interconnected layers of subsystems in learning and teaching.

Math-Students-Instructor interactions occur in Instruction. Instruction is a subsystem, an object of study, in Teaching-focused Professional Development (TPD). TPD, as an object of study, includes interactions among Providers and Instructors as they work on Instruction. TPD is, in turn, a component in an even broader system of Leadership Development where leaders facilitate learning by Providers to offer TPD. Human interactions include:

- Students engaging in learning mathematics via collaboration, guided by an Instructor,
- Instructors learning to teach mathematics, guided by a Provider,
- Providers learning to teach about teaching mathematics, guided by a Facilitator.

In this exploration of theory, we utilize prior work (Hauk & Speer, 2023; 2024) to expand on the model. We offer and extend a visual representation of the above. The aim is to capture the work Stewards do as they draw on broad and deep knowledge to guide efforts across (sub) systems across time. We explore the use of authentic group-worthy tasks for professional learning (i.e., tasks relevant to the work of teaching and leadership) and what is necessary for those who orchestrate such learning to know and do. Outcomes will inform designs for learning across multiple layers of the system and leverage the robust base of literature on authentic tasks, collaborative groupwork, and scaffolded learning in mathematics.

Theoretical contributions are two-fold: (1) synthesizing work across several fields to inform the nascent theory-building about leader and Steward development, and (2) exploring how practices used by instructors can be beneficial both for undergraduate student success in the learning of mathematics and in supporting the learning of stewardship. Poster-side conversations will focus on gathering stories about Provider, Facilitator, and Steward development to stress-test the model. Just as the mathematics community has benefited from both theory- and practice-focused research on students and their instructors in the context of learning mathematics, we contend that analogous work focusing on Stewards offers valuable insight into leadership development in post-secondary mathematics education.

Observation Protocols as Research Tools for Video-Based Analyses of Undergraduate Calculus Recitations

Lauren Sager
University of New Hampshire

Rebecca Butler
Virginia Commonwealth University

Keywords: Observation protocol, active learning, classroom observation

Active learning is broadly recommended as an instructional approach for improving student outcomes in undergraduate mathematics classes (Smith & Funk, 2021). However, some research suggests little active learning is being implemented, leading to questions about how time is spent in these classrooms (Ellis et al., 2014). To address this, observation protocols have been developed that categorize instructor and student actions over time. Classroom Observation Protocol in Undergraduate STEM (COPUS) (Smith et al., 2012) and Toolkit for Assessing Mathematics Instructors – Observation Protocol (TAMI-OP) (Hayward et al., 2021) are two such protocols meant to describe actions taken in classrooms, especially to identify those using active learning methods. While these tools are typically utilized as a means of professional development and in evaluation processes, less is known about how they can function as analytic tools within the research process. We address the application of these observation protocols to mathematics education research, asking: What are the affordances and challenges of applying the TAMI-OP and COPUS protocols to undergraduate mathematics classroom video recordings from a research perspective?

This data comes from a larger NSF-funded study on active learning in introductory STEM courses at a medium Northeastern University. Here, we focus on Calculus recitation sessions which are led by a graduate teaching assistant (GTA) and supported by an undergraduate learning assistant (LA). The classroom recordings were selected from two semesters of recordings from the same GTA, used for a case study on the GTA's changes in classroom actions (Sager et al., 2024). The recordings were then coded using both COPUS and TAMI-OP by both authors. Any discrepancies were resolved by discussing until a consensus was reached. In COPUS and TAMI-OP, codes can be analyzed by calculating the percentage of 2-minute time intervals in which the code was marked, or as the percentage of a specific code is marked out of the total codes marked. We provide both computations to illustrate the different perspectives each of these protocols brings to the same dataset.

From our analysis, we show that COPUS and TAMI-OP can both be valuable research tools, but each has strengths that highlight distinct aspects of classroom interactions. TAMI-OP emphasizes questioning and answers, with multiple options to count types of questions and answers. We suggest it is advantageous for research aiming to capture the type of conversation or instruction in a classroom. Alternatively, COPUS tends to show an outline of actions taken in the classroom, making it more suitable for research settings focused on the overall actions occurring. For example, if an instructor begins class with a 10-minute mini-lecture, the first 5 intervals in COPUS may be coded with *lecturing* and *posing questions* for the instruction, while TAMI-OP additionally provides a number and type of questions and answers in each interval, thus giving some information regarding the nature of student participation during this time.

Our work illustrates how these observation protocols can be appropriately adapted as research tools and how each provides different perspectives on active learning in undergraduate mathematics classrooms. We encourage future researchers to apply these protocols to additional contexts in order to further explore the role they can play in the research process.

Doing Math Instead of Watching Math: The Impact of In-Class Activities and Written Feedback in a Prerequisite Mathematics Course

Annie Edwards
Indiana University Bloomington

Corrin Clarkson
Indiana University Bloomington

Keywords: active learning, instructor feedback, student success, D/F/W rates

Research Aim

This study investigates how integrating frequent in-class mathematical problem-solving with individualized written instructor feedback influences student success in prerequisite postsecondary mathematics courses. Specifically, we examine whether redesigning daily instruction around structured engagement and descriptive feedback is associated with improved D/F/W rates and patterns of persistence.

Context and Rationale

Research shows that active learning and constructive feedback support deeper understanding and confidence in undergraduate mathematics (Cirillo et al., 2024; Vroom et al., 2022; Grove & Good, 2020; Bressoud & Rasmussen, 2015). Yet most studies examine calculus or upper-level courses, leaving open how these practices function in prerequisite mathematics courses where attrition is high. Few studies consider their combined influence or link instructional features to institution-level outcomes such as D/F/W rates and persistence. This study addresses that gap by analyzing success patterns following a redesign integrating in-class problem-solving, individualized written feedback, and scaffolded reflection, thereby extending and replicating prior findings in a critical gateway context.

Methods & Research Question

RQ: How does the integration of frequent in-class engagement and individualized written feedback relate to student success in prerequisite postsecondary mathematics as measured by patterns in D/F/W rates and persistence? Institutional outcomes from semesters before and after an instructional redesign, featuring structured problem-solving, individualized feedback, and reflective prompts, are compared using descriptive and comparative analyses.

Anticipated Findings

We anticipate that the redesigned instructional model will correspond with lower D/F/W rates and improved persistence, suggesting that prerequisite mathematics courses may benefit from greater emphasis on daily mathematical engagement and meaningful written feedback. By analyzing both instructional features together and focusing on a high-attrition gateway course, the study offers insight into how to move prerequisite mathematics from a barrier to a pathway for student success.

Implications for Practice

Findings may inform institutional reform efforts by highlighting how active learning, individualized feedback, and reflective practice can be integrated into daily instruction to promote engagement, confidence, and persistence. This work also demonstrates the value of replication studies in mathematics education and underscores the importance of systematically examining instructional redesigns in prerequisite mathematics courses, spaces where small pedagogical changes may yield large institutional impacts.

Multiplying Fractions with Sunlight: A Scaling Model

Eric Pandiscio
University of Maine

Justin Dimmel
University of Maine

Keywords: fractions, units, scaling, ratio

Physical models are frequently used in elementary mathematics classrooms to support students' understanding of multiplication. These models are discrete, and many represent multiplication as repeated addition, area or an array. Thompson and Saldanha (2003, p. 104) found that "thinking about multiplication as repeated addition leads to severe difficulties in later grades" and Hurst (2015, p. 11) suggested that "multiplication as scaling…is a key aspect of thinking that needs to be developed." McLoughlin and Droujkova (2013) developed a diagrammatic definition of multiplication using parallel lines to scale the length of one segment by the length of a different segment. We developed the SunRule, an interactive device that harnesses parallel rays of the sun to perform multiplication. Beams of light cast shadows from gnomons onto a measuring plane; by varying the tilt and height different multipliers, multiplicands, and products can be generated.

This proposal extends research with K-8 preservice teachers reported in (Dimmel et al., 2021) where participants made sense of multiplication as a scaling, continuous operation. They used informal language to describe the relationship between changes in the multiplier, multiplicand, and product - that they were growing (or shrinking) in similar ways. While not specifically mentioning ratios, the preservice teachers described the shadows as changing in ways that were multiplicative or proportional in nature.

The study will investigate the use of the SunRule specifically to explore fractions, using a new model that zooms in to numbers between 0 and 1. In this version the gnomons and the shadow plane are partitioned into fractions of a whole (typically eighths or twelfths, but it could be any increment). The unit gnomon is scaled down to fractions between 0 and 1 by tilting the device, and the multiplier is scaled between 0 and 1 by changing the height of the gnomon. We ask the question: "How do preservice teachers make sense of multiplying fractions between 0 and 1 when using a dynamic, continuous, scaled model?" One significant change/improvement of the new model is that every rational product falls on the shadow plane, even if it doesn't fall on a specified increment. We also ask: "How do preservice teachers make sense of rational products cast as shadows that do not fall on a ruled increment?"

Figure 1. 3 x 4 = 12

Figure 2. 1/2 x 2/3 = 1/3

Figure 3. 1/2 x 3/8 = 3/16

Analyzing How Course Modality Impacts the Learning of Mathematics of Students in a Hispanic Institution

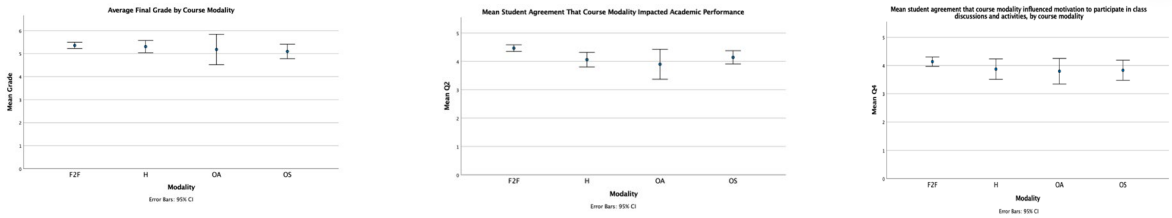
Bryan Barbosa
The University of Texas Rio Grande Valley

Keywords: Mathematics Education, Course Modality, Motivation, Engagement, Achievement

Universities have recently adopted the use of various course modalities to accommodate diverse types of students (e.g., distance-learning). It is important to investigate how the different course modalities affect students' achievement and affect (e.g., motivation, willingness to participate, confidence). Building on prior research that explores the relationships between course modality and student success (e.g., Fischer et al., 2020; Helms, 2014; Kundu et al., 2023), this study investigates how different instructional modalities–Face-to-Face (F2F), Hybrid (H), Online Synchronous (OS), and Online Asynchronous (OA)–affect the learning and motivation of undergraduate mathematics students. This study addresses this research question: How does the modality of undergraduate mathematics courses affect students' academic success?

Data were collected through an anonymous survey administered at the tutoring center of a majority Hispanic institution. This institution offers undergraduate mathematics courses in four modalities: F2F, H, OS, and OA. Survey participants were students in classes ranging from college algebra to ordinary differential equations. A total of 249 responses were analyzed over eight different courses; these responses included Likert-scale questions regarding how course modality affects their motivation to participate, the impact of their final grade due to modality, as well as their final letter grade for each respective class and modality. The data were analyzed using SPSS to compare means and confidence intervals of the survey scores across the four modalities. The means and confidence intervals are shown in Figure 1.

Across all measures, Face-to-Face and Hybrid students outperformed online students (see Figure 1a) and expressed a stronger perception of learning motivation (see Figure 1c).



(a) (b) (c)

Figure 1. (a) Average final grades across modalities with a 95% confidence interval. (b) Mean agreement that modality impacted academic performance. (c) Mean agreement that modality influenced motivation to participate.

The findings suggest that environments that promote active interaction, such as F2F and H, enhance students' achievement and motivation when it comes to the mathematics classroom. These results align with Kundu et al. (2023), who found that hybrid learning promotes satisfaction and engagement. For struggling students, immediate feedback, collaboration, and guided instruction appear to be crucial for both success and motivation.

How is Gender Discussed? A Textual Analysis of RUME Proceedings

Anne Cawley
Cal Poly Pomona

Matthew Voigt
Michigan State University

Ayesha Maliwal Bundy
Michigan State University

Andrew Baas
Texas State University

Gender has long been studied within math education, evolving from deficit and assimilationist models, positioning girls' lower participation as a problem to be fixed, to feminist and sociocultural frameworks that conceptualize gender as relational and intersecting with other axes of identity (Leder, 2019). The "leaky pipeline" continues to be well-documented (Blickenstaff, 2005) and persistent disparities in representation and persistence remain in math-intensive fields (Brown & Leigh, 2021). Despite this history, little is known about how the undergraduate mathematics education research community itself conceptualizes and engages with the construct of gender. Because gender functions as both an empirical tool and a critical lens (Leder, 2019), examining how it has been theorized, operationalized, and represented in RUME proceedings sheds light on the field's evolving commitments to equity and inclusion. *This gap motivates our landscape analysis of RUME proceedings from 2018 to 2024 to map how gender is being operationalized.*

Our gender textual analysis draws from previous work analyzing race (Contreras et al., 2025), and began by performing pattern-based text retrieval on the corpus, retrieving a 40-word list of gender-related terms. The list included terms related to binary identities (e.g., "woman", "male"), non-binary and fluid identities (e.g., "non binary," "two spirit"), transgender experiences (e.g., "trans"), related social and biological concepts (e.g., "cis gender," "pronoun"), and terms for gender expression (e.g., "masculine," "gendered"). We used the results of the text retrieval to assign each paper to one of several categories based on the terms they used, refining this categorization through regular team discussions. Papers were coded based on the role of gender in the research: *Core* for a central focus (and a summary noted); *Peripheral* if gender was substantive but not central (like positionality or an analytical tool component); *Non-Focal* if gender was only mentioned in passing (e.g., unanalyzed demographics or quotes); and *Unrelated* if gendered terms appeared only within the references or embedded within math problems.

Our preliminary analysis indicated that of the 1,426 reports and papers published in the proceedings from 2018-2024, 438 papers (30.7%) contained a keyword. Most of the keywords were found within contributed (50.7%) and preliminary reports (23.7%), with 17.8% of posters and 5.3% of theoretical reports containing keywords. 13.5% of all proceedings containing a keyword were identified as Core while 11.2% were identified as Peripheral, totaling 24.7%. This left 75.3% of papers identified as Non-focal or Unrelated (45.4% and 29.9% respectively). Therefore, a majority of the papers which contained at least one keyword used those keywords only in reference to participant demographics, other authors' work, or in the context of a mathematical problem. These counts demonstrate that less than a quarter of studies which reference gender incorporate it meaningfully in their work, with around one-eighth of papers utilizing it as a central focus to their study. Our poster will further analyze the papers coded as Core and Peripheral to understand the ways that gender is being captured and analyzed (e.g., focus on a specific group, binary comparison, critical intersections). We intend to expand this work to examine the ways in which gender topics are utilized within RUME, to identify the theoretical and methodological tools employed, and to elevate authentic ways of humanizing gender research in mathematics education.

Student Perspectives on the Mathematical Formalism in an Operator-Based Quantum Mechanics Course

Jason Tran
Georgetown University

James Freericks
Georgetown University

Leanne Doughty
Georgetown University

Keywords: Quantum Mechanics, Operators, Student Perspectives, Semi-Structured Interviews

Quantum mechanics represents a uniquely interdisciplinary learning environment where student success depends on navigating the boundary between mathematical abstraction and physical interpretation. Students must coordinate the symbolic reasoning (e.g., linear algebra, Dirac notation, operators) with conceptual quantum ideas like measurement. Prior research has shown how this intersection often creates cognitive and epistemological tension for learners, particularly in quantum (Schermerhorn et al., 2019; Wawro, Watson, & Christensen, 2020).

Within both the mathematics education and physics education research (PER) communities, scholars have noted that students' epistemic framings, such as their views on mathematics in constructing physical meaning, are critical to developing a deeper understanding. Wawro et al. (2025) found that students often interpret eigenequations differently across linear algebra and quantum mechanics contexts, revealing gaps in how mathematical symbols acquire physical meaning. Complementary work in PER highlights that representational and epistemological struggles manifest as affective and identity challenges, where learners continually renegotiate what "counts" as math or physical reasoning in their STEM courses (Schermerhorn et al., 2019).

Broader studies in undergraduate STEM education report that students' success in advanced mathematics and science courses is influenced by both their prior preparation and their self-efficacy in applying mathematics to novel contexts (Korpershoek, Kuyper, van der Werf, & Bosker, 2011). Moreover, Matthews, Adams, and Goos (2009) argue that many science curricula treat mathematics as a procedural prerequisite rather than a tool for sense-making, thereby limiting opportunities for interdisciplinary reasoning.

The data were collected through a series of semi-structured, think-aloud interviews conducted with undergraduate students enrolled in a junior-level quantum mechanics course. Each participant would provide their attitudes, opinions, and perceptions on a variety of topics pertaining to their quantum mechanics course. Responses were coded and analyzed, revealing a range of attitudes, from appreciation and confidence in mathematical precision to frustration with abstraction and a perceived lack of physical grounding.

This poster will focus on findings suggesting a correlation between students' sense of ownership of mathematical tools and their ability to conceptually bridge quantum measurement and experimental practice. The analysis emphasizes the pedagogical significance of explicitly linking symbolic operations to interpretive and experimental contexts. These findings align with the cross-disciplinary disconnects reported by Matthews et al. (2009) and Wawro et al. (2025), suggesting that challenges in integrating mathematics and physics extend beyond cognitive to include epistemological and emotional aspects. Importantly, this study provides a student-centered representation of these dynamics, revealing how learners articulate their own mathematical understandings within the context of quantum mechanics.

A Proposed Extension to the Productive Struggle Framework

Lucinda L. Ford
Georgia Southwestern State University

Keywords: Productive Struggle, Student Thinking, Undergraduate Developmental Mathematics

Struggling with mathematics can be beneficial for students (Hiebert & Grouws, 2007). However, we need to ensure that student tasks are developmentally appropriate (Hiebert & Grouws, 2007). Productive struggle (PS) is "the space within which a student's struggle is likely to be productive" (Hiebert & Grouws, 2007, p. 388). PS hinges on the participant reaching a productive resolution, maintaining the intended level of cognitive demand, and completion or moving forward with the task (Warshauer, 2015a). PS also involves the risks of vulnerability and self-reflectivity, for both student and teacher (Murdoch et al., 2020).

The research question related to this poster asked: What pedagogical approaches could be used to support undergraduate developmental mathematics students as they work toward constructing fraction understandings that will be useful in college-level mathematics courses? Specifically, what pedagogical approaches support an environment such that a student productively struggles in a difficult fraction task during a teaching episode? By undergraduate developmental mathematics students, I mean undergraduate students who do not test ready for college-level mathematics.

In this poster, I share insights from a larger dissertation study in which I used a productive struggle (Warshauer, 2015a; 2015b) approach while conducting clinical interviews (Ginsberg, 1997) and teaching experiments (TE; Steffe & Thompson, 2000) to explore how undergraduate developmental mathematics students understood fractions. Vivian (pseudonym) was recruited from a randomly selected undergraduate developmental mathematics class at a large research university in the southern United States. Her TE was during fall 2023 and spring 2024. Data were analyzed through ongoing and retrospective analysis (Steffe & Thompson, 2000). Using subtasks as my unit of analysis, I applied the PS framework (Warshauer 2015a; 2015b) to identify instances of Vivian's struggles. Vivian had to express a struggle in some form, for a subtask to be classified as containing a struggle, consistent with Warshauer (2015a). Using Warshauer's (2015a; 2015b) framework, I identified Vivian's productive struggles, then classified the teaching response(s) and move(s) used during the tasks. Multiple codes were applied when present.

Through the coding process, I found that Vivian experienced PS during 24 of the 31 subtasks in her TE where she struggled. When coding Vivian's PS for teacher responses (Warshauer, 2015a) I found that one subtask received a telling response. Vivian received directed guidance during four subtasks, where she was given probing guidance during 17 subtasks. Vivian received an affordance response, such as acknowledgement or giving time, during subtasks. The results for teacher moves (Warshauer, 2015b) used during Vivian's PS revealed that she was asked questions during 20 subtasks. She received encouragement during six subtasks. Vivian was given time to work through 11 subtasks, and her mathematical thinking and effort were acknowledged during 3 subtasks. Unexpected results included the telling and directed guidance moves, but they were productive when Vivian was reiterating the task prompt or being redirected back to the task goals. Additionally, Vivian had two unproductive struggles that remained unresolved when she chose to shift the focus of her solution strategy for a task, showing a potential extension to the PS framework (Warshauer, 2015a; 2015b) by adding an additional ending to an episode of struggle.

Finding Joy in the Abstract

Mary Ziegler Zimmerman
University of Maryland

Victoria Fernandez
University of Maryland

Jade Johnson
University of Maryland

Matt Bravo
University of Maryland

Nora Belfedal
University of Maryland

Keywords: Mathematics education, Rehumanizing mathematics, Mathematical play

"This is the most fun I have ever had in a math class," exclaimed one of the students during a collaborative homework session. A collective revelation followed - none of us had had this much fun in mathematics before. Our abstract algebra class, which started as a space of insecurity for some, had morphed into a community of joy and playfulness that encouraged us to explore mathematics in ways we had never considered before. This study aims to describe the characteristics of a joyful mathematics classroom through the lived experiences of researcher-participants in this course, which can be applied to secondary and post-secondary mathematics settings.

The Need for Joy and Play in Mathematics

Su (2020) declares, "We would teach math so differently if we thought of it as a playful sport, not a performance sport" (p. 62). Joy and playfulness lead students to develop more nuanced understandings of mathematics and encourage them to pursue it further (e.g., Takeuchi et al., 2016). Experiences of joy and play also contribute to rehumanizing mathematics and pushing the field towards much-needed culturally and historically responsive work (Gutiérrez, 2018). Research on joy and play in mathematics spaces has increased; however, while there are some exceptions (e.g., Ellis et al., 2024), most studies have predominantly focused on early education or primary school settings, overlooking the potential for joy and play as we mature into adulthood (McLennan, 2020; Solarski, 2018). There is little work on rehumanizing mathematics in postsecondary settings (Gutiérrez et al., 2025; MacArthur et al., 2025).

Methods and Preliminary Findings

This study examines our experiences as five doctoral students at a large mid-Atlantic university as we participated in an Abstract Algebra seminar class. Our group included four female students and one male student studying mathematics or physics education, two of whom had previously taken an abstract algebra class. One student identifies as Latina, one as MENA, one as Black, and two as White. We met weekly to explore topics in abstract algebra, including sets, groups, rings, logic, and fields. Homework was assigned weekly, and collaboration was strongly encouraged. We also read and discussed papers that defined algebra and its relevance to K-12 mathematics education. We applied a mixed-methods concept mapping analysis (Windsor, 2013; Trochim, 1989) to collaboratively synthesize our diverse ideas into a shared framework, identifying the characteristics of a joyful and playful mathematics classroom. Preliminary themes of structured flexibility, safety, exploration, and community have begun to emerge as among the most imperative characteristics of our joyful and playful mathematics class.

Instructor Moves in an Inquiry-based Undergraduate Mathematics Course for Prospective Secondary Mathematics Teachers

Kaylea L. Arif
The University of Texas at Arlington

James A. M. Álvarez
The University of Texas at Austin

Keywords: Secondary Preservice Mathematics Teacher Education, Functions, Instructor Moves, Inquiry-based Learning

To support the integration of inquiry-based learning practices in mathematics teaching, many studies have explored instructor moves and their effects on student outcomes (Deshpande & Guglielmo, 2019). In addition, on the topic of functions in mathematics, Breidenbach et al. (1992) apply Action-Process-Object-Schema (APOS) theory to describe the development of the process conception of function. Dubinsky and Wilson (2013) also use APOS theory and ideas of Quine (p. 89) to explore students' understanding of the function concept. Representations of functions (Even, 1998) and covariation (Thompson & Carlson, 2017) play important roles in the understanding of functions. This poster explores the research question: What are the key instructor moves used to facilitate student learning of functions in an inquiry-based undergraduate mathematics course for prospective secondary mathematics teachers (PSMT)?

This study is part of a larger study conducted at a large, diverse, urban university in the southwestern United States. Participants (n=27) worked in groups on an inquiry-based lesson on covariation in a mathematics course for PSMTs (Beach, et al., 2020) over three eighty-minute class periods. Student and instructor interactions were video recorded, focusing on two to three groups at a time. After audio transcription, open coding of instructor moves identified the following codes: Promoting, Probing, Redirecting, Revoicing, Mathematically Precise Speech, Relating to Other Concepts, or Vague/Non-Response. In addition, continuous periods of instructor engagement with a group, typically involving several instructor moves, were clustered as instructor move episodes (IME). Student discourse before and after each IME was assessed on a four-point scale, informed by instructor lesson logs. Level 0 indicated hesitant discourse while Level 2 characterized moderate, on-topic discussion of functions by most group members. Level 1 and Level 3 indicated minimal and maximal discourse, respectively. For each IME, the initial and final level of student discourse and instructor move frequencies within the IME were noted. The data analyzed consisted of four IMEs of the same student task worked by three groups.

Probing was the primary instructor move identified in episodes that shifted discourse about functions from Level 0 to Level 2 and Level 1 to Level 2. However, for the two episodes where discourse shifted from Level 2 to Level 3, Prompting surpassed Probing and frequencies of Mathematically Precise Speech, Relating to Other Concepts, and Revoicing increased.

Preliminary results suggest that the effectiveness of using a particular instructor move may be dependent upon the state of student discourse at the time of use. The move from Level 0 or 1 to Level 2 may be attributed to asking students direct questions (Probing) to facilitate engagement. In contrast, a shift towards a deeper level of discourse may require instructor moves that focus on the introduction of more specific information and precise language. Findings suggest that the shifts in student discourse after each IME also may indicate enhanced conceptual understandings of functions.

Approaching Zero: Exploring Calculus Students' Conceptions of Zero

Carlos Alejandro de Alba
San Diego State University & University of California, San Diego

Keywords: Zero, Calculus, Student Conceptions, Mathematical Understanding

Although it is perceived as trivial, zero plays a crucial and nuanced role in many topics of mathematics that often goes unnoticed by students. Zero's roles include that of a placeholder and an identity, but for most students zero is perceived simply as a number representing nothing. Previous studies have suggested that a conception of zero rooted in nothing is quite nuanced (Seidelmann, 2004; Vest & Alibali, 2024), but it may not align with all situations involving zero. Studies have also shown that teacher conceptions of zero vary greatly but are very similar to those of their students (Wheeler & Feghali, 1983). Ultimately, researchers have suggested that students' and teachers' understanding of zero is limited or incomplete (Inhelder & Piaget, 1969; Tsamir, Sheffer, & Tirosh, 2000; Seidelmann, 2004). These studies, of which there are very few, have yet to consider how one's conception of zero may be a fragmented combination of many different conceptions. By reframing conceptions of zero this way we can consider how students operationalize different elements of their conception of zero based on problem types and context.

In this study, I consider the many conceptions of zero held by calculus students and how they employ those conceptions based on different tasks. Calculus students have been chosen as the population of study because of the central role of zero in calculus and the fact that students have undergone many mathematical domains in which zero played an important role. Studying calculus students also presents an opportunity to uncover how early or traditional conceptions of zero do or do not align with calculus understanding and procedures. In this work I am guided by the following research questions:

1. In what ways do calculus students conceptualize the concept of zero and its many roles in mathematics?
2. In what ways do calculus students employ varying conceptions of zero to navigate tasks and mathematical situations?

To answer these questions, I have designed a two-stage mixed-methods study with high school and undergraduate calculus students as the population of interest. Students from two high school classrooms and two undergraduate classrooms will respond to a questionnaire that is meant to uncover how students conceptualize zero as an object as well as in the context of traditional arithmetic problems and calculus situations. I will conduct a thematic analysis (Braun & Clarke, 2006) with a series of a priori frameworks from existing literature as a guide to establish students' conceptions of zero. A subset of five to seven students with diverse conceptions of zero will be selected from each population to participate in a follow-up interview. The interview will consist of mathematical tasks and reflection questions that expand upon the topics covered in the questionnaire. A thematic analysis (Braun & Clarke, 2006) of the interview data will enrich my understanding of the conceptions of zero held by students and the ways in which they navigate tasks with these conceptions.

Although the primary data collection is set to take place in the spring, the pilot data suggests that students are comfortable using zero in mathematical situations but may not have a strong understanding of why zero behaves as it does. When some students describe zero, they find that their conception does not align with how they use zero to operate in domains such as multiplication, division, and limit calculations.

Calculus Students' Mindsets are Not So Simplex

Haile Gilroy
McNeese State University

Devin Hensley
Auburn University

Keywords: mindsets, growth mindset, metacognition, calculus, topological analysis

In Psychological Meaning System Theory, *mindsets* are attitudes that people hold about themselves (Dweck, 2000). Traditional studies on mindsets are rooted in psychological methodologies, relying on surveys, questionnaires, and psychometric scales. While these tools give researchers initial insight into the mindset phenomenon, due to their nature, they also prime participants to think about specific mindsets in isolation. To study mindsets from a different methodological perspective, Hensley & Gilroy (2025a, 2025b) analyzed the differences in how Calculus I students' mindsets manifest over a semester depending on students' first exposure to a Calculus course (high school or university) using data collected from short reflective prompts during an actual Calculus course. Results suggested that students who took Calculus in high school tend to exhibit different mindsets than those taking it in college for the first time.

In Topology, an intuitive definition of a *simplicial complex* is a space with a triangulation (Weisstein, n.d.), which is useful for modeling the structure of multi-dimensional combinations of objects. Each simplicial complex contains a variety of sub-dimensional objects; a vertex is zero-dimensional, an edge is one-dimensional, a filled-in triangle is two-dimensional, a solid tetrahedron is three-dimensional, and so on. The purpose of this study is to revisit the coding results from Hensley & Gilroy (2025a, 2025b) and to conduct a novel analysis of the mindsets exhibited by students who were "successful" in Calculus I. We defined "success" as those earning a final grade of "A" ($n = 31$) or "B" ($n = 28$). For each student, we assigned a "mindset simplex." For each of Units 1, 2, 3, and 4, we constructed a simplicial complex that modeled each student's combinations of mindset codes. Then, we tabulated the frequency of simplices in each unit whose vertices represented productive mindsets (growth, mastery, strategic, and curious), non-productive mindsets (fixed, helpless, non-strategic, and non-curious), and mixed mindsets (at least one productive and at least one non-productive mindset). We note that the mindset simplices are similar to the Code Co-Occurrence Model produced by software like MAXQDA (*Code Co-Occurrence Model*, n.d.). Viewing these combinations of mindsets through a topological lens allows for them to be viewed in higher dimensions.

We calculated the relative frequency of the types of simplices (productive, non-productive, and mixed): first, on the aggregated data, then disaggregating initial frequency tabulations by gender, final grade earned, and first setting of Calculus, and comparing between groups. We saw the largest differences between students who first saw Calculus in a high school (HC) setting versus a university setting (CC). CC students had higher proportions of strictly productive mindsets than their HC counterparts.

This provides further evidence of the conclusions in Hensley & Gilroy (2025a, 2025b) that these two groups of students exhibit different mindset profiles, implying that they experience a typical general Calculus I course very differently. Furthermore, it may be advantageous for instructors to consider these differences when teaching the course. An extended version of this writing with figures can be accessed at https://tinyurl.com/MindsetSimplex.

A Covariational Lens for Proofwriting in Undergraduate Mathematics

Gabriel Chavez
CSU Monterey Bay

Katarina Fenner
Arizona State University

Keywords: Proofwriting, Chunky and smooth framework, Undergraduate Mathematics

Literature Review

We examine how undergraduate students navigate proof writing through two complementary images of activity: chunky assembly and smooth development, and how students transition between these modes while producing a final proof write-up. While the chunky/smooth framework was originally developed to characterize students' images of change in covariational reasoning, Castillo-Garsow et al. (2013) emphasize that these distinctions also describe how mathematical activity itself is organized, independent of domain.

In this study, we adapt the chunky/smooth distinction as an analytic lens for describing modes of engagement during proof construction. Proof writing often involves alternating between discrete exploratory episodes without attention to the larger argument (chunky) and more continuous episodes in which students attend to the overall logical throughline (smooth). Existing literature documents related distinctions, such as exploration versus validation (Weber, 2008) and dimensions of proof comprehension and coherence (Mejía-Ramos et al., 2012), but offers limited language for characterizing how students move between these modes during authentic proof writing.

By framing proof activity in terms of chunky and smooth episodes, we aim to provide a descriptive vocabulary that complements existing proof frameworks and enables fine-grained analysis of how students organize, refine, and translate exploratory work into coherent written proofs.

Research Questions

RQ1. What episode types (e.g., exploratory "chunky," throughline "smooth," resource-use) arise during students' proof writing, and with what typical sequences?

RQ2. What triggers students' commitment from exploratory "chunky" work to a sustained "smooth" throughline, and what triggers stalls or switches?

RQ3. How do ideas generated during exploration survive (or not) into the final written proof, and how does resource-use (text/web/notes) inform that translation?

Study Design

We conduct exploratory think-aloud interviews (40–60 minutes) with undergraduates enrolled in proof-based mathematics courses. Participants work through two multi-route proof tasks, selected strategically from Hammack's *Book of Proof* (2018), with access to resources as in an authentic homework setting. Data sources include audio recordings, scratch work, and final written proofs.

Episodes will be coded to identify chunky and smooth modes of activity, transitions between them, and their alignment with features of the final proof write-up. Following the interviews, participants complete Likert scale items probing their beliefs about proof writing and what constitutes a "good" proof, allowing us to situate observed activity patterns within students' stated views of proof.

We are beginning the interview phase and anticipate initiating episode coding in January.

Examining Undergraduates' Conceptions of Series Convergence via Script Writing

Eduardo Torres Manzanarez
The University of Texas at Arlington

James A. M. Álvarez
The University of Texas at Austin

Keywords: calculus, script writing, series convergence

Students typically encounter the definition of series convergence as the limit of a sequence of partial sums in second-semester calculus. However, students struggle coordinating series and partial sums (Martin, 2013; Martínez-Planell et al., 2012), which Martínez-Planell et al. attribute to a weak limit schema. This supports claims by McDonald et al. (2000) that students require a "a rich sequence schema … to fully understand series as the limit of a sequence of partial sums" (p. 98) and that students encounter difficulties in applying their understanding of sequences to subsequent mathematical concepts. Other research on student understanding of series includes how students think about series convergence (e.g., Eckman & Roh, 2022; Martínez-Planell et al., 2012) and how students interpret or develop series notation (e.g., Eckman & Roh, 2024a, 2024b; Larsen et al., 2024). Researchers recognize the challenges students encounter in learning series and the need for meaningful tasks that enhance student learning about series (e.g., Lindaman & Gay, 2012; Torres Manzanarez & Álvarez, 2025; Vroom & Alzaga Elizondo, 2025).

This exploratory study centers on examining students' understanding of series convergence using both non-scripting and scripting-based tasks to gain insight into the affordances of script writing for assessing understandings in this context. Script writing requires student engagement in imagined role-play by writing a script that extends a prompt that begins a dialogue between a teacher and student or between two students. In 2018, Zazkis issued a call-to-action for researchers to use script writing to explore or assess mathematical understandings. This poster addresses the following research question from a larger study: What is the nature of possible conflict factors with regard to students' concept definition and concept image of series convergence that arise in student responses to non-scripting-based tasks and a scripting task?

In a departmentally-coordinated second-semester calculus course, over a 15-week semester, 105 students across ten different sections granted researchers access to their second midterm exams and scores. Participants (n=18) scoring in the third and fourth quartiles consented to engage in two interview sessions. They completed two interview sessions which included: (a) a non-scripting task-based interview, (b) a script writing training activity, (c) a scripting task, and (d) a semi-structured interview about their script. Half engaged in the non-scripting task in the first interview session and the scripting task in the second interview session. The order was reversed for the other participants. Qualitative data analysis entailed coding interview responses using a priori codes on student conceptions of series identified in the research literature and using the theoretical lens of concept image and concept definition (Tall & Vinner, 1981). In addition, emergent codes from the data were identified.

Aligning with Martin (2013) and Martínez-Planell et al. (2012), participants encountered difficulties relating the sum of a series and the limit of the series' sequence of partial sums. However, the scripting task revealed aspects of participants' understanding of series in relation to partial sums even for participants who were unsuccessful demonstrating this on the non-scripting tasks. This exploratory work underscores the potential viability of scripting tasks as a tool for investigating student understanding of series convergence. Furthermore, this study shows promise for future work in developing and using new scripting tasks on series in second-semester calculus courses and tracking their effectiveness for improving student learning.

Towards a Tribal College and University Mathematics Education Research Agenda

Belin Tsinnajinnie

Jessica Benally
University of California, Berkeley

Lisa Savčak
WestEd

Keywords: tribal colleges and universities, developmental math, math pathways

Background

There is a vast underrepresentation of contexts of Indigenous learners and from the contexts of TCUs. Further exacerbating this underrepresentation is the general lack of presence of research in developmental mathematics education in mathematics education research spaces. Research in undergraduate mathematics education focusing on developmental math and research on mathematics education in TCU contexts are each severely lacking. Research at the intersection, developmental mathematics education in TCU contexts, is scant if not nonexistent. In order to advance knowledge in these areas, there is a need to highlight the work being done at TCUs.

TCU faculty are tasked with aligning mathematics education with TCU missions to revitalize language and cultures, but there are limited existing mathematics resources that are ready to implement in the classroom in ways that directly align with TCU values and missions (Marshall, 2018; Crazy Bull & Guillory, 2018; Crazy Bull et al., 2020). Furthermore, TCU faculty are often working with extensive teaching and service duties in small mathematics departments. This results in little time and few resources to engage in mathematics-specific collaborative learning opportunities (Al-Asfour & Young, 2018). While TCUs work to provide innovative STEM education to Indigenous communities, what is known and published about STEM education in TCU contexts is limited. With such limited research on developmental math education in TCU contexts, there is rich potential that such research can contribute to the RUME community by taking perspectives rooted in TCU missions and values.

Current Trends in Mathematics Education at TCUs

This project provides snapshot of current contexts for developmental mathematics education and mathematics pathways in TCU contexts, with a particular focus on developmental mathematics and math pathways, consisting of: a literature review that provides an analysis of trends in the literature pertinent to mathematics education at TCUs, targeting trends and needs in research and practice in the areas of developmental math and math pathways; a landscape analysis consisting of summary of qualitative and quantitative data on mathematics programs, in particular developmental math and math pathways at TCUs; and a Promising Practices report summarizing innovative and promising practices in developmental math and mathematics pathways as shared by TCU math faculty participating in the project.

Towards a TCU Mathematics Education Research Agenda

Given the current trends in mathematics education at TCUs, we call not only for more research and opportunities to highlight innovative mathematics education at TCUs. We also outline a research agenda that situations math ed research in the context of TCU's roles of empowerment of Indigenous communities and tribal nation building.

Keywords: Student Outcomes, Prerequisites, Prior Knowledge, Curricular Coherence

According to constructivist and cognitivist theories, students learn through the reconstruction of new knowledge using related, existing knowledge (Rach & Ufer, 2020). The greater the depth of a learner's prior knowledge, the easier it is to integrate new information into existing cognitive structures (Kollar et al., 2014). Prerequisite courses provide access to "domain-specific prior knowledge, [which] has been found to be the most important variable influencing student achievement" (Hailikari et al., 2007, p. 59).

This study examines two prerequisite pathways, Quantitative Literacy (QL) and College Algebra (CA), leading into the target course, Elementary Mathematics for Teachers (EMT), at a public, state university in the United States. QL courses are typically taken by non-STEM majors and focus on building data literacy, while CA courses are typically taken by STEM majors and focus on building procedural fluency. This university's QL courses are assessed non-traditionally, opting for projects and article analyses, whereas the CA courses are assessed conventionally, using tests, quizzes, and homework.

Our exploratory analysis was guided by the following question: How, if at all, does a student's prerequisite pathway impact their final course grade in EMT? We began with institutional course-tracking data across the past two academic years (Fall 2023 to Spring 2025) to compare final course grades (4.0 GPA scale) between students entering EMT from these two pathways. After cleaning the data (e.g., removing duplicates), we generated visualizations (e.g., grouped bar chart) and used both descriptive (e.g., comparing median grades) and inferential (e.g., Kruskal-Wallis test) statistical methods to conduct our analysis.

Preliminary findings indicate that students entering from the CA pathway tend to earn higher final grades, on average, than those entering from the QL pathway. This result in isolation, however, obfuscates the complex nature of student outcomes; to claim that one pathway is stronger than the other inherently dismisses the multifaceted nature of students' mathematical experiences and learning outcomes. Instead, it encourages further questioning of the pathway's underlying mechanisms. Are certain skills emphasized within the CA pathway more easily transferable to EMT? Do similarities in assessment modalities between the EMT course and courses within the CA pathway positively facilitate this transfer? Could pedagogical choices within the CA pathway be positively influencing affect?

Future work will extend this analysis by incorporating additional contextual variables, such as class size and start time (Hurdle & Mogilski, 2022), to identify potential sources of student performance variation. If information about students' past experiences can offer insight on their future experiences, then a student's outcome in a pre-requisite course could indicate a positive experience to be had in the following course.

Modeling the Relationship Among Classroom Climate, Math Self-Concept, and Math Interest in College: A Proposed Humanizing Framework

Abel Sekone
San Diego State University & University of California San Diego

Keywords: classroom climate, math self-concept, math interest, African philosophy of Ubuntu

Mathematics self-concept and interest are key predictors of student achievement and future career choices (Geisler et al., 2023; Pietsch et al., 2003). Studies have demonstrated that the two psychological processes of motivation can be related to the psychosocial environment in the classroom, also termed as classroom climate (Erdem & Kaya, 2024) for students at all educational levels in mathematics courses (Sekone, 2025; Wang et al., 2017; Yin et al., 2020). However, those studies were mostly grounded in Eurocentric sociocultural theories including Moos's (1979) framework, Bronfenbrenner's (1979, 2005) ecological systems, Vygotsky's sociocultural (Walshaw, 2016), and the four-phase model of interest development (Hidi & Renninger, 2006) to either describe the classroom climate and/or examine its contribution to self-concept or interest in mathematics (e.g., Stone-Johnstone, 2023; Yang, 2015; Yin et al., 2020).

To gain a comprehensive and sociopolitical understanding of the mechanism of the causal relationships among the three constructs, this study proposes a framework that integrates sociocultural Eurocentric theories with the African philosophy of Ubuntu (Blackwood, 2025; Tutu, 1999) which translates to "I am, because we are" (Mbiti, 1989, p. 106). Ubuntu emphasizes the interconnectedness and shared humanity of all people and in education, Ubuntu pedagogy is considered "a learner-centered pedagogical approach that promotes democratic atmospheres where students feel respected, cared for and have the freedom to co-learn in an environment where power relations are grounded in humanism." (Ukpokodu, 2016, p. 155).

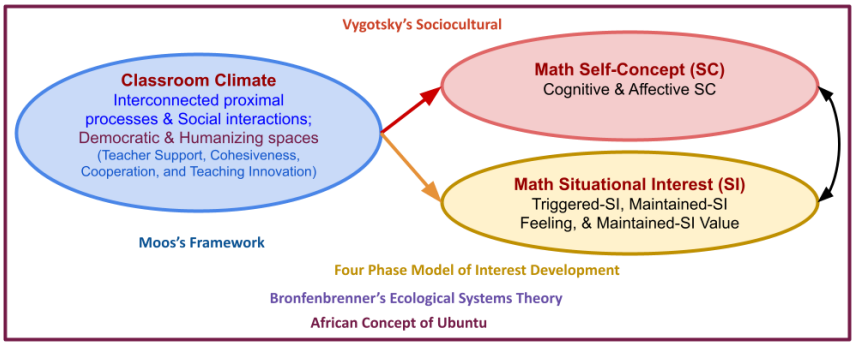

Figure 1. Hypothesized Model of Causal Relationships Among Classroom Climate, Self-Concept, and Interest

In the poster, I include the modeling process that resulted in the hypothesized model (see Figure 1) depicting how the humanizing African philosophy of Ubuntu can provide a sociopolitical lens that enriches the descriptive and/or explanatory power of the four Eurocentric sociocultural theories to gain a comprehensive understanding of the influence of classroom climate on self-concept and interest in mathematics. From this study, RUME researchers could identify avenues for using this model to inform classroom practices and curriculum design aimed at fostering mathematics motivation. I also discuss how my future research will collect quantitative surveys and qualitative data in Calculus I courses to test the proposed humanizing framework.

Where and to Whom Should Students Talk About Math: Mathematicians' Contemplations of Student-Instructor and Student-Student Interactions

Lindy Hearne
Virginia Tech

Keywords: Active learning; changing pedagogical practice; linear algebra; university mathematics instruction

Aims

In this poster, we focus on discussion or communal problems-solving to promote higher-order thinking, aiming to identify where instructors are open to employing instructor-student and student-student interaction in teaching and learning of abstract linear algebra.

Literature review

Despite effective alternative research-based practices showing positive effects on student learning outcome (see Freeman et al., 2014), most university mathematics courses are taught predominantly by lecture (Fukawa-Connelly et al., 2017; Johnson et al., 2018; Johnson, 2019). In response, Artigue (2016) recommends "collaborative projects, building and negotiating, jointly with mathematicians … [finding approaches] … that make sense for all … and meet their respective … needs" (p. 12). As proposed changes to instructional practices occur in environments where there are obligations to mathematics as a discipline, to students, and to their institutions (Charzan et al., 2016), considering adoption of active learning strategies involve managing sometimes-conflicting obligations.

Methods

We utilize data from a collaborative project between mathematics education researchers and mathematicians where together they attempted to integrate active learning pedagogy into mathematicians' lectures in a proof-based linear algebra course. We used the method of constant comparison through the grounded theory approach (Strauss and Corbin, 1994) to form a preliminary codebook using Atlas.ti software. Next, we focused on the interactions where instructors were considering in class and out of class activities. The table of code was further developed to code the instructors' responses to active learning strategies which focused on two different interlocutor pairs, namely student-student and student-instructor.

Preliminary Results and Discussion

We found instructors cited time and student preference as the two major constraints to implementing discussion in the classroom. Overall, the participating instructors were more open to student-instructor interaction (coded 119 times) than student-student interaction (coded 21 times), though not in all cases (12 student-student coded by a single instructor, who had facilitated active learning as a graduate student).

Outside of class activities were raised as an alternative, by the instructors when discussing both time, and student preference obligations that constrained their use discussion in the classroom. In these cases, 7 were coded student-instructor interactions and 5 were coded student-student interactions. Outside of class discussion activities overcame the in-class time constraint and were viewed as beneficial. Furthermore, they were student initiated, and so respected and encouraged student autonomy.

Investigating the Alignment of Instructors' and Students' Perceived Self-Efficacy Levels and Sources in an Introduction-to-Proofs Course

James White
University of Oklahoma

Keywords: self-efficacy, proving techniques, alignment

This study investigates whether there is alignment between an instructor's and students' perspectives on students' self-efficacy levels and sources for using proving techniques in an Introduction-to-Proofs (ITP) course. It uses Bandura's self-efficacy theory (1977) and its four sources of self-efficacy (performance accomplishments, vicarious experience, verbal persuasion, and emotional arousal) as a basis for understanding where students' self-efficacy levels may originate. This builds on an established interest in understanding Bandura's four sources with respect to mathematics self-efficacy levels (Gainor & Lent, 1998; Gao, 2020; Parsons et al., 2011; Regier & Savic, 2020; Usher & Pajares, 2009; Watkins & Middleton, 2021).

Klassen and Lynch (2007) investigated the perspectives of Grade 8 and 9 students with learning disabilities and their teachers regarding the students' self-efficacy levels and sources. They concluded that the students' and teachers' perspectives of the students' self-efficacy levels and sources were misaligned. My study investigates if there is a similar case of misalignment between student and instructor perspectives in an ITP course, as "the differences in teacher and student perceptions and understandings of self-efficacy may result in teachers' providing interventions that are not valued by students, and possibly even counterproductive to their academic performance" (Klassen & Lynch, 2007, p. 504). This study is therefore guided by the following research question: Do teachers' and students' perspectives regarding students' self-efficacy levels for using proving techniques and the classroom experiences that influence students' self-efficacy levels for proving techniques align?

Data collection is ongoing from an ITP course that is running during the Fall 2025 semester by observing and recording each class session and conducting interviews with six students and the course's instructor. There will be, in total, three rounds of student interviews (SI) and two rounds of instructor interviews (II) that take place in the following order: SI1, II1, SI2, II2, SI3. Each interview consists of three phases. The first phase focuses on each participant's recent experiences in the course. The second phase's questions focus on two proof-based problems that I give each participant. Note that SI1 and II1 have the same problems, as does SI2 and II2. In the third phase, I show participants four classroom recordings and ask them questions about their recollection of each moment and each moment's possible impact on students' self-efficacy levels. This phase is being conducted similarly to Lew et al.'s methods (2016) that showed a real analysis course's students and instructor the same classroom recording to investigate alignment between what the instructor intended to convey during the lecture and students' understandings of the lecture's material.

This poster will focus on the study's preliminary results. The preliminary findings suggest there is some alignment between the instructor's and students' perspectives on students' self-efficacy levels and sources for using proving techniques. For example, the perspectives of the instructor and several students agreed that students were more confident in their ability to prove a statement directly than in their ability to prove a statement by contradiction. Additionally, the instructor and most of the students said that the in-class example of proving $\sqrt{2}$ is irrational by contradiction did not positively impact the students' self-efficacy levels for using contradiction.

Exploring Student Engagement With Concept Maps

Devin Hensley
Auburn University

Ryann Firestine
Auburn University

Melinda Lanius
Auburn University

Keywords: concept maps, connection making, student engagement, multivariable calculus

Successful students see mathematics as connected ideas (OECD, 2013). Concept maps can be used to visualize these connections (Jeong & Evans, 2021). Research suggests that concept mapping can lead to high-quality learning (Schroeder et al., 2018); however, there is little recorded usage of them in mathematics education (Jeong & Evans, 2021). Between 2019 and 2024, only 4 out of 50 studies in a meta-analysis on concept maps with measurable outcomes related to learning and/or engagement were explicitly about mathematics (Kefalis et al., 2025), underpinning the notion that research is needed to examine the efficacy and engagement of students with concept maps in mathematics. We will answer: how effective are concept maps at eliciting student engagement with the derivative?

In a supplemental instruction session (SIS), 16 multivariable calculus students created concept maps using up to 23 terms from a word bank (derived from known derivative frameworks (Likwambe and Christiansen, 2008; Zandieh, 2000)) and provided reasons for each connection they identified. We analyzed connection reasons using the Relational Scoring Method created by McClure and Bell (1990) with context-specific modifications by the authors (Figure 1). Procedural (P) and conceptual (C) relationships were the focus because P and C knowledge of the content is needed for student success (Rittle-Johnson, 2017). Scoring was chosen because it is one of the most common analysis tools for concept maps (Ekinci & Şen, 2020).

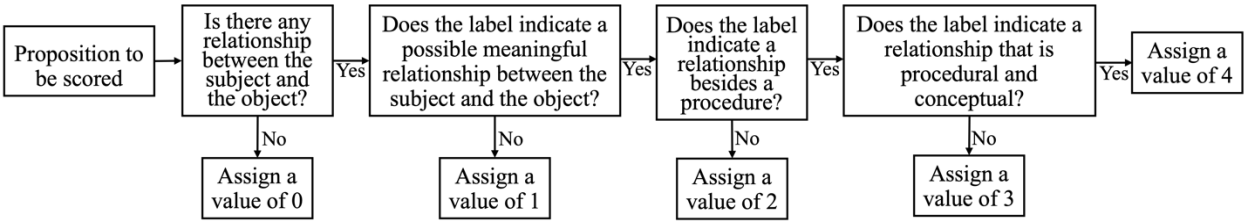

Figure 1. Modified scoring protocol.

As seen in Figure 2, the median number of words from students was 62. The median score of the concept maps was 66.5. More details about scoring and its implications will be discussed in future work. This study suggests that current approaches to analyzing concept maps make them an ineffective tool for deeply understanding student reasoning about the derivative. However, in future work, we will explore novel approaches to analysis that might bring new life to concept mapping for research.

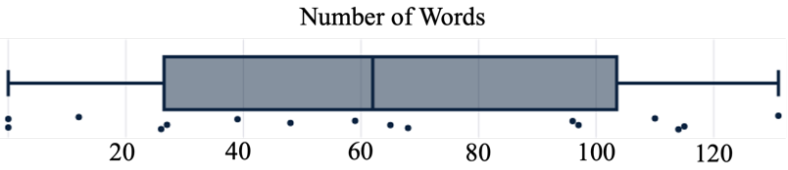

Figure 2. Number of words box plot.

Preliminary Analysis of Problem Solving in Introductory Environmental Engineering

Kyla Robinson
University of Nebraska at Omaha

Keith Gallagher
University of Nebraska at Omaha

Keywords: problem solving, environmental engineering, water systems, flow diagrams

Strong computational and algebraic skills are commonly understood to be a prerequisite for success in engineering. In a 2021 review of the literature on mathematics in engineering education, Pepin, Biehler, and Gueudet discussed a need for "bridging" between school mathematics and the mathematics needed in university engineering courses. This study homes in on aspects of problem solving in engineering that may be challenging for students.

Written data were collected, including homework assignments, midterm exams, and final exams, from consenting students in an introductory environmental engineering course on designing small water systems at a mid-sized university in the Midwestern USA. This poster will focus on a preliminary analysis of the midterm exams of 17 students from this course.

A modified version of Carlson and Bloom's (2005) Multidimensional Problem-Solving Framework was used to code the data. This framework consists of four main phases: orienting, planning, executing, and checking. However, the nature of our data prevented us from being able to identify instances of students' planning and checking in their problem solving. We therefore modified this framework and used an open coding process (Strauss, 1987) to identify instances of students *orienting*, *setting up a problem*, and *executing a solution strategy*. Codes were applied at the level of a question-part. This was then used to determine in which phase of the problem-solving framework students most frequently committed their first error in multi-part problems.

Data analysis is ongoing; in this proposal we present preliminary findings from the midterm exams of five students. Among these five students, no student successfully identified all system boundaries when given a flow diagram for a small water system (Question 2). This task requires only engineering knowledge to complete. However, the subsequent three questions required students to use their knowledge of these reaction boundaries to write symbolic mass-balance equations, and three of the five students were able to write correct equations for all three of these questions. This suggests that these three students did not recognize the significance of the reaction boundaries and their relationship to these equations. On Question 1, students were given information and asked to draw and label a flow diagram for a small water system. All five students drew the correct structure, but two mis-identified masses as volumes and a third produced an incorrect number for a variable that was not given. Both students who incorrectly labeled masses missed follow-up calculation questions because of this mislabeling, suggesting an understanding of mathematics that was undercut by a misunderstanding of engineering content.

Though preliminary, these findings suggest that the engineering students in our sample had the mathematical skills necessary to solve problems related to the design of water systems, but their ability to solve these problems successfully was inhibited by gaps in their understanding of engineering content. In the completed poster, we will present results from the midterm exams of all 17 students in our data corpus, and future research will analyze the final exams and homework assignments of all students in this sample. We will identify the problem-solving phase in which students encounter the most difficulty and examine students' trajectory throughout the course to identify transient and persistent obstacles to their successful solving of engineering problems.

Examining a GTA's Knowledge for Teaching Statistics via Scripting Tasks

Abby Sine
Penn State University

Neil Hatfield
Penn State University

Keywords: Statistics Education, Graduate Teaching Assistants, Knowledge for Teaching

According to the Conference Board on Mathematical Sciences survey in the Fall of 2021, approximately 1 in 4 (24%) introductory statistics instructors in statistics departments at 4-year institutions were graduate teaching assistants (Blair & Kirkman, 2025). Despite reliance on graduate teaching assistants (GTAs) in providing introductory statistics instruction for undergraduates at a time where data science and statistics programs are growing in popularity, research into statistics GTAs' knowledge for teaching is sparse. Previous work highlights GTAs' desire for support in multiple areas including technology, content, and pedagogical practices (Green, 2010) and an inconsistency in preparation for GTAs' across institutions (Justice et al., 2017). This leaves many GTAs to construct their knowledge and beliefs about teaching statistics independently which may result in their practice being rooted in their own classroom experiences and beliefs rather than recommended educational practices.

We conceptualize knowledge for teaching statistics using aspects of the Technological, Pedagogical, and Content Knowledge model (TPACK; Mishra & Koehler, 2006), Ball et al.'s (2008) domains of mathematical knowledge for teaching, and Groth's (2007) model of statistical knowledge for teaching. In this way, we draw upon the important aspect of technological knowledge in the realm of statistics while also utilizing Ball et al.'s subcategorizations of content and pedagogical-content knowledge in our exploration of GTAs knowledge for teaching statistics. The incorporation of Groth's model of statistical knowledge for teaching allows us to explore some of the non-mathematical aspects of knowledge for teaching statistics which differ from knowledge for teaching mathematics. In this poster, we aim to show how the use of scripting tasks allows us to explore GTAs' knowledge for teaching and how their knowledge may affect their pedagogical decisions, which may position them as helpful activities for use in the preparation of GTAs to be statistics educators.

In this project, five GTAs participated in a two-part sequence of one-on-one interviews centered around a scripting task. Scripting tasks (Crespo, 2018) are a type of activity designed to engage future educators in thinking about the process of teaching by providing a hypothetical, written scenario and asking them to continue the scenario in a script format where they control all actors in the scene. Our scripting task modeled a discussion between the GTA and two students while working on an activity exploring bootstrapping and confidence intervals in the large-enrollment introductory statistics course at the GTAs' home institution. In their first interview, each GTA was asked to "prepare for class" by reviewing the activity students would be working on in their hypothetical class. Then, they were given the scripting task and asked to continue the script, talking aloud about their decision-making process. For their second interview, GTAs' worked through a set of alternative scenarios based on their original script that were designed to present common alternative conceptions students may have in the context of the activity, again discussing their thought process and decision making.

This poster will focus on the interviews with one GTA, Norman, with a focus on identifying areas where aspects of his knowledge for teaching statistics were made visible through the use of the scripting task. Additionally, we'll discuss the potential of scripting tasks for engaging GTAs in thinking about students' alternative conceptions in statistics.

Redesigning Assessment for Growth in Mathematics for Elementary School Teachers

Jeffrey Slye
SUNY Oswego

Sarah Hanusch
SUNY Oswego

Keywords: Alternative grading, redesign, preservice teachers

Our institution is increasingly concerned with the success of students in their first-year courses, especially underrepresented minority students. As part of an institution-wide push to redesign courses with higher failure rates, we redesigned the assessments and grading scheme in our two-semester sequence of courses for future elementary teachers.

Literature and Redesign

The redesign efforts were aligned with the four pillars for alternative grading (Clark & Talbert, 2023), which include clearly defined standards, helpful feedback, marks indicating progress, and reassessment without penalty. Working backwards from revised course standards, we created methods of assessment that fell into four categories: skill checkpoints (in-class, written assessments), videos (short recordings showcasing a student's knowledge of how to teach math with manipulatives), and projects (longer, multi-week homework targeting broad skills).

Each assessment is graded as either a "pass" or a "not yet", with written feedback provided for each "not yet". Additionally, each assessment can be either revised and resubmitted or reattempted with no penalty to the grade. Letter grades were assigned based on the number of assessments passed, with cutoffs set for each letter grade in each category.

To assess the effectiveness and reception of this redesign, we asked the following questions: (a) is there a statistically significant difference in DFW rates between redesigned sections and non-redesigned sections, and (b) what are students' opinions about the new grading system?

Methods

Since 2023, the redesigned grading system has been used in 7 sections of the first course and 3 sections of the second course. Grade distribution data for sections of the course taught by the authors since 2022 was analyzed computing the pass rate for each section, defined as the number of students with a C- or better divided by the number of students enrolled.

In the fall of 2024, focus group interviews were conducted with 5 participants. The interviews were conducted by a third party. The participants were asked to reflect on their experiences using the grading system. End-of-semester course evaluations for the redesigned sections were also included in the analysis in order to cross-reference student sentiment.

Results

Comparing the pass rates with a t-test gave the following results: the mean of the redesigned sections is 0.617, the mean of the traditionally graded sections is 0.662, which was not a significant difference (p=0.36).

Qualitatively, students' opinions were divided. Some were positive about the reduction in anxiety enabled by reattempts. Others experienced more anxiety, as falling behind led to an ever-growing number of reattempts. Some praised the redesign for its focus on growth and understanding, while others felt that an all-or-nothing "pass" marking system was preventing them from succeeding. Students' receptiveness was impacted by the instructor's experience with the redesign.

Integrating Computational Thinking in Undergraduate Statistics Projects: A Comparative Analysis

Valentina Postelnicu
Governors State University

Xiaobo She
Governors State University

Andrius Tamulis
Governors State University

J. Christopher Tweddle
Governors State University

Keywords: computational thinking, statistics

Computational thinking (CT) is a way of approaching problem-solving by breaking the problems into steps or algorithms that can be executed by humans, computers, or both (Aho, 2012; Li et al., 2020; Wing, 2006, 2008). In statistics education, CT may be employed as a problem-solving strategy (Postelnicu, 2025a, 2025b; Postelnicu & Postelnicu, 2020) by guiding students to decompose complex problems or datasets in manageable parts, recognize patterns, abstract key features, and design algorithmic processes for data analysis (Weintrop et al., 2016; Wing, 2006). Recent studies (Astuti et al., 2025; Irawan et al., 2025) pointed out to the benefits of CT integration in the teaching and learning of statistics in high school and college, and the effect of the type of learner and the statistics curriculum on student performance across the CT core components.

We present here the findings from a pilot study, part of an ongoing study, conducted with college students from two undergraduate courses – an elementary statistics course addressed to students with various majors (Group 1), and another course addressed to future early childhood and elementary education teachers (Group 2). The statistics curriculum for Group 2 students included only descriptive statistics. Students from both courses completed a statistics project designed to incorporate CT features and reflected on the CT approach. The following research question was addressed: What similarities and differences emerged in CT integration between the two project sets?

Data was analyzed across the CT core components (Astuti et al., 2025; Irawan et al., 2025; Postelnicu, 2025a, 2025b; Postelnicu & Postelnicu, 2020): i) *decomposition*- dividing problems into manageable parts; ii) *pattern recognition* – identifying patterns, trends, correlations; iii) *abstraction* – simplifying the problem, focusing on essential variables or characteristics; iv) *algorithm desig*n – constructing an algorithm or a sequence of computational steps.

Across both groups, decomposition consistently achieved the highest scores. This was expected, given the structure of the projects, containing the following: title and research question, data collection/ dataset description, descriptive statistics and/or inferential statistics, visual representations, analysis and interpretation, CT reflection, references, data source documentation. Some of the projects from Group 2 demonstrated strong pattern recognition, especially those projects requiring comparisons between various populations with respect to some characteristics. The projects from Group 1 achieved higher scores in abstraction and algorithm design. Overall, Group 1 reflections showed stronger CT integration, connecting each CT component to the design and execution of the project. Group 2 reflections were more of a practical nature, focusing on how to perform calculations or use the software.

The CT integration is promising, but we need to account for its variability across educational contexts (Astuti et al., 2025; Grover & Pea, 2018; Irawan et al., 2025; Postelnicu, 2025b; Shute et al., 2017).

Exploring Calculus Students' Technology Use With Dynamic Graphing Technology

Ariana Castoreno
University of Texas at San Antonio

Benjamin Sencindiver
University of Texas at San Antonio

Keywords: Technology, Graphs, Conceptual Understanding, Cognitive Load

Technology is commonly used in mathematics education to communicate ideas and support understanding of complex concepts. It can assist students by providing automated feedback on practice problems, such as in online homework environments (Dorko, 2020), and by individualizing problem sequences based on students' responses to prior questions (e.g., ALEKS). Drijvers (2012) describes students' use of technology as either doing mathematics or learning mathematics, with the latter including practicing skills and developing conceptual understanding. Roschelle et al. (2017) expand on this by considering productive and transformative perspectives of students' purpose to situate to describe the broader literature on educational technology.

Technology can support student understanding in several ways, such as reducing cognitive load by offloading calculations to technological tools, allowing students to focus more on conceptual reasoning (Paas, Renkl, & Sweller, 2004; NGA & CCSSO, 2010). Interactive technologies can also be programmed to follow formal mathematical rules, thereby supporting students' understanding of different representations (Heid & Blume, 2008). In this poster presentation, we explore how this framework helps us understand students' engagement with dynamic graphing software (Desmos) in a calculus context using Roschelle et al.'s framework.

Our data comes from one-on-one, task-based interviews with two undergraduate students enrolled in first-semester calculus. Students were asked to reason about function values, rates of change, and how these quantities vary when presented with a graph. They first interacted with a static image of the graph and were then given access to a dynamic version in Desmos.

We found that the students interacted with the technology in distinct ways and with seemingly different purposes. Roschelle et al.'s framework was useful in capturing this variation, as both students used Desmos in productive and transformative ways. Their engagement included doing mathematics, practicing skills, and developing concepts. For instance, one student used Desmos to practice a skill in a transformative way by alternating between reasoning with the printed static graph and the dynamic version. Notably, one student's understanding of changing quantities and slope evolved after leveraging Desmos features such as continuous sliding and zooming. We interpreted this as evidence of a transformative shift in their conceptual understanding. One student had taken a new understanding of an output $f(a)$ during the interview, and the task designer used the Desmos software to remind and reinforce that understanding– reducing cognitive load– by visually depicting the naming convention in the graph, supporting the student in maintaining that understanding throughout the task. Overall, we found the transformative categories to be more applicable to the data, possibly due to the nature of the graph interpretation task, which emphasize estimation from visualized measurements rather than numerical calculation. Future work will explore different tasks that incorporate other technologies (e.g., matrix calculators), which may yield different categorizations within Roschelle et al.'s (2017) framework.

Identifying Barriers to Success in First Year College Mathematics Courses

Dana Olanoff
Widener University

Keywords: first year mathematics, barriers to success

For first year students, their first semester GPA is a strong predictor of college persistence, that is, whether they return to university in the fall of their sophomore year (Steward, Lim, & Kim, 2015). This study was conducted at private, nonprofit university in the northeastern United States. Approximately 75-80% of the roughly 900 first year students enrolled in the Fall 2025 registered for a mathematics course. While many of these students are successful in their mathematics courses, too large a number of them struggle. This poster presents on a study designed to identify these barriers and suggests ideas of future work in designing interventions to help overcome some of the barriers.

For this study, the researcher went to 35 sections of what are traditional first year mathematics courses (e.g., elementary and college algebra, precalculus, calculus 1, intro statistics, math for elementary teachers, intro discrete mathematics) to ask students to fill out a preliminary survey discussing their high school mathematics experiences. 464 of the approximately 700 students enrolled in these courses filled out the survey in its entirety. The questions on the preliminary survey asked mainly about students' experiences in their prior math courses as well as their expectations for their current mathematics course. Some preliminary results include approximately 44% of respondents identifying as first-generation college students and nearly 22% of students not having taken a mathematics course in the previous year. 36% of the students reported taking online tests in their previous mathematics course, with 20% of those students reporting that they had no exams on paper. (3% of the students reported not having exams at all.) Nearly 92% of the students at least somewhat agreed that they had the knowledge and skills necessary to succeed in their current mathematics course with a similar number anticipating that they would earn a grade in the A or B range in their current course. When asked what they anticipated would be their biggest barriers to succeeding in their mathematics courses, the answers reported by the most students were "I don't do well on tests/have test anxiety" (46%); not being fully prepared for their current course (40%); and "I am not a math person" (37%).

At the end of the semester, students will be asked to complete a post-survey with similar questions regarding their current mathematics course. Then the researcher will use students' final course grades to try identify a profile of students who were least successful in their mathematics courses, as well as those who were most successful. Using final course grades, attendance records, and pre and post surveys, we hope to be able to determine factors that contribute both to students struggling and succeeding in their first year mathematics courses. We will also look to see if strong differences exist in reported experiences in high school versus college courses, as differences between the way that high school and college mathematics courses were structured and taught can lead to students struggling in their STEM courses (Meaders et al., 2019).

After gathering and analyzing all of the data, future work will entail designing interventions to help students overcome the identified barriers, such as review modules for missing content areas and test preparation advice for studying and taking college math exams.

Keywords: Introduction to Proof, Sense of Belonging, Proof Reading

Introduction to Proof (ITP) is a pivotal point in the trajectory of mathematics majors. The Reading and Appreciating Mathematical Proofs (RAMP) project is a multi-year study that developed a series of proofs and accompanying author biographies for use in ITP courses (Contreras et al., 2025). Mathematicians each created three proofs designed to be both accessible and engaging for students at this level. The mathematicians were purposefully selected to broaden the kinds of mathematical stories students encounter challenging narrow, stereotypical images of "who does mathematics" and supporting a stronger sense of belonging in mathematics, factors linked to women's underrepresentation and attrition in the field (Good et al., 2012; Piatek-Jimenez, 2008).

Data thus far has been collected from nine sections (four using the curriculum; five not using the curriculum) of introduction to proof from two institutions. The final round of data collection is occurring this year. Students in the classes took a pre- and post- survey covering proof (Logic; Roh & Lee, 2024) and Sense of Belonging (SB; Good et al., 2012): 56 students in (15 women; 41 men) RAMP classes and 47 students (20 women; 27 men) in non-RAMP classes. In this poster, we will present some preliminary analyses of this data, including additional data collected from classes this semester. Our base model (women as reference group) for each survey is $\text{Post} = \beta_0 + \beta_1(\text{Pre}) + \beta_2(\text{Treatment}) + \beta_3(\text{Gender})$. Assumptions were checked and reasonably met. Pretest scores were standardized to allow meaningful comparison. In our initial exploration, the pre-surveys and gender were substantial predictors of logic post-surveys. For sense of belonging, pre-surveys were the only substantial predictor of post-surveys. A one standard deviation increase in the pre-survey score predicts a 3.57-point increase for the logic post-survey and a 5.34-point increase for the sense of belonging post-survey. Women are predicted to score 1.87 points higher on the logic post-survey.

Table 1. Regression Model Predicting Logic and Sense of Belonging Post-Test Scores.

Logic			Sense of Belonging		
	Estimate (SE)	*p*-value		Estimate (SE)	*p*-value
(Intercept)	21.44 (0.83)	<.001***	(Intercept)	55.30 (1.59)	<.001***
LogicPre	3.57 (0.44)	<.001***	SBPre	5.34 (0.87)	<.001***
Treatment	1.17 (0.88)	.19	Treatment	-0.38 (1.77)	.83
Gender	-1.87 (0.92)	.045*	Gender	0.83 (1.84)	.65

Note. * $p < .5$, ** $p < .01$, *** $p < .001$. Adjusted $R^2 = 0.41, 0.29$ respectively.

By the time of the poster, we will have additional student background data and more data to allow for better addressing moderators. For example, we hypothesize that the RAMP classes may have an impact that is moderated by pretest (e.g., those with lower sense of belonging may see more substantial gains.)

Keywords: First Generation Students, Graduate School Applications, Social Capital

An important factor in attaining a graduate degree in mathematics is an applicant's familiarity with the graduate school application process—a form of knowledge that is not always formally taught but instead passed through familial networks. Research shows that first-generation college students frequently encounter unique challenges in navigating higher education, including limited access to guidance, financial barriers, and unfamiliarity with academic systems (Cragg, 2009; Davis, 2010; Engle & Tinto, 2008; Holley & Gardener, 2012; Pascarella et al., 2004). We apply the theory of social capital to explore how family members influence first-generation students' understanding of the graduate school application process (Coleman, 1988). This study surveys 519 undergraduate mathematics students across 181 institutions to examine how the highest level of education attained by an immediate family member impacts familiarity with the graduate application process. A Chi-squared test found that participants with family members who have a bachelor's degree or higher were more likely to report familiarity with the application fee waivers and that doctoral programs do not always require a master's degree. This finding reinforces the theoretical framework of social capital, which holds that educational knowledge is often passed down informally through familial and relational networks. This allows some applicants to navigate the admissions process with greater confidence and insight, while others are left to figure it out alone. These findings highlight the need for early advising on the norms of graduate school in mathematics, transparent funding guidance, and mentorship programs to support first-generation students.

Table 1. Chi-squared test results for selected items for the question, "Please rate your familiarity with the following concepts about the graduate school application process."

Item	Education level	Never heard this before	May have heard this before	Definitely heard this before	Values	*p*	*w*
Some programs offer ways to reduce or eliminate application fees	First-Gen Bachelors Graduate	24 43 36	43 49 72	36 53 133	15.631	.004	0.17
Some doctoral programs do not require applicants to get a master's degree first	First-Gen Bachelors Graduate	37 28 38	28 27 50	38 67 160	24.382	<.001	0.22

Keywords: Metacognition, Resource Awareness, Social Learning, Learning Strategies

Students entering college face an educational landscape that is vastly different from their high school experience. Many first-year college students encounter challenging mathematics courses that demand new forms of self-regulation and require adaptation of existing and developing new productive learning strategies. To aid students with these challenges in mathematics classes, we have integrated three dimensions of learning: metacognition, resource awareness, and social learning. Research shows that students who engage in metacognition and self-regulated learning (e.g., Zimmerman, 2002)—systematically analyzing and refining their learning approaches—perform better academically. However, learning is not an isolated process, so social learning plays a crucial role in shaping students' understanding. These dimensions encompass three key ideas of one's own learning: helping students learn about different learning strategies and discover their own learning strategies in the process.

The objective of this project is twofold. First, we aimed to design adaptable instructional materials that provide a systematic approach to integrating three mutually reinforcing dimensions of learning: (1) developing metacognitive skills, (2) increasing awareness and use of university learning resources, and (3) fostering social learning. Examples of such activities include weekly reflective journals, a scavenger hunt for locating campus learning resources, and a variety of out-of-class collaborative assignments. Second, we aimed to assess the effectiveness of these instructional materials, in particular, in terms of students' abilities to develop and articulate productive learning strategies. As such, our central research questions are: 1) What is the effectiveness of the proposed activities in developing metacognitive skills, fostering social learning, and increasing awareness of resources? 2) What learning strategies do students develop as a result of their experiences with the proposed activities?

To answer these research questions, we implemented the designed instructional materials in one section of general education Calculus 1 taught by the third author. Using a mixed-method approach (Johnson & Onwuegbuzie, 2004), we collected data through surveys and semi-structured clinical interviews (Clement, 2000). The survey items were adapted from existing inventories (e.g., Brown et al., 1996; Schraw & Dennison, 1994) and supplemented with our own items targeting various aspects of social learning. Clinical interviews provided richer, open-ended insights into students' perceptions of the activities and learning strategies they developed.

The data analysis is ongoing. During the poster presentation, we will share our instructional materials, preliminary findings on their effectiveness, and students' professed learning strategies.

Undergraduate Students' Bijective Reasoning about Fibonacci Numbers

Dru Horne
University of Georgia

Keywords: Bijective Reasoning, Combinatorial Reasoning, Combinatorics Education

Bijection is an important topic in undergraduate mathematics. Although researchers have studied whether students use bijections to compare infinite sets (Hamza & O'Shea, 2011; Tirosh & Tsamir, 1996; Tsamir & Tirosh, 1992; Tsamir, 1999) and how students understand group isomorphisms (Larsen, 2009; 2013; Leron et al., 1995; Melhuish et al., 2020; Rupnow, 2017; Weber & Alcock, 2004), there is little direct research on how students understand and use bijections. One content area where researchers have looked explicitly at bijections is combinatorics (Lockwood & Ellis, 2022; Mamona-Downs & Downs, 2004; Muter & Uptegrove, 2011). These studies have shown mixed results, suggesting that although students are capable of constructing bijections, it is a challenging topic. More research is needed to understand how students think about and reason with bijections. The research question guiding the current study is: *How do undergraduate students' ways of understanding and thinking about bijections support their combinatorial reasoning and vice versa?*

To investigate this question, I conducted a small-group teaching experiment (Steffe & Thompson, 2000) with six undergraduate engineering majors. I collected 16 hours of data across 12 teaching episodes (each episode was 60-90 minutes). Each episode was video- and audio-recorded, and each student had an iPad which captured screen recordings of their written work. The teaching experiment was broken into three phases: 1) Developing students' combinatorial reasoning, 2) Developing students' bijective reasoning, and 3) Refining students' bijective reasoning. For this poster, I will discuss data from four teaching episodes conducted during phase 2 where students were given a list of written descriptions of sets counted by the Fibonacci numbers and asked to construct bijections between the different sets. Prior to engaging in this series of tasks, students constructed a definition of bijection as a whole class and at the end of these teaching episodes, I asked the students to each write a personal description/definition of what a bijection is. I am currently analyzing this data set to understand how students think about bijections and how they drew on their combinatorial thinking to reason about bijections. To frame my analysis, I draw on Lockwood's (2013) model of student's combinatorial thinking and Harel's (2008) notions of *ways of thinking* and *ways of understanding* to capture students' thinking about bijection

I am currently in the early stages of analyzing this data set to identify students' ways of understanding and thinking about bijections and how these connect to their combinatorial thinking. By the time of the conference, I expect to share emerging findings that illustrate how students reason bijectively when working with Fibonacci-related combinatorial tasks. These findings will contribute to understanding how undergraduate students construct and reason with bijections and can inform instructional approaches for supporting students' bijective reasoning.

Analysis of the Conditions and Constraints Shaping a Modelling-Based Course of Life Sciences

Garima Gogia
Texas State University

Jennifer A. Czocher
Texas State University

Keywords: mathematical modelling, anthropological theory of didactic, didactic transposition

Teaching mathematics to students in non-mathematics undergraduate programs remains a persistent challenge because of difficulties in engaging students with genuine problems and models from the disciplines they study (Barquero et al., 2013). Life Sciences is one of those disciplines where the role of mathematics in relation to genuine problems is often questioned (Cozzens & Roberts, 2020, p. 87; Garfinkel et al., 2022) despite its increasing relevance to biology, physiology, and other disciplines (Cozzens & Roberts, 2020). The sense of *applicationism* (Barquero et al., 2013) that runs through mathematics courses for life science majors is amplified by the perception that mathematics is not a tool for understanding biological phenomena. This situation calls for the creation of a course that can engage students from life sciences more meaningfully with mathematics, where mathematics takes on a role as an integrated discipline (Bosch et al., 2020).

One of the approaches to creating such a course was to focus on the biological themes that "resonate deeply with life science students" through "a mathematical framework for making simulating and analyzing dynamical models" (Garfinkel et al., 2022, p. 42). With a greater focus on modeling phenomena, this course stressed concepts like feedback loops, dynamical systems, and bifurcations through differential equations. It also included computer programming, defining derivative as a linear approximation to a point, and analyzing the stability of equilibrium points of single-variable differential equations (Garfinkel et al., 2017). To enroll in this course, life science students do not need calculus as a prerequisite.

A course is an empirical object. The Anthropological Theory of Didactic (ATD) allows us to question, model, describe, and analyze the didactic transposition of the knowledge of the course (Bosch et al., 2021). Didactic transposition is the process of selection, adaptation, organization, and declaration that shapes the knowledge to be taught within school institutions, including universities. The reasons that shape this knowledge can be located at the levels of codeterminacy (Chevellard, 2002). This brings us to our research question: *What conditions and constraints for didactic transposition contribute to shaping the modelling-based course? At what levels of the scale can these conditions and constraints be identified?*

To address this question, we present the genesis and shape of this modelling-based course for life sciences developed by a quantitative biologist at a large public university in the USA. Our account is informed by the course developer's retrospective interpretations of the process of production of the course. We use praxeological analysis to generate an in-depth account of mathematics in the modelling-based course. Comprising a practical (praxis) block and a theoretical (theory) block, praxeology for teaching (didactic praxeology) of the modelling-based course enables us to account and analyze the practical and theoretical nuances of the course. The reasons for the conditions and constraints that affect the production of the course are obtained from the levels of codeterminacy, providing empirical evidence for the dependence of the course on specific institutional factors (Bosch et al., 2020).

Examining Graduate TAs' Mathematical Knowledge for Teaching in a Teaching Seminar Context

Laurie Short
North Carolina State University

Logan Gray
UNC Chapel Hill

Bex Nelson
UNC Chapel Hill

Keywords: Graduate Mathematics Teaching Assistants, Teaching Assistant Preparation, Mathematical Knowledge for Teaching

Graduate mathematics teaching assistants (GMTAs) carry a substantial portion of the responsibility for teaching undergraduates (Speer, Gutmann, & Murphy, 2005), yet many enter their graduate programs with little to no prior teaching experience (Speer et al., 2005). With limited guidance, GMTAs are expected to help undergraduates bridge the gap between high school and college-level mathematics. Although GMTAs often possess extensive and nuanced content knowledge (Sarkar et al., 2024), content knowledge alone is not sufficient for effective teaching (Grossman, 1990).

Researchers in K-12 mathematics have long examined ways to conceptualize what knowledge is required besides content expertise. One of the most influential frameworks is mathematical knowledge for teaching (MKT), which is defined as the specialized understanding of mathematics required to support students' learning (Ball et al., 2008). MKT is strongly linked to instructional quality and student outcomes (Ball et al., 2008; Hill et al., 2005). More recently, studies have sought to expand MKT definitions to secondary and post-secondary teaching contexts, highlighting that both student populations and institutional contexts influence how MKT is defined and enacted in practice (Speer et al. 2015; Ko et al., 2021).

Building on this research, our study aims to answer the overarching research question: *How does participation in a graduate mathematics teaching seminar shape TAs' Mathematical Knowledge for Teaching?* We conducted a mixed-methods case study of a semester-long teaching seminar course for a group of thirteen beginning GMTAs at a large, public, research university in the Southern United States. Our data collection methods included observations of the seminar, semi-structured interviews with the instructor and GMTAs, and document analysis of course materials, which were triangulated to ensure reliability (Stake, 1995). Additionally, we administered a condensed and altered version of the Mathematical Knowledge for Teaching College Algebra Community College Version (MKT-CCA) instrument (Lim, Duranczyk, & Akoto, 2024) to examine GMTAs' mathematical knowledge for teaching in practice. As many graduate students at this university will eventually serve as instructors of record for college algebra, we administered this instrument at the beginning and end of the seminar to measure growth and compare quantitative findings with TAs' interviews, class interactions, and teaching.

Early evidence suggests that GMTAs enter their programs with highly variable MKT, but structured seminars can enhance this knowledge. A particularly influential mechanism for this development is facilitating increasingly legitimate peripheral participation.

The goal of our poster presentation is to engage RUME conference participants in discussing how we can support GMTAs in their development of MKT. Building on this work, we will pursue a design-based research project to iteratively refine the seminar curriculum and further investigate how structured support shapes GMTAs' growth in MKT.

PRIME-ing Teaching Assistants for Inclusive and Effective Instruction in Gateway Math Courses

Jayna Resman
University of Maryland

Emily Berman
University of Maryland

Keywords: Teaching Assistants, Student Belonging, Mindset, Professional Development

Preparing Responsive and Inclusive Instruction for Meaningful Mathematical Experiences (PRIME) builds on research demonstrating the critical role of instructor beliefs, expectations, and pedagogy in shaping student outcomes in mathematics (Boaler, 2015). In this novel, in-service training and professional development community, the role of the graduate teaching assistant (GTA) is leveraged to implement evidenced-based practices for math learning in gateway college algebra, precalculus and calculus courses with historically high DFW (drop, fail, withdraw) rates.

Recent work has identified the critical and impactful role of GTAs in freshman and sophomore-level math courses (Bressoud et al., 2015; Pilgrim et al., 2025; Speer et al., 2005). We posit that GTAs are uniquely positioned to impact student belonging and mindset, two conditions critical for math learning (Fitz, 2025). Furthermore, GTAs who lead discussion sections in large-enrollment math courses self-report as being under-supported. Thus, this pilot program was developed to support and prepare GTAs to enact responsive pedagogy grounded in academic mindsets and growth-oriented instruction.

PRIME GTAs were supported with a $1500 stipend and a semester-long series of working sessions intended to build a community of learning and support. The primary learning objectives were (1) identify a capacity to learn in every student (2) foster meaningful mathematical discourse and (3) recognize and develop the elements of an effective math discussion section. Curricular components were informed by Farrington's work (2012) which identifies academic mindsets—including students' sense of belonging, growth orientations, and students' perceived value of their work—as foundational to deeper learning.

Survey data from GTAs and undergraduates, short participant reflections, and end of course grades were collected to investigate two primary research questions:

1. How does participation in the PRIME program impact GTA instructional practices in gateway math courses?
2. What effect does GTA participation in PRIME have on undergraduate students' sense of belonging, engagement, and learning in mathematics?

We consider the efficacy of PRIME in terms of the GTAs' behaviors & self-reflections and their undergraduate students' reports of belonging, learning and persistence. However, this work also examines the praxis of instructional reform within the context of our institution. The value of collaborative efforts between teaching and learning centers and disciplinary departments to implement sustainable change in teaching practices is well-documented (Condon et al., 2016; Finelli et al., 2014). Typically departmental change is initiated internally, but PRIME was designed and proposed by staff from the university's teaching and learning center. Still, over the course of this project, positive, collaborative relationships with mathematics faculty and department leadership have grown in ways that may pave the way to further pedagogical and instructional change with the math department, and this endeavor may later serve as an institutional case study for implementing inclusive and effective instruction across other STEM departments and gateway courses.

Mathematical Knowledge for Teaching in Undergraduate Contexts: A Literature Review

Praveen Chhikara
University of Illinois Urbana-Champaign

Keywords: Mathematical knowledge for teaching, literature review, undergraduate mathematics

Understanding what teachers must know to teach effectively has consistently been a central focus in educational research. The Mathematical Knowledge for Teaching (MKT) framework is one of the foundational models to explore professional knowledge of mathematics teachers (Ball et al., 2008). The MKT framework comprises two groups—subject matter knowledge and pedagogical content—each containing three domains of knowledge, for a total of six knowledge domains. Subject matter knowledge includes common content knowledge, horizon content knowledge, and specialized content knowledge. Pedagogical content knowledge (PCK) includes knowledge of content and students, knowledge of content and teaching, and knowledge of content and curriculum. Originally, the MKT framework was designed and has been extensively applied for elementary education (Hoover et al., 2016). Over time, the framework has been utilized for higher grades. This review asks: What patterns emerge regarding the theoretical frameworks utilized, methods employed, purposes, and participant selection in MKT studies focused on university-level teaching? The review results are: (1) conceptualization of MKT domains, (2) diversity in participants and instructional contexts, (3) methodological innovations. Only the first two of them are briefly discussed below due to space constraints.

Several studies in the MKT literature focus on defining and making sense of the MKT knowledge domains in typical or new undergraduate contexts (Hauk et al., 2014; Speer et al., 2015; Johns & Burks, 2023). For example, Speer et al. (2015) argued that the distinction between CCK and SCK became blurred as we move beyond elementary teaching to higher educational contexts. Many tasks identified as SCK (e.g., evaluating student-generated solutions) for mathematics instructors appear in everyday research practices of mathematicians (e.g., evaluating a proof in a manuscript for publication). Future studies in the undergraduate context need to clarify what SCK means.

This review highlights diverse participants type: from university mathematics faculty (Speer et al, 2013), community college faculty (Hauk et al., 2014; Nabb & Marawska, 2020), dual enrolment in high school and community college (Beckford et al., 2023), and graduate students as tutors (Johns & Burk, 2023). An interesting trend emerged in many studies involving non-university mathematics faculty participants, which focused on relational and socio-cultural aspects (e.g., caring, trust, affective, cultural, practical, and contextual) of teaching, and suggested that these be incorporated into MKT.

Many studies draw heavily on self-reported data such as interviews (Nabb & Murawska, 2020), online working group sessions (Kim & McCrackin, 2024), and surveys (Beckford et al., 2023), which focus on what these participants say they know or do. Two gaps are noted concerning the limited ability to connect MKT and student learning. Firstly, few studies draw on real classroom practice (Johns & Burks, 2023; Speer et al., 2013). Secondly, none of these studies reviewed include how MKT translates into classroom impact or student learning data. Future research needs to include classroom transcripts, student work, and evidence of how students respond to certain MKT domains in instruction.

The poster will present all the patterns with gaps and future steps. I look forward to discussions with conference attendees about more results mentioned in the poster.

Using AI to Adapt Secondary Mathematics Discourse Frameworks for Graduate Teaching Assistant Development

Michelle Cirillo
New Jersey Institute of Technology

Keywords: Discourse, Teaching Assistants, TA Training, AI

Graduate teaching assistants (TAs) play a pivotal role in undergraduate mathematics instruction, often leading recitations that shape students' early university experiences. However, while the literature on TA training highlights the need for pedagogical preparation (Shannon, Twale, & Moore, 1998; Speer, Gutmann, & Murphy, 2005), few resource materials have been developed specifically for this audience. This gap exists, for example, in the area of classroom discourse, and contrasts with the robust set of discourse-based professional learning tools available for secondary mathematics teachers. As a result, TA training often lacks the concrete, discipline-specific examples necessary to help novice instructors develop productive discourse practices in settings where their assistantships are situated (e.g., calculus recitations). This is important because in mathematics, a recitation is not intended to replicate the lecture but to provide a smaller, discussion-based environment where students actively engage with problems and reasoning. Ideally, in this context, TAs facilitate collaboration, questioning, and sense-making rather than delivering additional content. Such active-learning structures have been shown to enhance students' conceptual understanding and engagement in undergraduate mathematics (Freeman et al., 2014; Laursen & Rasmussen, 2019).

Upon learning that students in my first-semester TA-training course were unhappy with being asked to learn about engagement, classroom discourse, and teacher discourse moves using materials for secondary instructors, I used AI (i.e., Chat GPT 5), to generate new transcripts that made use of discourse frameworks (e.g., Freeburn and Arbaugh's (2017) communication moves for productive struggle and Herbel-Eisenmann et al.'s (2017) Teacher Discourse Moves. Thus, this project builds on two research-based established frameworks and analysis of classroom roles and participation structure to generate Calculus Transcripts that adapt secondary-level discourse cases for the graduate TA context. The new materials were designed for use in a semester-long TA training course at a research-intensive university. The cases were created to simulate authentic challenges TAs face—such as encouraging student reasoning and sustaining mathematical discussions—while maintaining fidelity to the original pedagogical constructs.

The poster shares the adaptation process, examples of the resulting Calculus Transcripts, and reflections from pilot implementation. Preliminary observations suggest that ChatGPT did a reasonably good job of generating these transcripts with the following exceptions - the AI: (a) consistently had students providing correct, polished answers with precise vocabulary, (b) had the instructor continuously praise student contributions, and (c) continuously went into telling mode after the vignette to point out all of the things in the case that I wanted the TAs/students to notice about the discourse. Ultimately, this project contributes to addressing the need, identified by Speer et al. (2005), for providing a mechanism to generate research-based pedagogical tools and resources that explicitly bridge the K–12 and postsecondary mathematics education communities. By expanding discourse-based case study resources to the calculus classroom, this initiative supports a more coherent trajectory of teacher learning across educational levels and offers a model for developing reflective, discussion-oriented TA training in mathematics.

How Cultural and Familial Ideologies Shape MENA Students' Mathematical Identities

Sara Elakesh
Michigan State University

Keywords: mathematical identity, cultural ideologies, MENA students

Research in mathematics education has increasingly recognized that learning and identity are intertwined, and what mathematics means to people is socially produced (e.g., Nasir, 2002). These meanings differ across settings and are mediated by race, gender, and culture (Walker, 2012). Students' racialized experiences and sociohistorical contexts shape how they interpret mathematics (Martin, 2000). Yet, little research has examined how students' cultural ideologies, belief systems that help people make sense of the world (Shah, 2017), influence their perceptions of mathematics. This study examines how Middle Eastern/North African (MENA) students, a group largely absent from education research (Modir & Kia-Keating, 2018), negotiate their mathematical identities and perceptions of mathematics with respect to their cultural and familial ideologies. The question guiding this study is: How do MENA students' cultural and familial ideologies shape their mathematical identities and perceptions of mathematics?

This study draws on research on mathematical identity to explore how MENA students' ethnic and cultural backgrounds influence how they view and value mathematics. I define mathematical identity as how students see themselves and are seen by others as math doers, developed through social practice and recognition within communities (Martin, 2000; Cobb et al., 2009; Hall et al., 2025).

Participants were eight undergraduate students who self-identified as MENA and had completed at least Calculus I or equivalent. Semi-structured interviews explored (1) participants' feelings about mathematics, and (2) the influence of cultural and familial ideologies on their mathematics trajectories. Data analysis followed an inductive and iterative coding process informed by thematic analysis (Corbin & Strauss, 2014).

Findings suggest that many participants experienced familial pressures to perform well in mathematics, pursue STEM degrees, or follow similar paths as relatives with mathematics backgrounds. Most expressed that these pressures stemmed from MENA cultural ideologies which conflate mathematics and STEM achievement to success and socioeconomic stability. They felt that because of their culture they "have the potential to be engineers and doctors" and that "the expectation to succeed is linked to mathematics." For many participants, success was often equated with prestigious fields, many of which required mathematics.

Participants' narratives reflected the complex negotiation of self, family, and culture with respect to mathematics identity, revealing how recognition and expectation shaped how they saw themselves in relation to mathematics. Sentiments shifted from obligations tied to family expectations and cultural ideologies, to appreciation when they "found meaning and connections" to their majors or when family members framed it as beautiful. While some family members upheld and enforced cultural ideologies, others encouraged participants to make sense of mathematics in a positive light. This communal support fostered more positive feelings and meaning-making in the mathematics that they encountered. Although most participants described familial pressure as motivating, a few felt that these expectations were limiting. These findings align with Martin's (2000) argument that mathematical identities are shaped by community and broader cultural meaning, underscoring the need to examine how identity development in mathematics is influenced by social and cultural forces that may not be immediately visible.

Modules for Developing Statistics Graduate Teaching Assistants' Capacity for Teaching

Sunghwan Byun
North Carolina State University

Matthew Ferrell
North Carolina State University

Jennifer Green
Michigan State University

Maria Cruciani
Michigan State University

Justin Post
North Carolina State University

Keywords: graduate teaching assistant, introductory statistics, resources for teacher education

Although statistics graduate teaching assistants (GTAs) face the difficult task of teaching undergraduate students with a broad range of backgrounds, they often do so with little to no preparation in statistics teaching. There are resources developed for mathematics GTAs (e.g., http://collegemathvideocases.org); however, there is a lack of resources that can support *statistics* GTAs in addressing the disciplinary need of teaching and learning statistics. Based on a design-based approach, we developed four modules for **L**earning to teach **E**quitably with **A**uthentic **D**ata (LEAD modules; https:/sites.ced.ncsu.edu/lead-modules/), building on existing frameworks of teaching mathematics and recommendations for teaching statistics. We introduce LEAD modules and examine the research question: What problems of practice emerged when GTAs participated in LEAD modules at two GTA communities?

The first module, *Teaching Statistical Thinking*, introduces the distinctive features of statistical thinking compared to those of mathematical thinking: context, variability, and inference (GAISE Committee, 2016; Smucker et al., 2024; Wild & Pfannkuck, 1999). The second module, *Launch, Explore, Discuss*, provides a framework for GTAs to structure a lesson centered on exploring statistical concepts (Lappan et al., 2009). This module responds to the persistent pattern of narrowly focusing on procedural aspects of doing statistics (Justice et al., 2017; Noll, 2011). The third module, *Teacher Discourse Moves*, offers a set of discourse moves for GTAs to facilitate classroom discussions during the Discuss phase of the lesson (Herbel-Eisenmann et al., 2017). Lastly, the fourth module, *Promoting Participation*, reflects the challenge of eliciting student participation commonly experienced by GTAs. The module asks GTAs to examine initial patterns of student participation and consider opportunities to broaden participation across the classroom (e.g., Byun, 2024).

Our preliminary findings show multiple problems of practice (hereafter, problems) emerged as GTAs worked toward implementing teaching approaches included in the modules. Informed by Cohen et al. (2003), we broadly categorized the problems by student-, teacher-, content-, and environment-related problems. Student-related problems included the perceived lack of students' prior preparation and participation, and their negative disposition toward the subject. Teacher-related problems highlighted difficulties in adopting new teaching strategies and uncertainty about how to respond to a wide range of student contributions. There were fewer problems related to content and environment, but implementing new strategies within the time constraint was salient.

Without adequate teacher learning opportunities, GTAs are likely to fall back on more familiar teaching approaches that they have experienced as mathematics learners, which often entail attending lectures, taking notes, and doing homework problems (Findley, 2022; Justice et al., 2017). The identified problems of practice offer valuable insights for further iterations of LEAD modules so that modules can better fill the void of resources when course coordinators and instructional mentors work with GTAs to reshape undergraduate teaching.

Teaching the Teachers: What AI Student Agents Reveal About Preservice Teachers' Noticing in Statistics

Matthew Mauntel
Tarleton State University

Nicholas Witt
Towson University

Jennifer Suh
George Mason University

Michele Cudd
Morehead State University

Eunheye Flavin
Georgia Institute of Technology

Keywords: Pre-service teachers, Artificial Intelligence, Statistics, Data Science

The growing importance of data science and AI in the United States has sparked a need to prepare students for these emerging fields (National Council of Teachers of Mathematics, 2024). One natural place is working with pre-service teachers to develop core ideas in statistics and data science. In particular, the ability of a teacher to notice and interpret student work is essential. To address this need, we created a series of instructional activities, which were designed to help pre-service teachers (undergraduate and graduate students in mathematics teacher education) understand and notice statistical thinking of K-12 students.

In this activity, pre-service teachers interact with an AI student. An AI student is a custom agent powered by generative AI that is given a profile and told to act as a student in the classroom. The AI students are given mathematical conceptions related to a task about mean, median, and mode as developed by research on real students. They are also given personalities, dispositions to mathematics, and preferred forms of communication. Our first trial of virtual students (Authors, under review) resulted in pre-service teachers being able to attend, interpret, and respond at high levels. The AI students also produced a wide variety of student thinking for the preservice teachers to analyze due to their nature of being powered by generative AI. We extend this work with this poster by designing a new set of AI students that will be used in a classroom of preservice teachers covering the topic of centers of a distribution. The chosen task is the screentime task (Virginia Department of Education, 2025) which asks students to explore centers of a distribution of a data set to remain under a screen time limit imposed by parents.

Data was collected includes video recordings of the students while they interacted with the AI students (Figure 1) over Zoom while they shared their screen, their chatlog, and a post-activity reflection. For this poster, we present our preliminary analysis of the AI student's reasoning through descriptive coding and thematic analysis (Saldana, 2013). In order to analyze the preservice teacher's noticing, we combined the FAIR framework (Louie et al., 2021) with the five types of representations (NCTM, 2014) We discuss some analysis of the preservice teacher's noticing with regards to the AI students including what mathematics they attend to and how they respond to the AI students. This study has implications for the pedagogical design of undergraduate mathematics education courses by providing tools and activities to make training practices low-stakes, sustainable, and scalable.

Mathematics Identity and Belonging in an Undergraduate General Education Terminal Mathematics Course

Ryan Arif
University of Texas Arlington

Theresa Jorgensen
University of Texas Arlington

Keywords: Inclusive course design, inclusive instruction, mathematical identity, sense of belonging

This study directly follows from Homp et al., where inclusive instructional practices, like Open Educational Resources and biographies from mathematicians currently doing research from historically minoritized backgrounds, were implemented in a general education terminal undergraduate mathematics course from a large, predominantly White, land-grant based, public university in the midwestern United States. Homp et al. found a statistically significant increase in students' sense of belonging, illustrated from pre- and post- course survey data. Gutiérrez (2012), developed a framework for conceptualizing equity in mathematics through the axis of identity and power, and the axis of access and achievement. Building off this research, Riley (2022) utilized the Gutiérrez framework to perform thematic analysis on *Testimonios* (2022). In this study we thematically analyze student artifacts from one out of five sections of the course in Homp et al.'s research to understand why the feeling of belonging improved within the students across the duration of the semester.

This poster explores artifacts collected from students after being shown biographies of current, historically minoritized mathematicians three times throughout the semester, analyzed using a codebook derived from Gutiérrez's framework. The themes presented in the two axes, power, identity, access, and achievement were coded both as they related to the chosen mathematician and to the student. The frequencies of each code within each of the three artifacts were compared. Students at the beginning of the semester primarily focused on the achievement of the mathematician in the chosen biography, with little to no mention of the mathematician's identity, access, or power. As the semester went on, students chose to write about more than just the mathematician's success– focusing on the identity of the mathematician, the power they have to make societal change, and the access they have to education. Students also incorporated more aspects of their own identity within the later artifacts.

Many students indicated they had little to no knowledge on the various topics mathematics researchers study. Perhaps by introducing the students to mathematicians that share aspects of their own identities, students are able to relate more to complex topics like disease spread and gerrymandering, which many do not associate with mathematics. This analysis appears to show that students were able to form a connection to mathematics beyond the presented course material– allowing them the ability to feel they could belong in the mathematical community.

Through the RME Looking Glass: Utilizing Analogies to Bridge the Gap for Beginners

Rebecca Caudillo-Scariano
Colorado State University

Joseph Antonides
Colorado State University

Keywords: RME, Analogies, Numerical analysis, Embodied Cognition

According to Gentner (1983), an analogy maps a source domain (the unfamiliar) to a target domain (the familiar). Thus, the objective of an analogy is to capture the essence of the concept and demonstrate that idea in a familiar setting. In our poster, we will introduce an example of a carefully constructed analogy and how it can be a useful tool for beginners that are still gaining intuition in unfamiliar concepts. Consequently, the audience for the analogy assumes only comfortability in college algebra skills. The goal of our research is to demonstrate an example of the resourcefulness of analogies as a teaching tool and the notion of translating complex mathematical concepts into unconventional contexts.

The teaching topic in question is introducing a specific numerical method for solving linear variable-coefficient ordinary differential equations (ODEs) in a two-point boundary value problem (target) by utilizing an analogy involving a cube of varying density restricted to a ruler (source). Variable-coefficient ODEs are equations that are defined on an infinite domain and thus often must be restricted to a set interval to become manageable when solving. For a boundary value problem, the ODE is simply paired with the given solution at its boundary.

Our analogy relates an ODE and cube in the following ways: their restriction to a set interval (two-point boundary and ruler), dependence on varying characteristics (variable coefficients and varying density), solutions (function $y(x)$ and total weight of cube), boundary conditions (given say $y(1)$ and $y(4)$ and weight of cube at 1 in. and 4 in.), and method for solving (steps of numerical method explained in target and source domain). Along with the poster itself, we include manipulatives that represent the physical components in the source domain: a cube, ruler, tape measure, thumbtacks, paper slices acting as slices from the cube, etc.

Through our analogy, we introduce an approachable example that can engage students and, ideally, create a fun and memorable learning experience. These qualities are at the core of Realistic Mathematics Education (RME) and research in embodied cognition. RME urges that mathematical instruction should be realistic and rooted in real-world context. Gravemeijer & Doorman (1999) define "realistic" in RME to situations that students can imagine and comprehend and thus are relevant in the student's reality. Our analogy (or "the model") meets students at their level of understanding and thus allows them to reason and gain intuition in multiple unfamiliar concepts (Gravemeijer, 1999). Additionally, our analogy provides visual and interactive components that encourage embodied cognition. When students can engage their bodies in physical actions, gestures, object manipulation, and so on, this allows them to form a deeper understanding and have a more memorable learning experience (Antonides & Battista, 2022; Lakoff & Núñez, 2000; Nathan, 2021).

Overall, RME and embodied cognition education research tend to stray from the "traditional classroom" that involves no student engagement and only instructor-based lectures. Thus, with the support of RME and embodied learning, the addition of analogies to the classroom can hopefully open the doors for math to be more fun, memorable, and engaging—not only for children, but also for students in higher education. Feedback is welcomed on the proposed use of analogies as a teaching tool, the notions of unconventional math translations, and on the analogy itself.

Keywords: Professional Development, Factor Analysis, Descriptive Statistics

There is considerable research on effective professional development (PD) in both undergraduate and K-12 educational settings, but less on how the characteristics of PD can influence teacher uptake and retention of PD resources and lessons (Zhang et al., 2024, Hill et al., 2013, Henderson et al., 2011). The TADD 2.0 (NSF DRL No. 2405432) project focuses its research on teachers' perceptions of critical characteristics of PD impact on sustainably affecting teacher instruction and student learning. Using the preliminary findings and analysis of the survey of 157 teachers who participated in 1 of 6 chosen large-scale NSF-funded research projects within the last 1 to 5 years can shed light on the characteristics that could also be emphasized in STEM undergraduate PD.

The initial survey was designed to utilize Likert-scale items and follow-up open-ended questions, allowing participants to elaborate on their numeric responses based on six characteristics of PD. Upon factor analysis and Cronbach's alpha tests, researchers used a five-factor model to define the characteristics. These new categories included administrative support, resources and materials, community, classroom practices, and facilitation. The results of the factor analysis reveal that teachers' perceptions of what is thought to be well-defined in the research community may not be as explicit as thought. The same could be said about feedback in undergraduate PD, as the variety of training and experience can vary greatly in a department (Postareff, 2008).

Upon redefining and analyzing the categories, researchers determined the average scores of participants across each factor and conducted descriptive statistics, along with ANOVA tests, which showed that the factors were statistically significant across all PDs. Results showed that all PDs were of high quality, with no median value falling below 5. Fortunately, administrative support (median = 8.5-10) and facilitation (median = 9.2 - 10) were rated very highly. Sustained administrative support and facilitation are not always common in undergraduate PD and often inhibit scaling and uptake from professors (Chasteen, 2015, Henderson et al., 2011). Factors with lower medians were community (median = 7.5 - 10), resources and materials (median = 5.8-9.8), along with classroom practices (median = 6.5-9.2). Classroom practices surrounding pedagogy and content ratings being lower aligns with findings in K-12 spaces as it is more difficult to implement and takes longer to see sustained changes (Kennedy, 2016, Koellner & Jacobs, 2015). Pedagogical change is understandably challenging to support in undergraduate spaces, particularly due to culture and community (Reinholz & Apkarian, 2018, Chasteen et al., 2015, Postareff, 2008).

Each PD served different communities and had varying goals towards teacher pedagogical change, but the factors appear to show important attributes of PD. While K-12 schools have different contexts, nuances, and challenges than undergraduate teaching spaces do, these survey results may provide guidance when designing, implementing, and conducting research in undergraduate communities.

Impact of Reflective Practices and Videos on Graduate Teaching Assistants' Pedagogy

Kiley Pooler
Arizona State University

Jacob Cooper
Arizona State University

Keywords: professional development, novice instructors, TAs, decentering, reflecting

The development of instructional practices, skills, and pedagogical content knowledge is a key aspect of training Graduate Teaching Assistants (TAs) (Dehsler et al., 2015). Current work like the CoMinDS resource (2021), shared at RUME conferences aim to understand and support TAs as they develop these professional teaching practices. This study was conducted in a TA seminar for an inquiry based precalculus course at a large research university to investigate the impact of guided reflection, alongside video recording, on graduate teachers' pedagogy and how it supports decentering (Teuscher et al., 2016), a process advocated for and supported in previous literature (Hauk & Speer, 2023).

This semester, we introduced a self-reflection assignment following observation and recording by one of the graduate co-instructors. This included rating their practices twice: once immediately following teaching, and again while watching a recording of themselves and discussing their findings with one of the co-instructors. Comparing the ratings students gave themselves (on a scale of 1-3) before and after, showed no significant change in overall rating. However, most of the students realized they weren't initially using student centered practices. One TA noted:

> I really thought… I was engaging students… After I watched myself, I realized that I ask questions but don't give them enough time to think through it… I need to give them enough time to think about it. But, then again, when I do that I'm just pressed for time.

The narrative of 'Too much material and not enough time' is a common barrier for instructors in using student-centered teaching practices (Petersen et. al., 2010). During this teacher's second observation, it was clear they took wait time into account as they intentionally engaged with table groups and waited for the group to come to a conclusion before moving on. In the second interview when asked how they felt before and after watching their lesson:

> I felt way better than I did before. There was more engagement and I used a new approach…I gave them some time to think about the question and then if I wasn't getting my answer I tried to lead the students to answer the question or rephrased it.

This TA recognized the change in their practice and even increased their self-efficacy, which was an unintended consequence, but not unheard of (Chiu et al., 2019). From the observation, the co-instructor noted that the TA also repeated student explanations and asked students to explain what expressions represented, two decentering practices used on the reflection form.

Using reflection forms that intentionally prioritize decentering techniques, and problem-solving strategies can help graduate teacher assistants come to conclusions about their pedagogical approaches. Using recordings to reflect helps them gain specific insights into how they teach and ways they can individually improve their teaching. This poster will provide additional quotes from TAs to support the current literature, which highlights video and guided reflection as tools to improve instruction and move towards student-centered teaching practices.

"Here, students write math differently": An Exploration of Indian and USA Students' Non-proof Mathematics Writing

Omkar Devlekar
Texas State University

Garima Gogia
Texas State University

Keywords: Mathematical Writing, Calculus, International Comparison

As undergraduate instructors both in the USA and India, we observed that Algebra and Calculus students write mathematics differently across the contexts. We suspected that the differences related both to presentation and the student's purpose of mathematics writing. However, exploration into the literature suggested that RUME community has attended primarily to proof-based writing in mathematics (Guce, 2017; Nachowitz, 2019; Pugalee, 2010; Teledahl et al., 2024). This leaves open the question of how undergraduate students write in courses like Calculus where one needs to provide reasons, justifications and perform computations.

Students' written mathematical communication is a critical competence emphasized worldwide, serving as an essential part of mathematics. Defining and measuring quality in mathematical writing remains challenging (Guce, 2017; Kline & Ishii, 2008; Morgan, 2001; Pugalee, 2001; Teledahl et al, 2024). Students' mathematical writing in assessments revealed that there is a fundamental disconnect between teachers' expectations for evidence of conceptual reasoning and students' reliance on imitative or algorithmic solutions driven by perceived assessment demands (Boesen et al., 2010; Guce, 2017; Lithner, 2008; Miller et al., 2018; Morgan, 2006).

We employ Garofalo and Lester's (1985) framework to capture the metacognitive complexity by identifying the orientation, organization, execution, and verification behavior in students' written descriptions of their answer-writing and problem-solving process. We further analyze its relationship with the familiarity of the task (Boesen et al., 2010). In this study, we explore: *What forms of metacognitive behavior do students engage in while writing mathematics in an exam setting? What impact does familiarity of the task have on students' metacognitive behavior?*

Our poster will present the theoretical framework, methodology and the results obtained from to pilot task-based interviews with students. The pilot is intended to generate responses on four types of tasks which are classified based on their relatedness to textbook/reference material.

Results are expected to provide us with a viable range of cognitive monitoring acts (Garofalo and Lester, 1985) that Indian and American students engage in while writing solutions to obtain maximum points on familiar and unfamiliar tasks (Boesen et al., 2010). Not only do we expect this exploration to shed some light on the factors that caused us to hypothesize but we also expect that it would provide some base for further exploration of institutional factors affecting students' mathematics writing – both as a product and a process.

Acknowledgments

The authors would like to thank Dr. Kathleen Melhuish and Dr. Cody Patterson for their valuable feedback, thoughtful suggestions, and guidance throughout the development of the project.

A Model of Epistemological Justification for Teaching and Learning Linear Algebra Proofs

Avery Madden
The University of Oklahoma

Sepideh Stewart
The University of Oklahoma

Keywords: Linear algebra education, proofs, epistemological justification

Research on proofs has long been a topic of interest for the mathematics education community (see Melhuish et al., 2022). Despite this, linear algebra has not received substantial research attention in proof and topics in second courses (Stewart et al., 2019, 2025). Some of the conversations between studies in proof based linear algebra have been on how students should think about the proofs. For example, Stewart and Thomas (2019) observed that a group of students preferred to reason with familiar objects, and some desired to use symbolic or embodied examples to aid their thinking. Meanwhile, Harel (2019) argued that building too strong a geometric reasoning for students may cause difficulties in proving in abstract or unfamiliar cases. Regardless of the approach, there is evidence that a primary goal of instructors is for students to have a strong ability to prove (e.g., Rensaa et al., 2020; Johnson et al., 2025). Furthermore, some studies offer insight into how students perceive proofs in linear algebra. A common theme that has emerged is that students struggle with the interplay between concepts in linear algebra proofs (e.g., Stewart & Tran, 2022; Harel, 2024b; Stewart & Thomas, 2019). There is developing research into combating these challenges for students and fostering a strong proving ability. For example, Meyer et al (2024), examined an instructor's textbook where he promoted student-created proof and exploration. Altogether, more research on examining the instructor's decisions on promoting critical thinking about proofs in linear algebra is needed.

Capturing this idea of thinking critically about proving is something that needs to be defined. The aim of this study is to build a model explaining how students think about the formation of their knowledge and proofs in linear algebra. Harel (2024a) outlines a theoretical framework for analyzing student understanding in relation to both proofs and broad mathematical knowledge. He introduces the notion of epistemological justification, "a way of thinking that manifests itself through perturbation-resolution cycles revolving around the question why and how was a piece of mathematical knowledge conceived?" (Harel, 2024a, p. 1488). Epistemological justification has specific criteria for its existence, those are the intellectual need condition, the elicitation condition, and the awareness condition. Intellectual need itself comprises five different categories according to Harel, those being: certainty, casualty, computation, communication, and structure. Further, there are two types of observed epistemological justification, discerned and embedded (Harel, 2024a). He poses some open questions to continue building on the framework of epistemological justification. One of particular interest is "What instructional practices promote the habit of seeking epistemological justification among students?" (Harel, 2024a, p. 1499). To that end, we hope to apply Harel's (2024a) theory of epistemological justification to students' thinking about proof and identifying what instructor decisions may have promoted this thinking.

The research questions guiding this study are: What are some instances of students' epistemological justification, and what instructor decisions promote them? This proposed case study aims to bring attention to a gap in linear algebra education research on how instructors interact with students during the proving process. This model will be used in a second course on linear algebra.

Studying Solidarity Between Dalit Mathematics Faculty and Dalit Students: A Literature Exploration

Bhargav Kale
The University of Arizona

Keywords: caste, Dalit teachers, Dalit students, classroom pedagogy, equity

African American students and teachers in the USA and Dalit students and teachers in India share similar sociopolitical struggles in education, despite different historical trajectories (Goodnight, 2017). Dalits are historically positioned as the lowest group of caste communities in the caste hierarchy. They have been subjected to severe forms of segregation by "upper" castes, with Brahmins on top of the hierarchy, controlling educational access. Brahmanical ways of knowledge production have entrenched harmful stereotypes in mathematics (Subramanian, 2025) and higher education, while negating Dalit intellectuality (Kawade, 2019). I am investigating how Dalit mathematics faculty support their students in and out of the classroom, drawing parallels with existing mathematics education research that center Black teachers' contributions in supporting mathematics and affective needs of their students (e.g. Ortiz, 2024). In this poster, I share a literature review describing the state of research on the experiences of Dalit students and teachers in mathematics and higher education to inform my investigation.

My review started with a few publications recommended by Dr. Jayasree Subramanian, a mathematics education scholar working in anti-caste work. I used a snowballing method and general Google scholar search to identify other publications that are focused on the experiences of mathematics Dalit students and faculty in and out of the classroom. I found a limited number of published works in the area. So, I expanded my search to include works in higher education generally, and K-12 mathematics education. In my review, I identified two primary themes that play significant roles in shaping experiences of Dalit individuals in educational spaces: classroom pedagogy and curriculum, and institutional norms and practices.

In K-12 mathematics settings, some work is done to understand the impact of classroom pedagogy and curriculum on Dalit students. Subramanian and Visawanathan (2024) studied how mathematics is inaccessible for Dalit students by studying 'purity' of language in mathematics textbooks, while Sadafule and Berntsen (2017) studied how differential classroom practices negatively impact mathematical learning of Dalit students. In non-mathematics higher education research, Chand (2025) found that dominant caste teachers hypervisibilized and stigmatized Dalit students, segregated them during group work, and excluded Dalit icons from the curriculum. Campus climate pressurizes Dalit students to be discreet, impacting their "internal solidarity" resulting in isolation (Lum, 2019). When this aspect of being discreet is snatched by professors in instances like oral exams, there is hardly any support for Dalit students nor scrutiny for the discriminatory practices on an institutional level (Chand, 2023). At the same time, Dalit professors in universities are subjected to scrutiny by non-Dalit peers and students and are often the last option to collaborate (Ovichegan, 2015). In this literature review, I found that there has been no work done so far on building solidarity amongst Dalit teachers and students in higher education. There is hardly any work that discusses the caste questions in mathematics, and no work that discusses Dalit mathematics teachers' practices in and out of the classrooms that support Dalit students across grades. I aim to bridge this gap by studying how Dalit university mathematics teachers and students build solidarity and support each other in and out of the classroom to counter the brahmanical supremacy in mathematics spaces (Stinson et al., 2024).

Factors Influencing the Attitudes of Multilingual Learners in Undergraduate Mathematics Classrooms

Keywords: multilingual learners, mathematics attitudes, undergraduate education, identity

As U.S. undergraduate classrooms grow more linguistically diverse, attending to multilingual learners' experiences is vital for equity. From 2009 and 2019, undergraduate enrollment of Latino students, many of whom are multilingual, increased by 48%, even as total enrollment declined by 5% (NCES, 2021a, 2021b). Attending to this growing linguistic diversity is essential for building equitable mathematics learning environments at the undergraduate level. Prior research suggests that language identity influences mathematics engagement (Rios, 2024), yet few studies examine how multilingual students' identities shape their attitudes specifically within undergraduate mathematics contexts. We define mathematics attitudes as a blend of cognitive (value, confidence, self-concept), affects (enjoyment, anxiety), and behavior (willingness to engage with mathematics).

Our research aims to identify key factors influencing multilingual undergraduate students' attitudes toward mathematics, explore the role of language, culture, and identity in shaping these attitudes, and examine how students interpret and respond to instructional practices in mathematics classrooms, highlighting how inclusive, asset-based approaches can enhance mathematics learning experiences for multilingual learners.

We employed a mixed-methods design integrating qualitative interviews and quantitative ranking activities. Participants were purposefully selected multilingual undergraduates who had completed at least one year of education in the United States, ensuring that their reflections were grounded in undergraduate mathematics experiences. Five Hispanic undergraduates (ages 18–23) enrolled in Psychology, Pre-Nursing, and Spanish programs participated. Semi-structured interviews explored personal mathematics learning histories, language use in mathematics classrooms, and attitudes toward mathematics. Participants were also asked explicitly about instructional practices, such as teacher encouragement, use of language, and classroom climate, that shaped their confidence and engagement in mathematics. This was followed by a ranking activity identifying perceived influence factors. Data were analyzed thematically and supported by descriptive statistics from rankings.

Preliminary findings show personal drive and teacher support as the most influential factors shaping attitudes toward mathematics. Participants associated bilingualism with greater confidence and self-perception of ability when instructional environments acknowledged and valued their linguistic resources. Teacher encouragement, or lack thereof, was more influential than familial or peer perspectives. Students' conceptions of 'math people' shifted from focusing on grades to valuing conceptual understanding. Negative attitudes were often linked to deficit-based assumptions about language or identity.

We plan to expand this study by interviewing additional multilingual undergraduates across disciplines who are currently enrolled in, or have recently completed, undergraduate mathematics courses and conducting a deeper thematic analysis using MAXQDA. The goal is to identify specific strategies, drawn from students' reported experiences, that strengthen self-efficacy, value students' linguistic assets, and foster equitable participation in undergraduate mathematics.
