Preface

As part of its on-going activities to foster research in undergraduate mathematics education and the dissemination of such research, the Special Interest Group of the Mathematics Association of America on Research in Undergraduate Mathematics Education (SIGMAA on RUME) held its twenty-eighth annual hybrid Conference on Research in Undergraduate Mathematics Education in Alexandria, Virginia from February 26 – 28, 2026 hosted by Virginia Tech Mathematics Department. The hybrid modality enabled presenters and attendees to participate fully online such that travel was not a requirement. Of the 479 conference attendees, approximately 18% of them attended virtually.

The program included plenary addresses by Dr. Jennifer A. Czocher, Dr. Felix Ho, and Dr. Daniel Reinholz and 151 paper reports, including contributed, preliminary, and theoretical research reports, and 124 posters. Each paper report underwent a rigorous peer review process by three or more reviewers, including at least one member of the conference Program Committee. Each poster report was reviewed by two members of the Program Committee. The following are the acceptance rates for each type of reports for this year's conference:

Contributed Report: 89/114 (78%)
Preliminary Report: 42/58 (72%)
Theoretical Report: 20/28 (71%)
Poster Report: 126/138 (91%).

Two accepted poster reports were withdrawn prior to the conference. A new set of primary subject areas for submissions were introduced for this year's conference. The table below offers an approximation for the areas of research that were represented during the paper sessions. It is sorted by the most represented.

Primary Subject Area	Number of papers
Student Thinking	49 (32%)
Equity (access, achievement, identity, and power)	23 (15%)
Classroom Pedagogies & Teaching Practices (including tutoring)	18 (12%)
Affect (including attitudes, beliefs, anxiety)	17 (11%)
Curriculum & Curriculum Design	13 (9%)
Teachers & Instructors Professional Learning (including GTA Training, PD)	11(7%)
Assessment	6 (4%)
Classroom Dynamics & Discourse	5 (3%)
Institutional & Departmental Practices	5 (3%)
Research Methods	4 (3%)

The proceedings are organized by types of papers that represent current work in undergraduate mathematics education:

- Contributed Reports share findings from a completed research study that make meaningful contribution to existing literature.
- Preliminary Reports share preliminary findings from an ongoing research project in early stages of analysis.
- Theoretical Reports share scholarly works whose primary aim is to contribute to the development of theories or theoretical perspectives.
- Poster Reports are 1-page documents sharing a description of a research study at any stage of completion.

These proceedings, along with previous years' proceedings are available on the sigmaarume.org website. As announced at the conference, the searchable database of all RUME Proceedings has become available for use where readers can search by keywords, title, and authors. We thank Dr. Shandy Hauk for spearheading this effort.

Many members of the RUME community volunteered for the Program Committee where they reviewed many submissions such that every submission was reviewed by at least one member of the Program Committee. The Program Committee aided us in putting together this program and their hard work is greatly appreciated. The Local Organizing Committee were responsible for the smooth running of the presentations and on-site activities, which would not have been possible without the help of many volunteers, and we thank them for their tireless efforts to host a conference that runs smoothly.

Thank you to all the researchers who submitted such strong proposals and ultimately made the conference a fun and joyous event.

Aditya P. Adiredja, RUME Conference Executive Coordinator and Conference Chair
Estrella Johnson, RUME Conference Local Organizing Co-Chair
Megan Wawro, RUME Conference Local Organizing Co-Chair

Program Committee

Chairperson

Aditya P. Adiredja	The University of Arizona

Committee Members

Joseph Antonides	Colorado State University
Naneh Apkarian	San Diego State University
Anna Marie Bergman	Fort Lewis College
Anne Cawley	Cal Poly Pomona
Sam Cook	Boston University
John Paul Cook	Oklahoma State University
Jennifer Czocher	Texas State University
Tim Fukawa-Connelly	Temple University
Keith Gallagher	University of Nebraska Omaha
Neil Hatfield	Portland State University
Shandy Hauk	San Francisco State University
Billy Jackson	University of Illinois Chicago
Estrella Johnson	Virginia Tech University
Brian P Katz (BK)	California State University, Long Beach
Kristen Lew	Texas State University
Kathleen Melhuish	Texas State University
Hailey Milbourne	University of San Diego
Kevin Moore	University of Georgia
Debra Moore-Russo	University of Oklahoma
Mary E. Pilgrim	San Diego State University
Elizabeth A. Roan	Texas State University
Rachel L. Rupnow	Northern Illinois University
Jason Samuels	City University of New York
Kaitlyn Stephens Serbin	University of Texas Rio Grande Valley
Irma E. Stevens	The University of Rhode Island
Stephen Strand	California State University, Chico
Karina Uhing	University of Nebraska Omaha
Kristen Vroom	Michigan State University
Nicholas Wasserman	Teachers College Columbia University
Megan Wawro	Virginia Tech University
Franklin Yu	Virginia Commonwealth University
Holly Zolt	Middle Tennessee State University

Local Organizing Committee

Co-Chairs

Estrella Johnson	Virginia Tech
Megan Wawro	Virginia Tech

Committee Members

Rachel Arnold	Virginia Tech
Clare Bassano	Virginia Tech
Sean Clark	Virginia Tech
Kyle Flanagan	Virginia Tech
Lindy Hearne	Virginia Tech
George Kuster	Christopher Newport University
Talia LaTona-Tequida	Virginia Tech
Jacob Lineberry	Virginia Tech
Corinne Mitchell	Virginia Tech
Anderson Norton	Virginia Tech
Modiu Olaguro	Virginia Tech
Matt F. Park	Virginia Tech
Tracy Proffitt	Virginia Tech
Franklin Yu	Virginia Commonwealth University

Volunteers

Mitra Alizadeh	Bowling Green State University
Joseph Antonides	Colorado State University
Bryan Barbosa	University of Texas Rio Grande Valley
Kairi Black	Duke University
Rebecca Caudillo-Scariano	Colorado State University
Jhoel Chacon-Perez	James Madison University
Mathias Chacon-Perez	James Madison University
Jesse Combs	Lesley University
Jose Contreras	Michigan State University
Jennifer A. Czocher	Texas State University
Amy Daniel	Montclair State University
Omkar Devlekar	Texas State University
Nicholas Fortune	Western Kentucky University
Jason Guglielmo	Arizona State University
Devin Hensley	Auburn University
Jocelyn Hernandez	Fresno State University
Rasha Issa	University of California, Riverside
Bhargav Kale	The University of Arizona
Kristen Lew	Texas State University
Dexter Lim	University of Minnesota

Megan (Mack) McCormick	University of Michigan
Kathleen Melhuish	Texas State University
Eleanor Nelson	Colorado State University
Emily Olson	Montclair State University
Jessyca Olvera	Western Michigan University
John O'Meara	Montclair State University
David Plaxco	University of Georgia
Kiley Pooler	Arizona State University
Ama Ahenfoa Quansah	Oklahoma State University
Kaitlyn Roxby	West Virginia University
Dov Zazkis	Montclair State University (Bloomfield College)
Anthony Zhang	Teachers College Columbia University

Logic in Introduction-to-Proof Students: Mathematical Truth Table Tasks

Lara Alcock
Loughborough University, UK

Mathematics uses standard logic, in which the truth value of the conditional 'if A then B' is completely determined by the truth values of A and B. Specifically, when A is false, 'if A then B' is, by definition, true. This makes the mathematical conditional out of line with natural language, where research using truth table tasks shows that conditionals are often considered irrelevant in false-antecedent cases. What does this mean for mathematics undergraduates? Do they interpret conditionals according to standard logic, or do their responses align with everyday interpretations? Do they make consistent interpretations, or do these vary by content? This report contributes a first investigation of this issue.

Keywords: conditionals, if-then, logic, reasoning, truth tables

Introduction

In mathematics, conditionals – *if-then* statements – are ubiquitous. Many theorems and conjectures are naturally expressed as *universal* or *generalized* conditionals of the form '$\forall x$, if $A(x)$ then $B(x)$' (Durand-Guerrier, 2003). This is so well understood that the quantification is often left implicit (Shipman, 2016), as in these example theorems:

- If $f: \mathbb{R} \to \mathbb{R}$ is differentiable at a, then f is continuous at a;
- If G is a finite group and H is a subgroup of G, then $|G| = |H||G:H|$;
- If p is a prime number and $p \nmid a$, then $a^{p-1} \equiv 1 (\text{mod } p)$.

The interpretation of universal conditionals is underpinned by the standard mathematical interpretation of *if-then* as the *material conditional*, a truth-functional logical connective (Edgington, 2020). For propositions A and B, the truth value of 'if A, then B' is defined for every possible combination of truth values of A and B, and is completely determined by those truth values per the standard truth table – see Table 1.

Table 1. Defining truth table for if-then as a truth functional logical connective.

A	B	if A then B
T	T	T
T	F	F
F	T	T
F	F	T

Truth functionality is necessary for *if-then* to interact with the other connectives *and*, *or* and *not* in a way that enables unambiguous evaluation of logical equivalence and argument validity (Smith, 2020). And the standard truth table is the only viable option (Edgington, 2020). We want a universal conditional 'if $A(x)$ then $B(x)$' to be false only when there exist cases corresponding to the TF row, with $A(x)$ true but $B(x)$ false. We want it to be true if there are no such cases, compelling us to define it as true for TT, FT and FF rows. This interpretation confirms validity for standard argument forms. For instance, *modus tollens* inferences from *if A then B* and *not-B* to *not-A* are valid because the premises are true together only in the FF row of the table, where A is false (Velleman, 2006). However, the truth-functional conditional is

psychologically unnatural. It defines a conditional as true whenever its antecedent is false, where natural-language conditionals are often considered irrelevant in such cases (Nickerson, 2015). This issue is the focus of this report, which describes the development and use of mathematical *truth table tasks*.

Theoretical Background

Conditionals and their interpretation have been studied in mathematics education (Dawkins & Norton, 2022; Inglis & Attridge, 2016) and more generally in psychology (Nickerson, 2015), philosophy (Edgington, 2020) and linguistics (Douven et al., 2020). Reasoning *from* conditionals is often investigated using *conditional inference tasks*, which have been used to study mathematics students' reasoning about both abstract content (Attridge & Inglis, 2013) and everyday and mathematical content (Alcock et al., under review; Alcock & Inglis, under review). Interpretation *of* conditionals is often studied using *truth table tasks*, which have not so far been used with mathematics students or with mathematical content.

Truth table tasks come in various forms. One simple type presents a conditional and asks participants to generate examples that are true and examples that are false. People commonly generate TT cases for 'true' and TF cases for 'false'; a minority of participants additionally generate false-antecedent cases for 'true' (Nickerson, 2015).

A more standard type presents participants with a conditional and with cases corresponding to each truth table row; the task is to judge the truth value of the conditional in each case. Tasks vary in their response options: participants might be forced to choose between 'true' and 'false' or might be allowed a third option of 'irrelevant', 'indeterminate' or similar (Nickerson, 2015). When offered this third option, people typically use it for one or both false-antecedent cases. For instance, Newstead et al. (1997) asked participants to state whether each presented case 'supports', 'contradicts' or 'tells us nothing about' the relevant conditional. Across three studies, they found that people almost always judged that TT cases support the conditional and TF cases contradict it. For FT cases, responses were split almost equally between contradicts and tells us nothing; for FF cases, responses were split almost equally between supports and tells us nothing. This effectively gives the 'truth table' in Table 2.

Table 2. Common responses in truth table tasks, Newstead et al. (1997).

A	*B*	if *A* then *B*
T	T	T
T	F	F
F	T	F or I
F	F	T or I

Tasks also vary in semantic content. Newstead et al. systematically varied their content using conditional promises, threats, tips, warnings, and conditionals that they called temporal, causal, and universal. Universals (e.g., 'If the student is doing economics, then he is a socialist') are arguably closest to mathematical conditionals because they are effectively about set inclusion, though of course such claims would be treated as debatable – the bivalent logic of mathematics does not usually apply to everyday content (Oaksford & Chater, 2020). For universal conditionals, Newstead et al. reported higher proportions of tells-us-nothing responses, at 64% for FT and 63% for FF cases respectively; this meant that 46% of responses followed a TFII pattern sometimes referred to as a *defective implication* interpretation (following Wason &

Johnson-Laird, 1969). The full set of patterns considered by Newstead et al. were termed *implication* (TFTT, as in the truth-functional conditional), *equivalence* (TFFT, treating a conditional as a biconditional), *defective implication* (TFII), and two patterns based on their data, *defective biconditional* (TFFI) and *Pattern X* (TFIT). The implication pattern was extremely rare: interpretations of everyday conditionals do not align with standard logic, as is well documented across tasks of various types (e.g., Oaksford & Chater, 2020).

What does this mean for students learning mathematics? When faced with mathematical content, do they import everyday interpretations, or does their reasoning align with standard logic? This study was designed to find out.

Method

Designing a truth table task with 'realistic' mathematical content is nontrivial. Mathematical conditionals are easy to come by – as noted in the Introduction, many theorems can be expressed in this form. But theorems, of course, are true, whereas a truth table task requires cases for all four truth-value combinations, TT, TF, FT and FF. This means that both the conditional and its converse must permit counterexamples. I therefore used simple mathematical content to construct conditionals that sound sensible because a) the semantic contents of their antecedents and consequents involved related concepts, as is pragmatically expected in everyday conditionals (Grice, 1989), and b) the first case to come to mind would likely be a TT case. To keep the tasks short while providing at least some mathematical variety, I used three conditionals:

- If *n* is a positive odd number, then *n* is prime.
- If rectangle *R* has area 12 square units, then its perimeter is 14 units.
- If *x* is a whole number, then $x^2 > x$.

I used all three conditionals in each of three truth table tasks (using the word 'claim' rather than 'conditional' in these tasks to make the language more accessible).

- In the *generate* task, participants were asked to give one or more examples that would make each conditional true and one or more than would make it false;
- In the *true-false* task, participants were shown the conditional with TT, TF, FT and FF cases, and asked to judge the conditional true or false for each one;
- In the *true-false-irrelevant* task, participants were shown the conditional with TT, TF, FT and FF cases, and asked to judge the conditional true, false or irrelevant for each one.

For the true-false and true-false-irrelevant tasks, the provided cases are shown in Table 3. Rectangles were shown diagrammatically – see the example true-false-irrelevant task in Figure 1.

Table 3. TT, TF, FT and FF cases provided for each conditional in the true-false and true-false-irrelevant tasks; for task presentation format see the appendix.

Conditional	TT	TF	FT	FF
If *n* is a positive odd number, then *n* is prime.	3	9	2	8
If rectangle *R* has area 12 square units, then its perimeter is 14 units.	3×4	2×6	1×6	2×3
If *x* is a whole number, then $x^2 > x$.	3	1	3/2	1/2

Consider this claim:

If n is a positive odd number, then n is prime.

For each n-value listed below, would you say the claim is true, false, or irrelevant?

1. $n = 3$ A
2. $n = 8$ D
3. $n = 2$ C
4. $n = 9$ B

Consider this claim:

If rectangle R has area 12 square units, then its perimeter is 14 units.

For each rectangle shown below, would you say the claim is true, false, or irrelevant?

1. D
2.  A
3.  C
4.  B

Consider this claim:

If x is a whole number, then $x^2 > x$.

For each x-value listed below, would you say the claim is true, false, or irrelevant?

1. $x = \frac{3}{2}$ C
2. $x = 3$ A
3. $x = 1$ B
4. $x = \frac{1}{2}$ D

Figure 1. Example true-false-irrelevant task page (small letters to the right track randomization).

For each task, the order in which the conditionals appeared was counterbalanced. For the true-false and true-false-irrelevant tasks, the order in which the cases appeared for each conditional was randomized. Participants were first-year UK mathematics undergraduates in the third week of an introduction-to-proof course (the researcher had no involvement in the course). Each participant received one of the three tasks on paper, and papers were arranged so that students in adjacent seats would receive different tasks. The task took five minutes. For the generate task, 29 participants consented to have their data used. For the true-false task, 30 consented but one clearly misunderstood the task and two did not respond for all three conditionals so, for simplicity, data from 27 is presented. For the true-false-irrelevant task, 26 participants consented but one did not respond for all conditionals, so data from 25 is presented.

Results

The headline result is that in judging truth values for mathematical conditionals, introduction-to-proof students adhere much more closely to the defective TFII interpretation than to the truth-functional TFTT interpretation of standard logic. That is, they interpret mathematical conditionals as true in TT cases, false in TF cases, and – where permitted and indeed sometimes where not permitted – as irrelevant in FT and FF cases. Moreover, content appears to affect interpretations, and a substantial minority of students do not implement a consistent interpretation across contents. I report results for the generate task, then break down the results for the true-false and true-false-irrelevant tasks by conditionals then by participants.

Generate Task

Results from the generate task were clear and in line with common responses to tasks with everyday content (e.g., Nickerson, 2015): for examples that would make the conditional true, participants gave TT cases; for examples that would make it false, they gave TF cases. A small number made interpretation or calculation errors (e.g. failing to notice the whole number requirement for x and providing a range such as $0 < x < 1$). But most responded predictably: Table 4 gives examples that were most commonly listed first.

Table 4. Commonest first responses for examples that make each conditional true/false, with percentage of participants giving that response.

Conditional	True	False
If *n* is a positive odd number, then *n* is prime.	3 (66%)	9 (66%)
If rectangle *R* has area 12 square units, then its perimeter is 14 units.	3×4 (86%)	2×6 (69%)
If *x* is a whole number, then $x^2 > x$.	2 (55%)	1 (66%)

True-False Task

Results for the true-false task – see Table 5 – showed that for all three conditionals, small minorities of participants aligned with the material interpretation, with response pattern TFTT. But most went against it, either choosing 'false' for both false-antecedent cases (TFFF) or subverting the task by introducing 'irrelevant' as an extra option and applying it to those cases (TFII). No participant gave a biconditional (TFFT) response. For the conditional 'If x is a whole number, then $x^2 > x$', there were fewer TFFF responses but several TFTF responses, judging the conditional true for the case $x = 3/2$. This differs from the common everyday responses summarized in Table 2, but the task required written one-word responses only, so I have no qualitative data on why this might be. I hope this might generate discussion at the conference.

Table 5. Numbers giving the commonest response patterns for each conditional (26 participants).

Conditional	TFFF	TFII	TFTF	TFTT
If n is a positive odd number, then n is prime.	17	3	1	4
If rectangle R has area 12 square units, then its perimeter is 14 units.	17	4	1	1
If x is a whole number, then $x^2 > x$.	11	3	8	3

Analysing by participants reflected these results in that:

- 8 responded TFFF for all three conditionals;
- 5 responded TFFF for the n and R conditionals but TFTF for the x conditional;
- 3 responded TFII for all three conditionals;
- 1 responded TFTT for all three conditionals.

Of the remaining ten participants, nine were inconsistent – some gave different response patterns for all three conditionals. As in Dawkins and Cook's (2017) work on disjunctions, this shows that students do not necessarily recognize logical structures or apply these in the same way across different mathematical content. One participant responded IFII for all three conditionals, apparently unwilling to assign a truth value in any but the clearly false case. Although unusual in these data, this is in line with interpretations in which conditionals are not considered true unless there is an inferential link between antecedent and consequent (e.g., Douven et al., 2020).

True-False-Irrelevant Task

Results for the true-false-irrelevant task – see Table 6 – showed that for all three conditionals, participants who were offered the 'irrelevant' option commonly used it, leading to response pattern TFII. No participant offered this option responded according to the material conditional (TFTT), and again no participant gave a biconditional (TFFT) response. As in the true-false task, there were a few TFTF responses for the x conditional.

Table 6. Numbers giving the commonest response patterns for each conditional (25 participants).

Conditional	TFFF	TFII	TFTF	TFTT
If n is a positive odd number, then n is prime.	2	20	0	0
If rectangle R has area 12 square units, then its perimeter is 14 units.	4	17	0	0
If x is a whole number, then $x^2 > x$.	1	16	5	0

Analysing by participants reflected these results in that:

- 14 responded TFII for all three conditionals;
- 1 responded TFII for the n and R conditionals but TFTF for the x conditional.

Of the remaining ten participants, all were inconsistent across the conditionals – again, some gave different response patterns for all three.

Discussion

This is the first study to design and use a mathematical version of a truth table task to investigate interpretations of mathematical conditionals. Its main result is that for simple mathematical content, the interpretations made by introduction-to-proof students align much more closely with typical interpretations of everyday conditionals than with standard mathematical logic. That is, students most commonly think of conditionals as true in TT cases,

false in TF cases, and irrelevant in FT and FF cases. When forced to choose between true and false for false-antecedent cases, most pick 'false', giving a TFFF rather than a TFTT response. Many students are not consistent in their interpretations across content (cf. Dawkins & Cook, 2017). Finally, content seems to have an effect, with the conditional 'If x is a whole number, then $x^2 > x$' prompting some TFTF responses.

One question is how much this matters. Although the truth-functional material conditional underlies mathematical interpretations of logical equivalence and validity, 'real' mathematics rarely involves propositional conditionals. Consequently, it is possible to provide an introduction to proof that does not address propositional logic, instead focusing on the distinction between a (universal) conditional and its converse – several commonly recommended books do this (Alcock & Sa, 2025). Moreover, a defective interpretation does not appear fatal to strong mathematical reasoning. Although a material interpretation is technically necessary for validity of modus tollens inferences (Durand-Guerrier, 2003), these also submit to a longer but valid workaround ('if A were true, then B would be true, but B is not true, so A cannot be true'), and evidence from other tasks too indicates that this interpretation is common among successful undergraduates (Inglis & Simpson, 2009).

One way to approach an informed view on this question would be to find out how professional mathematicians respond to truth table tasks. It could be that all give TFTT responses, in which case an argument about developing expertise suggests that teaching the material conditional is worth the effort. But mathematicians, too, have little cause to consider propositional conditionals in their day-to-day work, so it is possible that they have little practice in thinking about these and that some would be influenced by everyday language and respond according to the defective TFII interpretation. In that case, the question becomes more nuanced – if the truth-functional interpretation is mathematically 'correct' but not necessary for a successful mathematical career, perhaps teaching it should not be a priority. By the time of the conference, I will have evidence on mathematicians' responses to these tasks.

In the meantime, my current view is that mathematics undergraduates should encounter propositional logic as part of exposure to the foundations of their subject (Alcock, 2025). However, we should expect that they will find it unnatural, and we should think carefully about whether and how our explanations leverage everyday content. In some cases, such content might support students in reaching appropriate interpretations (Epp, 2003). In others, it might encourage the reverse, or at least it might fail to raise the right questions. For instance, many textbooks that do cover the material conditional do so by presenting an everyday conditional (e.g. 'If it stops raining by Saturday, then I will go to the football game', Lay, 2014, pp.4-5); they invite students to consider when they would consider it false, then argue that it should be considered true in all other cases. As Alcock and Sa (2025) point out, this fails to engage with the irrelevance problem. To remedy this, the psychology literature suggests that an intermediate step might be useful: although people consider conditionals irrelevant for false-antecedent cases, they are often willing to concede that conditionals are *compatible* with those cases (Nickerson, 2015). The present research with mathematical content did not test this, but a follow-up is underway that will replicate the true-false and true-false-irrelevant tasks and add one testing judgements of compatibility. Again, I will hope to share the data at the conference.

Coordinating Point and Rate: A Framework for Students' Reasoning About Slope

Kyunghee Moon
University of West Georgia

This study examines how precalculus students reason about rate and point as multiplicative objects in the contexts of linear equations and approximation. To capture students' developing conceptions, I introduce a framework distinguishing three levels of abstracted ratio: generalized ratio, unit rate, and interiorized ratio. Findings show that although students progressed toward interiorized reasoning, their understanding was fragile when working with non-integer or symbolic values. They also struggled to coordinate slope with a reference point, which limited their ability to interpret points as records of covariation. Geometric approaches to linear approximation highlighted these conceptual difficulties more clearly than symbolic tangent line equations, underscoring the need for instructional support that fosters covariational reasoning.

Keywords: linear function, linear approximation, rate, point, multiplicative object

Studies have long documented calculus students' struggles with tangent line equations and linear approximations (Amit & Vinner, 1990; Çekmez & Baki, 2016; Moore-Russo & Nagle, 2024; Orton, 1983), yet less attention has been paid to underlying precalculus concepts—especially understandings of rate and point in linear equations. Classroom observations suggest that difficulties may stem not only from gaps in derivative fluency but also from underdeveloped conceptions of linear relationships.

To investigate, I conducted exploratory interviews with three precalculus students, focusing on the research question: How do students conceptualize rate and point as multiplicative objects in the context of linear equations and linear approximation?

Theoretical Framework and Literature

Students who view a function only as a correspondence between input and output (Thompson, 1994b), or who treat $L(x) = f(a) + f'(a)(x - a)$ as a formula to substitute values into, may compute correctly without visualizing the situation or interpreting the slope $f'(a)$. Such disconnections between computation and the graphical tangent have been documented (Code et al., 2014). In contrast, students who conceive *x* and *y* as covarying quantities—measurable attributes varying in coordination (Thompson & Carlson, 2017)—are more likely to interpret $L(x)$ meaningfully. A meaningful understanding of $L(x)$, I argue, depends on conceiving both *point* and *rate* as multiplicative objects (Saldanha & Thompson, 1998). A multiplicative object unifies two quantities into a single conceptual entity: a point coordinates horizontal and vertical displacements, and a rate coordinates changes in *x* and *y*. Recognizing these as multiplicative objects requires mentally integrating covarying quantities into one structure, rather than viewing them in isolation.

Rate as a Multiplicative Object

The concept of rate connects to the linear function *L* from two perspectives: calculus and algebra. From a calculus perspective, *L* embodies $f'(a)$, the instantaneous rate of change $\lim_{h\to 0} \frac{f(a+h)-f(a)}{h}$, interpreted geometrically as the slope of the tangent line. While this definition is central to calculus learning (Orton, 1983; Yu, 2024; Zandieh, 2000), a full treatment lies beyond

the scope of this study. Instead, the focus here is on students' conceptions of rate in algebraic contexts, where $f'(a)$ functions as a constant rate of change—the slope of L.

In Thompson's (1994a) framework, a rate is a reflectively abstracted multiplicative structure describing how one quantity changes in relation to another. A ratio may begin as a static comparison but can be abstracted from specific numbers to describe relationships between indeterminate, systematically related quantities. This progression reflects a shift from an *internalized* ratio—reasoning with repeated accumulations of a fixed ratio (e.g., scaling "three pears to four apples")—to an *interiorized* ratio, in which quantities are conceived as continuously varying while maintaining a constant relationship. Interiorized ratio aligns with covariational reasoning, where rate functions as a structural relationship that integrates and governs the coordinated changes of two quantities.

Research shows that students often struggle to construct rate as a multiplicative object. They may treat it procedurally (Lobato et al., 2003), rely on additive reasoning, or focus on isolated values instead of coordinating variation (Clark & Kamii, 1996; Yu, 2024). Even when producing correct values, they may not interpret them as relationships between covarying quantities. Thompson (1994a) emphasized that interiorizing rate requires conceiving it as a structural relationship that remains invariant across magnitudes. Johnson (2015) found that students often viewed rate as an extensive quantity—treating measures as separate totals—rather than as an intensive quantity that unites them into a single multiplicative relationship governing covariation. Together, Thompson and Johnson highlight the difficulty of moving from procedural or context-bound views toward structural conceptions of rate, underscoring the need for analytic categories that capture the partial ways students reason prior to full interiorization.

Point as a Multiplicative Object

A point can be understood not merely as a location—"over this much and up that much"—but as a multiplicative object that records the covariation of two quantities (Thompson et al., 2017). In this view, coordinates represent interdependent values integrated into a single structure. Yet research shows that many learners struggle with this conception. Thompson et al. (2017) found that accuracy in placing the initial point was closely tied to correctly sketching the entire graph. Similar challenges have been documented in contextualized settings where attending to covarying quantities is essential: Ellis et al. (2015) reported students' difficulties in interpreting exponential growth involving height and time, while Frank (2016) documented struggles to reason about points in motion or dynamically changing systems using the same task from Thompson et al. (2017). Collectively, these studies underscore the complexity of conceiving a point not merely as a location but as a representation of a quantitative relationship.

Methodology

Setting

This study took place at a small state university in the southeastern United States. From fifteen students recommended by precalculus instructors for their varied mathematical thinking, three—Tanya, Zada, and Sean (pseudonyms)—agreed to participate for an hourly stipend. Tanya, a dual-enrolled high school student, had completed Algebra 2; Zada, a first-year biology major, had recently finished college algebra; and Sean, a first-year computer science major, had completed precalculus in South Asia.

All precalculus courses used *Algebra and Trigonometry* (Abramson, 2018) as the textbook, which presents slope mainly as the algebraic ratio $\frac{y_2-y_1}{x_2-x_1}$ in slope-intercept form, with point-slope

form quickly converted. Graphs focus on parallel and perpendicular lines, per-unit concepts appear only in contextual problems, and nonlinear rate of change is omitted. Multiple representations are included but rely on discrete values, rational slopes, and integer intercepts, reflecting an algebraic–procedural emphasis.

Participants took part in five to seven interview sessions (90 minutes each) near the end of the semester, after instruction on slope, linear equations, and functions. Tanya and Zada completed seven sessions, while Sean completed five due to family circumstances. Using a semi-structured clinical interview format (Ginsburg, 1997) with elements of exploratory teaching (Steffe & Thompson, 2000), early sessions elicited existing understandings through tasks such as constructing equations from graphs or tables, without instructional support. Later sessions introduced targeted prompts, informed by prior responses, to probe reasoning about linear and quadratic functions and linear approximation.

Data Analysis and Development of New Analytic Tool

Data analysis began during data collection, following an iterative, comparative approach (Miles & Huberman, 1994). After each interview, I reviewed recordings, wrote analytic memos summarizing key content, and drafted rough transcripts of notable moments. This early work informed preliminary codes for students' conceptual difficulties with point, slope, linear equations, and approximation, which were refined through constant comparative methods (Glaser & Strauss, 1967) as patterns in reasoning emerged.

As analysis progressed, the coding scheme was refined through distinctions that supported cross-case comparisons of how students coordinated rate and point. Drawing on Thompson's (1994a) framework of internalized and interiorized ratios and related work on covariational reasoning (Johnson, 2015; Thompson & Carlson, 2017), I identified three analytic categories of ratio and rate: generalized ratio, unit rate, and interiorized ratio (Table 1). These categories provided the framework for interpreting students' levels of abstraction of ratio.

Table 1. Types of Abstracted Ratio

Level	Description and Examples of Student Reasoning
Generalized Ratio (Early Abstracted Reasoning)	Treated as a fixed multiplicative value across quantity pairs, applied symbolically without coordinating x and y. Example: "The slope between $(2, a)$ and $(5, b)$ is 3/4 because $(b - a)/(5 - 2) = 3/4$."
Unit Rate (Transition to Interiorized Reasoning)	Conceived as a per-unit change, enabling additive or multiplicative coordination of Δx and Δy, typically for integer Δx values. Example: "If x increases by 1, y increases by 3/4," then uses $3/4 \times 2$ to find Δy when $\Delta x = 2$.
Interiorized Ratio (Fully Abstracted Reasoning)	Conceived as a structural, covariational relationship, expressed as $\Delta y = m\Delta x$, that applies to any Δx, including symbolic or infinitesimal values, supporting flexible and general reasoning. Example: "For any change in x, the change in y is 3/4 times that," applied with h or 0.1.

Figure 1 illustrates how generalized, unit rate, and interiorized ratio conceptions influence students' approaches to linear approximation, highlighting how Δx and Δy are conceived as

displacements relative to the reference point $(a, f(a))$ rather than the origin. (Note: I use Δx and Δy instead of dx and dy to reflect students' reasoning in precalculus contexts.)

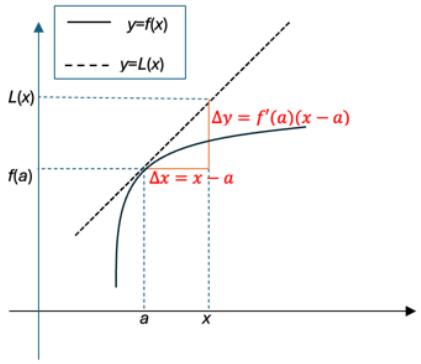

Figure 1. Understanding Linear Approximation from a Covariation Perspective

Results

The results synthesize students' reasoning across tasks on linear equations and linear approximation, organized by a developmental trajectory rather than by participant or chronology. Findings are presented in three parts: (1) pre-abstracted interpretations of rate, (2) emerging abstracted ratios—generalized ratio, unit rate, and interiorized ratio—and (3) conceptions of point as a multiplicative object. Subsections are titled by the transitional strategies observed (e.g., additive, multiplicative) when students' thinking did not fully align with a single level. Tasks were adapted to students' readiness; Tanya contributed the most complete data set, while Zada's more limited mathematical preparation and Sean's reduced participation due to family circumstances yielded partial but informative episodes. Together, these data trace how precalculus students coordinate rate and point and where conceptual fragilities persist.

Slope as a Ratio between Two Points and Construction of Linear Equations

At the outset, all three participants understood slope mainly as the formula $(y_2–y_1)/(x_2–x_1)$ and showed only partial familiarity with "rate of change." When constructing linear equations, Sean applied both slope and point-slope forms, while Tanya and Zada relied solely on slope-intercept form, succeeding only when the y-intercept was obvious. Tanya recognized parallel slopes but struggled to connect tabular data with equations, whereas Zada omitted equation form, misapplied slope in parallel tasks, and added x and y values directly from the table.

In sum, Sean and Tanya displayed stronger reasoning than Zada, yet all three treated slope as an algebraic ratio rather than as an abstracted multiplicative relationship, with little evidence of Cartesian or tabular connections.

Transitioning to Abstracted Ratio

Additive strategies and the emergence of multiplicative reasoning with integer Δx. When asked to find the rate of change between two points $(2, a)$ and $(5, b)$ that lie on the graph of $y = 3x – 7$ (Figure 2A), Zada proposed first calculating a and b and then applying the slope formula. This showed she did not interpret the coefficient 3 as the rate of change for all points on the line but instead viewed slope as something to be computed from particular pairs—an underdeveloped conception of slope as a generalized ratio. To find a and b, she suggested graphing and "counting up by 3" each time x increased by 1.

A. Points $(2, a)$ and $(5, b)$ lie on the graph of $y = 3x - 7$. What is the rate of change between these two points?

B. $(3, b)$ is on the line graph below. What is b?

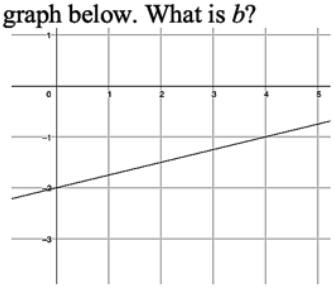

Figure 2. Tasks Requiring a Conception of Slope at an Advanced Level

To move her from counting to multiplication, I asked for the y-value at $x = 10$ on the graph of $y = 3x + 1$. She again counted by 3 until reaching (10, 31) (see Figure 3). For (60, b), however, she hesitated, noting that "it would take forever." With prompts about slope as "a rise of 3 for each run of 1" and the point (60, b) plotted, she initially claimed that b was 6 with a rise of 5, misled by the scale. Only after I clarified the diagram, labeled (60, 1), and reiterated that slope meant a rise of 3 per unit run did she compute the rise as 60 × 3. This episode suggests her multiplicative reasoning with slope was contingent on explicit visual and verbal scaffolds.

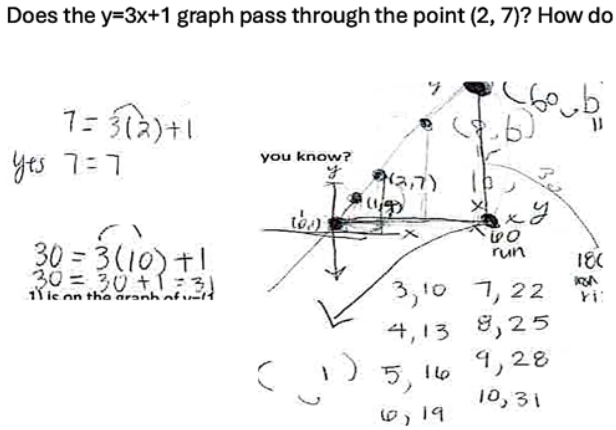

Figure 3. Zada's Transitioning from Counting to Multiplication

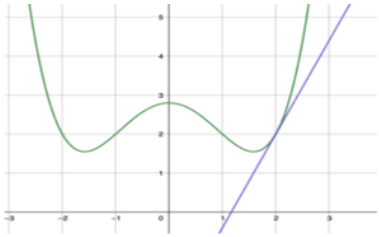
From generalized algebraic ratio to generalized geometric ratio. When asked to find b in the point (3, b) (Figure 2B), Sean applied both slope formula and point-slope form, producing $y = ¼ x – 2$. He then set up $\frac{1}{4} = \frac{b-(-1)}{3-4}$ and solved for b—indicating that he viewed ¼ as an invariant relationship, a generalized algebraic ratio. Yet he acknowledged knowing no method beyond algebraic manipulation. When I drew segments between (0, –2) and (4, –1) and asked about $y_2 – y_1$ and $x_2 – x_1$, he recalled from high school that they were "differences in the coordinates."

Sean carried this reliance on point-slope form into the linear approximation tasks. To estimate $f(2.1)$ (Figure 4a), he constructed the tangent line $y = \frac{12}{5}x - \frac{14}{5}$ and substituted $x = 2.1$

to obtain 2.24. When pressed to reason directly with slope, he hesitated until I drew displacements and labeled $\Delta x = 0.1$. Then he wrote $\frac{12}{5} = \frac{\Delta y}{\Delta x}$, substituted $\Delta x = 0.1$, and found $\Delta y = 0.24$—explaining, "x is increased by 0.1 and y is increased by 0.24." He also extended this to $\Delta x = 0.2$, showing movement toward conceiving slope as a generalized geometric ratio.

In a later task estimating $\sqrt{1.05}$, Sean again used the tangent line equation but explained that with slope ½ and $\Delta x = 0.05$, "Δy is ½(0.05)." Still, his reasoning reflected manipulation of the equation ½ = Δy/0.05, signaling a generalized ratio rather than an interiorized ratio.



The y=g(x) graph (in blue) is the tangent line of y=f(x) (in green) at the point (2, 2) and the slope of the line g is 12/5.

a) Estimate the value of f(2.1).
b) Find the equation of the line: y=g(x).
c) Estimate f(2+h).

Figure 4. Constructing Tangent Line and Approximating Function Values from Graphs

From a generalized ratio to unit rate: Additive/multiplicative reasoning with integer Δx. Tanya initially treated slope only as a generalized algebraic ratio, writing $\frac{1}{4} = \frac{b-(-1)}{3-4}$ to solve for b in Figure 2B. When asked what a slope of ¼ meant, she replied, "You go up once and go over four," reflecting an action-based geometric ratio. She also noted, "when the run is 1, the rise is ¼," but could not extend this per-unit idea to find b on the graph, repeating instead, "The rise is 1 and the run is 4."

With prompts connecting slope to displacements—"If x increases by 1, how much does y increase?"—she began using ¼ as a per-unit ratio, including decreases: "x is decreased by 1 and y is decreased by ¼." Using (4, –1) as a reference, she reasoned that (3, b) must be "¼ smaller than –1."

Tanya later used unit-rate reasoning more fluently in other tasks. When $\Delta x = -3$, she stated, "Go down 18," interpreting Δy as (–3)(6) without written calculation. In constructing equations, she often used unit-rate language, "Each time I move left by 1, I need to go down by 1/5." In Figure 4b, she subtracted 12/5 twice from the y-coordinate of (2, 2) to find $b = -14/5$. These episodes show her emerging ability to express accumulated change through unit rate reasoning, flexibly switching between addition and multiplication (cf. Thompson, 1994a).

From unit rate to interiorized ratio: Difficulties with non-integer Δx. Although Tanya demonstrated unit-rate reasoning in earlier tasks, she never directly applied the relationship $\Delta y = m\Delta x$ for non-integer values. Instead, she reconstructed the relationship through explicit equations, suggesting slope was not yet interiorized. For instance, in Figure 4b, she used an additive strategy for $\Delta x = -2$ when locating the y-intercept, but for $\Delta x = 0.1$ she set up 12/5 = Δy/0.1, then solved algebraically: $\Delta y = (12/5)(0.1) = 0.24$.

As approximation tasks grew more complex—shifting from numeric to symbolic slopes and from graphs to purely algebraic contexts—she consistently applied slope to estimate values. Yet

for non-integer Δx, she reverted to writing $m = \frac{\Delta y}{\Delta x}$ and solving for Δy, reflecting a generalized geometric ratio rather than an interiorized ratio. Her reliance on reconstructing proportions suggests she had not yet conceived slope as an interiorized ratio that operates flexibly on any Δx.

Shortened Treatment of Point as a Multiplicative Object

Although students also struggled with conceiving a point as a multiplicative object, this paper focuses primarily on their reasoning about slope as ratio and rate. All three students had difficulties coordinating quantities—specifically, horizontal and vertical displacements—encoded in both rate and point coordinates. While Sean and Tanya showed somewhat greater facility than Zada, all three struggled at times to use a known point and rate to determine a new point in linear equation and approximation tasks. *Due to space limitations, detailed analyses of students' reasoning about point as a multiplicative object are not included here and will be discussed in a separate paper.*

Conclusion and Discussion

This study examined how students coordinated slope in the context of linear equations and linear approximation tasks, with particular attention to how their reasoning reflected different levels of abstraction of ratio and rate. Building on Thompson's (1994a) distinctions between internalized and interiorized ratios, I proposed three analytic categories—generalized ratio, unit rate, and interiorized ratio—as a framework for analyzing students' reasoning. These categories captured important qualitative differences in how students conceived slope, ranging from applying it as a fixed algebraic relationship, to interpreting it as a per-unit change, to treating it as a structural multiplicative relationship applicable to any Δx.

The framework proved useful in distinguishing students' reasoning even when they produced the same correct answer. For instance, Tanya's use of unit rate reasoning allowed her to flexibly handle integer changes in x, yet her reliance on explicit equations for non-integer Δx revealed that she had not fully interiorized slope as an object of thought. Similarly, Sean's progression from algebraic manipulation of slope to its geometric interpretation showed how a generalized ratio could be extended toward more sophisticated reasoning. These distinctions highlight that students' difficulties with tangent lines and linear approximations are not simply procedural gaps in differentiation but reflect deeper issues in how they coordinate quantities through ratio and rate.

By situating students' reasoning within these categories, this study advances prior work on covariational reasoning (e.g., Thompson, 1994a; Johnson, 2015) by offering a finer-grained framework for distinguishing how students engage with slope in algebraic and geometric contexts. The categories of generalized ratio, unit rate, and interiorized ratio clarify not only *where* students encounter difficulties but also *how* those difficulties manifest in relation to symbolic versus graphical reasoning. This contributes to instructional design by highlighting the importance of tasks that explicitly bridge counting strategies, per-unit reasoning, and flexible application of $\Delta y = m\Delta x$. For example, tasks that press students to extend reasoning from integer to non-integer or symbolic Δx may be especially productive in supporting transitions toward interiorized ratio. Future research might investigate how such task sequences influence students' ability to coordinate slope with reference points in linear approximation, thereby deepening their preparation for calculus.

Student Perceptions of Norms Supported by Definitions in Proof-Based Courses

Ibrahim Oyeyinka
Northern Illinois University

Rachel Rupnow
Northern Illinois University

Sameh E. Saad
Northern Illinois University

Kristen Vroom
Michigan State University

Mathematicians' community values and norms play a vital role in shaping approaches to practice, including with respect to definitions. Mathematicians have suggested that in their instruction they portray norms related to the value of clear communication more than those related to freedom in their use of definitions, but limited work has examined what students take from instruction. Here, we examine survey responses from proof-based linear and abstract algebra courses taught by the same instructor. Results include widespread recognition of definitions' role in supporting arguments and facilitating unambiguous communication as well as some support for mathematical doers' agency in creating and using definitions, suggesting it is possible to portray this freedom in instruction.

Keywords: Values, Norms, Definitions, Linear Algebra, Abstract Algebra

Definitions are central to mathematical practice, as they stipulate the objects coordinated in theorems and algorithms. Extensive work has characterized what makes a good definition, including required aspects like being unambiguous and non-contradictory as well as preferences like elegance and minimality (e.g., Harel et al., 2006; Shir & Zaslavsky, 2001; 2002; van Dormolen & Zaslavsky, 2003; Torkildsen et al., 2023), though recent work suggests that the emphasis on minimality may have received more emphasis in the mathematics education literature than mathematicians place upon it (Torkildsen et al., 2025). Work has also considered the pedagogical value of different definitions for different groups, with teachers often valuing clarity and accessibility for their student audience (Leikin & Winicki-Landman, 2000; Torkildsen et al., 2025; Zazkis & Leikin, 2008).

However, comparatively limited work has examined how mathematicians' work with definitions upholds their broader values and norms of practice as a community. Based on interviews with algebraists, Rupnow and Randazzo (2023) found two such values: 'clarity in and for communication' and 'freedom for the use and creation of definitions'. 'Clarity in and for communication' was upheld by norms like *support arguments/get at truth* and *concept names give insight* while the 'freedom for the use and creation of definitions' value was upheld by norms like *mathematicians write definitions purposefully for utility* and *conventions may vary between mathematicians*. Of note, the interviewed algebraists suggested that their research work supported both of these values, but that their teaching gave limited if any support to 'freedom for the use and creation of definitions' and notions of agency in particular, largely because they were unsure how to do so.

Vroom et al. (2024) examined Introduction to Proof instructors' teaching practices for supporting students in revising their own definitions using the lens of Rupnow and Randazzo's (2023) norms. They noted most of the observed teaching practices focused on unambiguous, precise, and minimal definitions, as well as the fact that definitions are stipulated, may be given insightful names, and generally follow certain conventions of the community. Notably, these norms aligned with the 'clarity in and for communication' value. In contrast, only a few

instances aligned with the ideas that people author definitions or contextual conventions supporting the 'freedom for the use and creation of definitions' value. However, because the study focused specifically on the revision of definitions rather than their initial formulation, it is possible that opportunities to support the 'freedom' value arise more naturally in earlier stages of defining. Together, these works suggest that definition values may appear in mathematicians' teaching, and potentially the communication value more consistently. As such, more work is needed to understand how students experience such teaching. Here we address the research question: How do students in a linear or abstract algebra course characterize norms and values of definitions communicated in their course?

Theoretical Perspective

We use the values and supporting norms for mathematical definitions characterized by Rupnow and Randazzo (2023) as our lens. This lens is grounded in Laudan (1984)'s Triadic Network of Justification, which characterizes Axiology (Values), Methodology (Norms), and Factual Claims as mutually dependent in a field of study. Rupnow and Randazzo (2023) adapted Laudan's (1984) framing to the mathematical community's use and creation of definitions. In so doing, they highlighted two values, 'clarity in and for communication' and 'freedom for the use and creation of definitions', along with various supporting norms. Here we especially attend to the norms of practice, which served as codes for the open-response questions and were embedded in the closed-response questions, as described below.

Methods

A survey was administered to the Fall 2024 sections of one author's Linear Algebra (LA) and Abstract Algebra I (AA) courses. 10 students completed and 3 students partially completed the survey in LA (out of 20), and 12 students completed the survey in AA (out of 27). LA and AA were taken by math majors and minors, though in LA most were math minors, whereas in AA, most were math majors. AA required LA as a prerequisite, and five AA survey completers had previously taken the author's section of LA.

Both courses incorporated inquiry-oriented instruction, with linear algebra using the Inquiry-Oriented Linear Algebra tasks focused on span and linear independence (Wawro et al., 2012), linear transformations (Andrews-Larson et al., 2017), and change of basis and eigentheory (Zandieh et al., 2017). These sets of tasks were used to introduce the respective concepts, but more formal treatments and formal definitions of the respective concepts were given on subsequent days in fill-in-the-blank notes during interactive chalk-talk lectures (Artemeva & Fox, 2011). Abstract Algebra tasks focused on motivating and defining a group and group isomorphism (Larsen, 2013). Students were given the opportunity to work with examples of a group to abstract the concept of a group and define it themselves before fill-in-the-blank notes with an interactive chalk-talk lecture formalized what had been discussed in the previous weeks of tasks. Similarly, students worked with Cayley tables to consider examples and non-examples of isomorphisms before defining the concept themselves and subsequently having fill-in-the-blank notes during chalk-talk lectures. As Vroom et al. (2024) note, this inquiry setting opened up the opportunity for meaningful engagement with norms (from the instructor's perspective), particularly *definitions arise from/relate to examples*, *mathematicians make definitions* and *mathematicians write definitions purposefully for utility*.

The survey was available the last two weeks of the semester, and students received extra credit for submitting it. Questions on the survey focused on students' views of definitions and how definitions had been used in the course. Open response questions analyzed here focused on

how mathematical definitions are similar and different from dictionary definitions, the purpose of definitions, ways definitions were used in the course, how their understanding of definitions had changed during the course, and whether the instructor did or could do something more illuminating about definitions. Closed response questions provided simplified versions of the norms from Rupnow and Randazzo (2023) (e.g., 'Definitions allow the use of a single phrase to communicate complex ideas' was provided to ask about the *Definitions as shorthand* norm). Students were given a textbox in which to type a response to each open response question and were asked to drag each stated norm into a "I took these away from the class" or "I did not take these away from the class" box for the closed response question.

We used the existing definition norms from Rupnow and Randazzo (2023) as a starting point for analysis of the open responses but made space to add additional codes if needed, in alignment with codebook thematic analysis (Braun et al., 2019). One non-instructor researcher coded the LA open-ended items independently and another non-instructor researcher coded the AA open-ended items independently. Based on this, three additional norm codes were created: *mathematical definitions are subject to verification/justification*, *mathematical definitions are expressed through symbolic language and notation*, and *mathematical definitions can evolve over time.* We perceived the first two norms to support the 'clarity in and for communication' value, and the third norm to support the 'freedom of choice for the use and creation of definitions' value. Then these two researchers plus the instructor researcher discussed and came to consensus on codes present in each student's response to each question in both courses.

Results

Here we highlight students' responses with respect to the two values separately. Table 1 notes the number of students whose responses received a norm code (Open) or who signified that "I took these away from the class" by dragging the prompted norm into a box (Closed). Throughout we signify norms with italics.

Table 1. Student norm counts by course and question

Value	Norm	LA Open (n=13)	LA Closed (n=13)	AA Open (n=12)	AA Closed (n=12)
Clarity in and for communication	Rigor/precision	4	0*	4	0*
	Clarity/no ambiguity in communication	10	8	10	6
	Axiomatic system/work with definitions	6	10	4	12
	Support arguments/get at truth	11	12	12	12
	Norm of precision perpetuated through teaching	0	0*	4	0*
	Norm of precision irrelevant to laypeople	0	0*	2	0*
	Definitions as shorthand	6	11	2	10
	Concept names give insight	0	8	0	5
	Examples illustrate definitions	2	11	2	10

	Definitions are based on historical motivations	0	2	0	4
	Need more than definitions to understand concepts	4	0*	1	0*
	Definitions scaffolded for undergrads	2	0*	1	0*
	Norms of mathematical communication through formatting choices	1	6	0	7
	Mathematical communication has consistency	2	11	2	9
	Mathematical definitions are subject to verification/justification	0	0*	1	0*
	Mathematical definitions are expressed through symbolic language and notation	4	0*	2	0*
Freedom of choice for the use and creation of definitions	Definitions arise from/relate to examples	0	8	2	9
	Definitions permit inspection of relevant features	0	10	1	8
	Concepts are made through abstraction	0	5**	0	9
	Mathematicians make definitions	1	7	4	8
	Mathematicians write definitions purposefully for utility	7	7	4	7
	Conventions may vary between mathematicians	0	7	0	9
	Norm of agency perpetuated through teaching	1	0*	4	0*
	Mathematical definitions can evolve over time.	0	0*	1	0*

*No question asked on this topic

**Count reduced by one because a student noted they no longer meant to choose this in a later open-ended question

Clarity in and for Communication

A predominant norm for LA and AA students was the role of definitions to *Support arguments/get at truth*. This norm was articulated and selected across both open and closed responses, indicating a strong perception of definitions as foundational for logical reasoning and mathematical communication. Students noted how their instructor clarified this function of definitions, particularly their utility in proofs. One LA student stated, “She showed us how to use definitions to prove theorems.” Another LA student elaborated, remarking, “I feel like I better understand their purpose and am able to utilize them in the context of proofs and problem solving.” Many students emphasized how definitions provide a necessary foundation for constructing valid arguments, arriving at mathematical truths, and developing deeper results. As one AA student described the purpose of mathematical definitions: “To serve as the building blocks for the development of theorems, proofs, and mathematical structures.” This highlights

students' ability to see definitions not as isolated facts, but as interconnected components within a logical framework.

Students also showed awareness of the norm *mathematical communication has consistency*. This norm highlights the mathematical community's expectation for a standard and consistent way of conveying mathematical ideas to promote clarity and understanding. Responses reflecting this norm were noted in open responses but were affirmed more often in the prompted closed responses. One LA student reflected, "I've seen definitions in practice and developed a stronger sense of what they do and don't contain," demonstrating how exposure to definitions helped them notice patterns in how definitions are framed. An AA student echoed this norm, stating, "To establish a consistent rule or mathematical relationship, to describe a proven mathematical principle." Another AA student emphasized its broader significance: "They ensure clarity and consistency which allows us universal understanding and the ability to construct complex mathematical frameworks." These comments underscore that students viewed definitions not merely as isolated facts, but as critical tools for constructing precise, shared meaning.

The norm *Axiomatic system/work with definitions* was highlighted by students in both LA and AA. In open responses, this norm was mentioned by 6 LA students and 4 AA students, while in closed responses, it was selected by 10 LA students and 12 AA students. This pattern suggests that when explicitly prompted, students across both courses largely agreed with this norm as an expectation of practice, though fewer highlighted it unprompted. In the following LA student's response, we interpret species to mean examples of concepts: "This entire course relies on definitions building on each other. Knowing these different definitions allow[s] me to make assumptions as to how certain species will behave and more importantly why." Another LA student recognized the structure of mathematical definitions in describing a word or process: "During this class the way mathematical definitions were presented to me has helped me understand how topics relate to one another better. The use of theorems, lemmas, and corollaries, specifically was very helpful." Similarly, an AA student emphasized the foundational role of definitions: "It is clearer now that definitions play a huge part in the understanding and development of mathematics." This recognition reveals that students understood definitions as foundational, logical building blocks in mathematics.

Beyond their role in supporting arguments and axiomatic systems, students also recognized definitions for their *clarity/ no ambiguity in communication.* This norm was mentioned in both open and closed responses, suggesting that students valued definitions as tools for precise expression. One LA student characterized mathematical definitions as **"**more precise and straightforward**"** than dictionary definitions. They are designed to be **"**unambiguous**"** and **"**to distinguish similar but distinct ideas." Another LA student observed that the wording in mathematical definitions is specific, taking **"**into account every nuance." Nevertheless, this precision can sometimes make definitions long or hard to understand, as one LA student noted, "I personally think mathematical definitions are overly complex when they could be simpler. I understand that they are trying to not be ambiguous, but they are just complex." An AA student also focused on avoiding ambiguity, stating: "The purpose of mathematical definitions is to provide precise and unambiguous descriptions of ideas, forming the foundation for rigorous reasoning and logical deductions. They ensure clarity and consistency which allows us universal understanding and the ability to construct complex mathematical frameworks." These observations reveal that students recognized the communicative function of definitions, understanding their role in ensuring clarity, avoiding ambiguity, and supporting shared understanding across mathematical discourse.

Student responses, particularly in closed questions, revealed an awareness of the role of definitions as shorthand in mathematics. The norm *Definitions as shorthand* was characterized in open responses by 6 LA and 2 AA students and in closed responses by 11 LA and 10 AA students. This indicates that students, particularly when prompted, perceived definitions as concise ways to encapsulate complex ideas. This LA student noted, "Definitions package up entire concepts into concise words; This not only helps with communicating and understanding, it also helps with drawing out theorems." An AA student also reflected that seeing definitions as shorthand was a way "I used to keep the definition in the back of my head and then every now and then used it, but this course has made me study the definition and completely understand it. Made me realize how important the[y] are." Students' responses demonstrate the practical and communicative power of definitions as shorthand in mathematical practice.

Student responses revealed an awareness of certain aspects of the role of examples in mathematical understanding. The norm *Examples illustrate definitions* was not as frequently mentioned in open responses (2 LA students and 2 AA students), but it was more frequently chosen in closed responses (11 LA students and 10 AA students). One LA student noted: "The use of theorems and definitions paired with relevant examples or problems was helpful." Additionally, one Abstract Algebra student illustrated in their open response: "She gave examples of the definitions and how they truly were related to certain problems." Students in both courses indicated that examples help solidify understanding, associate concepts with processes, and demonstrate how definitions operate in practice. This shows that students viewed definitions not only as abstract entities but as tied to concrete examples and intuitive reasoning, though they especially attended to this when prompted.

Freedom of Choice for the Use and Creation of Definitions

Student responses, particularly in closed questions, showed an awareness of the norm *Definitions arise from/relate to examples*, which highlights that mathematical definitions are tied to concrete examples and intuitive reasoning. As one AA student illustrated: "They [definitions] provide a framework for constructing examples that satisfy certain properties or counterexamples that fail to meet specific criteria."

The norm *Mathematicians write definitions purposefully for utility* was consistently mentioned by students, with 7 LA students and 4 AA students in open responses and 7 LA students and 7 AA students in closed responses. Students both spontaneously articulated and recognized with prompting that definitions are not arbitrary but are designed for practical application. For instance, one LA student noted, "I feel like I better understand their [definitions'] purpose in the context of proofs and problem solving." Demonstrating an appreciation for the pragmatic use of definitions in mathematics, one AA student elaborated:

> A mathematical definition defines a mathematical structure or process and how to apply that process / utilize the structure. A definition in the dictionary is more to give meaning to a word. Both give meaning to some abstract object, but a mathematical definition has more nuance than just giving meaning.

Another AA student stated:

> Writing proofs has been extremely beneficial in my understanding of proofs. Before I became more familiar with proofs, I did not think definitions in math had much purpose other than just making rules in math that we have to follow. It is clearer now that definitions play a huge part in the understanding and development of mathematics.

These reflections show students had developed a sophisticated view of definitions not as static rules, but as essential tools in both reasoning and application.

The idea that *Mathematicians make definitions* appeared in open responses from 1 LA student and 4 AA students, and more frequently in the closed responses (7 LA students and 8 AA students), highlighting students' awareness that mathematical definitions do not merely exist but are created by individuals. This LA student expressed, "Mathematical definitions allow us to not only understand the world of math but also create it in a way that is universal," emphasizing mathematicians' active role in constructing tools for the discipline. An AA student further noted:

> My understanding of mathematical definitions is, in general, more developed than it was before because I was exposed to a lot of definitions in this class. I have more appreciation for the process of writing a definition and I know how to read mathematical definitions more accurately.

These reflections point to students' recognition of definitions as thoughtfully constructed tools for shaping and communicating mathematics.

The norm *Conventions may vary between mathematicians* was not spontaneously mentioned in any open responses, but it was selected in closed responses by 7 LA students and 9 AA students. While students did not highlight that mathematical definitions and conventions reflect choices made by mathematicians depending on context or purpose in response to the purpose of definitions, they did agree with this sentiment when prompted more generally.

Discussion

Students in both courses largely highlighted the same norms with fairly similar frequencies. Considering that the same instructor taught both courses and that both courses are proof-based, this perhaps should not be surprising. Across the open and closed responses in both courses, students commonly highlighted *support arguments/get at truth* as a purpose of definitions as well as that definitions support unambiguous rigorous communication (*rigor/precision* and *clarity/no ambiguity in communication*). Students also highlighted *axiomatic system/work with definitions*, *definitions as shorthand,* and *mathematical communication has consistency*, though these arose more in the closed than open responses. This suggests that students agreed with these norms when prompted to consider them but did not immediately highlight them from prompts focused on differences between mathematical and dictionary definitions, the purpose of definitions, or ways definitions were used in the course.

Of note, the norms *mathematicians make definitions* and *mathematicians write definitions purposefully for utility* also arose in the data, suggesting a recognition of mathematicians' (and potentially their own) agency in writing and using definitions. Relatedly, though less commonly, some students did suggest that agency in using and creating definitions was supported through instruction. This contrasts with the algebraists' claims about their teaching practice (Rupnow & Randazzo, 2023) and most of the Introduction to Proof instructors' teaching moves supporting students' definition revisions, though revising definitions comprises a limited portion of instructors' overall work in a course (Vroom et al., 2024). Thus, while supports for the 'freedom for the use and creation of definitions' value may not yet be commonly documented in the literature, it is possible to support this value.

Interpreting Student Code: Prospective Teachers' Scripted Responses to a Scratch© Coding Task

Dov Zazkis
Montclair State University

Ami Mamolo
Ontario Institute of Technology

We explore prospective intermediate and secondary school teachers' strategies for supporting students in coding and troubleshooting errors while working in Scratch ©. Participants were asked to create an imagined dialogue that addressed student-generated "starter" code, which included bugs, in order to explore the probability of different sums of two dice rolls and present these sums as a graph. Our analysis shows that participants attended to different possible student difficulties with the coding, yet few of them attended to the given starter code as an instance of student thinking when suggesting viable resolutions or ways forward. Instead, participants tended to introduce their own approaches and trajectories for how to advance the code. We suggest that while participants demonstrated useful teaching strategies to support student-characters, their attention was focused on advancing any code, rather than building with or on ideas presented by the student-characters.

Keywords: Probability, Prospective teachers, Computer programming, Scripting, Scratch©.

Recognizing and interpreting student errors as a way to advance student learning and understanding is advocated for in research and policy documents (e.g., NCTM, 2000; Son, 2013). A wide variety of learning theories and studies have emphasized the importance of learning trajectories that build with student thinking (e.g., Hershkowitz, et al., 2001; Simon, 2006). However, researchers have found that prospective teachers commonly prefer providing teacher guidance that mirrors their own thinking as opposed to building on students' thinking. Mamolo and Pali (2014) argued that robust mathematical knowledge is linked with prospective teachers' flexibility in adopting a variety of guidance strategies to support and advance students' thinking, even when the approaches are different from those teachers' own preferences or prior experiences as students. In this research, we are interested in how prospective teachers provide guidance that builds on a hypothetical student's thinking in relation to content for which participants had no analogous prior experiences as students - developing mathematical ideas through coding. Specifically, we address the following research question:

What can a scripting task reveal about how prospective teachers work with student ideas while debugging a coding simulation for rolling two dice?

Background Literature

Block-based coding in programming languages such as Scratch © have become increasingly common in teaching mathematics (e.g., Benton et al., 2017; Burke, et al., 2012; Passey, 2016). Francis and Davis (2018; see also Pei et al., 2018) describe coding as a competency that "can complement and co-amplify mathematics learning," emphasizing its "deep roots in and emergent powers for mathematics" (p.14). When used as a tool to address mathematics problems, coding has been described as transformative to learning (Papert, 1980), with benefits including fostering resilience, creativity, and learner-driven activity. Research has also pointed to benefits such as: self-motivation; experimentation; development of mathematical intuitions and approaches; critical reflection; and working with abstraction and different representations (e.g., Bailey & Borwein, 2011; Henderson, Cortina, & Wing, 2007; Howson & Kahane, 1986; King et al., 2001; Weintrop et al., 2016).

Notwithstanding the positive potential of teaching mathematics through coding, Resnick and Rusk (2020) noted a concern about teachers treating coding with an instrumental instructional approach – such as memorizing definitions, or copying lines of code – instead of fostering student reasoning, experimentation, and active engagement. They warn that the positive potential will be lost if coding is reduced to a memorization exercise. In the jurisdiction where this research took place, coding is newly embedded within the K-12 mathematics curriculum, and teacher education programs have sought ways to support prospective teachers in learning both related content and pedagogy (e.g., Gadandis, et al., 2017). Yet, there is limited research on how to best support prospective teachers in adopting this new-for-them approach (e.g., Gleasman & Kim, 2018, 2020; Mamolo, et al., 2022). Mamolo et al. (2022) suggest that "before coding can be thought of or used as a tool through which to develop and promote mathematics learning, there is a need to establish a foundation of coding practices, content, and confidence" (p.975). They highlight practices related to experimenting and iterating, remixing and reusing, testing and debugging, and stepwise refinement, amongst others.

The need for research in coding education for teachers, along with the concern raised by Resnick and Rusk (2020), compelled us to take a closer look at how prospective teachers attend to student thinking when developing teaching competencies and content knowledge related to coding. We chose the mathematical context of probability since this is a topic for which coding can serve as a useful tool (e.g., Franklin et al., 2015) and is a topic in which students teachers struggle (e.g., Chernoff & Russell, 2012; Shaughnessy, 1977; Stohl, 2005).

Theoretical Underpinning

A theoretical position that supports our research can be found in the work of Carpenter, Fennema, and colleagues, who advocate for cognitively guided instruction that builds on the knowledge of students (e.g., Carpenter & Fennema, 1992; Carpenter, Fennema, & Franke, 1996; Carpenter et al., 1989). In this perspective, teaching is conceptualized as a student-centered activity in which students' ideas, intuitions, and experiences are built upon in the pursuit of new learning. The premise is that by engaging with student thinking, teachers can uncover and expand students' mathematical understanding beyond procedural or rote learning. Researchers working from this perspective primarily research teacher training that focuses on teachers building on students' thinking. We instead use cognitively guided instruction as an impetus for asking, "Is this prospective teacher working to build on student thinking, and if so, how?" This parallels our research question.

Methods and Task

A total of 24 prospective intermediate and secondary teachers participated in this research by developing scripts of imagined dialogues as part of their regular classroom assignments for a methods course in coding education. Scripting or role-playing tasks in which participants imagine an exchange between a teacher-character and student-characters have been used in prior research to explore and develop mathematical knowledge (e.g., Bergman et al., 2023; Kercher et al., 2023; Zazkis & Zazkis, 2014) and pedagogical awareness (e.g., Campbell & Baldinger, 2022; Lajoie & Maheux, 2013; Mamolo, 2021, 2017). In this study, we extend the applicability of these tasks to explore how prospective teachers engage with student thinking in a coding context. Our data includes the scripts of fourteen prospective teachers who elected to work in groups of 2-3 and handed in joint work (referred to as Groups 1-7), and 10 participants who composed their scripts individually (referred to by pseudonyms). The scripting task had two core components: 1) an initial student-generated code, which was to be the starting point for the script (Figure 1), and

2) a goal of building on the provided background to debug the existing code and develop a future plan (Figure 2).

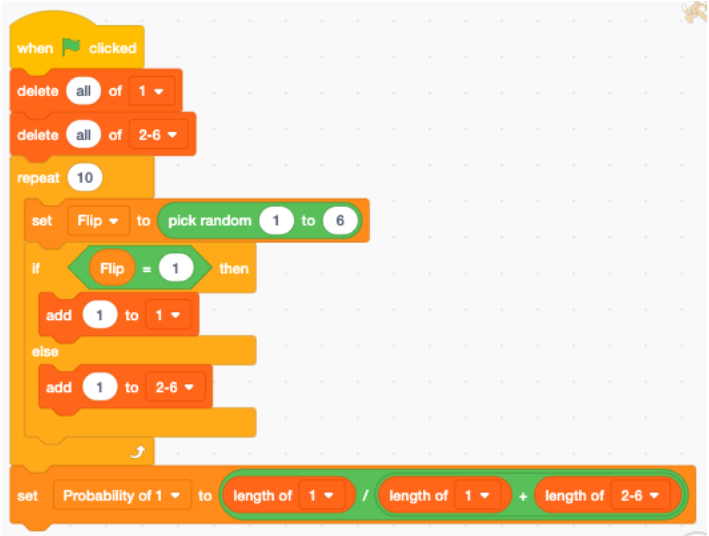

Figure 1. Initial student scratch code for scripting task

Background: A few students are creating a dice simulation for a probability assignment. They want to repeatedly roll two dice, record the sum and then graph the results. They have made a great start with their code: https://scratch.mit.edu/projects/324585345/editor
Bugs: The group notices the program is not recording the sum (it is only recording the most recent sum). They also realize that the program is repeating 10 times- they want the user to choose how many times to roll the die.
Future Plans for Project: The group wants to graph their results but does not know how to do this.

Figure 2. Two Dice Scripting Assignment

In analyzing the data, the authors, first individually and then jointly, carefully documented what occurred in each script. This included the trajectory the code followed from the initial code in Figure 1 to the finalized code that the student-characters in the script created. We also documented which benchmarks were accomplished by the time the script concluded (e.g., was the user prompted for a number of rolls? Did the final code have two dice? Did the code graph the results, and, if so, how?). Finally, we documented which difficulties the student-characters encountered and how these were overcome.

To better acquaint the reader with the scripting task and familiarize the reader with coding in Scratch, it is worthwhile to parse the initial code in Figure 1. The code begins by deleting the content of previously saved lists named "1" and "2-6." Then there is a loop that repeats 10 times. With each repetition, a variable named "flip" is assigned a random integer value between 1 and 6. Then if "flip" is 1, a 1 is added to the list named "1", otherwise, a 1 is added to the list named "2-6." The result is two lists of 1's with a total length of 10. The length of the first list represents the number of times a 1 occurred, while the length of the second list represents the number of times a value other than 1 was rolled.

There are several things to note about the code in Figure 1, given that the scripting task asks that it be interpreted as initial student work. First, only two outcomes are documented within the code, whereas the problem scenario encompasses 11 possibilities, as rolling two dice can yield any integer sum between 2 and 12, inclusive. Next, there is only one variable assigned to a random value. We would expect two variables since there are two dice in the problem scenario. Finally, one generally flips a coin and rolls a die. So, it is unusual to name the variable "flip", as opposed to "roll." A reasonable conclusion to draw is that the code in Figure 1 started as code for

flipping one coin. This explains all three of the above observations (number of variables, number of possibilities documented, and the variable name). So, a natural interpretation of this initial student code is that students started with code for documenting coin flips, began remixing it to account for the differences between coins and dice, and got stuck.

Results and Analysis

Only 4 of the 18 completed scripts included an assessment of the motivation behind the initial student code. All four of those paralleled the "started out as code for a coin flip" explanation discussed above. The other 14 scripts did not acknowledge the origins of the code. Those scripts proceeded by either pointing out the initial code's flaws relative to the task to make progress (8) or replacing the initial code with entirely different code to use as a starting point (6). Below, we exemplify each of these three observed approaches.

Motivating the initial scratch code

As mentioned, only 4 of the 18 scripts included motivation for why students might have generated the initial Scratch© code in the scripting task, as illustrated in Group 5's script:

> *Teacher*: It looks like you have some elements in your program that you don't use. Did you make this code or is it remixed from someone else?
> *Student1*: We used a code that showed the probability for flipping a coin. I made some modifications so that it would work for dice, but we can't get it to repeat 10 times.
> *Teacher*: Can you explain to me what the code is doing?
> *Student1*: Well, it starts with deleting all the previous results, then it flips the die by picking a random number from 1 to 6. Then, if the roll is 1, it adds to column 1, and if it's something else, it adds to column 2.
> *Teacher*: Before you go further with the code, you need to think about the problem you are trying to solve. If you want to remix this code, you need to think about the differences between calculating the probability of a coin flip and the sum of a pair of dice.

The student-character's motivations for the initial code in Figure 1 are evident when he states that the code started as "code that showed the probability for flipping a coin," and that he "made some modifications" so it would work for dice. This simultaneously provides a plausible explanation for why students working on the sum dice task might have generated the code in Figure 1, and provides the teacher-character with a starting point for guiding their progress. In Group 5's script, the teacher-character directs the student-characters to think about the differences between the single coin flip scenario the initial code addressed and the rolling two dice scenario they are working on. Consistent with the tenets of cognitively guided instruction, the teacher-character is building on the imagined students' work, and helping to direct them to the kinds of questions one might ask when trying to self-direct their coding progress.

Notably, a prospective teacher recognizing the code in Figure 1 started as code for flipping a coin does not necessarily mean that their approach is consistent with cognitively guided instruction. For instance, consider Felicity's script below:

> *Teacher:* Ok that sounds like a great idea. Let's see how we can work through the problems you are having. What is the code you currently have doing?
> *Student1:* Well we kind of used a code we found for the flip of a coin and tried to change it around and that didn't seem to work.

Student3: Right now it seems like the dice is rolled 10 times and if the roll is a 1 it gets added to the list of ones and if the roll is between 2 and 6 a 1 gets added to the 2-6 list.
Student1: But we don't want to know if the roll was a 1 or not we want to know exactly what the roll was and do that for 2 dice.
Student2: Does that mean we need to start over and try something else?
Student3: I think we should. [S2 and S1 nod in agreement.]

In the above script, the scriptwriter, Felicity, notes that the initial given code started as code for flipping a coin, when Student 1 indicates that "we kind of used code we found for flipping a coin." So, she has a viable explanation for why the code in Figure 1 might have reasonably emerged from students' work on the two dice task. However, instead of building on this code, Felicity uses a different code that she, as the scriptwriter, generated as a starting point for guiding the student-characters' progress. Although this idea is presented as coming from the student-characters when Student 2 says, "Does that mean we have to start over and try something else?", it is important to keep in mind that this is the work of a scriptwriter, not a student. By presenting the abandonment of the initial code as a student-character's decision, Felicity is, in a sense, avoiding the teacher-character being responsible for not building on the initial code. Felicity is instead using her own code as a starting point. As we discuss later, this is a common move in scripts that do not build on the given code.

Leveraging the flaws in the initial scratch code

A majority of scripts did not provide an explanation for the origins of the initial code in Figure 1. However, 8 of these scripts found other ways to leverage the initial code without such an explanation. This was primarily achieved by analyzing the initial code's functionality in relation to the rolling of two dice task. For instance, Group 6's script included this excerpt:

Teacher: What is happening in this small part of your code?
Student1: That's where we roll the dice.
Teacher: How many dice are you rolling?
Student1: Well, we want to roll 2 dice…
Teacher: Okay, so when you roll 1 die, what are the possible outcomes?
Student2: We can get 1, 2, 3, 4, 5 or 6.
Teacher: Exactly, so in the code here how many dice are you rolling?
Student1: Oh, we're only rolling once! Okay, so how do we roll twice?
Teacher: You've already rolled once, so do that again and combine them however you want. You could also pick a single random number that represents a roll of two dice, but I'd suggest just getting the sum.

Notice that in this excerpt, the teacher-character uses the initial student code as a starting point for guiding student-characters toward code that successfully addresses the rolling two dice task. This is achieved by highlighting the differences between the two dice task and what the initial code does. The above excerpt was used to motivate adding a second variable to record dice rolls, as well as replacing the two lists "1" and "2-6" with eleven lists named 2-12, each for recording one of the eleven possible outcomes of rolling two dice. This, in our view, is similar to Group 5's script, which focused on the differences between flipping a coin and rolling two dice to motivate the same changes to the initial code. Notable in Group 6's work is that the variables

used to record dice rolls are named “flip1” and “flip2”. This suggests that the scriptwriters overlooked the potential inappropriateness of those variable names in relation to the dice task.

Group 6 and Felicity’s scripts present an interesting contrast with respect to how the scriptwriters versus how the teacher-characters appeared to work with student ideas. While Felicity’s teacher-character lets the student-characters take the lead on deciding to shift away from the initial code, as a scriptwriter, Felicity does not attend to building on the student ideas that are represented in the initial code (e.g., the thinking which may have led to the code in the first place). In contrast, Group 6’s teacher-character offers direct instruction in response to a student’s question of “how do we”, suggestive of a model of teacher-centered instruction. Yet, we found Group 6 was attentive to the student ideas represented in the initial code. We suggest that Group 6’s consideration of the thinking that could have resulted in the initial bugs informed their approach in directing the students toward advancing their code, which is consistent with cognitively guided instruction. This contrast helps highlight the tension between how a scriptwriter represents a teacher-student interaction and that scriptwriter's actual attention to the presented student’s thinking.

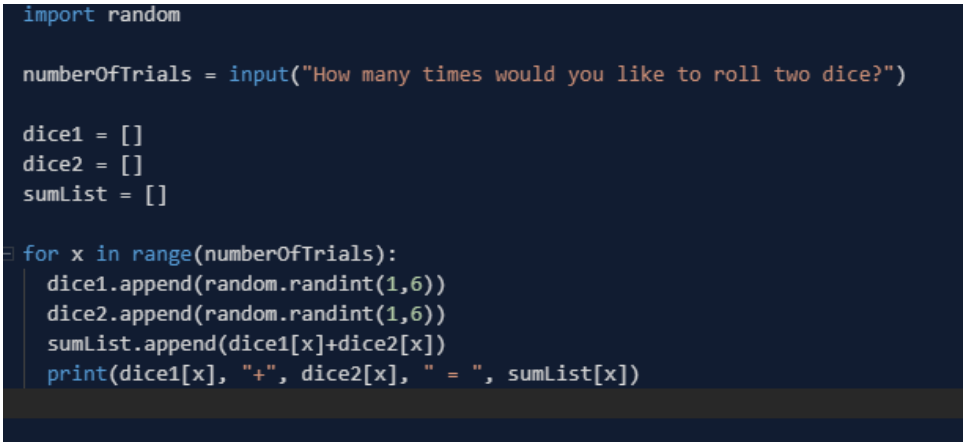
Replacing instead of building on the initial code

Some prospective teachers in our study avoided building on the initial code in Figure 1 entirely. This was commonly done by replacing the code in Figure 1 with scriptwriters own code and using that new code as a starting point for addressing the rolling two dice task. As alluded to in relation to Felicity’s script above, we view this as the scriptwriters avoiding engaging in the thinking and motivation behind the initial code in favor of interjecting their own thinking. Below is an excerpt from Sadiya, which does this in an exaggerated way:

> *Teacher:* Yeah, this code has elements that are necessary for this type of project but it feels like you may have not thought all the way through the problem before starting to code. Good job though on starting early! I like the initiative.
> *Student1:* May we use Python instead of Scratch for this assignment? I feel like for this assignment it would be easier, I remember a lot of how to use it from grade 11 functions and I really like making graphs on it.
> *Teacher:* Sure you can use it. However, Python is not as friendly as Scratch and you might have to google questions if I am not available as well as be prepared to debug things.
> *Student1:* Okay yeah I am prepared for that.
> *Teacher:* Are you okay with Student1 wanting to use Python instead?
> *Student2:* Yes, we already talked about it. I can use either language but I think Student1 might be right that Python could be more straightforward for this project.

In the above, the initial code in Figure 1 is abandoned in favor of a different starting code written in an entirely different programming language, Python. We interpret the teacher-character’s utterance, “it feels like you may have not thought all the way through the problem before starting to code,” as a way to avoid addressing student ideas. It may be that Sadiya was either unable to, or uninterested in, making sense of why a student might have generated the particular code in Figure 1. The Python code Sadiya introduced to side-step the initial code can be found below in Figure 3. As can be seen below, this code already receives user input for how many pairs of dice are to be rolled and records the sum of those pairs of dice rolls in a list called “sumList.” So, all of the “bugs” outlined in Figure 2 have already been addressed by the time the script begins in earnest. The remainder of Sadiya's script is focused on adding features and

graphical representations to the Python code (the "future directions" in Figure 2). We interpret this as Sadiya avoiding building on student thinking entirely. Instead, Sadiya and other similar scriptwriters completed the task themselves without leveraging the initial code or the thought process behind it at all. Then they represented their own personal coding journey in the form of a dialogue. This, in our view, is scriptwriter behavior inconsistent with the cognitively guided instruction perspective which underpins this paper.



```
import random

numberOfTrials = input("How many times would you like to roll two dice?")

dice1 = []
dice2 = []
sumList = []

for x in range(numberOfTrials):
    dice1.append(random.randint(1,6))
    dice2.append(random.randint(1,6))
    sumList.append(dice1[x]+dice2[x])
    print(dice1[x], "+", dice2[x], " = ", sumList[x])
```

Figure 3. Sadiya's Python code

Discussion and Future Directions

This paper provides an illustration of how scriptwriting can be used as a tool for researching prospective teachers' engagement with student thinking. We demonstrated that the scriptwriters engaged in leveraging student thinking did so by directing student-characters to the difference between where they are and their goal. This was done by either discussing the differences between a coin flip and rolling dice, as was seen in Group 5's script, or the differences between the initial code and the code the sum of dice tasks warranted, as was seen in Group 6's script. The prospective teachers who avoided engaging in this student thinking commonly did so by replacing the initial code in the assignment with scriptwriters' own code. This was seen in Sadiya and Felicity's scripts. Commonly, this decision was attributed to student-characters, to maintain the facade that student thinking was being leveraged.

We believe an additional contribution this paper makes is in helping illustrate the utility of parsing code when teaching. Increasingly, teachers are expected to integrate digital technologies and coding into their mathematics teaching. Yet most of these teachers have little if any experience coding and have not experienced coding in their own K-12 education. Tasks that engage teachers in parsing the thinking behind student mathematics have a long history in mathematics education. We suggest that coding tasks, with a similar flavor, which task teachers with parsing, not just what code does, but also the student thinking that might have generated it and how that thinking can be built upon, need to be further researched and studied in relation to teacher education and professional development. The scripting task we discussed here is one such task, and there are myriad others that can include or not include scripting, depending on the specific goals of teacher educators.

Teaching Practices Supporting Students' Awareness of Definition-Related Mathematical Norms

Rachel Rupnow
Northern Illinois University

Sameh E. Saad
Northern Illinois University

Ibrahim Oyeyinka
Northern Illinois University

Kristen Vroom
Michigan State University

The mathematics community has a variety of standard norms of practice by which it operates, which are guided by collective values, including in the context of definitions. However, these norms and values are not always shared with students in instruction. Here we examine teaching practices that linear and abstract algebra students perceived as influencing their understanding of norms around mathematical definitions. Teaching practices in linear algebra tended to align more with instructor-centered actions whereas teaching practices in abstract algebra tended to align more with student-centered activities. Implications include the impact of homework and classroom activities on students' perceptions, as well as the long-term use of activities seeming to be more salient in students' perceptions of influential activities.

Keywords: Teaching Practices, Norms, Definitions, Linear Algebra, Abstract Algebra

Mathematical definitions play a central role in both the discipline of mathematics and the teaching of it. They serve as essential tools for naming collections of objects or phenomena, communicating mathematical ideas, and supporting logical derivation (Edwards & Ward, 2008; Ouvrier-Buffet, 2006; Torkildsen et al., 2023). Within the mathematics community of practice (Lave & Wenger, 1991), there are well-established norms for definitions. Broadly, norms are shared expectations about how definitions should function and how they should be crafted. For instance, definitions are expected to clearly identify a property that characterizes a class of mathematical objects, with space for individual agency in how that property is framed, and to be minimal, non-contradictory, unambiguous, and elegant (Edwards & Ward, 2008; Ouvrier-Buffet, 2006; Rupnow & Randazzo, 2023; Van Dormolen & Zaslavsky, 2003; Vinner, 1991).

Understanding definition norms can offer insight into their foundational role in the discipline. However, teaching definitions can be especially challenging since norms in mathematics (generally and specifically to definitions) are often taken-as-if-shared within the community (Yackel & Cobb, 1996; Yackel et al., 2000). That is, they function as tacit expectations that typically go unspoken (Herbst et al., 2011) and thus can remain invisible to students. This could explain findings that identify differences in mathematicians' and students' understandings of the nature of definitions (Edwards & Ward, 2004; Fernández-León et al., 2021; Martín-Molina et al., 2020).

Few studies have directly investigated instructors' teaching of definition norms (Rupnow & Randazzo, 2023; Vroom & Ellis, 2024; Vroom et al., 2024). Rupnow and Randazzo (2023) found that instructors attempt to convey norms aligned with clear communication such as expecting students to use rigorous and precise definitions. Vroom and colleagues (Vroom & Ellis, 2024; Vroom et al., 2024) analyzed classroom video to identify instructional practices aimed at making these norms visible to students as they engaged in revising definitions, for instance, suggesting a particular revision with implicit or explicit reasons related to clear communication. Still, little is known about how students experience and make sense of these efforts. Understanding the student perspective is critical for improving students' opportunities to

engage meaningfully with mathematical definitions' norms. Here we address the research questions: (1) What teaching practices did students highlight as impactful to their understanding of definitions in a linear algebra course?, and (2) What teaching practices did students highlight as impactful to their understanding of definitions in an abstract algebra course?

Theoretical Perspective

We adopt Nachlieli and Elbaum-Cohen's (2021) definition of a *teaching practice* as our lens. They describe a teaching practice as comprised of a task and a procedure; the task is an instructor's educational goal while the procedure is an action or actions taken to accomplish that goal. Here, since we are examining students' perceptions of how understandings of norms related to definitions were supported, we infer the instructor's task from each question, which had a specific norm supporting a definition value of the mathematical community embedded in it. We view procedures as supportable by specified instructor-focused actions (e.g., instructor presenting definitions in a certain way) or specified student-focused actions (e.g., students engaging in a certain type of activity in the course at the behest of the instructor). We additionally highlight students' broad claims about the course as a whole or instruction around particular concepts that they viewed as supporting an instructor's task, but that do not fit the grain size of a procedure.

We drew on Rupnow and Randazzo's (2023) work to identify and articulate norms for definitions. In particular, the following norms increase the likelihood of clear communication with definitions: *mathematical definitions are unambiguous*, *definitions are an important part of an axiomatic system*, *definitions are used to support mathematical arguments*, *definitions allow the use of a single phrase to communicate complex ideas*, *names of concepts give insight into what the concept means*, *examples illustrate definitions*, *definitions are based on historical motivations*, *standard formatting choices in mathematics communicate information about definitions*, and *mathematical communication has consistency*. Additionally, the following norms increase the likelihood of freedom of choice in defining: *examples motivate the creation of definitions*, *the relevant features of a concept motivate the creation of definitions*, *abstraction motivates the creation of definitions*, *people make definitions*, *people write definitions purposefully for ease of use*, and *definition conventions vary between mathematicians*.

Methods

A survey was administered to the Fall 2024 sections of one author's Linear Algebra (LA) and Abstract Algebra I (AA) courses. 10 students completed and 3 students partially completed the survey in LA (out of 20), and 12 students completed the survey in AA (out of 27). LA served as the Introduction to Proof, was taught with a mixture of the Inquiry-Oriented (IO) Linear Algebra activities (Andrews-Larson et al., 2017; Wawro et al., 2012; Zandieh et al., 2017) and interactive lectures, and was taken by math majors and minors though most were math minors. AA had LA as a prerequisite, was taught with a mixture of the IO Abstract Algebra activities (Larsen, 2013) and interactive lectures, and was taken by math majors and minors though most were math majors. Five AA survey completers had previously taken the author's section of LA. Lectures in both courses were organized similarly, with LaTeX fill-in-the-blank notes posted before class and filled during class through interactive lectures where the instructor would lead students through the material, with times for students to ask questions and address examples themselves, in line with a chalk-talk lecture (Artemeva & Fox, 2011). IO lessons in LA focused on introducing concepts like span through concrete examples in which students would work in groups. However, students were not expected to write definitions themselves in those activities.

In contrast, lessons in AA introduced various groups in collaborative activities to scaffold students writing their own definition for group and later for group isomorphism.

The survey was available the last two weeks of the semester, and students received extra credit for submitting it. Questions on the survey focused on students' views of definitions and how definitions had been used in the course. The questions had definition norms supporting values of the mathematical community embedded in them, and the norms were ideas the instructor hoped to inculcate in students. In one question, students were asked to drag each stated norm into a "I took these away from the class" or "I did not take these away from the class" box. Norms that were dragged into the "I took these away from the class box" received a follow-up question asking, "What about the course gave you insight into [that norm]?" Students were given a textbox to type answers to these follow-up questions, and we focus on students' responses to the follow-up questions here.

We used Nachlieli and Elbaum-Cohen's definition of a teaching practice to guide analysis. Specifically, we viewed the definition norm from Rupnow & Randazzo (2023) that was embedded in the question as the instructor's task, since the instructor, as an author, did intend to share the norm in the question and students claimed that was an idea communicated in the course. We created procedure codes by having two non-instructor authors independently open code with the definition of a "procedure" in mind. Then these two authors and the instructor author met to consolidate a list of procedure codes. Next, one non-instructor author coded the LA and one non-instructor author coded the AA responses independently. Finally, the same three authors met to discuss and come to consensus on the procedure codes present in each student's response to the provided open-response questions. This process aligns with codebook thematic analysis (Braun et al., 2019), in that researchers had some idea of the types of procedures that might appear in the data but used the data to guide the creation of procedure codes.

Results

We present results by course, first Linear Algebra (LA) student responses, then Abstract Algebra (AA) responses. The bold heading indicates the procedure whereas italics indicate a task (norm goal, referred to as norms below) supported by the procedure.

Table 1. Procedural Codes Highlighted by Participants in Each Course.

Category	Procedural Code	LA Frequency	AA Frequency
Instructor-Focused Teaching Practice	Instructor presents clear and precise articulation of definitions.	6	3
	Instructor clarifies the function of definitions (e.g., utility for proving).	9	4
	Instructor presents motivating example(s) before definition.	2	4
	Instructor presents examples after the definition to illustrate.	5	4
	Instructor verifies examples fit the definition	3	2
	Instructor abstracts properties from the object to define the object.	2	3
	Instructor formats the notes consistently.	5	5
	Instructor emphasizes the importance of notation.	1	2
Student-Focused	Students verify examples fit the definition.	5	2
	Students write definitions (themselves).	1	4

Teaching Practice	Students practice after learning a new definition.	5	6
	Students explore before defining a concept (themselves).	0	8
	Students work individually on proofs for assigned work (tests/quizzes/homework).	7	10
	Students work collaboratively on activities in class.	1	6
	Students discuss readings or proofs for discussion boards.	1	5
	Students compare definitions.	1	2
	Students learn about mathematicians or mathematics history.	2	10
	Students are exposed to different notations outside class.	2	1
Salient Non-Procedure	Particular concepts support greater understanding.	5	9
	The course as a whole supports greater understanding.	9	9

Linear Algebra

Students identified a wide range of instructor and student-centered practices that contributed to their understanding of mathematical definitions, especially those involving the instructor's presentation of definitions, characterization of the utility of definitions, and formatting of notes.

Instructor presents clear and precise articulation of definitions. This procedure supported students' grasp of the *mathematical definitions are unambiguous* norm. This procedure highlights the instructor's direct presentation and elaboration of definitions, which included stating definitions and using them to prove theorems. Students emphasized that the definitions provided were clear. For example, one student noted, "Definitions that I was given were very clear and precise and left little to no room for misunderstanding/miscommunication." Another student observed, "The way definitions and theorems were written in our notes covered all bases, thus left no room for interpretation which is in an important part of any definition, they are supposed to provide clarity." This emphasis on clear and unambiguous presentation helped students understand definitions as foundational elements for logical reasoning, illuminating how "precise definitions act as the building blocks when proving a theorem." Students valued this precision because it "prevents misinterpretation" and allows for "clear results" and the ability to "distinguish similar but distinct ideas".

Instructor clarifies the function of definitions (e.g., utility for proving). This procedure especially supported the norms *definitions are used to support mathematical arguments* and *definitions are an important part of an axiomatic system*. Students cited instances where the instructor explicitly demonstrated how to use definitions in proofs. One student stated, "She showed us how to use definitions to prove theorems". Another student elaborated more, remarking, "I feel like I better understand their [definitions'] purpose and am able to utilize them in the context of proofs and problem solving." Students noted that definitions were purposeful tools that are used "to reach the end result of the theorem" and "in solidifying the validity of our proof and making it more accessible to people who might be unfamiliar with what we are trying to prove." The consistent explanation of how concepts build upon each other using definitions further deepened this appreciation for utility. This pedagogical choice enabled students to see definitions as tools for logical problem-solving, reinforcing the norm of clarity in mathematical communication and their practical utility.

Instructor formats the notes consistently. This procedure especially reinforced the norms *standard formatting choices in mathematics communicate information about definitions* and *mathematical communication has consistency*. One student noted, "Formatting choices, such as

uppercase letters for matrices communicate information about definitions, making it easier to identify and interpret mathematical objects." The consistent use of symbols and notation, such as "the different notations used, like the vector addition and scalar multiplication symbols, uppercase letters for matrices" aided understanding. Furthermore, students felt that the notes were structured; according to one of the students, "The types of theorems, many with corollaries and lemmas stayed consistent throughout the course and those ideas stay consistent throughout other math textbooks, too". This consistent presentation style, mirroring textbook conventions, illuminated that standardized formatting contributes to mathematical communication.

Students work individually on proofs for assigned work. This procedure directly fostered the norm that *definitions are used to support mathematical arguments.* Students consistently utilized definitions as the foundation for their proofs. As one student put it, "All the proofs I've had to do that have been based on definitions." Another student highlighted this foundational role, stating, "When I wrote proofs I used definitions all the time to support my arguments in each and every case." The consistent application of definitions in these assignments helped students solidify a relationship between definitions and proofs.

Particular concepts support greater understanding. While we did not code this as a procedure, we noted multiple student responses that focused on learning specific concepts related to the norms *names of concepts give insight into what the concept means* and *definitions allow the use of a single phrase to communicate complex ideas*. With respect to the former, one student wrote, "The names of specific concepts that we've learned in this course give insight into what the concept means by hinting at its algebraic or geometric interpretation." Numerous students noted different concepts for which shorthand was salient. One student noted, "Definitions like span, basis, and linear transformation allow the use of single phrases communicate complex ideas and relationships within vector spaces." Others noted examples such as the "invertible matrix theorem list" and the concepts of "one-to-one or onto" functions where a single term encapsulates extensive mathematical meaning. Another student said, "Relevant features of concepts like vector spaces or linear transformations, such as the need for operations to satisfy certain properties (e.g., closure, associativity), motivate the creation of definitions that capture these important characteristics for future reference."

The course as a whole supports greater understanding. Again, while not a procedure, students frequently expressed that the overall structure and approach of the course supported their understanding of definitions as part of a coherent mathematical system. This broad insight was reflected in responses to questions focused on norms of *people write definitions purposefully for ease of use* and *definitions are an important part of an axiomatic system*. This student recognized the utility for their work: "definition[s] are often used to categorize or distinguish concepts, and have been useful in conveying information in a more condensed manner." Another student noted**:** "definitions are critical to understand proofs." This interconnectedness was a key takeaway, as one student observed, "I have yet to see any definitions that contradict each other, only those that build on each other." The consistent use of definitions throughout the course facilitated communication, as students learned to "define terms so that we can talk about more complicated concepts easily." The course fostered the notion that mathematical definitions are "critical to understand proofs" and essential for consistent communication among mathematicians. This holistic view reflects the instructor's goal in conveying definitions not just as isolated facts, but as integral components of mathematical practice.

Abstract Algebra

Students identified a wide range of student and instructor-centered practices, especially those involving active engagement, conceptual exploration, and historical or contextual enrichment.

Students work individually on proofs for assigned work (tests/quizzes/homework). Students referenced proof-based assignments especially with regards to the *definitions are used to support mathematical arguments* norm. Students mentioned working individually on tasks such as tests, quizzes, and homework, where they were required to use definitions as the foundation for formal reasoning. These assignments provided repeated opportunities to see how definitions function as essential tools for constructing logical arguments and developing mathematical structure. As one student noted: "I started every proof by recalling the relevant definitions. This demonstrated that definitions are the foundation upon which all mathematical arguments are built."

Students explore before defining a concept (themselves). Closely tied to this was the theme of student exploration before creating a formal definition, where students engaged with mathematical ideas and patterns before seeing the official class definition. This practice was mentioned in response to several questions, including those focused on the norms *mathematical definitions are unambiguous*, *definitions are an important part of an axiomatic system*, *people write definitions purposefully for ease of use,* and *definition conventions vary between mathematicians*. This practice was valued for helping students build an understanding of a concept before encountering and crafting formal language to describe it. One student remarked: "A lot of the definitions we made in class were motivated by features of the defined object. Usually, these features were discovered first. But ultimately the definition is shaped around these features."

Students work collaboratively on activities in class. Collaborative classroom work was mentioned by students in relation to multiple norms, including *examples motivate the creation of definitions* and *relevant features of a concept motivate the creation of definitions*, highlighting how group activities helped deepen understanding of definitions through peer explanation and comparison. In these settings, students described learning to refine and revise their definitions as they worked through problems with others. According to one student, "Examples can help people understand what is going on and they make a broader explanation like definitions, like we did in activities."

Students learn about mathematicians or mathematics history. Historical and contextual information also played a role in shaping students' understanding of definitions. In connection to several norms, especially *definitions are based on historical motivations*, students referred to learning about the development of mathematical ideas or the mathematicians associated with them. As one student explained: "Historical context was used to explain how definitions evolved to address specific mathematical problems." Another noted, "Looking at the history of some concepts showed to me that there was motivation at one point to develop these definitions." This historical framing showed mathematicians engaged in creating definitions or attending to particular definitions in response to their needs at the time.

Instructor formats the notes consistently. In addition to student-driven practices, several instructor-centered strategies were mentioned by students. The most common of these was the instructor's consistent note formatting, which was highlighted in connection to most of the norms, especially the norms *standard formatting choices in mathematics communicate information about definitions* and *mathematical communication has consistency*. Students reported consistent notes helped them follow the structure of new concepts and clearly identify where definitions were introduced and how they were used. As one student described:

"Definitions were often presented as lists or bullet points, breaking down the properties into manageable components. This modular presentation made complex definitions easier to understand and apply." This suggests that formatting conventions to aid reading were perceived as useful for students.

Instructor presents motivating example(s) before definition. Students also emphasized the value of motivating examples provided before a formal definition, which helped generate interest and guide intuition prior to engaging with more formal language. Students related this procedure to norms of *examples illustrate definitions*, *examples motivate the creation of definitions*, and *abstraction motivates the creation of definitions*. One student noted: "After noticing a pattern in examples, we would try to generalize what we were seeing."

Discussion

Students highlighted a variety of course activities that supported their developing understanding of mathematical norms and values supported by work with definitions. While both instructor- and student-centered activities were highlighted by students in each course, instructor-centered activities were referenced more often by linear algebra students and student-centered activities were referenced more often by abstract algebra students. This result aligns with expectations from the course setup. While students in both courses engaged in inquiry-oriented (IO) activities and attended interactive lectures with organized notes, the IO activities in LA focused on creating intellectual need for learning new concepts and a concrete context to anchor students' developing understandings of span, linear independence, and change of basis (Andrews-Larson et al., 2017; Wawro et al., 2012; Zandieh et al., 2017). However, students were not asked to write new definitions themselves; these were introduced by the instructor in response to the activities. In contrast, students in AA were introduced to examples of groups through concrete activities but then scaffolded through writing a definition for group and group isomorphism themselves (Larsen, 2013). Thus, students in both LA and AA were exposed to ways their instructor formatted definitions and presented definitions in relation to examples, but only AA students were given opportunities to think about definition affordances and conventions as they wrote definitions themselves. This highlights that implementing IO materials is not a monolith with respect to expected student engagement in mathematical practices. Given that many LA courses are not proof-based and serve more non-math than math majors, we recognize that it is potentially beneficial for these materials to center different disciplinary practices.

Moreover, LA also serves as the Introduction to Proof course, meaning the instructor deconstructed how to write proofs and how they relate to definitions often, especially near the beginning of the semester, whereas this was less of a priority in AA, where students were expected to be familiar with this relationship between definitions and proofs already. This aligns with students in LA especially highlighting the instructor's role in presenting definitions and clarifying their function relative to AA. Nevertheless, students in both courses highlighted long-term activities. This included the utility of the homework, especially proof-based problems, in developing their understanding of definitions and viewing the course as a whole as supporting their understanding of definitions.

While some research at the university level has noted the impact of courses on students' beliefs about the nature of mathematics as a whole (e.g., Rupnow, 2023; Szydlik, 2013; Ward et al., 2010), here we instead consider the impact of course activities on students' perception of definitions and associated practices for creating and using them. In so doing, we gain initial insight into how teaching practices can impact students' perceptions of the values and norms held by the mathematics community.

Analysis Paralysis: On the Potential Overemphasis of Calculus and Analysis in the Undergraduate and Graduate Mathematics Curricula

Alan Parry

Joe Simons
Utah Valley University

In the United States, students in the K-12 system are often adversely affected by a so-called "race to calculus" that we believe to be caused, in part, by the emphasis on analysis found in the mathematics curriculum at both the undergraduate and graduate levels. This originates partially from a historical need for calculus in industry, a need which is no longer as prevalent as it once was. Here, we examine the curricula at 100 of the top graduate and undergraduate programs in the United States and the prevalence of a variety of topics in these programs, including calculus, analysis, linear algebra, abstract algebra, geometry, and statistics. As expected, analysis was much more prevalent than any other advanced topic. We discuss reasons for this prevalence and how such prevalence should be mitigated in the future.

Keywords: Curriculum Development, Calculus, Analysis

Introduction

It is well known that the structure of the mathematics curriculum at the K-12 level is currently based on a "race to calculus," that is, most of the curriculum is heavily influenced by a need to prepare students to take calculus in college (Bressoud, 2021). There are strong historical reasons for this focus, not the least of which include a need for graduates in physics, engineering, and mathematics during the Cold War (Tucker, 2013). However, today's industrial landscape has shifted and now the main mathematical needs in industry are no longer calculus-based, but rather based on the statistics and linear algebra needed for data analysis (Gravemeijer et al., 2017). As a result, there seems to be a significant societal desire for change in the mathematics curriculum and there are many suggestions about what that curriculum might look like (see, for example, Gravemeijer et al., 2017; Stanford Graduate School of Education, 2021). Yet, change in this regard has been relatively slow.

We have sought to better understand the influences that prevent meaningful changes in the mathematics curriculum from happening. One observation we made was the similarity in the undergraduate mathematics curricula we experienced at the various universities we have attended or taught at. Indeed, there were remarkable parallels in the initial courses that undergraduate mathematics majors were required to take at these institutions. These courses also significantly overlapped with the initial mathematics courses that STEM majors were required to take. These courses seem to typically include a single-variable and multi-variable calculus sequence, a course in linear algebra, and a course in ordinary differential equations. This is not too surprising as the calculus sequence for STEM majors is well understood to be the impetus for the race to calculus at the K-12 level (Bressoud, 2021). While it is clear why physics and engineering majors start with calculus, we sought to understand why mathematics programs also begin there when mathematics includes topics like modern algebra, geometry, topology, and discrete mathematics, each of which provide equally valid starting points.

Further similarities in the curricula with which we were familiar provided a possible explanation. We noted that these curricula seemed to continue to emphasize calculus and analysis throughout, typically requiring a considerably larger number of calculus- or analysis-based courses than courses in other topics in mathematics. This seemed to continue even into graduate school where the only course that we had personally observed almost always being required was a graduate level course in real analysis that typically covered measure theory and the Lebesgue integral. This suggested that the race to calculus might continue past K-12 education into the undergraduate and even graduate levels.

To verify whether our personal observations are typical in United States undergraduate and graduate mathematics curricula, we acquired and analyzed data on various mathematics programs throughout the nation. We also sought to better understand the motivations for such similarities if they were found.

As shown in this paper, we found that this emphasis on calculus and analysis in the undergraduate and graduate mathematics curricula is common throughout the schools that we considered. In the remainder of this paper, we explore the historical motivations for why this emphasis on calculus and analysis exists, provide an analysis of the data we collected which shows this emphasis is currently present throughout the United States, and discuss what this indicates about how we can address the race to calculus and modernize the mathematics curriculum at all levels.

Literature Review

Calculus has not always enjoyed its current privileged position within the college curriculum (Tucker, 2013). The teaching of mathematics at the post-secondary level in the United States has evolved greatly throughout the history of the United States. In the early days of the country, American colleges focused mostly on Euclidean geometry and algebra. Mathematics was "studied as a classical training of the mind rather than as the language of science and engineering" (Tucker, 2013, p. 1). Mathematics almost disappeared from college curricula in the later 1800s and early 1900s as colleges moved away from focusing on a classical education to a focus on practical education. Mathematics avoided falling into the same obscurity as other classical subjects, such as Greek and Latin, through the needs of engineers and similar technical professions that required mathematical training in their fields (Tucker, 2013).

In response to this declining emphasis on mathematics, in 1915 the Mathematical Association of America (MAA) began making suggestions on what should be included in undergraduate mathematics curriculum, with calculus as the introductory focus (Tucker, 2013). Additionally, colleges began introducing academic majors and general education requirements, further bolstering the place of mathematics within the college curriculum. During this period, mathematics was a career-oriented major focused on supporting engineers, actuaries, and teachers. However, mathematics gained its modern prominence in the wake of World War II as the national demand for engineers and mathematicians exploded (Duren, 1967; Tucker, 2013).

In 1957, the Soviet Union launched Sputnik, the first manmade satellite into space. This event is widely regarded as the ignition of the space race between the Soviet Union and the United States during the middle and latter parts of the twentieth century (Tucker, 2013). The space race led to an increased demand and respect for collegiately trained mathematicians and other science professionals from math-heavy fields. At the heart of all these suddenly respected fields was calculus, a mathematical subject seen "as a foundation for the modern world and one of science's greatest intellectual achievement[s]" (Tucker, 2013, p. 10).

The newfound demand for mathematically trained college students led to the formation of the Committee on the Undergraduate Program in Mathematics (CUPM), a group tasked by the MAA to set forth standards for what mathematics should be studied by college students seeking degrees in mathematically-based fields of study (Duren, 1967). In 1963, the CUPM published an influential report on the suggested curriculum for undergraduate students who one day wished to become research mathematicians (CUPM, 1963; Duren, 1967; Tucker, 2013). This report pushed for a heavier emphasis of calculus and analysis in the undergraduate curriculum as preparation for learning analysis at the graduate level, (CUPM, 1963). A 1965 report by the CUPM further emphasized the importance of analysis at the graduate level:

> The Panel has consulted many outstanding graduate mathematics departments; a solid grounding in algebra and analysis is what they most want from incoming students. If time and resources permit, it is, of course, desirable to introduce the pregraduate student to a broader range of material, but not at the expense of a depth in algebra and analysis. (CUPM, 1965, p. 450)

Even more influential was the 1972 CUPM report, which did reduce the number of recommended mathematics courses, but led directly to the traditional requirements of calculus 1 and 2, linear algebra, and multivariable calculus seen in many colleges today (Tucker, 2013). This report also acknowledged the preeminent place of analysis in their recommended program and questioned whether such preeminence was appropriate:

> A closely related question is whether the "core" of pure mathematics that all departments should offer is now the same as it was presumed to be a few years ago. As new fields develop, some older fields seem less relevant, and today some mathematicians even question the assumption that calculus is the basic component of all college mathematics. (CUPM, 1972, p. 36).

Despite this questioning of calculus as the basic component of all college mathematics, calculus is still often used as a "gatekeeper" or "filter" for STEM majors, including mathematics (Bressoud, 2021; Bressoud et al. 2015; Tucker, 2013). Many studies have explored how to improve calculus instruction, most notably the 2015 MAA national study of college calculus (Bressoud et al., 2015). These studies have often focused on instructional methods and improving student understanding, with little questioning of calculus as the basis for all college mathematics (see, for example, Berry & Nyman, 2003; Ellis, 2013; Epstein, 2013; Gundlach & Jones, 2015; Jones, 2013, 2016; Jones & Watson, 2018; Mesa et al., 2015; Musgrave & Carlson, 2017; Tallman et al., 2021). However, based on the previously quoted statement from the 1972 CUPM report, mathematics majors should be moving away from calculus or at least be emphasizing analysis and advanced calculus less than in previous years.

In our review of the literature, we also found no examination of the classes mathematics majors take beyond calculus across multiple institutions. In the 1972 CUPM report, undergraduate mathematics majors are advised to include at least three semesters of analysis, while upper-level modern algebra and geometry are only recommended for one semester. Wu (1999) did discuss creating multiple tracks for mathematics majors, with one track specifically for those aimed at graduate school. Still, there was no discussion of what topics would be most appropriate for mathematics majors bound for graduate school, though he did note that many mathematics major curricula are designed specifically with these students in mind.

Research Question

If the place of calculus as the gateway to college mathematics is accepted, yet many fields of modern mathematics do not have calculus as a core component (CUPM, 1972), it stands to reason that analysis should now be less emphasized, or at least equally emphasized with other mathematical topics. While there are many mathematical topics covered even in undergraduate mathematics courses, three main categories tend to be given priority: analysis, algebra, and geometry/topology (Harvard University Department of Mathematics, 2025; Wu, 1999). This led us to the following research question: Of the three major topics of analysis, algebra, and geometry, is there a difference in the number of courses the top 100 graduate and undergraduate math programs require from these three topics?

Significance of This Study

We hope that this study serves as the catalyst for future discussions and research into the most appropriate collegiate mathematics classes, both for mathematics majors and non-mathematics majors. This study seeks to examine two of the major influences on the mathematics curricula offered at colleges and universities: the mathematics major for students seeking graduate degrees and mathematics graduate degrees.

Methods

We compiled a list of the top 100 graduate programs in math, as ranked by US News and World Reports (US News and World Report, 2022, 2025). An initial analysis of required courses for graduate programs was completed using the 2022 list. After this data was revisited in 2025, we then completed a further analysis of undergraduate programs using the updated list. We did this with the intent of utilizing the corresponding undergraduate programs at these institutions, with the intent of seeing what a student preparing for graduate studies in mathematics is required to take. As such, we removed graduate programs at institutions with no corresponding undergraduate program. In place of such institutions, we included the subsequent institutions to complete our list of 100 universities. In this case, the only such institution was the CUNY Graduate Center, which we replaced with the institution ranked 101st at the time of our survey.

For the purposes of our survey, we grouped courses as being in one of the following categories, which we will define hereafter: Calculus, Analysis, Geometry, Linear Algebra, Abstract Algebra, and Statistics. Graduate school courses were only categorized by Abstract Algebra, Analysis, and Geometry. As the goal was to classify courses which are strictly required for graduation, we only counted a course towards a category if a course covering that category was required to satisfy a graduation requirement. We also did not count course prerequisites for courses taken before a Calculus 1 course, as such courses are commonly tested out of by students in a mathematics major.

For instance, if a student had to choose one course from a set including two analysis courses and an abstract algebra course, this would count towards no category, as the student does not need to take one course which fits strictly one category. On the other hand, if a student must take at least one course chosen from among three analysis courses, this would contribute one course to the required analysis courses for that program. In the case that a course covered multiple subjects, we split the course among the subjects based on the course description and course text. This is done while retaining the total value of one between the split, meaning a course covering geometry and abstract algebra would count as 0.5 abstract algebra, and 0.5 geometry, not one abstract algebra and one geometry.

As different institutions offer courses on different schedules, with the most common options being semesters and quarters, we recorded the number of blocks each institution offers in a standard academic year, excluding the summer block(s). This allows us to normalize all data collected into semester equivalents, so that schools on quarter systems are not represented with disproportionately high course requirements. For each undergraduate institution, if multiple emphases were offered with the major, the one most aligned to graduate study was selected.

The graduate data was reviewed by one researcher as such courses were more clearly aligned to a particular subject area. The undergraduate data was reviewed by five researchers, with each researcher reviewing 30 classes, with 20 being shared by other researchers. Situations in which there were inconsistent course counts were flagged and reconciled jointly. Reviewers counted courses as per the guidelines below, which we utilized as descriptions for each type of course.

We classified a course as a calculus course if it covered traditional calculus 1-3 material or differential equations, but with students not being graded or tested on proofs or proof-based material. This includes courses on differential calculus, integral calculus, multivariate calculus, ordinary differential equations, and partial differential equations.

We classified a course as an analysis course if it covered real analysis, complex analysis, or measure theory. Additionally, we classified courses which cover traditional calculus 1-3 material or differential equations with students being graded or tested on proofs and proof-based material as analysis courses. Note this is mutually exclusive with a being considered a calculus course.

We classified a course as a geometry course if it broadly covered the subjects of plane geometry, differential geometry, algebraic geometry, algebraic topology, or general topology. We specifically did not classify analysis courses which covered the topology of the real line or the complex plane as topology courses. This exclusion was so that nearly every introductory undergraduate real analysis course did not end up counted partially as a geometry course.

We classified a course as a linear algebra course if it covered the theory of linear operators, either directly by definition, or by the theory of matrices. We made no distinction between computational linear algebra courses, proof-based courses, or courses which are a combination thereof. We did not count algebra courses which covered matrices as an example space as linear algebra courses, so as not to conflate linear algebra courses with algebra courses, similar to the exemption made with topology courses.

We classified a course as an abstract algebra course if it covered the theory of groups, rings, fields, Galois theory, category theory, or any similar algebraic structures through a proof-based approach. As such, we do not count college algebra, intermediate algebra, or other non-proof-based courses towards this subject.

Finally, we classified a course as covering statistics if it covered statistical thinking, statistical methods, probability theory, or other statistics related subjects. This includes mathematical statistics, and measure-theory based statistics. However, measure-theory based courses were cross-listed with Analysis depending on the particular course description and text.

Results

The initial survey of graduate programs found that exactly half of the institutions examined had strict course requirements for their pure mathematics programs, with the other half only requiring advisor approval or satisfactory scores on qualifying exams. These institutions were excluded from analysis, leaving 50 graduate institutions. In our survey studying the undergraduate programs, an overwhelming majority (84) of the institutions examined worked on a semester system. All schools that worked on a quarter system had their number of classes for

each subject area multiplied by 2/3 to find the equivalent number of semester classes needed for each subject area.

Descriptive statistics for both data sets after norming the undergraduate data are found in Table 1.

Table 1: Descriptive Statistics for Normed Number of Classes by Subject Area

	Undergraduate Schools				Graduate Schools			
Subject Area	Min	Max	Mean	SD	Min	Max	Mean	SD
Calculus	2	4	3.46	0.561	-	-	-	-
Linear Algebra	0	3	1.18	0.496	-	-	-	-
Statistics	0	3	0.33	0.561	-	-	-	-
Algebra	0	2	1.07	0.575	0	3	1.20	1.030
Geometry	0	2	0.22	0.450	0	3	1.02	1.097
Analysis	0	4	1.73	0.900	1	4	2.22	0.840

After data was collected, SPSS was used to perform a one-way repeated measures analysis of variance (ANOVA), as all variables were repeatedly measured on the same subjects (Field, 2018). As the upper-level classes were deemed the most important ones to compare, the ANOVA was only performed on those variables. Data on the other variables is included to give additional context to these more important data points.

As part of this ANOVA, we tested the following hypotheses:

H_0: There is no difference in the number of algebra, geometry, and analysis classes required by the top 100 graduate and undergraduate math programs in the United States.

H_a: There is a statistically significant difference in the number of algebra, geometry, and analysis classes required by the top 100 undergraduate math programs in the United States.

After the ANOVA was run on the graduate data, the Huynh-Feldt estimate of departure from sphericity was $\epsilon = 0.844$. Using this adjustment, the difference between the number of classes offered in different subject areas was found to be statistically significant, $F(1.687, 24.819) = 53.833, p < 0.001, \omega^2 = 1.413$. This is convincing evidence that there is a difference between the number of required classes in algebra, geometry, and analysis for mathematics majors in the 50 of the top 100 graduate math schools that had stated class requirements.

All graduate class categories were then compared using a post-hoc pairwise comparison with a Bonferroni correction. When the two categories that generally had the highest number of required classes, analysis and algebra, were compared, more analysis classes were required ($M = 2.220, SE = 0.119$) than algebra classes ($M = 1.200, SE = 0.146$). This difference, 1.020, 95% CI $[0.699, 1.341]$, was significant $p < 0.001$ with an effect size of $d = 1.118$.

After the ANOVA was run on the undergraduate data, the Huynh-Feldt estimate of departure from sphericity was $\epsilon = 0.874$. Using this adjustment, the difference between the number of classes offered in different subject areas was found to be statistically significant, $F(1.747, 172.978) = 178.087, p < 0.001, \omega^2 = 0.476$. This is convincing evidence that there is a difference between the number of required classes in algebra, geometry, and analysis for mathematics majors in the top 100 undergraduate math schools.

All categories were then compared using a post-hoc pairwise comparison with a Bonferroni correction. When the two categories that generally had the highest number of required classes, analysis and algebra, were compared, more analysis classes were required ($M = 1.7283, SE =$

0.09004) than algebra classes ($M = 1.0700, SE = 0.05750$). This difference, 0.658, 95% CI $[0.461, 0.856]$, was significant $p < 0.001$ with an effect size of $d = 0.812$.

Discussion

From the above analysis, there is a heavy emphasis on calculus and analysis in both the undergraduate and graduate mathematics curricula at most institutions across the United States. Just as the introductory calculus sequence causes a race to calculus at the K-12 level, we believe that the typical requirement of graduate level real analysis is the cause of the emphasis on calculus and analysis in the undergraduate mathematics major programs. Both the introductory calculus sequence and the graduate real analysis course indicate pressure from above against any change in the curriculum. Indeed, one major reason why mathematics programs may find it difficult to move away from requiring the initial calculus sequence is the need to prepare their mathematics majors for that graduate level real analysis course required by the majority of graduate institutions. This suggests that for any meaningful change to happen at the K-12 level, the undergraduate mathematics curriculum first needs to change. But for the undergraduate mathematics curriculum to change, first the requirement of graduate real analysis needs to no longer be the norm.

We hypothesize that the graduate real analysis course plays more of a role in verifying that students are prepared for graduate work than in serving as a prerequisite for graduate mathematics courses or research, as most such courses and research topics simply do not use the content of that real analysis course. This preparation verification can be done with a graduate level course in practically any mathematical topic. Thus, the emphasis on analysis at the graduate level seems more due to convenience than necessity.

If the assumption of basing the curriculum on calculus was questioned in the 1970s because of changing times (CUPM, 1972), how much more should we question that assumption in the 2020s? This raises the question of what should be done with this data. One suggestion is that we replace calculus with data science, including statistics and linear algebra, because data science is more ubiquitous in today's industry (Stanford Graduate School of Education, 2021). However, if we shift to a curriculum that supports data science instead of one that supports calculus, we run into two potential problems. The first is also noted by the CUPM 1972 report, that the landscape of what mathematical topics are needed by society is constantly changing. Data science is the flavor of the day now, just like calculus was 50 years ago, but in another 50 years, it will likely be a new topic in mathematics. However we change the curriculum should be flexible enough to adapt to future changing needs. If the race to calculus should teach us anything, it is that embedding preparation for a specific topic into the curriculum creates a curriculum highly resistant to change. The second issue is that one of the main reasons why a race to calculus is so problematic is not just because calculus is becoming less important, but also because racing to a particular topic encourages a curriculum that focuses on skill preparation and proficiency in algorithms that support that topic rather than a more robust culture of mathematical thinking and exploration (Tallman et al., 2021; Tucker, 2013). Racing to any topic, regardless of how relevant, will continue to have that effect.

In future research, we look to explore ideas of how to develop a graduate, undergraduate, and K-12 curriculum that would be independent of the favored topic of the day, while still providing robust preparation in mathematical thinking that could quickly be adapted to support any mathematical topic at the college level.

The ACT UP Math project was a multi-institutional research practice partnership (RPP) formed to engage students, faculty, and administrators in collective equity-oriented work for critical change in undergraduate mathematics programs. Through careful critique of our own decisions and results, we identify opportunities with which we could have embraced greater criticality, especially in relation to disrupting our own white comfort. In doing so, we aim to provide guidance on better practices to enact when engaging in critical work. We orient ourselves to this critique with (critical) love, engaging with love for ourselves with the goal of growth as researchers, love for the research we do with the goal of growth for our field, and love for the research participants with whom we partnered with the goal of learning from one another.

Keywords: critical research methods, reflexivity, self-critique, narrative inquiry, research practice partnerships

A growing number of research studies investigate the inadvertent impact of introductory mathematics programs that were *initially* designed to support a predominantly white, masculine, and higher socioeconomic population (i.e. the population of people who initially had access to higher education, especially technically-oriented higher education). As more women, more people of color, more low-income students, and more first-generation students seek higher education, STEM degrees in particular, the mathematics education community increasingly grapples with how introductory mathematics programs are not structurally designed to support this increasingly diverse population of students (Ong et al., 2018). Improvements to existing programs have included tutoring programs, bridge programs, incorporation of active learning, and the creation of co-requisite courses, among other efforts (see Voigt et al. (2023) for many examples).

Some change efforts work to improve the experience and achievement of a more diverse group of students within the current structures of introductory mathematics programs. Other change efforts work to rethink the structure of programs altogether; these efforts often question aspects of programs historically taken as given and work to develop creative alternate ways to provide and conceptualize mathematics education for diverse populations of students. The latter efforts take a *critical* approach to improving equity - they work to change the system - whereas improvement efforts that work within the system take a *dominant* approach (Gutiérrez, 2009). Equity scholars have long argued the value of both approaches, to improve the existing system and simultaneously work to change the system as a whole (Martin et al., 2024). This report discusses the ACT UP Math grant, which engaged in research practice partnerships (RPPs) with three mathematics departments. Each department created a Networked Improvement Community (NIC) of faculty members, students, and/or administrators with the intention of using local data to make transformative changes to their introductory mathematics programs. As a research team,

we worked to support them in making *critical* changes, with the recognition that critical changes are much harder to conceptualize when one works within and has succeeded within the existing systems.

With each department partner, we supported a team of students, faculty, and administrators to develop critical perspectives and apply those perspectives to their introductory mathematics programs. We encouraged the use of data to inform critical perspectives, which included both quantitative and qualitative data on student experiences in the programs. As we supported the three mathematics departments, we also strove to engage in critical scholarship- by which we mean the interrogation of norms and hierarchies in dominant research. For instance, dominant research traditions attempt to adopt "objective" perspectives of observers and value the expertise of faculty over students; a critical approach embraces that all human experiences are subjective, and recognizes the value in hearing from diverse voices and students' lived experiences.

Our research team consists of mathematics education researchers with varied experiences in critical scholarship, and many previous experiences with dominantly-oriented research teams. To support our research team in enacting criticality, we asked (and paid) a *critical friend* with expertise in critical scholarship to attend meetings, view recorded meetings, read meetings notes, and respond to specific reflective prompts related to how we were and were not engaging with our work critically. One transformative part of the feedback that our critical friend gave was that we had centered *white comfort* within our researcher meetings and whole team meetings (which included the research team and the leaders of the department change teams). This specific feedback led to deep reflection from the team related to the ways in which whiteness and white supremacy culture impacted our orientation to our work, and inspires this report of a self-critique of how we engaged in critical scholarship. We orient this self-critique through, taking inspiration from Basile and Azevedo (2022), who used this approach to recognize where they could have done more in working to make transformative progress in STEM education. We also draw upon Foste (2020) who identifies "three reflexive considerations for white scholars beginning to take up the critical study of whiteness: creating contexts for racial comfort, validating racist beliefs, and missing educational opportunities to disrupt whiteness" (p. 132). Therefore, we guide our loving self-critique with the following research question: *How did our research team enact (white) comfort, and what opportunities did we (not) take to disrupt the tensions and contradictions therein?*

Literature Review

Our work follows a growing body of research that is grounded in love throughout theory and methodology. Paris and Alim (2014) critiqued the then-current operationalizations of asset pedagogies with an eye toward moving away from a dominant white gaze. They deliberately centered their critique in love: "we use loving critique to denote the position of deep respect from which we problematize and extend… scholarship and practice" (Paris & Alim, 2014, pp. 1-2). Basile and Azevedo later took up the idea of loving critique and oriented it to the self, in critique of their own "failures" as STEM educators: "Our loving (self) critique entails a willingness and courage to deeply interrogate our own complicity in the perpetuation of some of those same inequities we purport to stand firmly against" (Basile & Azevedo, 2022, p. 1087). We follow this tradition of loving (self) criticality.

Indeed, Clingan (2015) invites us to "consider what might be possible if love were intentionally and specifically identified as a methodology, pedagogical practice, and value in… education" (p. 1). However, as Johnson et al. (2018) remind us, we must use "love" with mindfulness and care. We do not refer to the romantic and often hierarchical love common in

Western culture, but rather we refer to "the type of deep-seated love that is cloaked in pain and that is bounded in action which disrupts… white supremacist patriarchy through the practice of humanizing love" (Johnson et al., 2018, p. 48). The latter kind of love demands self-transformation as we collectively labor for improved education systems. We offer in the next section a perspective for how queer theory supports us in this transformation through self-critical love; also see a theoretical development of *critical love* by Author 1 (under review).

Theoretical and Analytic Framework

After joining for two research team meetings, our "critical friend" – in an act of love for us and the project – shared critiques, the most provoking of which was that our meetings "gave off white comfort." To facilitate our deconstruction of our white comforts, we chose a theoretical lens of critical whiteness studies to "recognize, analyze, and critique the power and privileges associated with Whiteness" (Haviland, 2008, p. 41). Within this lens, we center power to challenge the power-evasive tendencies of whiteness (Haviland, 2008) and to attempt to avoid the confessional, rather than transformational, critique stemming from an overemphasis of privilege (Lensmire et al., 2013).

Within our centering of power, we maintain awareness of the interwoven nature of power and privilege (and the stronger form in supremacy). Therefore, we introduce a weaving metaphor whose structural backbone consists of Okun's elements of white supremacy culture (Okun, 2021). From Okun's work, we highlight white supremacy's *right to comfort*, *only one right way thinking*, *paternalism*, and *fear of open conflict*, as these components of white supremacy resonated with the team during reflections (for a more comprehensive discussion of white supremacy culture, we encourage the reader to visit Okun's website). We appeal to weaving as a metaphor, and consider as vertical threads the structures of dominant cultural traditions (including white supremacy culture), and as horizontal threads the ways we enact institutional and interpersonal norms, policies, and practices as a research team. We therefore consider how we inadvertently wove our project's "horizontal" interpersonal norms of care around the "vertical threads" of white supremacy culture, creating a space of white comfort. We now engage in the ongoing work of "tugging" on the horizontal threads to unweave them, seeking to reweave them elsewhere in critically transformative ways.

Foste (2020) encourages teams of predominantly white researchers, such as ours, to attentively engage in continual reflection and recognize that this work is ongoing. In this work, we both identify comforts and work to deconstruct them, and identify ways in which we are changing behavior and ways in which we still need to change behavior. We root our work additionally in queer theory which holds together the tension of product (this contributed report) and process (our continual engagement in reflection, even after this manuscript is "complete").

Our choice of queer theory also returns us to our namesake ACT UP, a queer grassroots coalition of activists. This coalition "exemplified the pragmatic ability of queer activists of the 1980s and 1990s to join 'deconstructive reading practices and grassroots activism together, laying the groundwork for… queer theory'" (Freeman, 2010; cf. Brim & Ghaziani, 2016, p. 15). We also work to deconstruct – or "*unweave"* – our "white comforts," which we view as inherently indiscrete. Likewise, "Whiteness is not monolithic" (Haviland, 2008, p. 41) and "white racial identities are multifarious messes of thought and feeling… we must remain open and attentive to the pedagogical possibilities of complexity and conflict" (Lensmire, 2010, p. 170). In recognition of this messiness, and the potential for transformation when embracing complexity and conflict, we see queer theory as a natural foundation for our critique--for its ability to deconstruct binaries, critique hierarchy, and engage with uncertainty (see Chapters 2

and 3 of Hall (2003) for what these entail). As such, queer theory offers a supportive frame for our (self-)critical love through the tugging and unweaving of our enacted white comforts.

Data and Method

Our loving self-critique is rooted in our critical friend's feedback and entries from ACT UP Math RPP members' journals reflecting on feedback and tensions felt in the RPP. These journals prompted members to think about their RPP experiences, areas of tension, and progress toward critical transformations. Amorphously, we also bring personal reflections of our time in the RPP -- in part to contextualize written journal entries and in part to dive into how tensions and comforts were addressed.

Our first stage of analysis consisted of identifying the comforts within the reflective journals, asking ourselves "if this space gave off white comfort, what is it that we found comfort in?" We looked broadly for areas of comfort in the data, whether tied to white comfort or not. We employed a reflexive thematic analysis (Braun et al., 2023). Initially, a PI and author of this paper created a preliminary grouping of entries which touch on similar ideas (e.g., white supremacy culture, identity, metaphors for tension, etc.). Then, we used these initial groupings to begin giving names to comforts identified. Next, we individually consolidated comforts under broader categories to allow for each member's unique interpretation of these comforts and how they relate. After comparison and discussion, we collectively reconciled the higher level categories that form the comforts we identified which formed the basis of our critique. The analysis did result in all of the comforts being rooted in white supremacy culture; we used (white) – with parentheses – in our research question to indicate that we were looking for all types of comforts that may have limited our criticality, including those not necessarily attributable to white supremacy culture.

Our second stage of analysis focused on how these comforts were (and are still) both influencing our work and being actively interrogated through our work as the ACT UP Math project team. We found it appropriate to use narrative inquiry (Clandinin & Connelly, 2000) for its ability to *queer* the context of these comforts – that is, queer theory and hence this critique are "perpetually becoming" (Browne & Nash, 2010, p. 1). Moreover, telling stories, especially about mathematics, allow people to unpack held beliefs (Gutiérrez et al., 2023) and heal traumas (Scott & Zuniga-Ruiz, 2024). We utilize the three-dimensional inquiry space (Clandinin & Connelly, 2000) to structure our restory process of comforts as follows: continuity (e.g., time before/after critical friend's feedback), situation/place (e.g., research meetings), and interactions (e.g., members of the RPP). Through these dimensions, we built a narrative that contextualized the things we found comfort in, and thereby giving form to our comforts which could be unraveled. By unraveling each thread, we begin to unravel *our* tapestry of (white) comfort. We share a piece of this narrative below.

Results and Discussion

Structuring our loving self-critique through narrative inquiry required investigation into the overall narrative of the ACT UP Math project. In the prologue to the ACT UP Math narrative, the PIs were involved in multiple past large grant-funded projects, all of which we experienced as rooted in patriarchal models Thus, as the ACT UP Math narrative began, the PI team came together to create an equity-focused project both in process and in focus. We endeavoured to create a non-patriarchal space with a distributed leadership structure that honored the knowledge and experiences of everyone rather than assigning status based on age, gender, or role. We also intentionally scheduled community building activities to begin every meeting, not just the first

few meetings. We set up project norms (later recast as community agreements) that were dynamic, and evolved to align with our growth as individuals and as a community, and as our community membership changed over time. These structures and norms, bundled together with the broader institutional ways of being we have been enculturated in, were woven horizontally, across the vertical threads of white supremacy culture as enacted more broadly in academia. For us, maintaining relational threads in every meeting helped to strengthen our overall weaving, and illuminate the community we were weaving together.

Our narrative then comes to our "critical friend" who, after joining two research team meetings, shared the critique that our meetings "gave off white comfort." Following this critique, we began and still continue the work of unravelling comforts rooted in white supremacy and those rooted in other systems of oppression. We first identified four threads through which comfort manifested in, and sometimes limited, the critical nature of our team's work: *Comfort in (Dominant) Tradition, Comfort in Easing Discomfort, Comfort in Hierarchy,* and *Comfort in Whiteness.* These threads were by no means distinct, but allow us to consider some of the ways in which white comfort worked to limit more critical progress.

In this paper, we share only a piece of the narrative so that the reader has the opportunity to consider one of our unravellings more deeply, rather than more surface-level unravellings of all four threads. We focus on unravelling the *Comfort in (Dominant) Tradition* thread. This thread consisted of ways in which we chose to (or defaulted to) not question research practices and research methodologies that are rooted in white, Western notions of academia. The vast majority of our research team was formally trained in traditional education research methodologies, and carry with us knowledge and comfort in those environments and methods. Both in the structure of our interactions with participants and in the methods we chose, we frequently fell back on what we knew from previous research experiences, rarely challenging taken-for-granted norms in how research is conducted.

Through this loving self-critique, we now recognize missed opportunities for greater power-sharing within our research-practice partnership that we did not take up. In conjunction with the *Comfort in Hierarchy* thread, we did little to dismantle the pedestal upon which research (and therefore, researchers) are often placed in professional development contexts. While we did explicitly encourage NIC members at our participating institutions to see themselves as experts in their own experiences, and to leverage their institutional expertise to inform critical changes, we missed opportunities to invite them to collaborate in research spaces throughout the project. Often, they were left in the dark with regards to *why* we were collecting the data we collected, and they were not asked to influence the types of data we collected.

In a particularly poignant example that stands out to our research team, during a final project interview, one participant explicitly shared some frustration with the fact that we repeatedly asked participants to illuminate "what data felt impactful" during the course of the project. When the researchers conducting the interview shared that we were curious about how participants' perspectives around data changed throughout the course of the project, the interviewee expressed curiosity around why we didn't share that with the local NIC leaders and participants, as it would have mitigated some of the confusion and frustration participants felt around being repeatedly asked the same question. Notably, the participant only felt comfortable sharing this frustration with us after three years of intentional relationship development; as is the case in traditional research and participant interaction, our research team did not make space for critique of our project from the participants, which undoubtedly would have served to enhance the project itself. This is but one reflection of the missed opportunities we had to share the purpose of our research

with the participating NIC members (or, more critically, allow our practitioner partners to shape the directions of our research).

As a result, the research side of our work, especially in the early years of the project, existed in a "black box" which was not visible to our participants, which diminished the *partnership* value of the RPP. As we unravelled this particular thread of comfort during the later months of the project (after our critical friend's critique), some intentional ways in which we rewove this thread included greater intentionality in extending invitations to NIC leaders and members to be a part of research propagation efforts. These invitations were made asynchronously via email and during meetings with NIC leaders at the three institutions, and contained summaries of *all* projects presently being worked on alongside opportunities to indicate interest in other research directions created by them. As more NIC leaders and participants have opted into engaging in the research side of our work, new challenges came to light; in particular, we needed to learn how to share data with participants while protecting the anonymity of other participants in the project, which we have handled on a case-by-case basis. We have found the challenge minimal compared to the immense value of having NIC leaders and participants in conversations that shape (and constitute) our research propagation efforts. While we are still working on many of these efforts, we have seen for ourselves the value that having NIC members and leaders actively involved in shaping propagation efforts has. Indeed, the ACT UP Math grant originally chose the term propagation—rather than dissemination—for its suggestion of growth rather than spreading. The involvement of NIC members has substantially contributed, and continues to contribute, to the growth of our research.

Even so, our propagation efforts continue to reflect traditional education research methods. The PIs of this project intentionally leveraged a grassroot activist organization's acronym with the intention of responding powerfully to the injustices that can be perpetuated by contemporary U.S. mathematics education policies and practices. Our desire was to partake in activism through a research lens—to be activist-scholars as we conducted and propagated this work on how to make change. However, we fell short of this desire, and rarely in the moment considered how the comfort we found in traditional academic and mathematics education research methods continued to feed into some of the systems we had so intentionally set out to disrupt.

For example, the vast majority of our propagation efforts have been filtered through traditional propagation channels: established journals and conference proceedings, which themselves are inaccessible to a broad audience and subject to forms of gatekeeping that maintain traditional academic practices. By choosing to submit our work (and in many cases, be accepted) to such avenues, we have already "played the game" – or at least, a component of the game – of academic prestige associated with publishing in traditional, dominant spaces: a game which a more radical stance might reject entirely. For example, a stance of refusal (Tuck & Yang, 2014) more radically questions and disrupts research as the highest form of knowing, noting that even more inclusive definitions of what research *is* continues to uphold *research* as the eclipsing way to make meaning of human experiences. Even when we use more critical or arts-based methodologies (such as poetic transcription or visual analysis), we continue to call them *research* and seek to publish them in normative mathematics education research spaces. This is done with genuine care and awareness for our colleagues (particularly those in their early career, where citations matter a great deal in terms of career trajectory) and for the research community, who we hope will learn from and build on our work. We continue to submit and publish work in traditional academic avenues of propagation (such as RUME). This care and continuation of practice exists alongside our more recent unravelling of how *Comfort in*

Tradition kept us feeling safe in these propagation practices.

Recently, we have explored other non-academic avenues through which we might share our findings, curiosities, and wonderings, as potential re-weavings of this thread. Drawing from creative spaces of subversion, we distributed a Zine at MAA MathFest 2025 focused on how we came to understand dimensions of creating authentic student partnerships in change-making groups (Bolick, 2025). The Zine featured artwork and poetry from a collaborative team of researchers and NIC participants, many of whom were students. When our project was funded, we also maintained a public blog *Get Lit: Mathematics Education* that discussed literature of interest to our team. Both of these avenues of propagation were not subject to any form of review and highlighted more critical ideas and presentation forms than may have been published in more mainstream journal or conference spaces, and thus allowed us to reflect more of the activist stances we had set out to take with this project, and distribute those thoughts more widely. Ultimately, these remain but two pieces of work, with the vast majority of our work published (even now) in mainstream academic spaces. This does not mean that such traditionally published work does not or cannot have value, but necessitates an acknowledgement that, in filtering through traditional channels, we are not necessarily disrupting research norms in a way aligned with our initial activist intentions. Our unravelling of the *Comfort in (Dominant) Tradition* thread leads us to critique the ways in which our work maintained traditional hierarchies between researchers and practitioners of mathematics education, alongside this recognition that we are continuing to perpetuate traditionally reviewed and published *research* as the highest form of knowing. Within a stance of care for colleagues and awareness of the need to "play the game", we continue to seek ways to reweave this thread.

Implications

We share our loving self-critique with the RUME community for multiple reasons, which bring with them implications for future practice. For many of us, the RUME community is our research home, so the practices we fell back on are exactly those practices shared, cultivated, and valued by this community. Thus, as we lovingly critique our own use of these practices (or comforts), we extend this loving critique to the RUME communities' continued use and comfort in these practices. We encourage our colleagues to consider ways that they default to research practices that uphold dominant tradition (especially in research methodologies and propagation efforts) and hierarchies (based on social and professional identities) – two tenets of white supremacy that have infiltrated our academic culture so much so that we may not notice them.

We also share this loving self critique as an example of the type of vulnerable and reflective work that can lead to growth, which we (and therefore our field) can all always benefit from. We envision a loving self critique of research projects available to all RUME colleagues, asking (and importantly sharing) not only what we believe we got "right", but also how our work could be improved. We do not want this room for improvement to be misconstrued as a robust "limitations" section of a traditional paper. Instead, we remind ourselves and others that courage, humility, curiosity, and a critical interest in *growing* one's own propensity to do meaningful work are all woven into the work of a loving self critique (Black, this volume). We see these values in our RUME colleagues, and recognize many may be doing their own internal loving self critiques. Here, we call for that work to become publicly valuable so that we may all learn from purposeful introspection, and to place those introspections into dialogue with broader societal discourses, such as white supremacy culture. Our hope is that the "deep-seated" and "humanizing love" (Johnson et al., 2018, p. 48) with which we engaged in this work is felt and can propagate within this community.

Acknowledgments

Thank you so much to everyone who contributed to the ACT UP Math project, particularly through vulnerable self-reflections. The ACT UP Math project was originally funded by the National Science Foundation (#2201486) until funding was terminated by DOGE April 19, 2025. All findings are those of the authors and not necessarily of the former funding agency.

Dual Enrollment Students' Perspectives on College-Level Mathematics Instruction

Tami Dashley Shah
University of Massachusetts Dartmouth

Beste Güçler, Ph.D.
University of Massachusetts Dartmouth

Dual enrollment (DE) students have simultaneous roles as both high school and college students. DE programs have been utilized to enhance students' access to higher education and post-secondary success. While many studies have focused on the effects of DE programs through quantitative, outcome-oriented frameworks, few studies utilized sociocultural, qualitative approaches to examine DE students' perspectives on their experiences by centering their own voices. Our qualitative case study addresses this need by exploring how three high school students taking a DE Calculus course describe their experiences with college calculus instruction. Student views about the affordances and limitations of college instruction emerged as themes in our study, which have critical implications for undergraduate mathematics education.

Keywords: dual enrollment, college-level instruction, student perspectives, calculus

In the US, dual enrollment (DE) programs, which allow high school students to take college courses, have drawn attention as an educational and policy issue with the goals of enhancing students' college readiness, access to higher education, and interest in pursuing STEM degrees (Cevallos et al., 2016; Hoffman, 2003; Jamieson et al., 2022; Kremers, 2010). Many studies involving DE students focus on the potential benefits of DE programs in relation to these goals through outcome-based approaches (e.g., undergraduate enrollment, matriculation, degree completion, and grade point average measures), often using quantitative perspectives. (e.g., Allen & Dadgar, 2012; An & Taylor, 2019; Blankenberger et al., 2017; Henneberger et al., 2022). While several researchers explored general experiences of US students taking DE college courses such as their adaptation to college environment or self-perceptions as college students (e.g., Cevallos et al., 2016; Kanny, 2015; Karp 2012; Lile et al., 2018), there are relatively few studies examining DE students' experiences with instruction while taking college-level mathematics courses (e.g., Cevallos et al., 2016), particularly through sociocultural and qualitative approaches that bring students' own voices and perspectives to the fore (Ramsey-White, 2012; Williams, 2015). Our research addresses these areas needing more attention by exploring the following research question: How do three high school DE students describe their experiences while taking a college-level calculus course with respect to mathematics instruction?

Theoretical Framework

We use a sociocultural perspective to purposefully frame our work through students' *descriptions* of their experiences rather than framing it via beliefs. While *belief* has been dominantly used as a construct to examine students' views about their experiences and themselves, researchers often treat beliefs as internal, individual, as well as stable cognitive "entities" and predictors of behavior that are detached from social context (Cobb, 2007; Lerman, 2002; Sfard, 2008). Treating beliefs as internal constructs fails to capture the social, discursive, and situated nature of students' practices and experiences (Cobb, 2007; Lerman, 2002). We argue that students' meanings, views, and positions about mathematics, learning, instruction, and themselves always occur within social contexts and are dynamic, contextual, discursive, and participatory rather than merely cognitive (Lave & Wenger, 1991; Lerman, 2002; Sfard et al.,

2001). By privileging student *descriptions* over *beliefs*, we treat talk as a unit of analysis in itself (Edwards, 1993) and align with the sociocultural perspectives that consider what students say not as a window to their inner states but as their evolving discourses and narratives through which they construct meaning (Sfard, 2008). We view students' descriptions and narrations as situated accounts, which are also influenced by students' interactions with us during the interviews, rather than as providing direct access to their internal beliefs about instruction. Consistently, we focus on how three DE students describe and narrate their experiences with their college-level calculus instruction.

Methodology

To examine the students' descriptions of their experiences, we used an exploratory qualitative approach through a case study design (Merriam, 1998). While there are different DE models through which high school students can take college coursework (An & Taylor, 2019; Andrews, 2001), our study focuses on the case in which students take a DE Calculus course (Calculus I) at a college simultaneously with an Advanced Placement (AP) Calculus course at their high school. Focusing our case study on this group of students allowed us to examine their perspectives on college-level instruction while having some prior experiences with calculus.

The three participants, who had dual roles as both high school and college students, were taking a DE Calculus course at a 4-year university called Tech College (pseudonym) located in northeastern US. The DE Calculus course was taught at the Tech College campus and was composed of seven DE students from two local high schools and three traditional college-aged students. All three participants were high school seniors, who had taken DE coursework since 10th grade. Our participants were Billy, Richard, and Catherine (pseudonyms), who all self-identified as Black/African American and attended a high school where 68% of the students were designated as low-income and consisted primarily of students of color. The high school the students were enrolled in offered several advanced coursework options including honors, AP, and DE coursework. The high school utilized DE to provide career-oriented coursework in computer science, engineering, and health sciences. All participants were taking part in the engineering pathway and had previously taken DE mathematics and engineering coursework.

The data we report here is based on two semi-structured interviews conducted with the students individually. The questions in the first interview elicited general information about students' DE program, courses, and overall experiences. The second interview followed up on the student responses to the first interview and provided more information about the experiences they previously mentioned, which resulted in questions related more specifically to mathematics instruction depending on each student's response. For example, if a student mentioned they liked or disliked the instruction in their DE Calculus course during the first interview, we asked the student to elaborate more on this issue during the second interview. Data analysis occurred simultaneously with data collection so that future interview questions could be informed by the prior collected data (Merriam & Tisdell, 2015). Data analysis involved coding the data both deductively and inductively to examine the themes in students' descriptions and narratives (Guest et al., 2012). Due to space constraints, this paper only focuses on the emerging themes about the affordances of and limitations of/barriers associated with DE Calculus instruction because how DE students describe their college-level instructional experiences has critical implications for undergraduate mathematics education.

Findings

Affordances of DE Mathematics Instruction

Learning about applications of mathematical concepts. Participants viewed seeing and learning more about the applications of mathematical concepts as a positive aspect of their DE Calculus instruction.

> *Catherine*: (In) Calculus I, we actually do projects with the stuff that we learn. So, I think the college part of it definitely has more of the aspects of like applying the math, rather than high school, where it's just learning and then seeing if you remember the information to take the tests.

Catherine provided further details about how the inclusion of real-life applications in her DE Calculus instruction helped her appreciate the usefulness and utility of mathematics.

> *Catherine:* The examples and the problems that we're made to solve in Calculus…they were…dealing with like planes and bridges and we were calculating different things that people, especially engineers, use a lot. So, it was good to see math in a practical way and see that it actually is used pretty often.

Similarly, Billy said that taking the DE Calculus course allowed him to "better understand" part of the "fundamentals" of mathematics, an aspect of which was "not knowing just how to solve an equation but knowing how to apply it to the real world." Billy further stated that calculus involved the study of mathematical applications as "calculus ties into basically everything related to engineering." It seemed that, through his exposure to the applications of mathematical concepts during the instruction of his DE Calculus course, Billy started making connections between different disciplines, such as mathematics and engineering. While Richard did not explicitly mention applications of mathematical concepts as a specific affordance of his DE Calculus instruction, he stated that "math is everywhere. I think a lot of people say that but it's just the truth. You need math for everything…math is pretty big in society." We interpret Richard's statement to suggest that he would likely respond positively to instructional approaches that showcased the real-life applications of mathematical concepts in the context of his DE mathematics courses. All participants directly or indirectly indicated that they viewed the focus on applications of mathematical concepts as an affordance of their experiences in the context of DE mathematics instruction, which appeared to have helped them develop a greater appreciation for the usefulness of mathematics, make connections between different disciplines, and learn more about how mathematics can be utilized in real life.

Deeper conceptual understanding of mathematics. Two students' instructional experiences taking DE Calculus seemed to assist them in developing deeper conceptional understanding of mathematics.

> *Billy*: I started to understand how to do math and …(how) a certain concept is the way it is, and not just how to do it…I just understood the fundamentals way more and how to get from A to B and why I'm getting from A to B in this certain way.

Billy elaborated further by stating that taking the DE Calculus course allowed him to go "beyond the world of (routine) problem solving and really seeing why math is that way it is. Like why you do things specifically this way and why and how, if you do it another way, then you know it's not gonna work."

Catherine acknowledged that the instruction in her DE Calculus course made her realize and utilize two types of mathematical skills: the procedural skills "when you see just like an integration sign and a function it's automatic about what you have to do", and the more conceptual mathematical skills, where "they don't just give you these numbers, they give you…a

situation and you have different variables to it…(in) optimization and related rates…you have to paint a literal picture and consider this and this…and you actually have to think about what you have to do." Catherine said she struggled more with the problems involving conceptual skills, jokingly noting that she was "a little traumatized from optimization and related rates", but also noted that she appreciated being exposed to such problems in her DE calculus course, which enhanced her overall understanding of calculus.

Both Billy and Catherine mentioned that the instructional approaches in their DE Calculus course helped them learn how to get from A to B (Billy), why mathematics is the way it is (Billy), paint a larger picture (Catherine), and actually think about what one has to do (Catherine), which are all components of deep and conceptual mathematical understanding (Rittle-Johnson & Siegler, 1998; Skemp, 1987). In addition, these experiences also seemed to help these students distinguish situations involving routine problems (Billy) and automatic applications (Catherine) from those that involve deeper effort and thought, indicating that they were also starting to differentiate between procedural and conceptual understanding.

Although Richard did not directly indicate deeper conceptual understanding through DE Calculus instruction, he noted that his second exposure to calculus concepts in his DE Calculus course (in addition to the AP Calculus course) helped him realize which calculus ideas and topics were important and where he needed to close the gaps in his understanding.

> *Richard*: There would be…this topic we went over in AP Calc and I kind of did not do so good on it. So, the fact that we went over (it) in the dual enrollment class, it kind of made me realize, wow I really need to go over this a ton more.

For Richard, although his DE Calculus instruction might not have led to deeper conceptual understanding, it helped him understand which calculus topics, concepts, and ideas occur again, are important, and where he needs to put more effort to enhance his conceptual understanding.

Limitations of and Barriers Associated with DE Mathematics Instruction

Negative assumptions about and experiences with college instructors. While some of the limitations and barriers mentioned by the students in relation to their DE Calculus instruction were based on their presuppositions, others were related to their actual experiences. All participants entered the DE Calculus course having some negative assumptions about college instructors. Catherine stated she was initially hesitant to enroll in the DE Calculus course until other classmates assured her that the instructor was "nice".

> *Catherine*: (Before taking DE Calculus) I thought if I take this calculus, they're probably not going to be as nice as my AP Calculus teacher but then my two friends that decided to take calculus…I was talking to them, and they were like…the teacher is so nice.

Billy related his viewpoint that his DE calculus instructor was not as lenient and approachable as his high school teachers by saying "it's not like the professor offers a lot of extra credit and a lot of second chances that teachers in high school do. You definitely have to be more careful of how you go about approaching the college calculus." Billy then noted that his perceived need to be more cautious with college instructors prevented him from seeking help from his instructors and said "I'd say, taking college courses, I haven't always asked for help too much."

Richard also stated that he was initially hesitant to ask his DE Calculus instructor for help as college instructors were not nice: "It would just be like me not knowing whether I can ask my college professor for help, because I would feel like college professors aren't really that nice." Richard said his assumption primarily came from the stories he heard from other students when they had negative experiences with their college instructors. In addition to what he heard from

his peers about college professors, Richard further revealed that he enrolled in the DE Calculus course because he was denied from enrolling in a different course he originally wanted to take: "the person who was running the class said they don't want dual enrollment students…. how can you just do that to a whole (group) of kids?" This personal experience, together with the experiences of his peers, likely reinforced Richard's negative views of college instructors. Despite viewing professors as uncaring or unempathetic towards their students, Richard stated that he ultimately became comfortable interacting with his DE Calculus instructor.

> *Richard:* I asked her this one question, she was actually pretty good, nice about it. I just kept asking her more questions and my learning was never stunted…because I felt like I was afraid to ask for help from my professor.

While all participants indicated that they ultimately interacted with their DE Calculus instructor, especially when they needed to ask questions, their assumptions about college instructors based on their own as well as their peers' experiences were initial barriers they had to work through in order to fully participate in the DE Calculus course.

Inability to attend office hours. All students brought up the issue of not being able to attend their DE Calculus instructor's office hours due to the scheduling of their high school courses. Billy and Catherine explicitly stated how scheduling prevented them from attending office hours.

> *Billy*: …office hours, we can't even attend those because it's during high school.
>
> *Catherine*: A difficult aspect of it, though is office hours. Because they're always at 11 am on a Thursday and I'm in (high) school then.

Richard also acknowledged his inability to attend the instructor's office hours and stated that he would work around this limitation by completing his DE Calculus assignments early so that he could ask any questions he had in a class meeting before the assignment was due.

> *Richard*: I would just wait until I had class again and then asked my teacher about it in class to get the additional help. Because I would always prioritize early college work over everything…So I'd always start on (the assignment) early so I had time to ask (the instructor) in class about the work.

Billy said he would utilize outside resources, like online math videos, to get help with calculus since he did not have the opportunity to get assistance from his instructor during office hours.

> *Billy*: I didn't ask for help too much. I think self-studying did help me a lot. Like taking time to use resources outside of class to understand (the course material) and maybe watch some math videos.

Catherine revealed that on the school days in which students did not have the DE Calculus course, the DE students would meet in their high school's library and assist one another as peers.

> *Catherine*: When we don't have class that day, we have like a free hour, which is supposed to be our last block of school, where we're in the library altogether and we take that time to do the homework and also projects (together)…we definitely use each other a lot for support.

While the DE students devised strategies to get around the challenge of not being able to attend their professor's office hours and find ways to get assistance with the DE Calculus material, they were unable to interact with their instructor regularly, which was a barrier to clarifying their questions, getting assistance from, and establishing a rapport with their instructor.

Time- and expectation-related challenges of DE students. During the interviews, the students did not directly attribute this challenge to DE Calculus instruction but mentioned it as a time commitment challenge. However, college instructors might be unaware of time- and

expectation-related challenges often faced by DE students. College instructors' potential unawareness of and lack of accommodation for DE students who operate in two spaces (high school and college) and work with at least two different sets of requirements at once (high school and college mathematics) can hinder their learning opportunities and success. So, we interpret this issue also as a potential pedagogical barrier.

During the interviews, all students expressed their difficulties in meeting the time and effort requirements for their DE studies in addition to their existing high school coursework. Richard said DE coursework was a time commitment as students would need to be transported to the college campus, which resulted in their DE coursework ending in the evening hours.

> *Richard*: You have to take the bus to go to Tech College…(and it's a) time commitment because at the start we literally got at Tech College at like two (p.m.), and then (class) would end at five (p.m.)…It was kind of crazy, honestly… We don't have that much time as high school students, because we have a whole day's worth of work we have to do.

Since the DE students finished their school days late, they had limited time in the evenings to then complete the homework required for all their courses. Billy stated: "Be prepared to set a lot of time aside after school and when you get home to do your college work and do your high school work." While Billy and Richard spoke more generally about the issue of not having enough time after school to do their studies for their coursework, Catherine was more explicit about her struggles:

> *Catherine*: I would get home at six (p.m), I had three AP (classes), and two regular (high school) classes, and (the DE) class, and to get all the homework done from six (p.m) to the time I have to sleep and eat and take a shower and do everything else in the middle of it…I was getting like five hours of sleep.

As expressed by Billy, these time limitations and different requirements of the courses impacted how much time the DE students could dedicate towards their DE Calculus studies and improving their understanding of the mathematics content.

> *Billy*: I was putting in so much work and putting a lot of time outside of class…to understand what's actually going on…It was something that was new to me so I didn't know how to exactly go about approaching the class and the material.

In the context of this theme, Richard mentioned an additional challenge regarding the faster pace of instruction in their DE Calculus course compared to the AP Calculus course, which further complicated catching up with the DE Calculus instruction, content, and assignments: "AP Calculus…they teach at a slower pace than college. So, I think there's more time to get the material." Richard's sentiment about the fast-paced nature of DE Calculus instruction was echoed also by Billy and Catherine, who said the DE Calculus course "is definitely faster, and it covers a lot more". The pacing of the DE Calculus instruction added another layer of complexity regarding students' time commitments as they needed to understand more material faster to meet the requirements of their DE Calculus course.

Discussion

Our findings help illuminate some affordances of college DE Calculus instruction when students have concurrent calculus instruction in their high schools. In particular, by taking the DE Calculus course, our participants stated that they enhanced their conceptual understanding of mathematics, studied calculus concepts more deeply, and targeted their studies to the topics with which they still struggled. Moreover, since the DE Calculus course included the study of mathematical applications, the students viewed calculus as useful in everyday life and made connections to other fields such as engineering. On one hand, this type of DE model (where

students take a calculus course at a high school and college concurrently), might be seen as wasteful in terms of institutional resources and students' time since students are essentially taking the same coursework twice. On the other hand, our findings indicate that there might also be some benefits to this type of DE model in terms of improving mathematical understanding of calculus, making connections, and appreciating the utility of mathematics.

Our participants also highlighted certain barriers impacting how they carried out their college mathematics coursework and limited their opportunities to seek assistance from their DE Calculus instructor. Typical systems utilized to support college students, such as office hours, were completely inaccessible to the DE students due to the time periods in which they were scheduled to be on the college campus. Our findings have implications with respect to the instructional practices utilized in DE mathematics courses offered at universities. Colleges and instructors offering DE coursework need to devise solutions and find ways to accommodate the needs of DE students to provide equitable access to course assistance and content support services. For instance, post-secondary institutions could develop agreements with their high school partners that DE students must have regularly scheduled time on the college campus to utilize college support services like tutoring centers. College instructors teaching DE students could structure their office hours so that they are more accessible to DE students such as offering evening or weekend office hours via video conferencing technologies.

Our findings also reveal the importance of college instructors' roles in building positive rapport with DE students to help students overcome any negative presuppositions they may hold towards college instructors and assist students in feeling more comfortable interacting with their college professors. One way college instructors can help build positive student rapport would be to acknowledge the time limitations that DE students face and work with them to help minimize any challenges in relation to DE coursework. For instance, college instructors might restructure assignment due dates so that they occur on weekends or some other day that is more accommodating of their DE students' schedules.

It is also important for college instructors to acknowledge that DE students have to balance various demands of high school and college courses. If college instructors do not recognize this challenge, are not willing to accommodate the students, and are inflexible, they might unintentionally create barriers for DE students' mathematical learning and success. This, together with potential emotional and physical burnout DE students can experience in the process, would negate the intended goals of DE programs and mathematics courses to provide students with enhanced access to higher education.

While some findings of this study align with the results from prior research such as DE students reporting difficulties in balancing their DE coursework and their high school courses (Lile et al., 2018) and taking DE coursework supporting students' time management and other study skills (Felder, 2020; Karp, 2007; Ramsey-White, 2012), some findings require more examination. Further questions to think about include: what specific aspects of DE Calculus instruction assist students in developing conceptual understanding of mathematics? How can college mathematics instructors develop instructional practices that would make DE students feel more welcome and feel a sense of belonging in their college courses? What are the additional needs of DE students taking college mathematics courses to feel emotionally and academically supported to achieve the aims of their DE programs in terms of access to higher education and interest in pursuing STEM degrees? A key issue our study underlines is the need to examine such questions through more studies that prioritize students' own voices and perspectives.

In this report we address the longstanding problem of the perceived relevance of upper division math courses for prospective secondary school teachers. Through a multi-year design-based research approach we are reimagining a Dynamical Systems and Modeling course and investigating ways to make the course more relevant to prospective teachers. In this work we report on the impact of these efforts on students' relational understanding of why a particular function is a horizontal shift to the left of another function, a high school topic that is often only instrumentally taught and understood. Analysis of beginning and mid-semester assessments indicate significant growth in our students' ability to provide meaningful explanations. We also report on students' perspectives on classroom activities that influenced their reasoning.

Keywords: function translation, university-secondary connections, prospective teachers

A longstanding international problem in the preparation of secondary school mathematics teachers is the perceived relevance and usefulness of upper division mathematics courses for the work of teaching (e.g., Álvarez et al., 2024; Klein, 1932). In recent years, progress has been made on this pervasive and concerning issue. For example, to explore and make strong connections to secondary mathematics, Cook (2018) conducted four Abstract Algebra teaching experiments with two students and Wasserman et al. (2022) redesigned a Real Analysis course.

Consistent with these and other efforts, we are redesigning an upper division mathematics course for prospective secondary school teachers and investigating ways to make the course more relevant to their future work as teachers. More specifically, we are engaged in a multi-year design-based research (DBR) project focusing on an Inquiry-Oriented Dynamical Systems and Modeling (IODSM) course. We have previously reported on the positive impacts of this work on future teachers' beliefs about meaningful learning and teaching (Goodchild et al., 2021; Qiu et al., 2025) and their participation in the Standards for Mathematical Practice (Cruz et al., 2024).

In this report we investigate the impact of leveraging IODSM content to revisit related secondary school mathematics. In particular, we address prospective teachers' ability to explain *why* the graph of $g(x) = (x + k)^2$, for example, is a shift k units left of the graph of $f(x) = x^2$ (when $k > 0$). This is a classic example of the need for future teachers to have an understanding that goes beyond a rule-based explanation for why the graph of g is a horizontal shift to the left of the graph of f so that they are in a position to teach their future students this particular transformation and related function transformations with meaning.

Our two research questions are: (1) What classroom discussions about the horizontal function translation do IODSM students report as being influential on their understanding? and (2) To what extent do the students in the redesigned IODSM course evidence growth in their ability to explain *why* a particular function is a horizontal shift to the left of another function?

Background Literature

In this section we examine the ways in which prospective secondary school teachers understand why the previously mentioned quadratics are horizontal shifts of each other in a particular direction. We therefore focus our literature review on studies that have examined students' and teachers' understanding of this seemingly contradictory relationship.

Researchers consistently acknowledge that horizontal translations of functions are conceptually challenging and counterintuitive (Yim & Lee, 2021; Zazkis et al., 2003). These challenges stem from multiple sources. Studies show that secondary school and university students often demonstrate a limited understanding of function (Yiğit Koyunkaya & Boz-Yaman, 2023; Yim & Lee, 2021). Zazkis et al. (2003) found that students reduce the abstraction or difficulty in accounting for why there is a horizontal translation by drawing on their prior experiences with arithmetic and number lines. Their intuition tells them $x + c$ is located c units to the right of x (i.e., adding means moving to the right). Yiğit Koyunkaya and Boz-Yaman (2023) found that future teachers relied on procedural knowledge like plugging in values and using memorized rules. Students' symbolic struggles with f, x, and y can also be a source of difficulty when working with composition functions like $y = f(x)$ and $y = f(x + 2)$. Misconceptions often arise when students treat f as just a "shape," x as a general label for points on the x-axis, and y as solely an output rather than a function x (Yim & Lee, 2021).

Both in-service teachers and students tend to rely on tables and graphing applets to notice patterns and the location of graphs. These approaches show what happens to the graphs but do not justify why the changes occur (Yao, 2024; Zazkis et al., 2003). Hence, students make generalized rules from observing patterns but cannot provide a conceptual explanation, so the transformations remain counterintuitive. Zazkis and colleagues (2003) found that many in-service teachers often cite rules like the "law of opposites" where one does the opposite of what you think and that many in-service teachers admit that they feel their explanations are insufficient, but they have never seen or developed for themselves a better explanation.

Theoretical Background

Consistent with the focus of our research questions on future secondary school teachers' content understanding, we detail here our theoretical framing for understanding mathematics and the importance of content knowledge for teachers. We draw on Skemp's (1976, 1978) construct of instrumental and relational understanding. Instrumental understanding is when one knows what needs to be done but does not have any reason or backing for why it is done. Whereas relational understanding considers both knowing what to do and why it is done. Knowing what to do and why to do it is critically important for prospective secondary mathematics teachers.

As our students are future secondary teachers, mathematical knowledge for teaching also plays important roles in our theoretical foundations. Shulman (1986, 1987) provided one of the initial delineations between content knowledge and pedagogical content knowledge. Similar to instrumental and relational understanding, Shulman argued that a "teacher need not only understand that something is so, the teacher must further understand why it is so" (1986, p. 9). Ball and colleagues (2008) elaborated on what they called domains of mathematical knowledge for teaching (subject matter knowledge and pedagogical content knowledge). Koehler and colleagues (2013) describe the technological pedagogical content knowledge framework. Most relevant here is that they view pedagogical content knowledge as the intersection of pedagogical knowledge and content knowledge.

The differences between the previous constructs are often described theoretically. Researchers in Europe have also investigated this empirically. For example, Krauss et al. (2008)

found that the degree of connectedness between pedagogical content knowledge and content knowledge in secondary mathematics teachers is a function of the degree of mathematical expertise. They, along with colleagues Baumert et al. (2010), argue that content knowledge supports the development of pedagogical content knowledge. Put another way, preparation programs for prospective teachers should focus on the importance of building relational (in the sense of Skemp) content knowledge. We align with this conception of content knowledge; that is, it is an important precursor to pedagogical content knowledge. In the next section, we briefly describe our course and the content learning opportunities that prospective secondary mathematics teachers had to expand their content knowledge related to function translation.

Mathematical and Course Background

In the IODSM course students frequently analyze the relationships between the context being modeled, the symbolic form of a differential equation (DE), a slope field, graphs of solution functions, and the general solution. Autonomous DEs play a central role in the course. Autonomous DEs are ones where the rate of change of the dependent variable depends only on the value of the dependent variable itself. Many real-world contexts are modeled well with autonomous DEs. The symbolic form of an autonomous DE is $\mathrm{d}y/\mathrm{d}t = f(y)$. Slope fields for autonomous DEs are horizontally invariant. Graphs of non-equilibrium solution functions to autonomous DEs are horizontal shifts of each other and the general solution manifests this structure. Importantly for this analysis, the general solution to an autonomous DE contains the term $(t + \mathrm{c})$, which parallels the quadratic equation $g(x) = (x + c)^2$. DEs where the rate of change in the dependent quantity only depends explicitly on time have the form $\mathrm{d}y/\mathrm{d}t = f(t)$ and the general solution contains the term "$+ c$", which parallels the quadratic function $h(x) = x^2 + c$.

Many of the relationships noted above occured a third of the way through the course in Unit 3 where students derived the general solution for separable DEs and then explored the relationship between the slope fields for an autonomous DE, a time-dependent DE, graphs of their respective solution functions for a given initial condition, and their respective general solutions. In an embodied cognition (Edwards & Robutti, 2024) inspired activity, students were given slope fields for the DEs $dL/dt = 0.5(1 - L)$ and $dh/dt = -t + 1$ and asked to sketch a solution for a particular initial condition on each slope field, make a copy of each solution graph on patty paper, and demonstrate how they would move the copy of the respective solution graph so that it was the solution for a different initial condition. The task also prompted them to: (1) discuss what feature of the differential equation justifies your approach, (2) find the two respective general solutions; $L(t) = 1 - \mathrm{e}^{-0.5(t+c)}$ and $h(t) = -0.5t^2 + t + c$, and (3) explain how their idea for moving the patty paper solution copy can be understood from the general solution.

This IODSM content laid the groundwork for the in-class end-of-unit section with heading "Translations: Connections to Secondary Mathematics." In this section, which took approximately 30 out of the 75 minutes of class time, students were first asked to explain why the graph of $f(x) = x^2 + 5$ is a vertical shift up five units of the graph of $g(x) = x^2$. Similarly, they were asked to explain why the graph of $f(x) = (x+3)^2$ is a horizontal shift three units to the left of the graph of $g(x) = x^2$. After developing their own why explanations, they were prompted to complete the following sentence to further justify the vertical shift: "For every input x, the output $f(x)$ is…" and for the horizontal shift they were prompted to finish the sentence "In order for every output of $f(x)$ to be the same as the output of $g(x)$, the input…".

As was the norm, student ideas and explanations on these tasks were the substance of robust classroom discussion and sharing of ideas. It was also the norm that after each class, students submitted, via their course learning management system, a response to the following end-of-class

reflection: "Who, either in small group or whole class discussion, said something that influenced your thinking and what did they say? Please provide a little bit of detail."

Methods

The IODSM course was implemented at two different universities; one large Hispanic-serving public institution in the Western United States (US) and one mid-sized predominantly white public university in the Southern US. The class sizes were 31 and 7 students, respectively.

The data for the first research question were students' end-of-class reflections from the day they completed the "Translations: Connections to Secondary Mathematics" section of the materials, as previously discussed. There were two sources of data to answer our second research question. The first was an ungraded beginning of semester assessment where students were given functions $f(x) = x^2$, $g(x) = x^2 + 3$, and $h(x) = (x+4)^2$, and asked to state how the graphs of f and g are related and why, and how the graphs of f and h are related and why. Note here that the questions themselves did not explicitly mention anything about shifting functions. The second data source was a question on the midterm exam that asked students to explain why the graph $f(x) = (x+4)^2$ is a shift of 4 units to the left of the graph $g(x) = x^2$.

All data were organized in a spreadsheet. Each row contained separate columns to identify each student, their responses to all data sources, and our coding. For each data source, subgroups of authors did initial coding which was then brought to the full research team for vetting and discussion until 100% agreement was reached. Following our initial coding, we engaged in thematic analysis (Braun & Clarke, 2006) to analyze all data sources.

Results

To answer our first research question, we analyzed the 33 submitted end-of-class reflections. 10 students reflected on a part of class that focused on something other than horizontal shifts and hence here we focus only on the 23 reflections that addressed horizontal shifts. The fact that 23 of the 33 students (70%) chose to write about horizontal shifts is an indicator of how impactful this class was for them regarding this particular concept. While the assignment asked students to discuss who influenced their thinking and what they said, 14 of these 23 students went further and explicitly mentioned a significant enrichment in or change in their understanding of why there is a horizontal shift in what for many is an unexpected direction. For example, Onyx (all names are pseudonyms) said,

> In all honesty, I had no idea how to answer that question when it was asked on the survey we took at the beginning of the semester. As mentioned in class, it was just a rule that we had learned and then implemented from then on out. Even in our individual groups, I was having a hard time coming up with an explanation for why this happened. So, when that group said to think about it as the transformed function being "ahead" of the other and needing to have its input "reduced" by 3 in order for the output to be the same, I felt like I actually understood for the first time what it was that that transformation did.

Similarly, Alina said, "Overall, I found this discussion of horizontal shifts to be very engaging because it's a rule that most people know by heart, but we're rarely taught *why* a horizontal shift $g(x + h)$ is a shift to the left" [emphasis in the original]. Heidi, like Onyx and Alina, reflected on the change in her understanding but went even further and commented on the relevance of this new understanding for her future teaching.

> I have known this shortcut since I was taught it many years ago but never fully understood its explanation. His discussion … made me reflect on how the shifting works and a better way to explain it to my future students.

Heidi's reflection is consistent with the assertion that content knowledge supports the development of pedagogical content knowledge (Baumert et al., 2010).

We next report on insights from the 23 students into *why* the graph f, where $f(x) = (x + 3)^2$, is a horizontal shift three units to the left of the graph of g, where $g(x) = x^2$. By far the most frequent insight taken from the class activity was that the same output for the graphs of f and g occurs or corresponds to when the input is "compensated." In other words, maintaining the same output necessitates that the input be altered in some way. 15 of the 23 student reflections included some form of the insight that the same output corresponds to a compensated input. We see this as a shift in perspective on the function machine metaphor. Typically, the function machine metaphor starts with an input and then examines the corresponding output. In accounting for the horizontal shift, it can be more insightful to focus on the output first and then backtrack to see what inputs led to the same output. Jude explicitly called out this shift in perspective in his end of class reflection, using a different pair of functions.

> When we were discussing about how to explain why the graph of $(x – 3)^2$ is shifted to the right 3 units, someone mentioned how instead of focusing on the input, we focus on the output. This made me realize how this particular graph will behave 3 units earlier than the parent function x^2, and thus will be shifted to the right by 3 units. This perspective of focusing on the output was something that I had not even considered, and I found very interesting.

In addition to calling out this shift in output first perspective, Jude uses the term "earlier." The term "earlier" relates to a race analogy discussed in class. Of the 15 that discussed the insight that the same output corresponds to a compensated input, 11 of these students also mentioned the race analogy. Skye's reflection captures nicely the various ways that the race analogy was discussed by her peers.

> While [my] group discussed how $f(x) = (x + 3)^2$ was a shift to the left, we had a few different ideas that emerged, and it was starting to click with me, but not fully. It wasn't until Glen explained to the class how their group used $g(x) = x^2$ to describe that $f(x) = g(x + 3)$ and seeing it in this notation really helped me fully comprehend it. In class we used words such as "ahead", "earlier", "behind" and "later" to describe these transformations. This vocabulary doesn't help everyone understand it, but it really helped me understand the transformations that are happening. I like the phrase that $f(x)$ as being 3 units "ahead" of $g(x)$, and it would need 3 units in order to catch up to $g(x)$. This can also be seen in the notation that $f(x – 3) = g(x)$ which helps me really see that it would be a shift 3 units to the left.

In addition to the race analogy, Skye's end of class reflection brings in composition notation, $f(x) = g(x + 3)$ and $f(x – 3) = g(x)$. The composition notation provides a generalized symbolic way to say that the outputs of f are the same as the outputs of g when the inputs are compensated or altered. Three students included composition as part of their reflection.

Lastly, 3 of the 23 students focused on the different location of the vertex to account for why the graph of f is a shift of 3 units to the left of the graph of g. For example, Lina's reflection, which also highlights the race analogy, foregrounds Skye's focus on the location of the vertex for the two parabolas.

> Glen had a good explanation of the shifted function being "ahead" three units in comparison to the original function, and I thought that was helpful. But the idea that really gave me a better understanding was Jamie's idea of setting $x + 3$ (vertex) = 0.

> Being that $x = -3$, that is sufficient enough to display why it's not shifting RIGHT three units.

A focus on the vertex *implicitly* centers an output first approach because for both f and g, their respective vertexes have an output value of 0. In Lina's reflection, it is implicit that the output values for both f and g need to be zero as this is the likely logical reason Skye set $x + 3 = 0$ because when $(x + 3)$ is zero, so is the output of f.

To answer our second research question we compared student responses on the beginning of semester assessment to a similar question on the midterm, which asked students to explain why the graph $f(x) = (x + 4)^2$ is a shift of 4 units to the left compared to the graph $g(x) = x^2$. In short, there was a significant improvement in students' ability to explain *why* the horizontal shifting relationship exists. On the beginning of semester assessment, 20 of the 39 students identified the correct horizontal shift, but of these 20, only 4 provided an explanation that went beyond a focus on a single point with no other supporting explanation. That is, most students started the semester knowing *that* the horizontal shifting relationship was true, but very few could explain *why*.

In contrast, 30 of the 39 students provided a meaningful explanation for why the horizontal shift exists. The remaining nine students either had a rule-based, incomplete, or incoherent explanation. We developed two themes to characterize students' meaningful explanations. One we refer to as an Explicit Output First approach and the other we refer to as an Implicit Output First approach. We alluded to both of these themes in answering our first research question. Next we provide operational definitions for each theme and give illustrative examples.

The Explicit Output First approach, which characterizes 21 of the 30 explanations, begins the explanation with a focus on the outputs (which Jude noted was a new perspective in his end of class reflection) and then shifts to explain how the inputs need to be compensated so that the outputs are the same. For example, Darrin's explanation began by comparing the outputs via a composition formulation. More specifically he said, "We can think of $f(x) = (x + 4)^2$ as $g(x + 4)$, where $g(x + 4) = (x + 4)^2$." This statement uses composition to make explicit the condition when the output of f is the same as the output of g. Darrin then continued to explain how the inputs need to be compensated so that the outputs are the same. Specifically, he said,

> When we look like this, in order to get $g(0)$ or any original $g(x)$ values, we will need to subtract 4 from x to compensate for the added 4. In this sense, we 'shift' $f(x)$ left 4 to compensate for the added 4 to the x (when compared to $g(x)$).

A total of nine students had similar composition followed by input compensation arguments. Two of these nine also included the race analogy.

For the other students whose explanations we characterized as an Explicit Output First approach, four began their explanation with a table of values followed by input compensation and five students began their explanation with a verbal description of the same output followed by input compensation. For example, Ann said, "In order for $f(x)$ to obtain the same output value of $g(x)$, your input value for $f(x)$ has to be …". The three remaining students whose explanations fell under the Explicit Output First approach had a more proof-like explanation, with one of these including the race analogy. Space constraints prohibit us from providing examples that made use of a table or a proof-like explanation. We do note, however, that all of these explanations spoke to the generality of the relationship as opposed to focusing on a single point, such as the vertex, as the sole justification for why there is a horizontal shift in a particular direction.

We characterized the remaining nine students that provided meaningful explanations as employing an Implicit Output First approach. The main difference between the two

characterizations is that in the latter explanations, students began their explanation with a focus on how the inputs need to be compensated to achieve the same outputs but the reason for doing so was so that the outputs would be the same. For example, Damien explained that the graph of f is a 4 unit shift to the left of the graph of g

> because 4 units more are needed from $f(x)$ to reach $g(x)$, meaning that it is constantly behind. Rewriting this with x in mind, shows this => $x = \sqrt{(g(x))}$, $x = \sqrt{(f(x))} - 4$. Here we see that focusing on the input rather than the output (x rather than y), the shift is negative, or to the left.

Damien alludes to the fact that f and g have the same values ("$f(x)$ to reach $g(x)$") but maintains a focus on the relationship between the inputs.

Another common meaningful explanation that we characterized as an Implicit Output First approach started with a general statement about how the inputs are related and then shifted to a specific example, typically the vertex. For example, Rhea gave the following explanation:

> The graph of $f(x) = (x + 4)^2$ is a shift 4 units to the left of $g(x) = x^2$ because the function of $f(x)$ is changing an input, rather than an output. So, say we want both of the graphs to equal 0. We see that our graph of $f(x)$ would get there 4 units earlier that our parent function when put side by side [sketches graphs of f and g with the respective vertexes circled]. Differently, our vertical translations such as $h(x) = x^2$ and $b(x) = x^2 + 3$, vertical translations affect our output, rather than our input.

Rhea's explanation begins with a focus on the inputs and then shifts to the conditions necessary for an example output to the same, using the vertex as an example. The phrasing "say we want" suggests that Rhea is using the vertex as a more generic example of the same output. This move to a more generic example stands in contrast to the explanations on the beginning of semester assessment that much more strongly used the empirical evidence of a single point, the vertex, as sufficient explanation for why the two graphs have the claimed horizontal relationship.

Conclusion

In this report we provided insights into what aspects of class discussion students found influential on their understanding of horizontal translations and the corresponding growth in their relational understanding, as evidenced by their meaningful explanations for why graphs are related in the way that they are. Our findings move beyond the many descriptions in the literature that focus on misconceptions and difficulties and instead highlight two asset-oriented themes characterizing their reasoning, both of which focus on the relationships between outputs and inputs, with a focus on the outputs first, which was largely a new perspective for students.

The next steps in our analysis are to analyze the classroom video recordings that we collected as part of our DBR as well as additional student responses to related homework problems. This will include analysis of participation patterns that might be correlated with growth of individual student reasoning. We are particularly interested in exploring how students' growth in relational understanding of secondary school content is related to their meta learning about what constitutes a meaningful explanation. This line of inquiry has both theoretical and practical implications. Lastly, we are currently making revisions to the curriculum based on this analysis and will implement these revisions in our next DBR iterations.

Approximation, Riemann Sums, and Coordination Class Theory

Andrew Izsák
Tufts University

Emmanuel Daring
Tufts University

Olha Sus
Tufts University

Researchers have recognized Adding Up Pieces (e.g., Jones, 2013) to be a critical interpretation when applying definite integrals to problems in physics and other domains. At the same time, researchers have not investigated as closely students' moment-to-moment reasoning when constructing pieces of an approximation and how that reasoning might vary across situations. We interviewed 11 students enrolled in calculus-based physics courses using tasks that asked for approximations, not definite integrals. Individual students approached approximations in more than one way—depending on the problem situation and how it was presented—and they did not always make connections among their different approaches. Based on this observation, we conjecture that approximation in service of Riemann sums is a good candidate for a coordination class (e.g., diSessa, 2002; diSessa & Wagner, 2005). We summarize the theory, present the case of one student, and draw out implications for research and instruction.

Keywords: Approximation, Riemann Sums, Coordination Class Theory

A growing body of research has reported on students' interpretation and construction of integrals, especially when solving problems in physics and other contexts outside of pure mathematics (e.g., Cui et al., 2006; Jones & Ely, 2023; Nguyen & Rebello, 2011; Oehrtman & Simmons, 2023; Thompson, 1994a, Von Korff & Rebello, 2012). One key area of interest has been whether and, if so, how students connect definite integrals with adding up small amounts of a target quantity (Ely, 2017; Jones, 2013, 2015). At the same time, research has not investigated in detail students' moment-to-moment reasoning when constructing pieces that contribute to an approximated target quantity. We report on results emerging from an on-going study that examines how undergraduate students enrolled in calculus-based physics courses respond to tasks that ask for approximations, not definite integrals. Individual students approached approximation in different ways from one task to the next, leading us to conjecture that Riemann sum approximation is a good candidate for a coordination class (e.g., diSessa, 2002; diSessa & Wagner, 2005).

In the sections that follow, we review key strands of research on students' reasoning when applying definite integrals to solve problems, primarily from physics. We follow with a brief description of Coordination Class theory. Then we present our research questions and summarize our methods. Finally, we present the case of one student, Daner, as an exemplar of empirical phenomena we observed across participants.

Literature Review

Applying definite integrals to physical situations requires reasoning in terms of quantities such as lengths, time, work, electric charge, etc. Past research has provided a variety of perspectives on such reasoning, much of it grounded in Thompson's account of quantitative reasoning (e.g., Thompson, 1994b, 2011). In one line of such work, Jones (2013, 2015) has identified several ways in which college students can interpret the $\int_a^b f(x)\,dx$ notation. One of these, the Adding up Pieces interpretation, consists of (a) partitioning a physical situation into small pieces, (b) approximating the target quantity within each partition piece, and (c) summing the small amounts of target quantity across all partition pieces to approximate the total amount.

The Adding Up Pieces interpretation is particularly useful when applying definite integrals to physics and other domains (e.g., Stevens & Jones, 2023; Oehrtman & Simmons, 2023).

In further work, researchers have identified reasoning about local relationships as a key challenge for many students (e.g., Ely, 2017; Jones et al., 2017; Oehrtman & Simmons, 2023; Sealey, 2014; Thompson & Harel, 2021). As one example, Oehrtman and Simmons (2023) proposed *Emergent Quantitative Models* as a tool for tracing how students' attention shifts across three scales when constructing definite integrals. They named these scales the Basic, Local, and Global models. A Basic model relates quantities with constant values, a local model restricts a basic model to small regions where varying quantities are approximately constant, and a Global model is an accumulation based on local models. Oehrtman and Simmons highlighted the interaction and co-evolution of the three scales.

Past research has established *that* students can have trouble reasoning with local approximations but has stopped short of examining *how* students reason in contexts that afford constructing approximations in ways compatible with Riemann sums. We take this next step.

Theoretical Framework

Coordination Class theory (e.g., diSessa, 2002; diSessa & Sherin, 1998; diSessa & Wagner, 2005) provides an account of certain concepts within the knowledge-in-pieces epistemological perspective (e.g., diSessa, 1993, 2006). diSessa (2002) motivated the notion of coordination classes with the following description of expert accomplishment: "The fundamental assumption behind the idea of coordination classes is that information is not transparently available in the world. Instead, we have to learn how to access different kinds. Indeed, in different circumstances, we may need to use very different means to determine the same kind of information" (p. 43). This description implies that (a) a collection of knowledge resources supports "seeing" the same concept-specific information across situations, a phenomenon referred to as *span*, and (b) different subsets of concept-related resources might be needed in different situations, a phenomenon referred to as *concept projections* (diSessa & Wagner, 2005; Wagner, 2010). Researchers have begun applying coordination class theory to gain insight into students' reasoning about several topics in mathematics and science (e.g., Izsák et al., 2021; Levin, 2018; Parnafes, 2007; Wagner, 2006), but not to approximations or Riemann sums.

We sketch how Riemann sum approximations could be interpreted in terms of Coordination Class theory. First, we acknowledge that researchers have taken different positions on whether one can always interpret the integrand, $f(x)$, as a rate in a definite integral, $\int_a^b f(x)\,dx$. If one does interpret $f(x)$ as a rate, then proficient reasoning about Riemann sums involves approximating $f(x)$ using locally constant rates over small changes in x. Furthermore, if one interprets areas of rectangles as products of constant rates and small changes in x, then such areas can serve as generic representations of small pieces that can be accumulated to approximate target quantities. Students might use such reasoning to approximate a target quantity in one context but then use quite different reasoning when approximating target quantities in other contexts. Employing different reasoning to construct approximations across contexts is consistent with using different concept projections. Furthermore, seeing that quantities across situations can be interpreted as rates need *not* be transparently available. As an example, students might have experience thinking of locally constant speeds when estimating distance travelled in a straight line over an interval of time, but not see density as a locally constant property that can be used in a similar way to estimate mass. Constructing parallel reasoning across situations is an example of increasing span.

Research Questions

1. What knowledge resources do students engage when constructing approximations of target quantities across problem situations?
2. To what extent are students' approaches to constructing approximations compatible with Riemann sum?

Methods

We recruited 11 students from second semester, calculus-based physics (Five in Fall 2024, six in Spring, 2025) at a selective university in the northeast United States. Each student participated in a series of three, semi-structured interviews (e.g., Bernard, 1994; Ginsburg, 1997) and was paid $50 per interview. The interviews lasted 60 to 70 minutes each and were spaced a few weeks apart. Students worked on tasks that afforded opportunities to construct approximations through addition of pieces, consistent with constructing Riemann sums. We began with approximation in contexts familiar to students (e.g., length • width = area, speed • time = distance) and then moved to approximation in contexts we conjectured would be less familiar (e.g., density • volume = mass, pressure • area = force). These choices were deliberate: We wanted to see whether and, if so, how students would draw on prior experiences constructing approximations in what, for them, would be novel contexts. We omitted formulae that related quantities, because they could short cut students' reasoning about multiplication when forming pieces of target quantities. In addition to text, several of the tasks included diagrams or graphs. Students worked on two or three tasks per interview, pacing that allowed for multiple follow-up questions to explore their reasoning in detail.

We recorded the interviews using two cameras, one to capture the student and interviewer and one to capture close ups of students' written work. After each interview, we collected all written work, combined the two video recordings into a single file, and transcribed verbatim. We analyzed each interview individually and met weekly to discuss our observations. We used students' utterances, inscriptions, and hand gestures to infer the knowledge resources they relied on moment-to-moment for each task. After group discussion we often rewatched videos to refine our analyses. We constructed accounts of reasoning for each task and looked for similarities and differences in the knowledge resources and approaches to approximation students used across tasks.

Results

Our top-level result is that all students approached approximation in different ways as they moved from one problem situation to another, and we conjecture that students' reasoning about approximation may be well captured using constructs from Coordination Class theory, as discussed above. Given space constraints, we have room to present key features of one case. Daner (a pseudonym) self-reported receiving a 4 on the AP Calculus BC exam, was enrolled in second-semester calculus-based physics (Spring 2025), and was majoring in mechanical engineering. The second author led all three interviews with Daner.

Interview 1: Multiple Concept Projections When Constructing Local Approximations

During the first interview, Daner demonstrated different approaches to approximating area from lengths and widths, distance from speeds and times, and mass from densities and volumes. The Lawn task asked students to approximate the area of a lawn whose boundaries were presented through a diagram that showed two perpendicular line segments and a third, curved line. Daner immediately recognized the relevance of an integral but was stuck initially without

"the equation of the line." He then partitioned the lawn into two regions, a parabola and a rectangle (Figure 1a). Here, his sense of approximation relied on guessing an algebraic expression for the parabola, choosing five as an upper bound for the definite integral, and treating the second region as a rectangle. He then wrote $\int_0^5(-x^2-3)dx$ for the area under the parabola (Figure 1b). When asked to explain the meaning of dx, he described a second method for approximating area more compatible with a Riemann sum:

> Like this is the process that does it, uses the equation of the parabola that is given, takes the height, multiplies by *dx* and it's like a small rectangle, multiplies by *dx*, and does it infinitely many times until five….The integral, what it does, it adds it up together.

When asked to illustrate his explanation, Daner drew a generic "small rectangle" (Figure 1b). Thus, he demonstrated two approaches to approximating the area of the lawn, and only the second was well-aligned with Adding Up Pieces and constructing a Riemann sum.

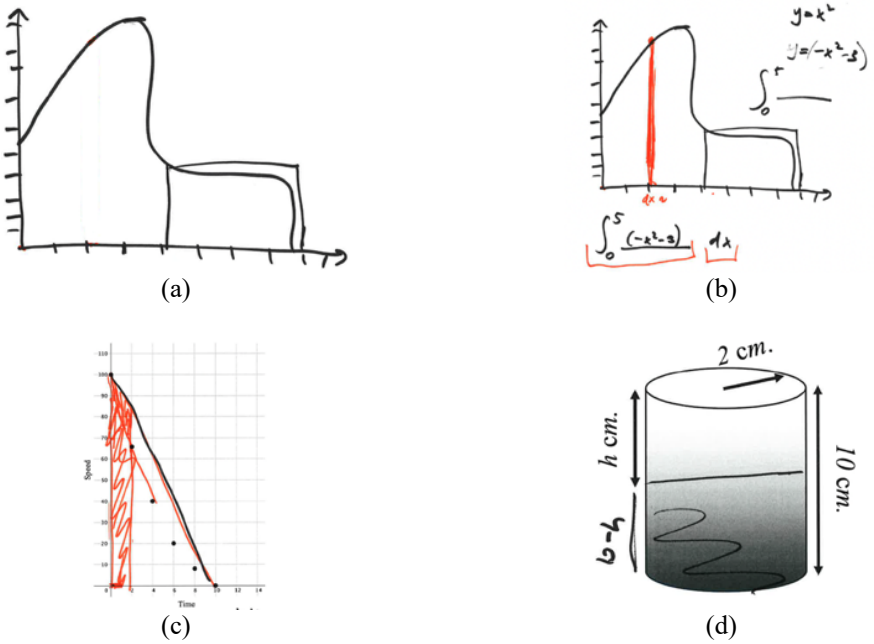

Figure 1. Daner approximates (a) Area using a parabola and rectangle, (b) Area using small rectangles only, (c) Distance using trapezoids, (d) Mass using basic models.

The Car task presented the speed of a car every 2 seconds as it slowed to a stop. The data were presented in a table with columns labeled "Time" in seconds and "Speed" in feet per second. Similar to the Lawn task, Daner commented that he did not have an equation with which to work. When he tried to recall an equation, he multiplied speed not by time, but by distance. At this point, the interviewer introduced the same data presented as discrete points on a graph whose axes were labeled "Speed" and "Time." Daner stated that "the distance is the area under the curve" and explained how to estimate using averages for each 2-second interval:

> I would find like, the velocity, the mean, like the mean velocity between the first one and the second one, and do the same like here, here, here, here, and multiply it by 2 seconds, and add them together.

Daner then used the given data to compute two examples of average speed correctly, (100 + 66) ÷ 2 = 83 and (66 + 40) ÷ 2 = 53. He multiplied both results by the duration of 2 seconds but, at first, said he could not "visualize" the corresponding 166 and 106 values on the graph. Then he changed his mind, drew a curve that connected the graphed points, and said that 166 would be

the area "under this curve from 0 to 2." Daner then clarified that 166 would not be exact, drew a straight line connecting the points (0, 100) and (10, 0), shaded the resulting trapezoidal region for the interval from 0 to 2 seconds (Figure 1c), and stated that 166 would be exact if the deceleration was linear.

From the data, we could not tell why Daner switched his focus from lengths and widths of rectangles on the Lawn task to average speeds and trapezoids on the Car task. Several interviewed students expressed a preference for midpoint Riemann sums over lefthand or righthand Riemann sums because they are often more accurate. The associated calculations can be associated either with areas of trapezoids or with areas of rectangles. The important point is that Daner maintained a focus on Adding Up Pieces but used different knowledge resources in each task, ones related to areas of rectangles versus ones related to averages and trapezoids.

The Sand task presented a cylinder containing sand suspended in water. The cylinder had a height of 10 cm and a radius of 2 cm. The density of sand in water was given by $\rho(h) = \sqrt{h}$, where h measured distance from the top surface. A diagram showed the cylinder with graduated shading to reinforce that the density of the sand varied continuously from the top to the bottom of the cylinder (Figure 1d). Daner recalled the formula "density is mass over volume" and the formula for the volume of a cylinder. At the same time, he interpreted the $\rho(h) = \sqrt{h}$ function to give a single value of density that applied to the top h cm of the cylinder. He then considered whether the sand would be in the top region with a height of h or in the bottom region with a height of $10 - h$. He wrote two expressions for mass based on basic models, one for each case: $m = \rho \bullet 4\pi h$ and $m = \sqrt{10 - h} \bullet 4\pi(10 - h)$. Daner explained the meaning of density using qualitative comparisons, "if there's a lot of density, that means that there's a lot of mass in a more compact volume." He then relied on this meaning to explain:

> In this case, if we're looking at sand, the lower part is more dense than the upper part, because there's less sand in it for the same amount of volume compared to the other one where there's more sand for a specific volume.

Finally, when asked if he interpreted $\rho(h)$ as the density for the entire top h cm or just for a thin slice of the cylinder, Daner reported, "I would think of it, yes, from the top to the bottom of h, not in terms of layers."

Daner's approach to the Sand task both resembled and differed from his approach to the Lawn and Car tasks. Parallels included both a correctly stated relationship among mass, density, and volume that paralleled a correct relationship among distance, speed, and time and a description of density in terms relevant for conceiving a unit rate—an amount of sand "for a specific volume." At the same time, he gave no evidence of constructing small pieces of a target quantity. It is plausible that his interpretation of $\rho(h)$ as a fixed value for a cylinder of height h obstructed his attention to small pieces of mass. We conclude that Daner drew on different sets of resources across the Lawn, Car, and Sand tasks tasks and that features of task presentation (e.g., diagrams, graphs, explicit variables) shaped which resources Daner employed. Such data are consistent with concept projections of resources relevant to approximating small pieces of a target quantity in some situations but not others.

Interview 2: Coordinating Knowledge Resources Toward Increasing Span

The second interview began with the Rod task, a task similar to the Sand task that involved approximating mass given a varying density. The rod was a horizontal cylinder of length L, radius R, and density $\lambda(X) = X^2 + 4$, where X was the distance from the left-hand end. The first version of the task used uniform gray shading on the cylinder, the second version used gradated

shading to help communicate that density increased continuously from left to right (Figure 2a). Daner reused knowledge resources evident in his reasoning on the Car and Sand tasks: He interpreted density, $\lambda\,(X)$, first to be a single value for a cylinder of length X and then reasoned about midpoints and averages.

(a) (b)

Figure 2. Daner approximates mass (a) Partitioning the rod into fourths, (b) Using a graph.

Daner began by recalling density equals "mass over volume" and the formula for volume of a cylinder. Once again, he treated density as a single, fixed value and used a basic model to multiply density and volume for the entire rod: $M = (L^2 + 4) \bullet \pi R^2 \bullet L$. At this point, the interviewer sought to help Daner perceive density as varying. He began by presenting a second image of the cylinder in which gradated shading reinforced density increasing from left to right. Daner stated that the new diagram did not change his interpretation of density as a single value: "It just doesn't make any sense why the density would increase if it goes to the right."

When the interviewer asked to view density as varying anyway, Daner partitioned the rod into fourths (Figure 2a) and explained that he would "subtract the distances from each other and plug it into L again." He subtracted $\frac{3L}{4} - \frac{2L}{4}$ and generated: $M = (\frac{L}{4} \bullet \pi R^2) \bullet ((\frac{L}{4})^2 + 4)$. Thus, he interpreted $\frac{L}{4}$ as a new length and reasoned in ways that paralleled his work on the Sand task and his initial work on the current task. When the interviewer asked about the mass of the segment between $\frac{L}{4}$ and $\frac{2L}{4}$, Daner saw that his work implied that the mass of two regions would be the same while the actual masses should differ. At this point, he was stuck: "The answers are going to be the same for mass. So I don't really, I don't really know how to find the different masses."

Realizing that he needed a new approach, Daner turned his attention to the graph of $\lambda\,(X) = X^2 + 4$. He partitioned the horizontal axes from zero to L into six pieces, considered the interval between $\frac{2L}{6}$ and $\frac{4L}{6}$, and asked how "to find a like density between two lines" (Figure 2b). After considering and rejecting using differences in densities at two points, he returned to notions of midpoints and averages. First, he used the example $\lambda\,(X) = 2X$ to explain that using a midpoint would work for a density that increased linearly: "Like if it was a linear, because it goes linearly the average density would also, like it would be just the half of, the half value." This reasoning resembled his reasoning about average speed in the Car task. Then he computed midpoints *for distances* and generated expressions for mass in the third region from the left, $M = (\pi R^2 \bullet \frac{L}{4}) \bullet ((\frac{5L}{8})^2 + 4)$, and in the second region from the left, $M = (\pi R^2 \bullet \frac{L}{4}) \bullet ((\frac{3L}{8})^2 + 4)$. Notice that these expressions could contribute to a normatively correct midpoint Riemann sum approximation. Daner did *not* draw anything that looked like rectangles or trapezoids that approximated area under a curve.

At this point, the interviewer asked Daner to identify similarities or differences across the Lawn, Car, Sand, and Rod tasks. Not surprisingly, Daner saw similarities between the Sand and

Rods tasks and found the Lawn task to be less similar to the other three tasks. Daner said that the Car and Rod tasks were similar but, an exchange later, said they were not similar. When the interviewer asked about these two points of view, Daner described in more detail parallels that he saw. First, he compared interpretations of area under the graph in the Car task (Figure 1c) and in the Rod task (Figure 2b). He knew the former represented distance and after a 75-second pause discussed whether the latter could represent mass:

> It has to be density multiplied by length. Because [in the Car task] this region is speed multiplied by time, which gives us distance. And so this region is distance. Whereas [in the Rod task] it also has to be density multiplied by length. But I was thinking like why would you multiply length with density, like what would that ever give? But then I just understood that that's basically, that's basically the volume. Like multiplying by length can be the same as multiplying by volume for a shape. So that will give you mass.

On the one hand, Daner drew sensible parallels where units on axes (speed and time, density and length) determined units represented by areas under curves. On the other hand, he knew that in the Rod task "it has to give you basically mass." He then included πR^2 on the horizontal axes:

> So you can just give pi r squared to L, multiply L by pi r squared, which will give you volume. And when you multiply volume by density, it gives you mass.

Although Daner articulated normatively correct coordination of density, volume, and mass represented as area, he had trouble maintaining that coordination when he wrote: $\lambda\,(X) = (\pi R^2 L)^2 + 4$. In response to further questions, Daner explained that the Lawn, Car, Sand, and Rod tasks were all similar based on the solution process: "what you do basically at the end of each task is you find the area underneath of the, of any like equation that you get." At the same time, when he stated that "density is not similar to speed here at all" we could see that the parallels he perceived between constructing approximate distances in the Car task and approximate mass in the Rod task were incomplete. Thus, he made partial progress towards increased span.

Discussion

In the Background section, we organized past research on definite integrals into two strands, one that has identified different interpretations of integrals and one that has delineated layers of attention (e.g., Basic, Local, and Global models). Our tasks combined with semi-structured interview methods allowed us to investigate in more detail how students construct approximations moment-to-moment within and across problem situations. We presented Daner's case as an exemplar of our overall finding that the students we interviewed often approached approximation in different ways as they moved from one problem situation to next. This suggests that constructing parallel reasoning across situations that include speed, density, and other quantities is not straightforward and involves developing disciplinary perspectives on what counts as a rate—for instance, the independent variable does not always have to be time.

Compared to past research, our results suggest that more precise theory is necessary if we are to account for students' reasoning about definite integrals in ways that can ultimately inform instruction. Tools from Coordination Class theory have helped us describe with some precision the complexity of constructing approximations across situations in ways compatible with Riemann sums. In this regard, we build on Wagner (2016), who took a first step in this direction when arguing that students' various interpretations of definite integrals could be understood as different concept projections. As noted by diSessa (2002), relevant information is not always transparently available, and students may need different means to construct approximations when assembling target quantities and solving problems in areas outside of pure mathematics.

Intersections of Active Learning and Instructor Care: Undergraduate Women's Perspectives on Their Instructor's Role in Supporting Their Sense of Belonging in Calculus

Casey Griffin
University of La Verne

One's sense of belonging, or their sense of feeling like an accepted member of an academic community, has been identified as a major contributor to women's decisions to stick with or leave their STEM major. Prior work has examined ways in which pedagogical practices such as providing opportunities for students to engage in active learning in undergraduate courses might influence women's sense of belonging in STEM. However, the focus had been on students' perceptions of the practices themselves rather than the person enacting those practices – the instructor. With this study, I explore ways in which women describe the role their instructor plays in supporting their sense of belonging in an active learning Calculus course. Women's survey responses suggest several ways in which their instructor supported their sense of belonging by portraying care both through their enactment of active learning as well as other pedagogical and personal attributes.

Keywords: calculus, gender, instructor care, sense of belonging

Fewer women than men choose to major in STEM early in their college education (Bressoud, 2023; Eagan et al., 2016), and women leave STEM majors at higher rates than men (Chen, 2013; Seymour & Hunter, 2019). Calculus is a common exit point for all STEM students, but especially for women (Ellis et al., 2016; Rasmussen et al., 2019; Seymour & Hunter, 2019). Their reasons for leaving are not for lack of interest or ability, but rather women, especially those who leave, report feeling a low sense of belonging in STEM (Seymour & Hunter, 2019; Shapiro & Sax, 2011). Prior work has examined ways in which engaging in active learning can support women's sense of belonging in Calculus (Griffin, 2023, 2025). The current study aims to investigate women's perspectives on the role their instructor, rather than the pedagogical practices, plays in supporting their sense of belonging in an active learning Calculus course.

Literature Review & Theoretical Framing

Feeling a sense of belonging has been equated with feeling accepted and valued within a particular environment as opposed to isolated or excluded. Good et al. (2012) studied students' sense of belonging to an academic domain, which they define as "one's personal belief that one is an accepted member of an academic community whose presence and contributions are valued" (p. 701). This definition of sense of belonging (SB) is most relevant to the current study. Feeling a SB has been linked with persistence in STEM (Seymour & Hunter, 2019; Shapiro & Sax, 2011), however women are less likely than men to develop a strong SB (Good et al., 2012; Rainey et al., 2018; Seymour & Hunter, 2019; Shapiro & Sax, 2011).

One major factor that can influence one's SB in an academic domain is the classroom learning environment. The learning environment consists of several features, including (but not limited to) the physical space, the ambience or climate, and learning opportunities (Evans et al., 2009). Researchers have identified links between the types of learning opportunities instructors provide, the ways in which instructors portray care, and students' SB (Fraser, 1998; Griffin, 2021; Lahdenperä & Nieminen, 2020; Rainey et al., 2019).

Active Learning

The pedagogical contexts of the learning environment, such as the learning opportunities the instructor provides during class, have been shown to influence students' engagement and persistence in STEM. Over the last few decades, there have been efforts to reconsider traditional modes of undergraduate STEM instruction to work toward improving student engagement, performance, and retention (Chickering & Gamson, 1987; Freeman et al., 2014; Mesa et al., 2015; PCAST, 2012), specifically by providing opportunities for students to engage in active learning (i.e., during which students have the opportunity to do or talk about mathematics during class rather than passively listening and taking notes while the instructor lectures).

Some research has indicated that engaging in active learning can support students', especially women's, SB, engagement, performance, and retention (Griffin, 2025; Aji & Khan, 2019; Freeman et al., 2014; Fuchs & Sahmbi, 2024; Lahdenperä et al., 2019; PCAST, 2012; Rasmussen et al., 2019; Theobold et al., 2020). However, the benefits of active learning may depend on its enactment (Deslauriers et al., 2019; Johnson et al., 2020). Johnson et al. (2020) found that the instructors in an active learning class posed conceptual questions to women at lower rates than men and highlighted women's contributions less frequently than men's contributions, which they suggest may have contributed to men outperforming women in the course. Meanwhile, participants in Rainey et al.'s (2019) study reported feeling more cared for by their instructor in an active learning environment. And as previously reported in Griffin (2025), women found that interactive learning opportunities like group work supported their feelings of belonging. Therefore, given its potential to influence women's experiences, active learning classrooms provide a rich context in which to explore women's SB.

Instructor Care

The notion of caring has been equated with concepts such as compassion, empathy, and helping (Eisenberg, 1992; Ferreira & Bosworth, 2000; McCroskey, 1992). Care is relational, meaning there is always someone who is doing the caring and someone who is being cared for (Noddings, 1984, 1992). Thus, when considering instructor care, it is necessary to identify ways that students perceive care from their instructors; otherwise, the caring relation (Noddings, 2005) is not complete. Straits (2007) noted that there are elements of instructor care that are learning-centered (i.e., emphasizing content mastery and higher-order thinking) and learner-centered (i.e., emphasizing mutually trusting and respectful relationships). Researchers have identified several ways that students perceive that their instructors care about them and their learning, including learning-centered portrayals of care like involving students in lessons, checking for comprehension, providing help to students, being available to students; as well as learner-centered portrayals of care like establishing a safe and encouraging learning environment, showing a personal interest in students, and reflecting a kind disposition through actions, recognizing students' learning differences, and preparing lessons and enacting them with enthusiasm (Bandura & Lyons, 2012; Garza, 2009; Straits, 2007).

Scholars have identified links between students' perceptions of instructor care and their SB (Cheng, 2004; Rainey et al., 2019). Cheng (2004) studied factors that influence undergraduate students' sense of campus belonging and found that students' feelings of being cared for contributed directly to their SB. Further, Rainey et al. (2019) found that students who felt they belonged in STEM were more likely to report their instructors cared about them than students who did not feel like they belonged in STEM. Thus, demonstrating care to students might be a way instructors could support their students' SB.

Purpose & Methods

Prior work (Griffin, 2023, 2025) has shown that women in this study found engaging in active learning to be supportive of their SB. However, as discussed in Johnson et al. (2020), active learning can have a negative impact on students' experiences depending on its enactment. The purpose of the current study is to explore women's perspectives about the role their instructor played in supporting their SB in their active learning Calculus class, thus placing more emphasis on the instructors than on the active learning practices they employed. For this study, I focus on women's experiences without comparing them to men's experiences because women's experiences are worthy of study in their own right (Du Bois, 1983; Kitzinger & Wilkinson, 1997). The current study is qualitative in nature with open-ended survey responses being the primary source of data.

Research Context

This study was conducted at a midsized, mid-Atlantic R1 public university during the 2022-2023 academic year. The university offers a two-semester Integrated Calculus course as an alternative to the university's standard one-semester Calculus course for STEM majors. The course and sample have been described in detail in prior work (Griffin, 2023; Griffin et al., 2023). Students enrolled in the course are typically first-year students who have declared or are considering a STEM major.

The course was designed to incorporate frequent opportunities for students to engage in active learning. The course is highly coordinated in that instructors teach from collaboratively designed lesson plans, which include recommended active learning opportunities. Specifically, instructors follow a cycle of brief lecture, followed by students working on problems in groups or individually, followed by whole-class discussion. While the course was designed to incorporate opportunities for active learning, students do not know that upon enrolling.

Data Collection and Analysis

At the time of study, there were two sections of the course offered, taught by two different instructors, both committed to active learning. There were 63 and 64 students enrolled in each section. Students enrolled in the course were invited to complete a survey via email during the first week of the course. Those who completed the initial survey were asked to complete a survey during Weeks 21 and 28 of the year-long course (i.e., middle and end of spring semester). The survey included an item asking participants to respond to the following prompt in an open-ended response box: "Give 1-2 examples of what your instructor has done that has impacted your SB (either positively or negatively). If your instructor has had no impact on your sense of belonging, give 1-2 examples of what they could do to support your sense of belonging."

To analyze the open-ended descriptions, I read all the responses multiple times and recorded emerging themes. It became apparent that instructor care seemed to be an overarching idea conveyed by participants. This inspired the use of student perceptions of instructor care as potential codes, while still allowing other themes to emerge. With the instructor care literature in mind, I clustered responses by theme and read them multiple times to determine subcategories of responses within each larger theme. The larger themes and subcategories together comprised the codebook, which was used to code all responses. Data that could not be coded with the codebook were identified and analyzed to determine whether they represented a new category or a subcategory of one of the pre-existing codes. I engaged in an iterative process of coding the data and revising the codebook four times. Each code was binary, and each response could be assigned multiple codes. To achieve reliability, 10% of the responses were coded with three

colleagues not involved in the study. Together, 78% interrater reliability was achieved. Once reliability was achieved, I coded the remaining responses a final time.

Results

At Weeks 21 and 28 of the course, participants responded to a prompt asking them to provide examples of times they felt their instructor supported their SB. Women's responses tended to align with themes from the literature on instructor care, describing ways their instructor demonstrated care such as showing a personal interest in students and being available to provide help (Bandura & Lyons, 2012; Garza, 2009). Table 1 shows the six different portrayals of instructor care that emerged from women's responses along with the frequencies of women who discussed each theme. Reported *n* counts refer to the number of distinct women who provided a response within each category at either Week 21 or 28, as the goal was to capture a landscape of ways in which women articulated their SB being impacted by their instructor rather than to explore changes over time. Corresponding percentages are based on the total number of distinct women who responded to the prompt at either Week 21 or 28 (N=40). Responses could be double-coded, so percentages do not add to 100%. In the sections that follow, I provide several examples of each theme, highlighting the various ways in which the instructors supported women's SB. The sections that follow are presented in order from most prevalent to least prevalent theme, as in Table 1.

Table 1. Type of Perceived Instructor Care that Emerged from Women's Descriptions of How Their Instructor Supported Their Sense of Belonging

Portrayal of Care	Example response	Frequency, *n* (%)
Involved students and checked for comprehension (Bandura & Lyons, 2012)	"My instructor has approached me during group work to make sure I am on track with the material."	19 (48%)
Provided help during a teaching episode (Garza, 2009)	"[The instructor] has come to our table several times to make sure we understand the problems and explains it when we do not."	19 (48%)
Established a safe and encouraging environment (Bandura & Lyons, 2012)	"[The instructor] doesn't make us feel bad about getting something wrong and treats everyone the same."	14 (35%)
Showed a personal interest in the students' well-being (Garza, 2009)	"[My instructor] wants to get to know all of her students. She has spoken to me not only on math, but also empathized with me when I said that I miss home."	14 (35%)
Was available to students (Bandura & Lyons, 2012; Garza, 2009)	"[The instructor] is always available to answer questions."	8 (20%)

Reflected a kind disposition through actions (Garza, 2009)	"Our instructor is always kind and welcoming. She is also very approachable and never yells at students."	8 (20%)

Involved Students and Checked for Comprehension

When describing the impact of their instructor on their SB, many women described the ways that the instructor involved students in the lesson. For example, one woman stated, "[My instructor] encourages everybody to participate and share their ideas." Another woman noted, "[The instructor] usually engages with the class as he lectures, which keeps us more attentive and feeling valued." More specifically, other women reported their instructors encouraging them to interact with their classmates during group work. One woman said, "Our math instructor encourages us to work with each other regularly. She encourages us to talk." Another reported, "I think the group work she has us do does a lot for my social interactions with my classmates and I also think she tries her best to make sure everyone is engaged in class."

Women also identified ways in which their instructor would check to see if they were understanding the material. For example, one woman reported, "[My instructor] asks us questions constantly," referring to interactive lecture, and another stated that her instructor "checked our work and made sure we understood what was going on." Some women described this in the context of group work – as students worked on problems together, the instructor would circulate and check in at the different tables to see how students were doing. As one woman noted, "[My instructor] approaches me during group work to make sure I am on track with the material." Another woman reported, "[My instructor] is great at getting to every table and speaking with students while we're doing group work." These checks for comprehension made participants feel like the instructor cared whether they understood the material or not.

Provided Help During a Teaching Episode

In many cases, those checks for understanding led to another common theme. Many women described their instructor's efforts during class to help them learn as supportive of their SB. Women reported that when they had questions about the material, their instructor provided clear and thorough explanations to help them understand. For example, one woman said, "One time, I was struggling to solve a problem in class and I asked my instructor to help me. He made me understand the concept the second time around and told me he would help me understand the concept as many times as needed." Another woman echoed this idea: "[My instructor] makes sure we feel the content in our hearts and does not just throw content at us... She explains it very thoroughly and makes sure that you understand it."

Some women (n=5, 13%) reported on receiving help during group work specifically. One woman described the instructor providing help after checking for comprehension: "During group work, the instructor goes around and makes sure everyone is on the right track, and if not, they go and help them." Further, another woman said:

> [My instructor] always walks around to talk with us during group work and doesn't give us a hard time if he sees something wrong. He sticks there and works with the student even if it means giving a little extra group time.

This one-on-one attention during group work is something that made participants feel supported.

Establishing a Safe and Encouraging Environment

Some women explained that the safe and encouraging environment the instructor established contributed to their SB. In their descriptions, some reported feeling comfortable and not feeling

stupid or judged. For example, one woman shared, "She explains and teaches things in a way that makes me feel more comfortable being in the class." Other times, they mentioned that their instructor reassured them when they were incorrect. One woman said, "She doesn't make us feel bad about getting something wrong." Another noted, "He explained why I did poorly without making me feel like an idiot." The instructors made them feel safe to make mistakes and kept them from feeling stupid or inadequate.

One of the ways instructors can establish a safe and encouraging environment is by continually providing words of encouragement (e.g., Banduras & Lyons, 2009). In describing what their instructor did to support their SB, several women commented on the encouragement they received from their instructor. Participants reported their instructors communicating that they believed in students' potential and ability to succeed in the course. For example, one woman explained, "[My instructor] encourages us and sees our potential even if we don't see it ourselves." Another reported, "[My instructor] assured us on the first day of class that he believes anyone can learn this material and we can all pass the class."

Showed a Personal Interest in Students' Well-being

Some women reported that their instructor supported their SB by showing a personal interest in them and getting to know their students as people. For example, one woman stated, "[My instructor] wants to get to know all of her students. She has spoken to me not only about math, but also empathized with me when I said that I miss home." Another woman reported, "[The instructor] remembers who I am and details about myself so I feel like I am seen despite being in a larger sized class." Others reported times that the instructor would relate to them by sharing their experiences as students. One woman said that her instructor "related his experiences back to ours and explained that even he had struggles with the material that we do," which helped her feel included. Another woman reported that her instructor was "understanding of what we are going through in and out of class." Relating to students and forming personal connections with them, despite the larger class size, made these women feel like they belonged.

Was Available to Students Outside of Class

Some women explained that their instructor supported their SB by being accessible and available to students. These responses were similar to those coded as *provided help during a teaching episode* but specifically mentioned the instructor as "always there" for them or described the instructors' availability outside of class. For example, one woman reported, "[My instructor] is always available to answer questions and will spend lots of time making sure you understand." Another woman noted, "My instructor is very supportive whenever I contact him. He provides me with any answers to any specific questions that I have." Other women stated that their instructor was "open to helping outside of class," and "there if we do have questions."

Reflected a Kind Disposition

Finally, some women reported that their instructors supported their SB by being kind, approachable, or positive. For example, one woman reported, "[My instructor] is super approachable and cares about students." Some women described the instructor as kind in conjunction with some other way they showed care. One woman said, "[My instructor] is a positive person and really pushes for everyone to get an A or B in the class. This shows she really cares about her students' well-being and learning." Here she both describes the instructor as positive and reports that the instructor encourages students that they can succeed in the course, which is part of *establishing a safe and encouraging environment*. Another woman reported,

"[My instructor] is a sweet human who just genuinely wants you to understand the content and makes sure you understand it." This woman describes the instructor's kindness in conjunction with the way they *provide help* and make sure students understand the material.

In summary, when asked to provide examples of what their instructor has done to support their SB, women tended to describe different ways that their instructor showed care. Considering Straits's (2007) learning-centered versus learner-centered care, participants seemed more likely to discuss ways their instructor portrayed learning-centered care such as getting them involved in the lesson and providing help during a teaching episode or group work. Being encouraged to speak with their classmates and share their ideas, while also knowing they could go to their instructor for help made them feel like their instructor was on their side. Some women provided context in which the instructor showed care, which sometimes occurred during more interactive learning opportunities like group work and interactive lecture. Further, on occasion, participants seemed to view active learning opportunities and instructor care as overlapping rather than the context in which instructor care can be conveyed. For example, women reported that their instructor supported their SB by involving them in the lesson, which is the very essence of active learning. Women's responses not only highlight benefits of employing active learning opportunities, but they provide details into how these opportunities can be enacted in a way that makes students feel cared for and like they belong in the class.

Discussion

Prior work has claimed that students can have varying experiences with active learning. On one hand, some scholars have found that women who engage in active learning report a higher SB (Griffin, 2021) and feel more cared for by their instructor (Rainey et al., 2019) than students who do not engage in active learning. On the other hand, other scholars have found that active learning classrooms can have unintended negative impacts on student experiences depending on its enactment (Deslauriers et al., 2019; Johnson et al., 2020). With this report, I aimed to explore ways in which instructors can support women's SB outside of the learning opportunities they provide. Women's descriptions of the ways in which their instructor supported their SB aligned with actions other scholars have identified as ways that students perceive instructor care.

Interestingly, some of these ways of showing care suggest specific actions instructors can take in facilitating active learning opportunities. For example, giving students time to work on problems in groups or individually might support their SB because this is one way to involve students in the lesson. As students work, the instructor can circulate the room to monitor students' comprehension, make themselves available to students with questions, and provide help when needed. Interactive lecture or whole-class discussion is another context in which instructors can involve students, check for comprehension, and provide help. In the context of any pedagogical practice, even traditional lecture, instructors can establish a safe and encouraging environment by providing words of encouragement and reassuring students that making mistakes is part of learning. While prior research has linked SB with instructor care and instructional approaches (Rainey et al., 2019), the current study contributes concrete actions Calculus instructors can take in the enactment of their instruction such as responding to wrong answers with encouragement rather than judgment and sharing belief in students' potential.

Future work should explore potential gender differences in portraying care via instruction. The current study included two instructors, one man and one woman, but all descriptions of ways they supported women's SB were pooled. While both instructors were mentioned within each code category, it would be interesting to see if any portrayal of care was more or less prevalent across instructors, especially in terms of learner-centered or learning-centered types of care.

Exploring the Relationship Between Group Roles and Participation Patterns in an Inquiry-Based Mathematics Course

Ruo Ning (Nancy) Qiu
San Diego State University

This report examines how group roles and instructional practices shaped student participation in an inquiry-oriented undergraduate mathematics course. Using classroom video with thematic analysis and equity analytics, findings indicate alignment with the four pillars of Inquiry-Based Mathematics Education (IBME). The role responsible for reporting to the class (called reporter) most clearly influenced participation, while other roles were taken up more fluidly as students responded to the needs of the group's mathematical exploration. The results suggest that IBME design fosters collaborative learning while also highlighting opportunities for future research on how group roles and instructional practices can be refined to support equitable participation.

Keywords: group roles, equity quantified in participation, inquiry-based mathematics education

Collaborative group work is central to many active learning, inquiry-based mathematics classrooms, where the goal is not only to solve mathematics problems as an active participant, but also to collectively engage students in making sense of mathematics. To support equitable participation, instructional strategies from Complex Instruction (Cohen & Lotan, 2014) suggest assigning students group roles to distribute group work labor and responsibility (Lotan, 2022; Reinholz, 2023). A substantial body of research in elementary and primary education contexts has shown that assigning group roles can positively influence participation and collaboration (Cohen & Lotan, 1997; Herrenkohl & Guerra, 1998), but relatively little is known about how such roles are taken up in undergraduate mathematics classrooms. Some scholars have argued that roles can feel artificial, as students may ignore assigned roles, self-assign roles that align with ability or status, or rely on teachers' reminders rather than developing autonomous collaboration (Good et al., 1989). While the idea of assigning group roles for group work is not new, questions remain about how students take up these roles and how the roles may (or may not) influence participation patterns in undergraduate classrooms.

This report examines how students in an upper-division undergraduate mathematics course engaged with their assigned group roles during small group work, and how these roles shaped patterns of participation, collaboration, and mathematical thinking across both small-group and whole-class discussions. To study participation through an equity lens, I used the Equity Quantified in Participation (EQUIP) tool to analyze participation disaggregated by student demographics such as program and pronouns (Reinholz & Shah, 2018; Reinholz et al., 2024). Instructional practices and peer interactions were also considered, drawing on the four pillars of Inquiry-Based Mathematics Education (IBME) as a guiding framework. Specifically, I address the following research questions: (1) How did assigned group roles shape students' participation in small-group and whole-class discussions? and (2) How did the interplay of group roles and instructional practices shape students' engagement with mathematics?

Theoretical Background

This study draws on three areas of literature: IBME as a framework that informs course design, group roles as a method to foster collaboration and equitable participation, and equity analytics, particularly the EQUIP tool, to examine who participates and how students participate.

IBME, as a theoretical framework for instructional practices, consists of four pillars: (1) Students engage deeply with coherent and meaningful mathematical tasks, (2) Students collaboratively process mathematical ideas, (3) Instructors inquire into student thinking, and (4) Instructors foster equity in their design and facilitation choices (Laursen & Rasmussen, 2019). These principles position students as active participants and instructors as facilitators who shape classroom norms and structures. Norms such as explaining one's reasoning and making sense of others' ideas support inquiry-based learning (Yackel & Cobb, 1996). Instructors further sustain these norms by attending to group composition, crediting student contributions, and using students' reflections to adapt instruction (Kuster et al., 2018; Rasmussen & Marrongelle, 2006), thereby centering student voice and fostering equitable participation.

One strategy for structuring equitable group work is group role assignment. Featured in instructional strategies from Complex Instruction (Cohen & Lotan, 1997), Reinholz (2023) describes four roles—starter, reporter, moderator, and spy—to support collaborative inquiry and distribute responsibility. The starter initiates the task by reviewing the prompt, asking clarifying questions, and helping the group establish a shared starting point. The reporter communicates the group's progress or ideas to the whole class. The spy visits other groups to gather insights and strategies, whereas the moderator ensures that all group members have opportunities to contribute. These group roles aim to scaffold meaningful collaboration and foster equitable participation by splitting the responsibilities among the individuals in a group. Prior studies show that roles can boost engagement (Herrenkohl & Guerra, 1998), increase talk and joint activity, and clarify group responsibilities (Cohen & Lotan, 2014).

However, the influence of group roles on student participation is unclear, especially in university classrooms. Students may reinterpret, disregard, or remain peripheral to assigned roles (Good et al., 1989). As Esmonde (2009) argued, equitable learning depends not only on what teachers design but also on how students interact, and a single cooperative structure may be taken up in ways that both support and constrain equity. Since assigning group roles has the intention to influence who speaks, who justifies, and whose ideas are taken up, it is essential to study how group roles actually shape student participation. To examine how strategies like group roles work in practice and whether they promote equitable participation, equity analytics tools like EQUIP can be used to analyze the discourse patterns in the classroom (Reinholz & Shah, 2018). EQUIP allows researchers to analyze classroom discourse data disaggregated by social markers such as race, gender, programs, or language background. This disaggregation helps identify participation patterns that might otherwise be invisible, such as the dominance of certain voices or the marginalization of others. Each imported contribution to EQUIP is coded based on multiple dimensions, including solicitation method (called on or volunteered), length of talk, and contribution type, to categorize the nature of a student response (Reinholz, 2023).

EQUIP has been applied in both research and professional development to support instructional change. For instance, Reinholz (2023) showed how an instructor used EQUIP data to adopt strategies like wait time, structured turn-taking, and inviting quieter students to share. Reinholz et al. (2024) also demonstrated how participation analytics can support assigning competence by highlighting overlooked contributions from marginalized students, thereby reshaping classroom status dynamics. Extending this work, Yeh et al. (2025) examined how students with multiple marginalized identities engage through embodied modes (e.g., gestures, movement, and manipulatives), showing that mathematical participation extends beyond speech. These studies position EQUIP as a powerful tool for analyzing equity in classroom participation.

In this study, I use EQUIP to examine how group roles and instructional practices shaped who participated, how they participated, and what forms their mathematical contributions took.

Methods

This study was a design-based research project aimed at redesigning an inquiry-oriented undergraduate mathematics course on dynamical systems and modeling at a large Hispanic-serving public university in the Western US. The course enrolled 31 students: 4 graduate students in the Master of Arts in Teaching Service (MATS) program, 14 prospective secondary teachers in the single-subject teaching credential (SSTC) program, 2 in mathematics education, and the remainder in programs such as mathematics, applied mathematics, biology, computer science, or computer engineering. Collaborative group work was central to the course, with four group roles introduced at the start of the semester and rotated in every class session.

Data for this report comes from a mid-semester class session consisting of two 75-minute video recordings. In this inquiry-oriented class, students spent most of the time working in groups, with the rest participating in whole-class discussion. During the small-group discussion, each camera focused on a small group to capture their discussion and shared whiteboard work. During the whole-class discussion, one camera recorded the full class, while the other centered on the speaker (instructor or presenting students). This setup produced two synchronized recordings of the session (see Figure 1 for class layout). In addition, demographic information (academic level, program, and self-reported pronouns) was collected. Recordings were transcribed using Rev AI and then manually reviewed for accuracy.

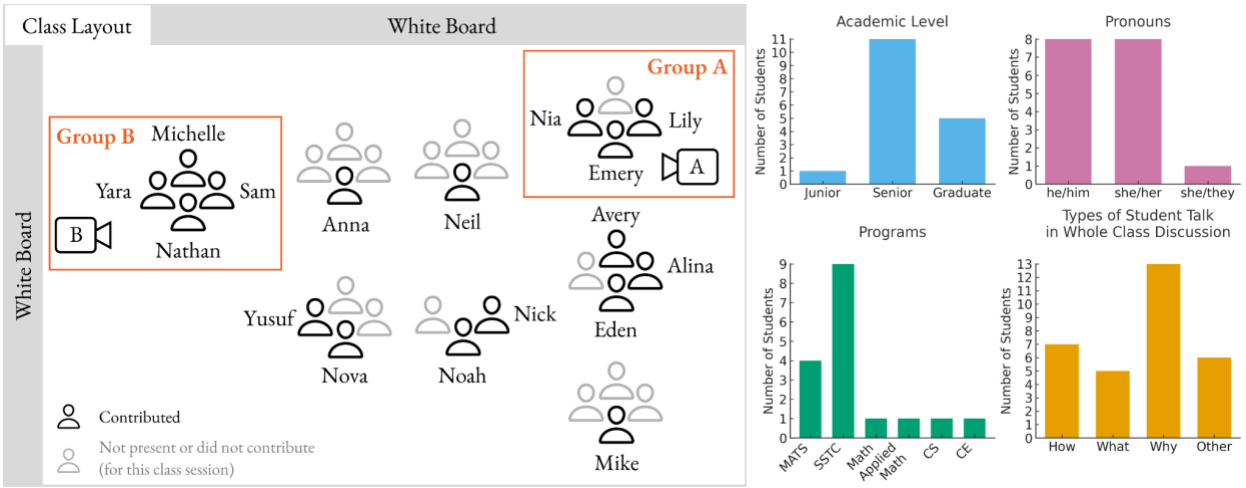

Figure 1. The class session layout, students' demographics, and types of student talk in whole-class discussion.

The class session focused on modeling coffee cooling with autonomous derivative graphs. Given temperature data over time, students approximated and fitted a differential equation for the cooling rate graphically in order to model the phenomenon of coffee cooling. They then analyzed the fitted differential equation by interpreting equilibrium behavior with slope fields and phase lines, connecting the symbolic equation, graphical representation, and situational context of coffee cooling to deepen understanding of autonomous differential equations.

I conducted a thematic analysis (Braun & Clarke, 2006) to examine students' participation patterns under the influence of group roles and mathematical engagement. Themes were iteratively developed through both inductive coding and deductive coding informed by the IBME framework, with attention to how students contributed mathematical ideas and how group roles

shaped (or failed to shape) these patterns. To systematically investigate participation patterns, I used the EQUIP tool (Reinholz & Shah, 2018), which allows researchers to import demographic and classroom data and code participation at the level of individual contributions quantitatively. Following the EQUIP protocol, contributions were classified as talk types of why (explaining or justifying disciplinary ideas), how (describing steps or processes), what (providing factual answers or recall), or other (e.g., asking questions). Contributions were then analyzed quantitatively and disaggregated by demographic variables such as academic level, programs, and pronouns. By integrating thematic analysis with EQUIP's metrics, I examined how group dynamics and participation varied across group roles and individuals, including whether certain roles were more likely to involve justification or engagement with peers' ideas. For this report, only students who made at least one contribution during small-group or whole-class discussion were included in EQUIP (17 of 31 students; see Figure 1 for demographics). All student names are pseudonyms.

Results

RQ1. How did Assigned Group Roles Shape Students' Participation?

Students in both featured groups rotated their group roles from the previous session and wrote them on the corners of their whiteboards. Group A did this even before the instructor's reminder, while Group B did so afterward. It was explicit that rotating group roles was an established class norm.

The reporter role most clearly shaped participation in this session. Lily (reporter) regularly asked clarifying questions in anticipation of reporting, and Sam (reporter) summarized his group's mathematical ideas. Other roles were taken up more fluidly. For example, Nia (starter) often initiated discussions and clarified goals, while Emery (spy) prompted her group to revisit instructions in starter-like ways. In Group B, Yara (starter) frequently restated problems and suggested approaches, while Michelle (moderator) posed questions and alternatives without explicitly signaling her role. Nathan (spy) did not participate in the spy role, likely because the instructor did not prompt spy time. Instead, he was among other students who focused on sense-making and problem-solving the modeling task within their group.

EQUIP metrics indicated how participation was distributed within groups. In Group A, Nia contributed 23 of 45 talks (51.1%), Emery had 13 (28.9%), and Lily had 9 (20%). Based on talk types, Nia (8 how, 7 what, 4 why, and 4 other) and Emery (8 what, 2 why, and 3 other) contributed more during the solving and reasoning phases, and Lily (1 how, 8 other) contributed primarily through questioning. In Group B, participation was more evenly distributed: Yara had 28 of 96 talks (29.2%), Michelle had 27 (28.1%), Sam had 24 (25%), and Nathan had 17 (17.7%), with a different mix of talk types. These data complement the qualitative analysis, showing that the amount of participation and the specific ways students contributed to group work by talk types were not dictated by roles alone; students adapted and blended roles based on group needs organically to contribute to discussions.

Overall, group roles provided a structure that occasionally influenced participation patterns, most notably through the reporter role. More often, roles functioned as background structures, as students focused on sense-making and problem-solving, with responsibilities shifting naturally to the needs of their mathematical exploration.

RQ2. How did the Interplay of Group Roles and Instructional Practices Shape Students' Engagement with Mathematics?

By comparing the thematic analysis on the class recordings with the EQUIP analysis, I observed evidence that students' engagements indicated context-rich mathematical discourse and collaborative sense-making, whereas the instructor's moves supported students' mathematical thinking and participation. The results demonstrated strong alignment with the IBME pillars.

Pillar 1: Students engage deeply with coherent and meaningful mathematical tasks. Students in both groups consistently engaged with the real-world problem that involved interpreting empirical data of cooling coffee, constructing differential equations, and reasoning about equilibrium solutions. The use of technology (e.g., GeoGebra) enabled dynamic visualization and deeper interpretation of their models. Yara used the software to empirically determine the rate of change from the data, noting that "This form [of the symbolic representation of the differential equation] is more important because you can clearly see the equilibrium solution", whereas Emery suggested that the equilibrium solution occurs at room temperature contextually. Students further contextualized the mathematical model in relation to their daily experiences. For example, Michelle discussed whether the differential equation should depend on temperature, time, or both with other group members: "Just because you leave your coffee hotter, it doesn't mean it's going to cool down faster... it's more just going to take longer to cool down to whatever your room temperature is." These episodes exemplified the kind of mathematically meaningful activity outlined in Pillar 1.

Pillar 2: Students collaboratively process mathematical ideas. Pillar 2 was evident that the two featured groups collaborated effectively to interpret coffee cooling data, calculate average changes, and create different representations of the cooling coffee phenomenon. Both Group A and B collectively reasoned about whether time or temperature was involved in the rate of change. The group roles also gave students clear responsibilities and positioned them to understand the group's mathematical progress. For example, Sam asked for clarification being the reporter when the instructor visited their group and asked the reporter to report back for the whole-class discussion, and his group supported him by helping interpret the slope of the dy/dt vs. y graph. In addition, Michelle and Yara elaborated on Sam's comments during the whole-class discussion, showing that group members saw themselves as co-contributors even when not assigned to report. Group A's Lily also interacted with the other two peers similarly.

Students even collaborated with students outside of their small group without any intervention from the instructor. In particular, Emery initiated a "spy" visit to Group B without prompting, reflecting a culture where students felt empowered to gather ideas from not only group members but also other peers. Similarly, Avery from a group near Group A visited Nia and Lily for help. These self-initiated interactions across groups further reflected a shared classroom culture that supports collaborative learning organically.

Pillar 3: Instructors inquire into student thinking. The instructor played a facilitative and responsive role throughout the class session, aligning well with Pillar 3. The instructor inquired into students' thinking, often prompting elaboration or clarification. When one group's explanation lacked clarity, the instructor asked, "Can you say it again without using the word it?", encouraging students to articulate their ideas more precisely. The instructor also made efforts to build on student-generated ideas during whole-class discussions. As the instructor walked around to answer questions or observe the ongoing exploration during small group work, they noticed students' confusion or struggle. The instructor always asked a student, usually the assigned reporter, to present their group work strategically to address struggles. The instructor

also built up ideas from students' thinking by crediting their mathematical ideas collected from small-group discussions or whole-class discussions. For example, the instructor revoiced students' reasoning: "Your table has a way of making sense for you, and I think Neil and Avery have articulated why at least it could make sense to put it in the first row", and "I love [Anna's hand gesture]… You may not have seen Anna's hand gesture because the rate of change is going this [way], almost shifting the graphs over."

Pillar 4: Instructors foster equity in their design and facilitation choices. Evidence of Pillar 4 emerged through both the classroom design and teaching practices. The use of rotating group roles distributed responsibilities and aimed to support participation across students, as discussed earlier. In addition, the instructor intentionally composed small groups to ensure there are at least two women in a group of 3 or 4, suggesting particular attention to the underrepresented voice of women students in small groups (e.g., to not be outnumbered). A counterargument about the structure of calling on reporters is that it might limit participation to one student per group. However, while reporters like Noah (he/him) and Neil (he/him) were the primary speakers during this class session's whole-class discussion (see Figure 2(b)), other students who were not reporters also supported or supplemented their ideas without solicitation. For example, Nia (she/her) helped Noah (he/him) answer a question from Avery (she/her). Another example of this was when Sam (he/him) presented their group's thinking, Michelle (she/her) jumped in to elaborate on the direction of the slope and the sign of it on the graph. These contributions suggest a culture of shared contribution, even within a possibly constrained called-on reporters structure. EQUIP metrics also aligned with these qualitative observations, as for not-called-on students, more students with she/her pronouns contributed to questions or answers during the whole-class discussion (see Figure 2(a)).

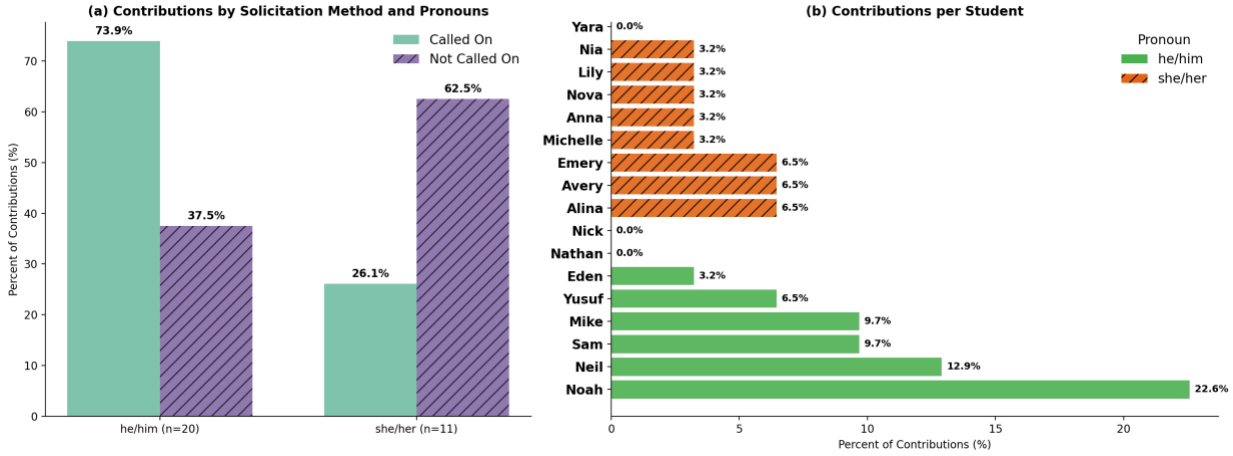

Figure 2. The percent of contributions in the whole-class discussion disaggregated by (a) solicitation method and pronouns and (b) per student.

Discussion and Conclusion

There was limited evidence that roles directly shaped student participation, aside from the reporter role. Both reporters in group A and B consistently summarized group ideas in preparation for whole-class discussions, aligning with the role descriptions and the class norm of the instructor calling on reporters. Broader participation appeared driven more by individual dispositions, class norms, and task demands than by assigned roles. For example, Nia's frequent contributions in Group A might reflect her enthusiasm and confidence rather than her role as a

starter (a pattern I observed consistently across multiple class sessions). Group B students participated more evenly, with a mix of talk types regardless of their assigned roles. In both groups, supportive group dynamics enabled students to contribute, with roles functioning more as background structures than primary drivers of participation.

Rather than viewing the fact that the majority of the group roles did not directly shape participation patterns as a disadvantage, I argue that group roles' purpose is to support collaboration and classroom management, not to dictate or prescribe students' intellectual contributions. This interpretation aligns with prior studies (Bianchini, 1997, 1999). In other contexts, such as efforts to elevate students' status (which is students' perceived academic ability and popularity), group roles may need to be assigned more strategically to promote equitable participation (Cohen & Lotan, 1997). These findings suggest that the reporter role, in particular, can be assigned strategically since it most clearly shaped participation.

Data analysis showed alignment with all four IBME pillars that foster effective mathematical discourse. Students engaged with a meaningful, real-world modeling task on coffee cooling, using empirical data, differential equations, and technology to connect math models to everyday contexts (Pillar 1). Collaboration emerged both within and across groups, supported by group roles and peer-to-peer interactions (Pillar 2). The instructor facilitated by probing and revoicing student reasoning in whole-class discussions and by visiting groups to elicit and inquire into students' thinking (Pillar 3). Equitable participation was encouraged through intentional group composition and role rotation, which created a supportive space where even non-reporters, especially women students, contributed voluntarily (Pillar 4). The classroom norms supported students to actively construct, share, and refine mathematical ideas collaboratively.

The strong engagement observed in this study was likely supported by both the design of the course and the particular context of the class. Many students were seniors or graduate students in teaching credential or math-related programs, and the instructor brought extensive experience with inquiry-based teaching. In other settings, structures like group roles may play a more central role in shaping participation, especially for less experienced students or instructors newer to inquiry-based teaching. Future research should explore how different student populations and instructor experience levels mediate the impact of group roles on students' participation, engagement, and mathematical thinking.

While some norms like calling on reporters directly shaped students' participation, the findings indicate that contributions from students with she/her pronouns were more common among those not called on. This suggests that calling on reporters alone did not ensure comparable visibility in whole-class discussion for this group of students. Future instructional designs could invite co-reporting or rotating roles multiple times per class to provide more called on chances. Another limitation of this study is the focus on a single class session, which may not capture the full variability of participation over time. Future work will compare multiple class sessions to provide more insights on how participation patterns evolve.

In conclusion, this study found that the reporter role most clearly shaped participation patterns, while other group roles blended into collaborative dynamics, and overall participation and mathematical engagement were further influenced by the interplay of group roles and instructional practices. Together, these findings highlight the promise of IBME as an instructional framework that empowers instructors to design equitable and meaningful learning experiences. For instructors, this means treating group roles and other IBME pillars as evolving instructional guidelines, refining them in response to student feedback and class dynamics to sustain equitable participation and deepen students' collaborative engagement with mathematics.

A Comparative Case Study of Student Reasoning about Planes and Vertical Change in Multivariable Differential Calculus

Megan Ryals
University of Virginia

Deborah Moore-Russo
University of Oklahoma

Rafael Martínez-Planell
University of Puerto Rico at Mayagüez

This is part of a larger APOS-grounded study where we investigate students' reasoning about and between multiple components of multivariable differential calculus. We report on the different reasoning of the strongest interview participants from two sections taught by the same instructor. One section used the locally linear approach; the other was taught traditionally. The locally linear approach leverages the geometric understanding of the point-slopes equation of a plane to help students develop key ideas for the differential calculus of two-variable functions. We used semi-structured interviews to investigate students' understanding of multiple components of differential calculus and the relations established between those components. In this report, our analysis focuses on the relations that two high-performing students established between the components of plane and vertical change. Findings suggest that the locally linear approach may help students obtain a deeper understanding of vertical change on a plane than traditional instruction.

Keywords: multivariable calculus, plane, locally linearly approach, APOS, differentials

Introduction

Multivariable calculus is an important tool to model different phenomena in science and engineering. Typically, its study begins with the simplest case, two-variable functions. The study of the didactics of two-variable functions has gained traction in the past twenty years (for a survey, see Martínez-Planell and Trigueros, 2021). In an early paper, Tall (1992) proposed how students may visualize differentials in two and three dimensions. He proposed a model to enable students to think of a two-variable function as locally approximated at a point $(a, b, f(a, b))$ by its tangent plane, with the change in function values modeled by the total differential

$$[df(a,b)](dx, dy) = \frac{dz_x}{dx}dx + \frac{dz_y}{dy}dy$$

where *dx* and *dy* are independent variables representing horizontal change at (a, b) and dz_x, dz_y are the corresponding vertical changes along the tangent plane (Figure 1) for $\frac{dz_x}{dx} = f_x(a, b)$ and $\frac{dz_y}{dy} = f_y(a, b)$. Martínez-Planell et al. (2017) built upon Tall's idea to describe the notion of vertical change on a plane (Figure 2, left) which may be symbolized as

$$\Delta z = \Delta z_x + \Delta z_y = m_x \Delta x + m_y \Delta y.$$

From this idea, you can obtain

$$z - c = m_x(x - a) + m_y(y - b)$$

the point-slopes equation of a plane,

$$z - f(a, b) = f_x(a, b)(x - a) + f_y(a, b)(y - b)$$

the equation of a tangent plane at a point, and directional derivatives (Figure 2, right). While the idea of vertical change appears when interpreting directional derivatives, students find it

challenging to construct this notion on a plane. Students do not readily generalize slopes to three dimensions and have difficulty combining rates of change in the *x* and *y* directions into a single rate of change (Martínez-Planell et al., 2015, 2017; Moore-Russo et al., 2011; Weber, 2015; Yerushalmy, 1997). McGee & Moore-Russo (2015) observed that students tend not to think of partial and directional derivatives as slopes of lines on the tangent plane. This led to the design of activities to help students construct a locally linear approach to the differential calculus of two-variable functions.

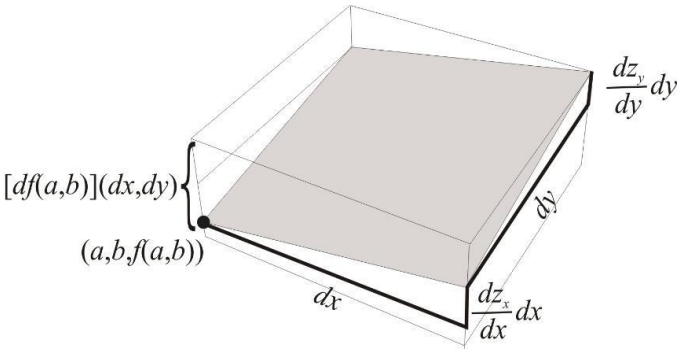

Figure 1. Total differential at a point.

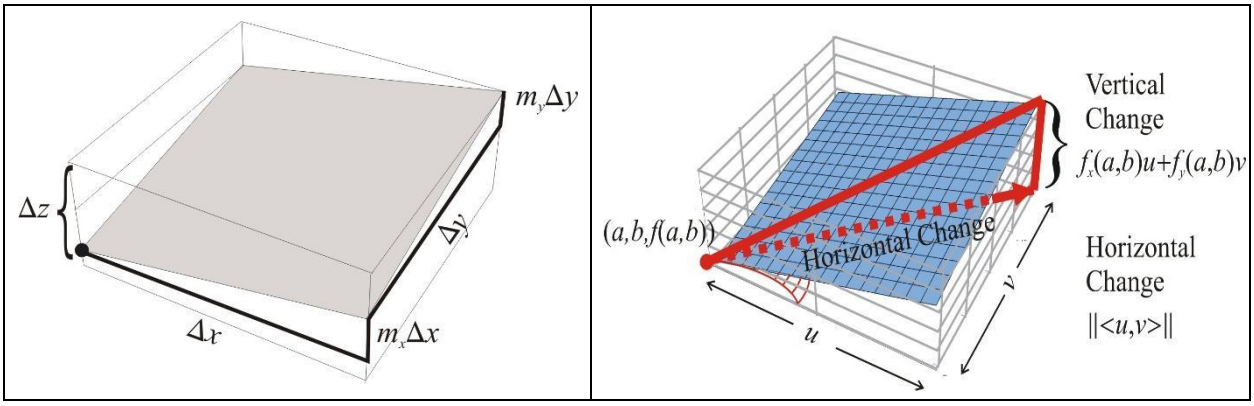

Figure 2. Vertical change on a plane, $\Delta z = \Delta z_x + \Delta z_x = m_x\Delta x + m_y\Delta y$ *and directional derivative,* $D_{\langle \Delta x,\Delta y\rangle} f(a,b) = \frac{f_x(a,b)\Delta x + f_y(a,b)\Delta y}{|\langle \Delta x,\Delta y\rangle|}$.

Borji et al. (2023, 2024) used previously documented activities to observe improved student understanding of partial and directional derivatives. The present study adapted some of these activities for an interview protocol. In this paper, we focus specifically on the relations students established between plane and vertical change. The research question driving this study is: How do two high-performing students, one taught with the locally linear approach and one not, differ in the types of relations they demonstrate between two key components of multivariable differential calculus, plane and vertical change, when solving a series of tasks involving geometric interpretation?

Framework

APOS Theory (Arnon et al., 2014) considers how students carry out Actions (step-by-step manipulations) mechanically until they are able to internalize these as Processes where they can imagine actions without actually performing them. These processes are then encapsulated into a mental Object that in and of itself can be acted on and manipulated. Finally, a Schema of a

mathematical concept is a structured collection of Actions, Processes, Objects, and previously constructed Schemas. These components are interconnected so that an individual can recognize when a problem fits within the Schema's scope (coherence) and can activate it to address a task that is presented. Schemas constantly evolve as the students face new problems and learn new mathematics.

In this paper, we use the notion of types of relations between Schema components, introduced by Trigueros (2019), as helpful in describing this evolution. A *correspondence* (C) relation exists between components when, out of habit or repetition and with limited external prompting, the individual correctly relates one component to another without being able to justify the relation. A *transformation* (T) relation between two components exists when a student is able to explain or justify how one component relates to another, possibly through the use of other mediating components. An *equivalence* (E) relation exists between components if properties of one component are conserved or maintained in another such that changes in one component can fluently be interpreted as changes in the other. The result is that a person is able to move easily and efficiently from one component to another, in a consistent manner, across tasks despite the particulars of any given task.

Methodology

One of the researchers taught two multivariable calculus sections for engineering students in Spring 2024. Both sections used the Stewart (2012) textbook and had the same homework exercises with only a few pre-class assignments that differed. Both sections dedicated the same amount of class time to differential multivariable calculus and had common assessments. One section with 19 students was taught traditionally. In particular, the point-normal equation of a plane was underscored and used to develop the differential calculus. This is convenient algebraically but can mask the geometry. With the traditional section, the point-slope equation of a plane was introduced later but was not emphasized. The experimental section with 40 students used activities based on those discussed by Martínez-Planell et al. (2017) and adapted them for use with 3D printed surfaces and the digital application CalcPlot3D (Seeburger, 2016). Within these activities, students developed an approach to compute vertical change on a plane using a 3D-printed surface and later used this to construct the point-slope equation of a plane, prior to exposure to the point-normal equation.

All students were invited to participate in two 45-minute semi-structured interviews at the end of the semester; ten agreed to participate. Most of the 27 questions posed were taken from Borji et al. (2023, 2024). Two of the authors independently coded each participant's response for each question; then, all three discussed and analyzed codes until a consensus was reached. The coding process involved first identifying the components of differential calculus the student was relating in their response, including Function (F), Slope (S), Partial Derivative (PD), Directional Derivative (DD), Gradient (G), Vertical Change (VC), and Plane/Tangent Plane (P). We then decided on the type of relation (i.e., no relation (NR), correspondence (C), transformation (T)) between components, if any, the student was demonstrating in their answer to that particular question. Finally, we looked at each pair of components and identified for which problems that pair had been coded. Looking across the problems and the type of relation coded for each problem, we were able to assign a type of relation for a pair of components. An equivalence (E) relation was assigned to a pair of components only if it was established consistently and fluently across the different problems involving the components.

For brevity, we report only on our coding for the relations established by two students between the components plane or tangent plane (P) and vertical change (VC). Note that the VC code refers to a process conception of vertical change on a plane or tangent plane when there is horizontal change in both the x and y directions.

Results

In this report, we compare the cases of Jackson and Daphne. They were the strongest performers on the interview tasks in the experimental and traditional sections, and they received course grades of A and B+, respectively. We focus specifically on the relations Jackson and Daphne established between plane/tangent plane and vertical change and the components they used to mediate these relations. Below, we present and discuss transcripts from the three interview questions which provided opportunities for students to relate the plane or tangent plane to vertical change.

For question 1, students were given Figure 3. After finding slope of the line for question 1a, in 1b students were asked: *Starting at any point on the plane, find how much the z coordinate changes if the x coordinate increases by 4 units and the y coordinate increases by 5 units*.

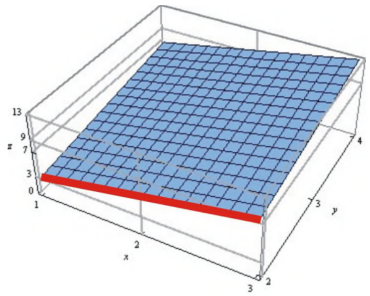

Figure 3. Plane for question 1b.

Jackson: So, I have m_x, to complete the problem I need to find m_y [he correctly finds m_y] so, the change in x is equal to 4, change in y equals to 5. So, with that in mind … change in z is equal to 3 times 4 plus 2 times 5, 12 plus 10, 22

Without prompting or assistance, Jackson used slope and a given amount of horizontal change to determine a resulting change in z in one direction. Additionally, he was able to coordinate the change in z resulting from movement in two directions to find vertical change. This was coded as a transformation relation because Jackson was able to explain how he moved from plane to vertical change, using slope as a mediator (P-S-VC). We now consider Daphne's response to question 1b.

Daphne: So, $\Delta x = 4$, $\Delta y = 5$ … I'm setting up the equation of a plane… that won't work…Okay, I don't really know how to, like, think about this one.

Interviewer: Let me give you a hint. What would be the change in the z coordinate if the x coordinate increases by 4 units? Only the x coordinate.

Daphne: If the x coordinate increases by 4 units, the z would increase by 12

Interviewer: Good, and what would happen if the y coordinate increases by 5 units?

Daphne: If the y coordinate increases by 5 units, then the z coordinate will also increase, but I don't know by how much… I guess I could find the … entire equation of the plane.

Interviewer: Just like you found how much z increases when x changes, could you use the same idea to find out how much z changes when y changes?

Daphne: … I guess; I don't know.

Interviewer: Let me give you another hint, can you find a slope in the y direction?

Daphne: [She was able to find the slope in the y direction.] … delta x would equal 3 times 4, and delta y would equal 5 times 2, that's 12 and this is 10, so then, in that case, could you square those two values, add them together? … I just don't know what to do with this information now that I have it.

Interviewer: Okay, so you are standing at a point, you move in the x direction, and you go up 12 units. Then you move in the y direction, and you go up 10 units. So, how much did you go up overall?

Daphne: Oh! It's just 22.

We see that Daphne eventually related the given plane component (P) with the requested vertical change (VC), using the slope component (S) to mediate. However, this happened only with significant scaffolding from the interviewer. We therefore coded "no relation" (NR) for P-VC for Daphne on problem 1b, despite her eventually producing the correct answer of 22. Daphne demonstrated a tendency to rely on habit or repetition, more than once suggesting finding the plane's equation without any indication that she understood its meaning. She first needed to be prompted to compute the slope in the y direction and the changes in z due to moving solely in the x or y direction. Moreover, Daphne showed difficulty coordinating changes in the x and y directions, as Yerushalmy (1997) and Weber (2015) have observed in their work.

Problem 1c asked students to find the equation of the plane in Figure 3. They each did so correctly. Then, they were asked to relate this equation to the previous calculations in part b.

Daphne: I mean, yeah, it includes both of the slopes, and, like, it shows us how x and y, like, change independently of each other …

Daphne produced the point-slope equation of the plane with no assistance. This appears to be a memorized process for Daphne. When asked to relate the equation to prior calculations, she focused on the symbolic calculations in the formulas without any geometric interpretation. Therefore, this was coded as a correspondence relation (P-S-VC). For Jackson:

Jackson: I guess it's, yeah, related in the sense that if I plugged in an (x, y) point, an x point of, x change by four, x equal to 5 [from the initial x equal 1] and a y equal to 7 [from the initial y equal 2], I'd get a change in z of 22. So, depending on where I start, if I were to change x by 4 and change y by 5, my final z value would be z initial plus 22.

For problem 1c, Jackson was coded as establishing a transformation relation between plane and vertical change (P-S-VC). In his explanation, we can see that Jackson assigned geometric meaning to specific algebraic expressions within the plane equation. Specifically, he identified $(x\text{-}1)$ and $(y\text{-}2)$ as horizontal changes. When Jackson said "depending on where I start," this suggests that he was aware that vertical change is independent of initial point, but depends only on the slopes and horizontal changes. He also went further to show how he used his equation to produce a vertical change of 22 units to correspond with what he calculated in Problem 1b.

Problem 4a (in Figure 4) presented a different plane as the plane tangent to a surface at a particular point and asked, "What can you say about the change in the value of the function if x increases 0.02 units and y increases 0.03 units?"

We note that problem 4a is computationally the same as 1b. The difference is that in 4a, the plane is presented as a plane tangent to a surface and the problem asks about the change in z for

the surface, rather than the plane itself. Both Jackson and Daphne first attempted the problem very similarly to one another, using a visual approach.

Jackson: We can expect if *x* slightly increases in the positive *x* direction and *y* slightly increases in the *y* direction, the *z* value should increase.

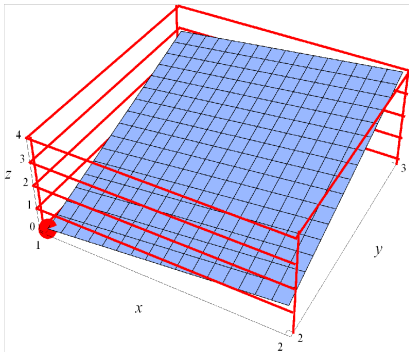

Figure 4. Plane for question 4a.

Daphne, in answering question 4a, first made a connection to problem 1b.

Daphne: This is asking a similar question to, I think, one of the ones on the first or second page. And, then, so if *x* increases 0.02 and *y* increases 0.03 units, the change in the value of the function would be positive, cuz, like, this way it goes like that [starting at the base point, pointing along the edge of the plane shown in the figure, corresponding to increasing *x*], and that way it goes like that [pointing along the edge of the plane, corresponding to increasing *y*], so the net vector would be positive.

Each student made a claim that the vertical change would be positive. The interviewer then prompted each student to calculate, or explain how to calculate, a value.

Jackson: I'm going to find the equation of the plane, m_x times the change in *x* plus m_y times the change in *y* equals *z*. Next, I was gonna try and find m_x . To find m_x I just fix it at the plane *y* = 2 and see how *z* changes when I move from *x* = 1 to maybe *x* = 2. And same thing for m_y. I'm in the plane *x* = 1, and see how *z* changes when I change *y*. And my change in *x* and change in *y* is gonna look like *x* - 1 and *y* - 2 and when I plug in the points, if *x* increases, okay, my change in *x* is given to me. They told me 0.02 and my change in *y* is 0.03, so the main work is just finding m_x and m_y and I should get my final *z* value.

Here we see consistency between Jackson's approach and a geometric interpretation of algebraic expressions in problem 4 with those in problem 1. For example, he identified "*x* - 1" as "change in *x*" and "*y* - 2" as "change in *y*." Jackson recognized that .02 could be used instead of *x* - 1 and .03 instead of *y* - 2, showing that he could give geometric meaning to the algebraic expressions in the formula. When the interviewer asked Daphne to calculate a value for the vertical change, she did not make any further connections to problem 1b.

Daphne: Yes, I could find, um…I know there is a way to do this. I'm just gonna say that it's around 1 for the *z* value.

Daphne ultimately abandoned this question with no further explanation or attempt at computation. In contrast to Jackson, Daphne did not identify that she needed to find slopes in the *x* and *y* directions, despite having been prompted to do so in Problem 1b. It appears that the process she had used for computing vertical change in problem 1b had not been interiorized; her actions had been guided externally by the interviewer. It was not apparent to Daphne that she

could use the equation of a plane to compute vertical change. Therefore, for problem 4a, we coded Daphne as not demonstrating a relation between tangent plane and vertical change.

We see evidence that using the locally linear approach with CalcPlot3D and 3D-printed surfaces enables Jackson to construct a geometric understanding of ideas in differential calculus of two-variable functions in a way that makes sense for him and that he can explain. Jackson, possibly as a result of the classroom activities, was able to give meaning to movements along a plane, slopes, and vertical change. Throughout the interview, Jackson was consistent and fluent in relating the plane, slope, and vertical change components. He considered that properties of the plane component are conserved in properties of the vertical change components, so we considered Jackson to have established an equivalence relation for P-S-VC.

Daphne was quick to produce equations of planes when a problem involved a plane, whether helpful or not. She was not able to relate the algebraic expressions in her plane equations with geometric representations. Overall, we considered that she established the relations P-S-VC as a correspondence relation because she relied on a memorized procedure to produce equations of planes and needed significant scaffolding to relate components in unfamiliar question formats. The relations established by Jackson and Daphne are summarized in Table 1.

Table 1. Comparison of coding of PTP-S-VC relations for Jackson and Daphne

Problem with Description		Coding for Jackson		Coding for Daphne	
		Code	Justification	Code	Justification
1b	Compute VC on plane	T	Computed and explained computation	NR	Computed with significant scaffolding
1c	Create equation of plane and relate to computation of VC	T	Created equation and explained connection between algebraic expressions and geometric features	C	Created equation but could not interpret computation geometrically
4a	Estimate VC on function using tangent plane	T	Made visual estimate and was able to explain how to compute VC	NR	Made visual estimate but was not able to compute VC

Implications and Limitations

This study provides further evidence that constructing vertical change on a plane and geometrically interpreting components of the point-slope equation of a plane are non-trivial for multivariable calculus students. Jackson's understanding of the components of plane and vertical change is more robust than Daphne's, in the sense that he can interrelate the components through slope flexibly across different problems and justify his solutions based on his geometric insight. We hypothesize that the activities using digital visualization and 3D-printed surfaces in Jackson's section supported him in developing these relations. However, we note that greater similarity of classroom activities to the interview tasks in Jackson's case, and the focus on only two participants of all interviewed, limits the conclusions we can draw about the impact of these activities relative to traditional instruction. The study also provides a theoretical contribution by considering the types of relations between Schema components, which is a relatively new idea in APOS theory that can be better understood through further applications to empirical research. Future studies can report on the analysis of all participating students and the relations between all the differential calculus schema components.

"I Can Make a Difference Through Mathematics": Mathematics Majors' Conceptualizations of Justice in the Context of Teaching Mathematics for Social Justice

Anne Cawley
Cal Poly Pomona

Angel Bisson
San Diego State University

José Franco
Cal Poly Pomona

There has been a call to emphasize how mathematics can be used to tackle social issues in ways that create a more just world. Such efforts can take the form of an explicit topic, entire course, or as a call-to-action impacting communities in various manners. This study analyzed course reflections of 15 mathematics majors enrolled in a Teaching Math for Social Justice course. We used open coding and constant comparison analysis to analyze pre-class and post-class reflections to understand the ways that students conceptualized the notion of "justice". Eight themes emerged from the data, with notable differences between the ways students described justice before and after the course, with students' conceptualizations demonstrating change or becoming solidified after completion of the course. These findings contribute to the larger body of research that continues to investigate how mathematics students engage with incorporating social justice contexts into mathematics teaching and learning.

Keywords: Teaching Math for Social Justice, Justice

In the past 40 years, there has been a call to emphasize how mathematics can be used to tackle social issues in ways that create a more just world. Social justice pedagogy "can be used in mathematics classrooms to help students interpret and apply mathematical knowledge to answer questions that will potentially empower their lives and their communities" (Leonard et al., 2010, p. 264). Scholars like Bob Moses (2002), Rico Gutstein (2006), and Rochelle Gutiérrez (2013) are a few in a long list of scholars who have committed themselves to using mathematics to engage in and address real-world issues. Grounded in critical pedagogy (Freire, 1970/1996), which asserts that education can be used to transform and improve society, using mathematics to understand and address issues of social justice is a way to understand and "engage in political and economic realities of everyday life" (Kirylo et al., 2010, p. 332). With a recent sociopolitical turn in the mathematics education field (Gutiérrez, 2013), there has been a more focused attention towards issues of social justice. Gutstein (2006) defines reading the world as using mathematics to "understand issues of power, resource inequities, and disparate opportunities between different social groups and to understand explicit discrimination based on race, class, gender, language, and other differences" (p. 25-26), which he argues is necessary for students.

Teaching mathematics for social justice (TMfSJ) has become an explicit topic in teacher preparation programs, courses in mathematics departments, and as calls to action for college mathematics faculty. We believe that the education system is one of many institutions in the United States that has been historically oppressive, violent, racist, sexist, ableist (and more). Asking students to engage and learn about these facets in a safe space in the context of mathematics is one way that we can begin to acknowledge these oppressions in ways that we can make important shifts towards change. Gonzalez (2012) shares four components of TMfSJ: 1) access to high-level, quality mathematics instruction for all, 2) recentering the curriculum around the experiences of students from marginalized communities, 3) use of mathematics as a critical tool for understanding social life and injustices within it, and 4) using mathematics to actively advocate for social change toward a more equitable society (p. 128-129). There are multiple authors who have published materials to support the conceptualization of using real-world social

issues to engage in mathematics learning. Gutstein and Peterson's (2013) book provides context and "examples of how to weave social justice issues throughout the mathematics curriculum and how to integrate mathematics into other curricular areas" (p. 1). Berry III et al. (2020) developed a textbook that helps mathematics teacher educators support future high school teachers to understand relevant social justice standards in the classroom context while also providing ready-to-use lesson plans. Karaali & Khadjavi (2019/2021) provide examples of lessons for the college classroom, in which they point out that college mathematics instructors have "the opportunity and the responsibility to help…students develop strong analytical skills and empower them to tackle complex issues" (p. 3).

In recent years, more emphasis has been placed on preparing future mathematics teachers to incorporate social justice contexts within their mathematics lessons. This has been challenging, however, given that many students have not experienced instruction that utilizes societal issues as context for the mathematics content. Leonard and Evans (2012) found that it is difficult to change preservice teachers' beliefs and dispositions around social justice via short-term interventions (e.g., five-week module or after participating in a social justice activity), indicating that it may take more time to assist in developing a commitment to social justice. Bartell (2012) asked preservice mathematics teachers to articulate how they conceptualize the notion of TMfSJ, in which students felt they better understood their community, were more motivated to be more active citizens, and that they saw mathematics as a tool to change the world. However, it has also been challenging to find appropriate examples that connect to the content in the mathematics classroom (Leonard et al., 2010). Bartell (2013) found that preservice teachers struggled to find cohesion between the mathematics content goals of the lesson to the social justice goals, with students often focusing on mathematics content in the start of the lesson and finalizing the lesson by returning back to social justice goals, not finding ways to negotiate both at the same time.

Theoretical Framing

This study is framed by the notion of social justice pedagogy (Leonard et al., 2010), which allows students from all backgrounds to engage in meaningful mathematics grounded in relevant contexts which develops their mathematics identity. Social justice pedagogy provides the opportunity for students to develop an awareness of their world, while also developing critical mathematics literacy to accomplish goals relevant to them (Martin, 2000). Larnell and colleagues (2016) argue that it is important for a student to have agency within the mathematics classroom while also developing their mathematics identities – but that their identities are impacted by social structures. That is, a student's mathematics identity develops within the context of understanding the world around them. We believe that part of the development of mathematics identities through social justice pedagogy is that students have the need to develop a personal understanding of what justice means to them within the contexts of their own lived experiences. Parsons (2005) argues that oftentimes, the literature presents justice and caring as incompatible ethics. On the one hand, justice is seen as addressing moral problems through previously established rules (Parsons, 2005). However, from an ethic of caring, individuals approach moral dilemmas differently, considering "responsiveness to others and the nurturance of interpersonal relationships as paramount in determining action" (Parsons, 2005, p. 26). Parsons argues that "justice and caring must come together in the act of teaching; if not, systemic inequities and inequalities are preserved and perpetuated by the teacher's actions" (p. 26). Su (2020) defines primary justice (treating people with dignity and care) and rectifying justice (spotting something wrong and trying to make it right). Su argued that if primary justice was the only type of justice present, then rectifying justice would not be needed. Defining justice is a nuanced task–Gutiérrez

(2018) believes that concepts such as equity are difficult to engage in when people hold different conceptualizations of it—we argue the same is true related to the concept to justice. We believe that a student's engagement in social justice pedagogy can shape their understanding of the ethic of justice such that their definition of justice can take on a more caring perspective, and that this can impact their mathematics identity. Our study investigates how mathematics majors enrolled in a TMfSJ course: 1) conceptualize the phrase "justice" prior to and upon completion of the course and 2) change/develop their perspectives on what "justice" means to them.

Methods

This study took place at a large, public Hispanic- and Asian American Native American Pacific Islander-serving institution (HSI & AANAPISI). A total of 15 mathematics students enrolled in an upper-division mathematics course intending to engage students in using mathematics as a tool to investigate issues of social justice. Within this course, students engaged in social justice lessons and were expected to develop and implement their own lesson. Students were labeled with identifiers S1-S15. Eleven students majored in pure mathematics, three majored in applied mathematics and one majored in electrical and computer engineering with a minor in math. There were a total of nine men and six women in the course. Three students identified as Asian (one woman; two men), six identified as Latine (four women and two men), two identified as Latine and White (one woman; one man), three identified as White men, and one student identified as a Latine, Asian, & Black man. Six students spoke another language at home, including Spanish, Mandarin, Vietnamese, and Bengali. Two-thirds of students were first-generation status while 80% of students received financial aid. Two-thirds of students worked while enrolled in the course, with two of those students working a full-time job. Not all students who enrolled in the course intended to go into the field of teaching–only half of students had this as a goal, whereas others planned to work in industry.

All course assignments were collected consisting of homework, reading reflections, students' lesson plan, and a final portfolio. The data for this paper is pulled from two course assignments. Prior to the first day of class, students were asked to read Chapter 1 and 10 from Su's (2020) book *Mathematics for Human Flourishing* and to reflect on what the phrase justice means to them. At the end of the semester, students were asked to submit a final portfolio where one component asked students to reflect on their first write-up and to re-evaluate their definition of justice. Students were not obligated to change their conceptualization and were encouraged to utilize any experiences in the course in their reflection. For sake of analysis, we will call these pre-class (PreCR) and post-class reflections (PostCR). One student did not submit her PostCR and therefore will not be included in the change analysis.

The PreCRs and PostCRs were analyzed in two rounds using open coding (Merriam, 2009) and constant comparison analysis (Corbin & Strauss, 2008). First, two authors coded each assignment individually, developing and grouping themes that came from the data. All authors met to discuss these themes, developing a set of eight themes (discussed in the findings). Next, two authors analyzed the differences in the students' conceptualization of justice. We categorized these differences as 1) moderate change, 2) profound change, or 3) solidified. We defined a change in their conceptualization based on 1) whether the students explicitly stated that their definition had changed, 2) students indicated that they wanted to expand their definition, or 3) when a student did not make explicit mention, all authors discussed the students' PreCR and PostCR accounting for nuances in their writing (in which we utilized the presence of the eight themes developed from the initial coding to determine whether the change was moderate or

profound). A student's conceptualization of justice was labeled solidified if the student explicitly stated that their definition had been "solidified" from their initial writing, indicating no change.

Given the nature of TMfSJ, we recognize the importance to share the authors' positionalities. Author 1 is a cisgender, white, disabled, queer woman who is a tenured professor at a HSI in a large urban city. She is also the instructor of the TMfSJ course analyzed in this study. Author 2 identifies as a white, able bodied, neurodivergent, cisgendered woman. She is a doctoral student at a large public HSI. Author 3 is a cisgendered Hispanic Chicano male who is a masters student at the same institution as Author 1. He was enrolled as a student in the TMfSJ course analyzed in this study. Due to proximity of both Author 1 and Author 3 to the course, both authors consistently reflected on and discussed possible subjectivity during the analysis process. All data were de-identified, yet due to the small sample, full anonymity may not always be possible.

Findings

We will first discuss the students' conceptions of *justice* in their PreCR and PostCR through the themes that developed from their responses. Then we will discuss the changes we saw in students' conceptualizations from start to end of the semester. Table 2 shows the eight themes demonstrating the total counts from the PreCRs (270) and PostCRs (172) across all responses; each theme contains a set of subcodes that made up that theme. An excerpt could receive more than one subcode when it contained multiple ideas (e.g., "justice means fairness and equality" was coded as "fairness" and "equality" which both fell under the theme JFEO). Repeated mentions of the same term within a single statement/sentiment were not double-coded. It is important to note that different themes could apply to the same statement. For example, the statement, "[Justice] is actively working to give voice to individuals who do not have one or need help being heard." which would be coded under themes JP and JRV.

Table 1: Themes Related to Conceptualizations of the Word "Justice"

Justice as…	PreCR Freq (N=15)		PostCR Freq (N=14)	
Fairness, Equity, & Opportunity (JFEO)	48	(17.8%)	27	(15.7%)
Systemic/Institutional (JSI)	40	(14.8%)	26	(15.1%)
Contextualized (JC)	98	(36%)	50	(29%)
Care, Dignity, & Ethical Guidance (JCDE)	19	(7%)	8	(4.7%)
Rectification (JR)	18	(6.6%)	8	(4.7%)
Recognition & Valuation (JRV)	24	(8.8%)	15	(8.7%)
Identity, Positionality & Empowerment (JIPE)	9	(3.3%)	12	(7%)
Praxis (JP)	14	(5%)	26	(15%)

Pre- and Post-class Conceptualizations of *Justice* by Theme

Of the eight themes, we will discuss four that demonstrated most variance from PreCR to PostCR. The most frequently coded themes across both reflections were Justice as: Fairness, Equity, and Opportunity (JFEO), Systemic/Institutional (JSI), and Contextualization (JC). The first, JFEO, refers to students' associations between justice and familiar terms such as fairness, opportunity, equality, equity, access, and support. JFEO captured moments when students emphasized equal opportunities are a core component of justice. JSI reflected the ways students connected justice and injustice to broader systems, institutions, and structures. JC encompassed the ways that students drew on specific examples, metaphors, and lived experiences to define justice. Reflections in JC stressed that justice is dependent on context and is up for interpretation. We noticed significant decrease in these three themes from pre to post with one theme

demonstrating a notable increase, Justice as Praxis (JP), which represented views as justice as action through advocacy, responsibility, and efforts to redress injustice.

Justice as Fairness, Equity, and Opportunity. JFEO was coded 48 times (17.8%) in PreCR and 27 times (15.7%) in PostCR. Within the JFEO theme students most often invoked concepts of fair/fairness and opportunity. Early responses framed justice in individualistic and concrete terms, equating justice with fair and equal chances. There were cases in the PreCRs where students used the terms equity and equality interchangeably, S6, a first-gen, white man wrote "justice means to treat everyone with equitability and fairness...upholding the idea of equality". This illustrates how students collapsed equity, equality, and fairness into a single cluster of ideas. By the end of the course, however, references to fairness and opportunity had declined, and some students began to articulate clearer distinctions between equity and equality. S10, a first-gen, Latina woman explained that "equitability isn't the same thing as equal". Such statements signal a progression from broad, interchangeable framings towards more precise definition of justice.

Justice as Systemic/Institutional. JSI was coded 40 times (14.8%) in the PreCR and 26 times (15.1%) in the PostCR. The PreCRs highlighted the absence of justice within systems through references to discrimination, prejudice, bias, and stereotypes. By contrast, PostCRs contained fewer references to these individual or interpersonal manifestations and instead demonstrated an increased emphasis on a larger view of social justice and systemic injustice, and the notion of "more than individual" appeared. S1, a first-generation, Asian, Bengali-speaking man reflected in their PostCR, "Justice, I now realize, is a concept that extends far beyond individual fairness." Another student, S7, a white man, admitted that in their PreCR, "I believe I focused too heavily on what justice means for me". Such statements capture students' movement away from describing isolated manifestations of injustice toward recognizing the structural mechanisms that sustain injustice. In PostCRs, students began to reflect on larger, systemic oppressions that may inhibit justice. S13, a Black/Asian/Latine man shared the value of TMfSJ, indicating that "If we want to give justice to those that have been systematically oppressed by the U.S government, then teaching mathematics for social justice will be a necessary step."

Justice as Contextualized. JC was coded 98 times (36%) in the PreCR and 50 times (29%) in PostCR. The subcode contextual most often applied in PreCRs, marking when students made up an example to ground their definition or indicated that the definition was dependent on the context of a scenario or situation. Students also frequently relied on lived experiences (moments when a student would recall a time in their life or retell a story from someone they knew) and connections to education (when a student mentioned anything related to the presence of justice/injustice within education) to make sense of justice. While JC decreased in frequency from the PreCRs to PostCRs, various subcodes shifted in density; all three subcodes above decreased by more than half. A code that increased significantly in the PostCR was *connection to math*. This was coded whenever a student mentioned mathematics or the math classroom, oftentimes referring directly to the power that mathematics has when addressing issues of social justice. S15, a white man, shared, "I can make a difference through mathematics" and S5, an Asian Vietnamese-speaking man indicated that he recognized that "the intersection of mathematics and social justice reveal[s] how math education can be a powerful tool to address and understand social justice issues." This shift indicated that students were formulating a more attuned perspective of justice within their world as mathematicians.

Justice as Praxis. JP was coded 14 times (5%) in the PreCR and 26 times (15%) in the PostCR, illustrating a significant increase in responses related to collective action. There was an increase in the subcode *practices, advocacy and action*, which was applied any time a student

mentioned the importance of justice-oriented practices, recognized injustices, called for action, or provided examples of how they or others could engage in justice work and the subcode *responsibility of justice*, captured when moments when students described a personal or collective responsibility to act, reflecting on the roles individuals play in correcting injustices, or contributing to justice. In their PostCRs, S7 and S15 (both white men) shared this shift to action. S7 shared "You instead need to look at the greater efforts and ask yourself how you can help in such efforts". S15 viewed his role as one who influence his community, "I will continue to challenge those around me to speak out on injustice and take the necessary actions to bring positive change to the community I serve." Taken together, this theme showed notable growth and suggests that students' conceptualizations of justice shifted from abstract ideas toward enactment and commitment to transformative action. The rise in responsibility language highlights a deepened sense of both personal and collective obligation.

Development of Conceptualizations of *Justice* at the End of the Course

Of the 14 students who submitted both PreCRs and PostCRs, five students showed moderate change, seven students exhibited profound change, and two students' views were solidified.

Moderate Change. Students that demonstrated moderate change mostly indicated adjustments they would make to their original conceptualization. For example, S2, a Latina Spanish-speaking woman, initially described justice as "a staircase with many exit points" indicating that the world has little respect for justice of fairness. She chose the staircase analogy because "you can step off when you're done or tired of fighting…where some people keep fighting till the top, some people fall off the stairs and some sit on the stairs instead of getting off". In her PostCR, she slightly modified her analogy to indicate that "everyone is actually on their own ladder regardless of what they want to be." S9, a Latino/White Spanish-speaking man, initially stated that, "justice is a response to make matters right as much as possible for victims of wrongdoings and for consequences to ensue for the perpetrators of the wrongdoings." Later, he indicated that overall he still agreed with his first definition but with a slight change in what "the scope for which the word justice could be used for" indicating that initially he only saw it as used purely in legal issues, however, now he sees "that justice is not only for legal cases but for issues of social inequity beyond the lens of legality."

Profound Change. Seven students indicated profound change in their conceptualizations of justice, indicating complete re-definition of the concept. For example, S6, initially described justice as "treating individuals equitably and fairly, regardless of their background, identity, or circumstances." Yet, in his PostCR he indicated that he sees it as much bigger than being equitable and fair, indicating that using the word "fair" was too ambiguous. He expanded his thoughts by sharing, "Justice to me is ensuring that everything is taken at face value from person to person, circumstance to circumstance, regardless of any assumptions or pre-existing notions. However, this course hasn't just changed my understanding of justice, it's changed the way I approach and think of issues and broadened my mind about how people think." S10, initially conceptualized justice as "when everyone gets a chance to experience life equally." Later, in her PostCR, she shared that justice "means making sure everyone is given the tools they need so that everyone is at the same level or in other term everything is equitable for everyone. The reason for this is because equitability isn't the same thing as equal because equal just means to give everyone the same number of things while equitability means to make sure everyone is at the same starting point."

Solidified. Two students were labeled solidified. Both students utilized this word in their write-up, indicating that this course reaffirmed their initial view of justice, making it a more

stable conceptualization for them. S8, an Asian Mandarin-speaking woman, initially indicated that "justice isn't just righting a wrong but showing the true qualities of something." Later, she indicated that her understanding had been solidified after the 15-week course. S13, a Latino/ Black/Asian man, initially described justice as "righting any wrongs that have been done upon another and stopping those wrong doings from happening again. I think I understand justice more as rectifying justice due to how much discrimination I see everyday from the news to social media." Upon completion of the course, he shared that the course solidified his definition.

Discussion

This study sought to understand how mathematics majors enrolled in a TMfSJ course conceptualized the notion of *justice* before and after the course experience. Our analysis of students' reflections highlights several important shifts in how students understood, described and located justice. The findings suggest that engaging undergraduates in explicit study of social justice pedagogy both broadened conceptualizations and elevated their identities as mathematicians and future educators. Our data points out that conceptualizing *justice* is a complex and challenging task, yet being able to begin defining such a nebulous word is important to rehumanize mathematics learning and its impacts in the classroom and on society (Gutiérrez, 2018). However, we did see that most students developed and expanded their conceptualizations of the phrase, which shows promise that a semester course can have impact.

We saw four notions arising from the data: 1) movement from individualized justice to collective views, 2) a shift from the view of fair/equal to more equitable stances, 3) an overall increase in viewing justice as action or a way of being, and 4) more direct connections to how students see the power of mathematics contributing to justice. In initial descriptions of justice, students often gave individual experiences as examples to demonstrate the concept. By the end of the term, students spoke in much larger perspectives, indicating that achieving justice was part of a sociopolitical movement (Gutiérrez, 2013), of which many students saw themselves as one part of a bigger process. Next, students initially discussed justice with many words that were used interchangeably, including *fair*, *equal*, and *equitable*. Students end of term reflections suggested a deeper understanding of the differences between these words, including direct acknowledgement of how they felt prior to the course they did not necessarily understand the differences between them. We noticed a large decrease in use of the word *fair* at the end of the course, with students demonstrating an awareness that there is a lot to consider when determining fairness. The theme of Justice as Praxis demonstrated a significant shift in students' perspectives of action. Students often indicated ways to advocate and enact justice, reflecting views of rectifying justice (Su, 2020). We noticed that students began to write more about *who* is involved in the concept of justice, but also *where* and *when* justice (or injustice) takes place. Students also indicated more about *how* power and resources tie into justice. These tie into the notion of *reading the world* (Gutstein, 2006), in which students think about these types of issues related to power and identity. Finally, students reflected more on how mathematics is a powerful tool with which to use to consider justice, which is an important tenet to transitioning to TMfSJ (Gonzalez, 2012).

We note that, generally, students did not explicitly discuss issues of race or gender, often referencing injustices of oppressed or marginalized groups without naming the oppression. Milner (2003) argues that preservice teachers specifically need to be comfortable discussing issues of race within larger contexts. Due to the small sample size, we were unable to find any trends in the data related to students' demographics (e.g., race, gender). We plan to investigate this further with future data collection.

Characterizing Instructor Questions Intended to Support Quantitative Reasoning

Allison Olshefke-Clark
University of Delaware

Teo Paoletti
University of Delaware

Meanings for the definite integral are most productive when rooted in quantitative reasoning. However, little is known about how instruction may effectively support these meanings. This study examines the discourse actions of one instructor who intended to promote students' quantitative reasoning in a lesson exploring ideas foundational to the definite integral. We draw upon video data of the instructor's conversations with three undergraduate students who were working together during class. We analyzed whether his conversational turns could promote quantitative reasoning and characterized them according to a discourse action typology. Results suggest most of his discourse actions did opportune quantitative reasoning and that different types of discourse actions had the potential to elicit quantitative reasoning in distinct ways. We also identify two additional discourse actions not in the original typology. We conclude with implications for practice and suggestions for future research.

Keywords: quantitative reasoning, discourse, definite integral, instructional practice

A burgeoning body of research suggests quantitative reasoning (QR) is crucial to developing productive meanings for the definite integral (see Jones & Ely, 2023). This work has led to rich descriptions for meanings about the definite integral that are useful across various situations as well as documentation of the strengths and limitations students bring to bear as they develop these meanings (e.g., Oehrtman & Simmons, 2023; Sealey, 2014; Stevens & Jones, 2022). Given most studies investigate the development of students' meanings via teaching experiments or clinical interviews which center only one or two students at a time, additional work is needed to understand how these findings can inform effective instructional practice in classroom settings.

Research suggests larger groups of students have developed these meanings in classroom settings (Ely, 2019; Lehmann, 2024), but little is known about the instructional practices that may have supported students to develop these meanings. It is important to highlight that each class in these studies was taught by that study's author, and we presume that their instructional practices are influenced by a deep background knowledge about this body of research. To help prepare instructors who are less familiar with this literature to effectively facilitate students' developing QR related to the definite integral in whole class contexts, it would be useful to study the practice of instructors who intend to foster QR in this area.

With this goal in mind, we explored an instructor's practice during a lesson on accumulation from rate of change (one approach to developing QR with the definite integral; e.g., Thompson, 1994). This lesson took place within an undergraduate math course for preservice middle school math teachers that has developing quantitative and covariational reasoning as a central aim. Specifically, we address the research questions (RQs): *To what extent does an instructor's conversation with students have potential to elicit QR? In what ways does this occur?*

Conceptual Framework

Instructor discourse is widely accepted as an important facet of math instruction and has been studied extensively from various perspectives (e.g., Morgan, 2014; Ryve, 2011). We adopt Gee's (1996) definition of discourse as "connected stretches of language that makes sense" (p. 127), and we define discourse actions as the comments and questions an instructor verbalizes.

Researchers have proposed a variety of frameworks to characterize the kinds of discourse actions instructors pose at both the K-12 (DeJarnette, 2020) and post-secondary (e.g., Paoletti et al., 2018; Viirman, 2015) levels. Common across these frameworks and other research (e.g., Reiten et al., 2025) is that the types of discourse actions instructors enact are related to their goals for students. Hence, we hypothesize an instructor with a goal of promoting QR may pose certain types of discourse actions that they expect could elicit this type of reasoning from students. In line with Thompson (2011), we consider QR to include the mental construction of quantities, (i.e., measurable attributes in a situation), the relationships between quantities, and the process of solving problems based on quantitative operations.

In this study, we adopt Drageset's (2014) teacher discourse actions framework to identify trends in instructors' discourse actions that have the potential to elicit QR. This typology consists of 13 distinct discourse actions organized into four categories. Redirecting Actions (RAs) include questions or statements intended to redirect current ways of thinking. Progress Actions (PAs) include actions that seek to move problem-solving forward. Focusing Actions (FAs) include actions that draw students' attention to details in the problem. FAs considered Requests for Student Input (RSI) aim to elicit these details from students. In FAs considered Pointing Out Information (POI), the teacher provides these details. For brevity, we present discourse actions that constitute these categories in Table 1. See Drageset (2014) for more detail and examples.

Table 1. Drageset's (2014) Teacher Discourse Actions Framework

Discourse Action		Description
RAs	Put Aside	Dismissing a student's response
	Advising a New Strategy	Explicitly suggesting an alternative approach
	Correcting Questions	Asking a question that affirms something *and* suggests a deficiency
PAs	Demonstrating	Explicitly indicating the next step(s) in a process
	Simplifying	Providing hints or scaffolds
	Closed Progress Details	Asking how to move a process forward with a next step in mind
	Open Progress Initiatives	Asking for students' ideas of how to move a process forward
FA-RSI	Enlighten Details	Prompting students to elaborate elements of their explanation
	Justification	Prompting students to justify elements of their explanation
	Apply to Similar	Prompting students to replicate thought process in related situations
	Request Assessment	Prompting students to comment on a classmate's response
FA-POI	Recapping	Restating student's response and emphasizing important detail
	Noticing	Restating student's response and adding information

Methods, Analysis, and Tasks

Data collection occurred during an undergraduate math course for third-year, pre-service middle school math teachers at a large, public university in the Mid-Atlantic United States. Each course session was three hours long, and there were ten students enrolled. The second author, Dr. Paoletti, served as the course instructor. His research interests include QR, and this expertise deeply influences his teaching practice. Indeed, the primary goal of Dr. Paoletti's course was to support QR about core concepts spanning middle school to secondary and even post-secondary mathematics.

This report focuses on the fifth session of the course, which was a lesson on accumulation from rate. During this session, students worked together in pairs or trios to address the task sequence. The data for this study consists of video and audio recordings of the conversations and written work of one trio, Meghan, Amber, and Lydia (pseudonyms), all of whom consented to

participate in the study. Relevant to this report, the recordings also captured the conversations the trio had with Dr. Paoletti, who circulated the room to assist and provide feedback to groups.

Analysis

We first isolated segments of the recordings during which Dr. Paoletti was interacting directly with the trio. We transcribed these segments and identified the conversational turns (i.e., a period of speech bounded by another's; Ford et al., 1996) in which Dr. Paoletti responded to student thinking. We coded this set of turns for discourse action type and potential to elicit QR.

To analyze the *extent* to which these turns had the potential to elicit QR, we used a combination of provisional (Saldaña, 2021) and open coding (Braun and Clark, 2006). That is, we began with a codebook that outlined criteria for whether a conversational turn had the potential to elicit QR. When existing criteria was not sufficient, we inductively developed additional criteria. To analyze *how* Dr. Paoletti promoted QR, we deductively coded (Saldaña, 2021) each turn using Drageset's (2014) framework. Throughout this process, Dr. Paoletti shared his "perspectives of practice" (Lampert, 2010) as the course instructor, which provided additional insight to the data. As we coded, we discussed discrepancies to come to a consensus and refine our codebook. This process also led us to generate two, new discourse action codes: Endorse and Counter-Justification. These codes capture elements of Dr. Paoletti' discourse that were not described by the existing framework. We describe these further in the Results. Finally, within each code, we identified patterns in the criteria with which conversational turns had been identified as having the potential to promote QR (or not).

Tasks

To provide additional context for the interactions described in the results, we briefly outline the tasks from this class session. The main purpose of these tasks was to extend the meanings for rate students had begun developing earlier in the course and to provide a foundation for QR with the definite integral. Each of the three tasks in this session leveraged relationships between speed, distance, and time by asking students to make more accurate estimates of distance using various representations of speed and time data. Students began with the *Which Racetrack?* task in which they determined the track a car may have completed based on speed and time data and the total length of each potential track. In *Where's the Car?,* students used instantaneous speed information from a video of a racecar's dashboard to track its location over time. Finally, in *Drag Race,* students used a model of a drag racecar's speed, i.e., $v(t) = 71 \times (1 - (1/3)^t)$, to write an accumulation function for the car's approximate distance from the starting line. See Olshefke-Clark (2025) for more detailed task information.

Results

We address our first RQ by summarizing the frequencies of the different discourse actions Dr. Paoletti employed as he responded to the trio's mathematical thinking and the percentages of turns with potential to elicit QR. We address our second RQ by describing trends in how Dr. Paoletti's different discourse actions had the potential to support QR.

Frequency of QR

Dr. Paoletti contributed 128 turns across 17 small group conversations with the trio. These conversations ranged in length from five seconds to three minutes and totaled approximately 24 minutes of the three-hour lesson. Table 2 summarizes the frequency of Dr. Paoletti' discourse actions organized by category as well as the percentage of turns in each category that we

identified as having potential to elicit QR. Overall, the majority (62.1%) of Dr. Paoletti' turns had the potential to elicit QR. Moreover, the potential to elicit QR was substantial across all four of the discourse action categories; three of the four categories had over 55% of its turns tagged as having potential to promote QR, and the fourth had 45%.

Table 2. Breakdown of Dr. Paoletti's discourse actions

Category	Frequency	Frequency of Quantitative
Redirecting Actions	20	9 (45%)
Progress Actions	38	21 (55.3%)
Focusing Actions- Request for Student Input	48	34 (70.8%)
Focusing Actions- Pointing Out Information	26	18 (69.2%)
TOTAL	**132**	**82 (62.1%)**

To further characterize Dr. Paoletti' responses to the trio's mathematical thinking, Figure 1 organizes turns by code and potential to elicit QR. Notably, all discourse actions except Request Assessment from Other Students had at least one quantitative instance. Moreover, 10 of the 14 discourse actions had over 50% of instances coded as quantitative. In what follows, we describe ways Dr. Paoletti promoted QR by outlining trends in specific discourse actions that had especially high and low proportions of turns with potential to elicit QR.

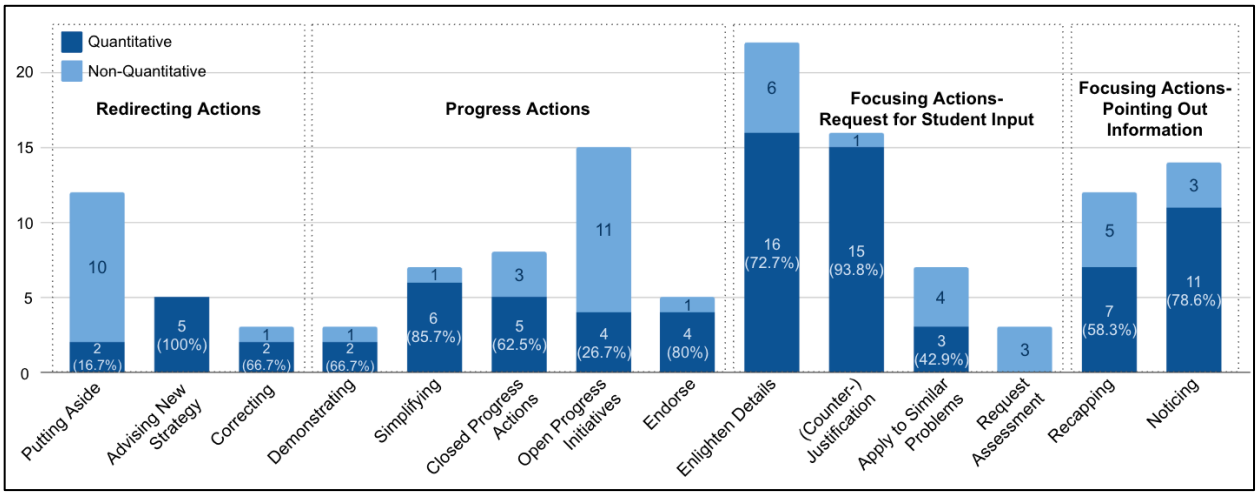

Figure 1: Frequency of (non-)quantitative conversational turns by specific discourse action

Redirecting Actions

RA was the only category with less than a majority (45%) of turns coded as potentially eliciting QR. This was also the smallest category overall, representing only 15.2% of total turns. RA also contained Advising a New Strategy, which was the only type of discourse action type in which 100% of turns had the potential to elicit QR. In these five turns, Dr. Paoletti urged the trio to consider the meaning of their processes in the situation, rather than calculate with no rationale. For example, in certain instances where the trio did not have a justification for their process, he advised them to change their strategy, exhorting, "don't just randomly multiply and divide things!" and "we can't just average things for the sake of averaging things." With these statements, Dr. Paoletti told the trio that their current strategy was insufficient and implied that

they should pursue a process that was not "random" or done "just…for the sake of" it. These kinds of statements have the potential to elicit QR because, from Dr. Paoletti's perspective, a more intentional strategy should include considering how process related to the quantities in the situation and the relationships between them.

Progress Actions

PA turns made up over one quarter (28.8%) of total turns, and over half (55.3%) had the potential to elicit QR. Specific actions ranged from having 80% or more (Simplifying and Endorsing) to only about 25% (Open Progress Initiatives) of turns with potential to elicit QR.

Endorsing. During the process of coding Dr. Paoletti' turns, we identified a type of discourse action that was not captured by Drageset's (2014) existing framework. These turns explicitly encouraged students to continue progressing through a particular process by providing confirmatory feedback (i.e., endorsing) their current approach. We considered this discourse action to be a type of PA because they "serve to move the process forward" (Drageset, 2014, p. 298). This type of discourse action included statements like "I think now you're on track. Follow that line of reasoning further and see." Most (80%) of these codes had the potential to promote QR because Dr. Paoletti often endorsed the trio's explanations when they made suggestions for a next step that was motivated by quantities in the situation. In one instance, when the trio were proposing an idea to improve their estimate of the car's distance in *Drag Race,* Meghan shared, "We were talking about going, like, in between the two, like one and a half seconds." Dr. Paoletti replied, "So I think that's a good idea," thus endorsing a line of thinking that referenced situational quantities and encouraging them to progress along this path.

Open Progress Initiatives. Although Dr. Paoletti encouraged the trio's QR with endorsing turns, we found he demonstrated less potential to elicit QR when he asked the trio general questions about how they might progress. Similar to Put Asides, Open Progress Initiatives were often too vague or non-specific to be considered having potential to elicit QR. For example, on multiple occasions during *Where's the Car?* and *Drag Race*, Dr. Paoletti simply asked, "how can we get more accurate?" Though a potential (and perhaps ideal) response to this question could involve considering the relationships between quantities, we do not consider these questions of this nature to be clear in communicating to the trio that they should consider quantities instead of just calculation. Because Open Progress Initiatives are, by definition, open to students' authentic suggestions, it makes sense that these turns may not be dense in potential to promote QR. Dr. Paoletti was soliciting the trio's ideas for moving forward, not explicitly guiding them.

Focusing Actions – Request for Student Input

FA-RSI turns were both the most frequent (36.4% of total turns) and had the highest percentage of quantitative turns (70.8%). Interestingly, FA-RSI contains discourse actions that had both the highest (93.8%; (Counter-)Justification) and lowest (0%; Request Assessment from Other Students) densities of potential to elicit QR.

Request for Student Assessment. No turns that requested the trio to provide feedback on another member's response were identified as having the potential to elicit quantitative reasoning. However, very few (3) turns were coded as requests for student assessment, and it is possible that with more turns of this type, the potential to elicit QR could be observed. As a hypothetical example, if Dr. Paoletti had asked the trio to assess a group members' QR-rich explanation, this could be considered as having the potential to elicit QR.

(Counter-)Justification. This was the most common type of turn that Dr. Paoletti contributed, and all but one had the potential to elicit the trio's QR. Almost all of Dr. Paoletti

prompts to justify were phrased as a "why?" question and asked the trio to explain how a process they had completed worked based on the relationships between quantities in the situation. Notably, when coding for Justification, there were multiple instances in which Dr. Paoletti asked the trio to explain why a process didn't work, which is slightly different from Drageset's (2014) definition of Justification as "questions about why the answer found or method used is correct" (p. 295). We consider Counter-Justification to be a special case of Justification because it elicits QR in a similar way but is specifically focused on why an answer or method is not correct.

As an example of how Counter-Justification was intended to promote QR, consider when the trio was explaining to Dr. Paoletti how they combined speed and time data in *Which Racetrack?* to come up with an estimate for distance which they believed was too large:

Meghan: I multiplied these two together for all of them and then added them.

Dr. Paoletti: Why shouldn't that work?

Meghan: Why shouldn't-? Because they're not equal speeds. Like, you're not doing 13 per- Well, 'cause you're multiplying meters by seconds by seconds. That's meters per second per second. And that's not what we're looking for.

Dr. Paoletti responded to Meghan's first explanation (which only referenced arithmetic calculations) with a request for Counter-Justification, asking why her process *would not* make sense. Although her response was not normative, it did explicitly reference quantities in the situation. As such, Dr. Paoletti' Counter-Justification both promoted and successfully elicited QR because it required Megan to interpret her arithmetic calculations in terms of the situation, which helped her consider why her process did not produce an expected result.

Enlighten Details. Almost three-quarters of Enlighten Details turns (72.7%) provided opportunities to engage in QR. The details that Dr. Paoletti asked the trio to enlighten were often prompts to connect their calculation to relevant quantities in the situation. In some cases, he paused the trio in their explanation of their process and prompted them to add units to a number they referenced (e.g., "3.7 what?"). In others, he asked more generally what a number represented in the context of the task (e.g., "what do these numbers represent again?"). In either case, these prompts encouraged them to keep quantities at the forefront of their explanations.

Focusing Actions – Pointing Out Information

Almost 70% of FA-POI turns had the potential to elicit QR, and both types of discourse actions that compose this category had a majority of turns with the potential to elicit QR. Recall that in FA-POI turns, the instructor himself is pointing out important information. It makes sense, given his overarching goals, that Dr. Paoletti would frequently point out information related to quantities and their relationships, thus giving students opportunities to engage in QR.

With Noticing actions, that is, instances where Dr. Paoletti paused the trio's progress to emphasize an important detail in their explanation, he often reiterated and/or expanded upon elements of QR present in their explanation. For example, consider the exchange:

Lydia: Like, the difference between it is 24.

Dr. Paoletti: The difference of what? [Enlighten Details]

Lydia: The difference in speed.

Dr. Paoletti: It's the difference in speed, right? [Noticing]

Dr. Paoletti used a Noticing action to emphasize the quantity that Lydia had added to her response to his Enlighten Details question. As such, this provided the potential to elicit QR by further pointing out that this detail of Lydia's explanation was important. We note that although in some cases, this kind of discourse action may provide implicit endorsement of their approach, we consider this distinct from an Endorsing actions because they are not explicit affirmations.

Dr. Paoletti's way of opportuning QR was similar across instances of Recapping as well, except Recapping actions focused on the conclusion of a process rather than intermediate steps.

Discussion

This report provides an account of the discourse actions posed by one instructor in a whole class setting who had a goal of promoting QR about ideas foundational to the definite integral. Specifically, we explored the extent to and ways in which Dr. Paoletti's conversational turns had the potential to elicit QR for a small group of students in his class. We found that the majority (62.1%) of Dr. Paoletti's discourse actions had the potential to elicit QR, suggesting that his discourse did align with his overall goal. Moreover, we illustrated different ways that Dr. Paoletti presented opportunities for the trio to engage in QR across various types of discourse actions.

Our results suggest there is not a single type of question or statement that instructors need to rely on to elicit students' QR; Dr. Paoletti posed 14 types of discourse actions, and he provided opportunities for the trio to engage in QR with all but one. However, FAs may be a particularly important skill for instructors to hone. We highlight FA-RSI and FA-POI had the highest densities of potential to promote QR, and together these made up the majority of Dr. Paoletti's turns. Dr. Paoletti used FAs to direct the trio's attention to relevant quantities in the situation and pushed them to explicitly include the quantities and the relationships between them in their explanations of calculations and results. Prior research (e.g., DeJarnette et al., 2020) indicates that teachers have particular difficulty posing questions and comments that "mak[e] specific connections or relationships explicit" (p. 9). Practicing incorporating FAs, which can be as simple as asking students a Counter-Justification, "why not?," is one way that instructors can promote QR in class by pushing students to explicitly consider relationships and connections.

Additionally, our identification Counter-justification and Endorsing actions contribute to research on instructor discourse more generally by extending Drageset's (2014) framework. We do not believe these two discourse actions are particular to classes emphasizing QR and conjecture both discourse actions could be leveraged by teachers with other foci.

Implications and Future Directions

It is important to emphasize this study does not draw a link between the types of questions Dr. Paoletti poses and their impact on the trio's QR. Rather, we intended for this study to provide an illustration of how instruction focused on promoting QR may be enacted and to begin a conversation on bridging existing research on students' QR about the definite integral with instructional practice in the undergraduate math education space. Additional work is needed to understand what types of questions and other learning opportunities actually result in development in students' QR related to the definite integral.

Though understanding the questions that an instructor poses to support QR may support other instructors in doing the same, DeJarnette et al. (2020) remarked that "even if teachers learn to pose questions that should elicit meaningful explanation, justification, and mathematical relationships, these questions will not make productive contributions if students do not recognize or respond to the demands" (p. 10). Thus, future research should attend to how these QR-focused discourses are co-constructed with students and consider questions such as: How do students respond to questions intended to elicit QR? How do instructors respond to normative and non-normative student responses? How might students' take up instructors' QR-promoting discourse actions in their discourse with one another? Investigating questions such as these in whole-class settings can provide important insights about how instructors can support students in developing meanings about the definite integral that are productive in their future coursework and careers.

What does it mean to engage in equity work and critical transformation efforts? We asked mathematicians who were part of research-practice partnerships addressing inequities in their departments to create or find an image to represent what it meant to them to engage in critical transformation work. We interviewed them about their images, and categorized images in overlapping domains of the processes of critical transformation efforts, emotions, and relative positioning of members. Many participants illustrated and voiced the process of building community, which often included an inclusive power dynamic and positive and productive feelings. Images without both community and inclusivity present instead centered loneliness and discouragement. A key implication for engaging in critical transformation efforts includes the need to center building inclusive communities.

Keywords: equity, arts-based research, critical transformation, research practice partnership

Despite the values of diversity, equity and inclusion being demonized politically in the United States in 2025 (e.g., Executive Order, 2025), mathematical teaching and learning in United States K-12 and institutions of higher education do not yield equitable student outcomes, largely attributable to structural inequities and racism (e.g., Tatapudy et al., 2024; Womack et al., 2024). As part of the larger *Achieving Critical Transformation in Undergraduate Programs of Mathematics* (ACT UP) project (NSF #2201486, 2022-2025, we established a research-practice partnership with three university mathematics departments that each acknowledged their inequitable student outcomes and sought to make critical transformations to improve (Bolick & Voigt, 2023; Hagman et al., 2024; Quaisley et al., 2025).

What does it mean to engage in equity work and critical transformation efforts? We asked mathematicians who were part of research-practice partnerships addressing inequities in their departments to create or find an image to represent what it meant to them to engage in critical transformation work. We asked them about their images, and also learned about their processes and emotions. Multiple people mentioned experiencing discomfort with the request, or being uncomfortable trying to represent their work visually. However, the overall responses were positive, and people found the exercise valuable and enlightening.

One way we as researchers can challenge dominant traditions and enact critical transformations is by questioning what counts as research, rejecting reductionist methodologies that suppress individual experiences, and engaging in multiple representations of research data. As a note, we use Gutièrrez's (2012) conceptions of non-orthogonal axes of equity comprising the dominant (access, achievement) and the critical (identity, power). We considered discomfort with arts-based research (Boyd & Barry, 2024)--for those providing data and those analyzing data--to be analogous to the way we might encourage our students to embrace discomfort and struggle in learning mathematics.

Within the larger ACT UP project, mathematicians in three different departments engaged in a research practice partnership with a RUME research team, in which each department formed a

networked improvement community (NIC; Bryk, 2020; Bryk et al., 2015) comprised of faculty, students, and sometimes administrators (the community), working toward a common aim of critical transformation to address inequities (the improvement). By connecting the three NICs with the research team in a broader research practice partnership, the improvement communities could learn from each other (the network). Each NIC selected their own focus, which spanned improving coordinated (lower-division) courses, revamping placement processes, better understanding student experiences, and confronting varying assumptions about mathematical rigor. The ACT UP project launched in 2022; federal grant funding was terminated in spring 2025 by the U.S. Department of Government Efficiency. For this analysis, we focus on the research questions:

- What are the images, emotions, metaphors, positioning of self to NIC, and conceptualizations that people describe when engaging with equity-focused critical transformations?
- What is the utility of using visual imagery to make sense of critical transformations?

Methods

As part of the larger ACT UP project, we interviewed 22 NIC members and NIC leaders in early spring 2025; interviews occurred via Zoom and lasted up to one hour each. NICs were comprised mainly of mathematics instructors (faculty, graduate students), and undergraduate students; NICs had 8-13 members each. Prior to the interviews, we shared the full interview protocol and asked the interviewees to create or take a picture related to their experience of engaging as a NIC member working toward critical changes. During the interview, we then asked them, "Please describe this image - what feelings or emotions does it invoke for you?" The larger project utilized a mixture of arts-based (Boyd & Barry, 2024) and more traditional forms of data collection and analysis.

Our analysis team includes some members of the original ACT UP research team and some members of the ACT UP department-based NICs. Salient dimensions of our identities and researcher positionalities we bring to this work include being women, queer, and/or non-white in ways that are "othered" in mathematics settings; being part of families; holding university positions (e.g., postdoc, non-tenure-track, pre-tenure, administrative responsibilities); being neurospicy; and being mathematics instructors, mathematicians, and mathematics education researchers.

Our analysis team took the combination of images and explanations and used a thematic arts-based analysis process (Boyd & Barry, 2024) to tag the images with hashtags. We iteratively considered how to group and name the hashtags, and ultimately decided to group the hashtags as having to do with critical transformation processes; emotions; positioning relative to the NIC; metaphors; and other (which included mathematical connections). We used the full list of hashtags to create a word cloud (Fig. 1) to represent both the range and relative frequency of the ways we categorized images and the ways participants discussed the meaning behind the images they created or selected. We then created separate word clouds to capture the critical transformation processes (Fig. 2), positioning relative to the NIC, and emotions (latter two images omitted for space constraints). We did not create a word cloud for metaphors, as each metaphor was unique; similarly, we did not create a word cloud for the mathematical connections ($n = 2$) nor pop-art references ($n = 2$).

Findings

Our findings center the themes of engaging in critical transformations as a process, emotions, and how NIC members felt they were positioned in their NICs. Mentions of the NIC as community were the most frequent comments overall, as well as participants using metaphors, discussing connections to teaching (omitted here for space constraints), and sharing how the NIC helped them feel connected to each other (see Fig. 1). Using imagery, NIC members were able to convey the complexities and nuances of engaging in critical transformation work in mathematics departments.

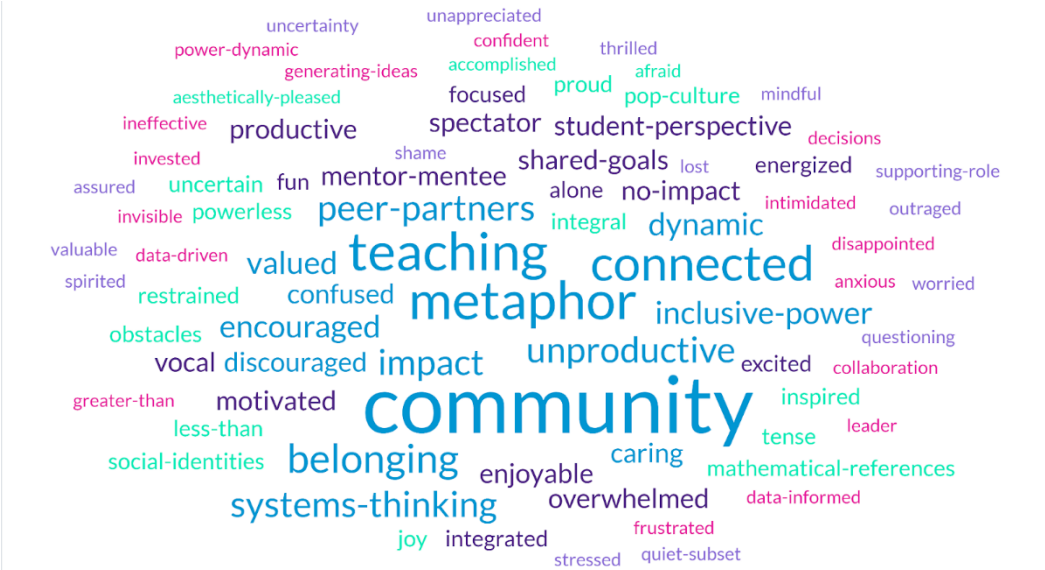

Figure 1. Word cloud illustrating the relative frequency of the hashtags we applied to the images

Figure 2. Word cloud illustrating the relative frequency of hashtags related to processes of transformation

Engaging in Critical Transformations as a Process

Engaging in critical transformations is a process. For our NICs it involved establishing and nurturing collaborative communities and shared goals, making data-informed decisions, questioning systems and generating ideas, trying to make a difference or impact within their mathematics community, and reflecting on ways to change systems and navigate barriers to change across ecological levels (e.g., institutional, departmental, personal, etc.) (see Fig. 2). Many of these processes were illustrated using visual metaphors (Fig. 3). For instance, people collaborating to put together a jigsaw puzzle represents how individual ideas can fit together to form shared goals, and a guide dog represents the NIC's shared goal to guide the direction of mathematics departments, and at the same time, empower students to be puppeteers with more autonomy over their own journey within a mathematics program. As another example, one NIC member used a chaotic cloud of question marks and colorful arrows pointing in different

directions to illustrate questioning systems and generating ideas. Concurrently, this cloud hovers above NIC members engaging in systems-thinking as a process similar to deconstructing and rebuilding a brick wall.

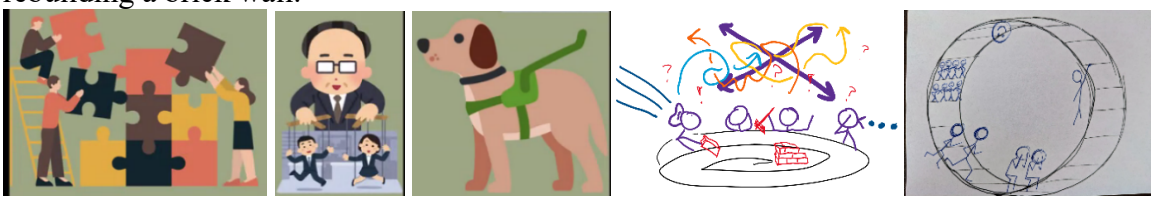

Figure 3. From Left to Right: Shared Goals as a Jigsaw Puzzle; Student as Puppeteer; NIC as a Guide Dog; Systems-Thinking as Communal Questioning, Deconstructing, and Rebuilding; and Making an Impact as a Cycle of Emotions on a Hamster Wheel.

These transformation processes were deeply connected to emotions, whether the NIC member voiced them or depicted them visually. In general, many of these processes conveyed and evoked mixed emotions. For instance, when showing or describing the process of trying to make a difference or impact within the NIC's mathematics community, some NIC members described entirely positive emotions like feeling proud, thrilled, and invested, whereas others described feeling either positive and negative emotions, such as integral, but invisible and unappreciated, or entirely negative emotions, such as discouraged, disappointed, overwhelmed, powerless, frustrated, unproductive, uncertain, lost, or confused. One NIC member specifically portrayed making an impact as running on a hamster wheel and cycling through a multiplicity of emotional states, which were both vocalized and captured in the positions and angles of the stick figures' bodies. The hamster wheel drawing in Fig. 3, depicts energized figures with elbows and knees bent to run, which transitions to worried, afraid, and shameful figures hunched over and covering their faces or dangling off the wheel with one hand. A smiley face returns the NIC member back to a state of enjoyment and fun, followed by groups of figures with arms around each others' shoulders to indicate a sense of belonging. As described in the next section, however, there were processes that consistently represented and evoked positive emotions.

Community and Belonging Fosters Inspiring, Joyful, and Accomplished Emotions

Examining the processes of transformation word cloud (Fig. 2), the relative frequency of the hashtags indicate a shared perspective that building community is one of the most important aspects of what it means to engage in the work of critical transformation. Processes of building community were conveyed through a multiplicity of media, such as real-life photographs of NIC members, including faculty and students, smiling together; AI-generated images of intently focused NIC members huddling together to make sense of and discuss data; found images of excited officemates; or mixed images of inspired NIC members generating ideas (Fig. 4). The AI-generated image and mixed image in Fig. 4 additionally demonstrate the ways in which other processes, in these cases, making data-informed decisions and generating ideas, often intertwined with images depicting a community of NIC members.

Community and Belonging Mitigates Feeling Alone, Discouraged, and Overwhelmed

A few of the images that did not center both community and an inclusive power dynamic instead highlighted feelings of being alone, alongside other negative emotions such as feeling discouraged, lost, or overwhelmed. In Fig. 5, we see an image (Starfish Students) of a young girl attending to one of many starfish spread over a beach. This NIC member described an initial and lingering feeling throughout their time on the project, stating, "I just felt so obtuse, like this was

impossible.” Although this NIC member also expressed that they felt they finally understood what a critical change was – “some sort of massive structural change within the university” – they expressed a view of limited impact, stating, “I can't say that I pulled that off… I didn't really necessarily pull off a big, huge structural change. But I think I made a significant impact to some students in my classes.”

Figure 4. Images Depicting Collaborative Communities.

Fig. 5 also shows an image (“No Tracks in the Ground”) of a person standing alone, proportionally smaller than the rest of the winding labyrinth-esque landscape that seemingly leads nowhere in particular. During the interview, the creator of “No Tracks in the Ground” described their process of deciding on an image. At first, the NIC member considered Sisyphus’s unending punishment of “pushing a rock up a hill in Hades and having it roll back down and then pushing it back up and then having it roll back down” but ultimately decided on “multiple, confusing paths, not knowing which way to go.” They elaborate on why they chose this image:

> there's no tracks in the ground to see where anyone has gone before.. I thought people were going to tell me what to do. And now I realize that no one knows. Now I have to try to navigate. I have to pick a path and see if it brings me right back where I started, or if it brings progress... I feel alone sometimes.

Figure 5. From Left to Right: Starfish Students; “No Tracks in the Ground”; and Community is the Best.

In contrast, NIC members who illustrated and vocalized both community and inclusive power dynamics highlighted positive and productive feelings, such as caring, motivated, and energized. Consider Community is the Best in Fig. 5, and this NIC member’s explanation for the choice of their image:

> The best part of participating in this has been just having the excuse to get together with my faculty that care so much about student engagement, and are just so interested in helping their students. Those monthly meetings are just really recharging, and just a great

reminder that as you're working through issues with your students, you're not alone. There are other people that have ideas you can use, and that are experiencing the same thing. And the community is just really the best part of the whole thing.

Discussion

Asking people to create or find images to represent their engagement in critical transformations led to nuanced representations of critical transformation processes, emotions, metaphors, and relative positioning. Engaging in critical transformation work as a community was the overwhelmingly cited process captured by nearly every participant; indeed, every image that conveyed transformation processes involved people. This stance reinforces approaching critical changes systemically, and the need to do this work together. Being in community was also associated with varied positive emotions and feelings of belonging and connectedness. At the same time, when the work has a transformative aim to change systems built to maintain the status quo, people experienced mixed emotions over the slow pace of change or the barriers they encountered. Trying to make systemic changes can understandably lead to feelings of confusion, being lost, and discouragement. Feelings of community and belonging helped to mitigate feelings of isolation, discouragement, and being overwhelmed.

Schnall et al. (2008) found that people's perceptions of the steepness of a hill were altered whether they were alone (more steep) or with a group (less steep). ACT UP participants who expressed more feelings of being alone also expressed other negative emotions related to the difficulties of critical transformation work. Conversely, participants who expressed feelings of belonging also expressed other positive emotions and feelings of impact and productivity. Generally, NIC members' visual imagery of the processes of engaging in critical transformations included people, implying that these processes are people-centric and subjective, rather than an abstract process of coming to some objectively ideal conclusion. Furthermore, we found that images representing community were intimately linked to positioning and emotions. Specifically, all NIC members who centered community and an inclusive or non-hierarchical power dynamic in their images also only described positive emotions, such as motivation, inspiration, and encouragement; excitement, joy, and fun; and productivity, focus, accomplishment, and pride.

Beyond the images, emotions, metaphors, positioning, and conceptualizations, one might ask what the utility is of asking people to visually represent their critical transformation efforts. Indeed, multiple people mentioned feeling discomfort with the visualizing request, or being uncomfortable trying to represent their work visually. However, in expressing these feelings, they also expressed finding value and being challenged in a productive way through the reflective exercise. We saw ample evidence that the reflection process was useful and helpful, even when those same participants were initially uncomfortable with the task. It can be easy to focus narrowly on the "now" and not stop to see how far one has come; some participants appreciated the invitation to make sense of the process and their progress with critical transformation efforts. As researchers, moving outside the typical reflection question to an arts-based reflection enriched our understanding of how participants viewed critical transformations as a complex, difficult, and rewarding endeavor. Arts-based responses captured not only critical transformation processes but also the power dynamics of participants' positioning in their NICs as well as a wide range of emotions and metaphors.

Implications

We see several implications for researchers and for those seeking to engage (or already engaged) in critical transformation efforts. One of the key implications of this research is that

emotions and perceived power dynamics are intertwined. When a person feels alone versus feels like they belong, this is accompanied by differing perceptions of agency. Knowing that sustaining change efforts takes passionate change agents (e.g., Koh et al., 2023), such passion is more easily maintained when the change agent feels more positive emotions. Further, mathematicians rarely have training on establishing and sustaining foundational trust and professional relationships (e.g., Kaschner & Neihaus, 2025). Yet, when NICs prioritized relationship building, NIC members perceived themselves more centrally in the change efforts, which is connected to higher perceived agency and more positive emotions (all of which can sustain change efforts).

Another key implication is to expect uncertainty, confusion, and tensions. Engaging in critical transformation work is more analogous to mathematical modeling than mathematical proof or problem solving. Critical transformation works from what is known and uses data to inform next steps, but there is not a single "best" path, nor a "right" answer. There are approaches that can improve outcomes (or not), but since change efforts revolve around people (with complex identities, beliefs, attitudes, skills, knowledge, power dynamics, positional authority, etc.) outcomes are also tied to the complexities of the individuals and cultural settings involved (e.g., Hagman et al., 2024; Kezar, 2014; Kezar & Gehrke, 2015). The images selected or created by our participants expressed a wide range of emotions, including conflicting emotions from single individuals (e.g., feeling both "proud" and "unproductive"). Further, by experiencing uncertainty and confusion, some instructors found themselves more empathetic to student confusion in class (similar to findings in Tremaine et al., 2024; Quaisley et al., 2025).

Engaging in visualizing critical transformation work also helped participants consider what it meant to prioritize values like diversity, equity, and inclusion, while those concepts are under increasing political attack (e.g., Harper, 2025) and being used to stoke fears (e.g., McElvane, 2025). The visuals created by reflection on critical transformation can provide concrete evidence of how people approach critical transformation, centering student outcomes, building community, and seeking to improve educational systems and policies.

Our research highlights the importance of community. When working toward difficult goals, various emotions are evoked; people cannot change systems alone. NIC members' modal feeling expressed through their visual depictions was that of community: being in community, feeling supported by community, and knowing they are not alone. Community is a remedy (perhaps the only remedy, e.g., García Peña, 2022) to feelings of isolation and overwhelm; community is the only way to change systems to address systemic inequities. NIC members' experiences of community through this project showcase what it means to combat negative connotations of DEI work, centering student outcomes to transform education systems.

Finally, we do not make generalized claims that all NIC members experience critical transformation work the way those in the ACT UP project did. Rather, we use our arts-based methods (Boyd & Barry, 2024) and findings to invite others to engage in similar efforts. We suspect that many researchers focused on undergraduate mathematics education, like us, were trained in traditional (reductionist/positivist) research methodologies that position researchers as observers of participants, and research as being a way to find out "truth." We challenge our community to seek out and try more critical methods, such as arts-based methodologies (Boyd & Barry, 2024), as ways to engage collaboration with participants in understanding unique experiences. By telling our stories, we can invite others into concomitant reflection, ideally in ways that can inspire people to initiate or expand local critical transformation efforts.

Acknowledgements

We extend our heartfelt thanks to all of the participants in the ACT UP project for engaging in a research practice partnership with us and being willing to be vulnerable, engage in the hard work of critical transformations, and engage in arts-based research with us. This research was supported in part by a grant from the National Science Foundation (2201486, 7/2022-4/2025). All findings are those of the authors and not necessarily of the funding agency.

"Rigor" is often used as a benchmark to determine whether mathematical work is sufficiently high-quality, and, thus, has significant bearing on students' course success and continuation in STEM majors. However, judgements about what constitute rigor are deeply subjective and may function as a vehicle for social bias. To interrogate possible connections between disciplinary standards and exclusionary gatekeeping, we analyze references to rigor by members of an "elite" mathematics department's equity-oriented change community. Our findings exhibit how participants' perceptions of rigor unveil a culture of power operating in undergraduate mathematics. We conclude with implications for research and practice.

Keywords: rigor, discourse, culture, power, equity

Introductory college mathematics courses, such as calculus, function as core pre-requisites for many university STEM majors and therefore impact STEM attrition rates (Weston et al., 2019). Given national disparities in tertiary STEM retention along axes of race, gender, and first generation status (e.g., Costello et al., 2023; Maloy et al., 2022; Park et al., 2020; Ortiz-Martínez et al, 2023; Suárez et al; 2021), advancing equity in the context of calculus curricula and instruction has become a central concern in undergraduate mathematics education. Mathematics departments and instructors often use "rigor" as a standard for the quality of their courses. Despite its role as a widely-used standard there is no agreed-upon definition of rigor; the term carries different meanings across individuals and mathematical contexts (Authors, under review). As an ambiguous standard that mediates inequitable STEM retention, it is possible that conceptualizations of rigor—and their implementations through instruction—embody unexamined disciplinary biases.

To further our collective understandings of how rigor and equity may interact in undergraduate mathematics instruction, we analyze an equity-oriented community of mathematics faculty and students at an elite institution, who adopted rigor as a focal issue to guide equity-intended change initiatives. Leveraging critical discourse analysis (Fairclough, 1989, 2013), we investigate implicit understandings of the term "rigor" and how those understandings get operationalized to maintain or disrupt hegemonically-focused practices in mathematics classrooms as a gateway to STEM degree attainment. Specifically, we guide this contributed report with the following research question: *How do discourses around rigor reveal a culture of power in undergraduate mathematics education?*

Conceptual Framework: Culture of Power

Delpit (1988) theorized that educational values are shaped by a culture of power (CoP), evidenced through five characteristics:

1. Issues of power are enacted in classrooms.
2. There are codes or rules for participating in power; that is, there is a culture of power.
3. The rules of the culture of power are a reflection of the rules of the culture of those who have power.
4. If you are not already a participant of the culture of power, being told explicitly the rules of that culture makes acquiring power easier.
5. Those with power are frequently least aware of—or least willing to acknowledge—its existence. Those with less power are often most aware of its existence (p. 282).

To elaborate on these characteristics, we leverage the original context of antiblackness in K-12 literacy education as an illustrative example. Delpit describes how issues of power are enacted in classrooms through the differential recognition of some forms of language as 'correct' while others are deemed incorrect or informal. Linguistic conventions deemed 'correct' are codes for participating in power. For example, students who speak and write 'correctly' generally have more access to careers that yield financial power and societal standing. These linguistic conventions align more closely with those commonly used in white households than in Black households, a reflection of cultural norms held by those with more societal power. Students, therefore, must be taught these linguistic codes of power when they do not acquire them through their households. However, many liberal/progressive white teachers oppose teaching these conventions directly in favor of approaches that encourage more freedom for students to use the language style that they prefer. Consequently, education systems may unjustly perceive Black children as requiring linguistic remediation upon entering formal education, which can have long-term ramifications for their access to power. In this way, teachers' desires to cultivate deep thinking and creativity can inadvertently perpetuate racial stratification through language instruction by centering children who have already assimilated to the CoP.

In the context of undergraduate mathematics education, we recognize that rigor plays an analogous role to language standards within K-12 literacy. Correctness is determined through rigor (however it may be interpreted by instructors/authorities), which can favor mathematical grammar over substantive reasoning. Rigor is capital; those who do mathematics with 'rigor' gain more access to success in their courses and STEM degrees. Here, we explore how rigor may function to uphold a CoP within undergraduate mathematics education.

Literature Review

Articles as early as 1920 argue for and also question the privileged role 'mathematical rigor' plays within mathematics education (e.g., Pierpont, 1928; Kitcher, 1981; Kleiner, 1991). These writings emphasize how conceptualizations of rigor, and thus the associated aims of enhancing such rigor, vary considerably. In particular, rigor is highly context- and position-specific; and thus mathematics students and faculty define general academic rigor differently (e.g., difficulty versus higher-order thinking; Cristobal et al., in press; Draeger et al., 2013; Draeger et al., 2015).

This ambiguity in what constitutes rigor raises questions about its potentially biased role in classroom practice and policy. Scholars have viewed rigor as completely separate from, or even in opposition to, care, equity, and inclusion in higher education (Marsellas, 2021; McNeill & Gresalfi, in press). Rigor can be operationalized through instruction to perpetuate existing inequities. Leyva et al. (2021) describe how instructors' standards for rigor can be experienced as part of a "weedout logic," through which students who are deemed "not cut out" for STEM are discouraged or prevented from continuing in mathematics coursework. One Latino student directly interpreted an instructor's remark as "t[a]k[ing] a shot at [his] self-esteem" through imposing "very rigorous" standards that activated racial stereotypes of mathematics ability. In

this way, standards of rigor may lend a false sense of legitimacy to the categorization of certain (groups of) students as mathematically incapable, akin to Delpit's (1988) observation of racial stratification justified by marking young Black students' language as incorrect.

Discussing the elitism of 'rigorous' mathematics within the engineering discipline, Riley (2017) notes that definitions of rigor are socially constituted; conceptualizations of rigor reflect existent social hierarchies and dominant presumptions about who can conduct 'rigorous' science. They assert that invoking rigor often functions to maintain exclusion through its assertion of white masculinized heterosexual power, drawing boundaries around what competent disciplinary practice and perspectives are, and academically punishing students to discount interdisciplinary or innovative scholarly work, including work which is oriented toward benefiting marginalized populations. They come to the conclusion below:

> "While many successful programs in mentoring and support for students of color and white females have been established over decades, these change efforts will be self-limiting as long as our standards of rigor work to reinforce gender, race, and class hierarchies in engineering, and further maintain invisibility of queer and disabled engineering students" (p. 261).

In response to this conclusion, Riley provides tenants upon which alternative conceptions of rigor might be built, one of which is facilitating abundance instead of the competition that common conceptions of rigor rely on. They highlight that this involves knowing that strengths can come from a variety of sources and working toward facilitating greater opportunity for broader engagement, as well as building up colleagues (and students) through "criticality in a caring process" (p. 262). Riley simultaneously acknowledges that coming up with an inclusive definition of rigor is an immensely daunting task, and straightforwardly advocates for "doing away with the concept altogether so we can welcome other ways of knowing" (p. 263).

However, in many institutional realities, rigor—as a word and as a concept—remains central to many conversations in undergraduate (mathematics) education. While departments work to enhance or maintain rigor in our undergraduate mathematics courses, it is necessary to think critically about how we define rigor, as well as what functions the invocation of rigor might perform. Towards this end, Gutiérrez (2013) argues that "making dominant discourses more apparent is a necessary step toward both recognizing how those discourses dis/advantage individuals and in challenging those discourses and their associated practices so as to put new ones into place" (p. 50). We respond to this call through a critical discourse analysis of rigor, and how an implicit CoP surrounding mathematical rigor may contribute to such dis/advantages.

Data and Method

This analysis comes from a larger study on Networked Improvement Communities (NICs) under the Achieving Critical Transformations in Undergraduate Mathematics Project (ACT UP Math). Through this project, education researchers with equity specializations partnered with three mathematics departments to initiate equity-intended changes, supported by equity-oriented professional development, quantitative and qualitative data, and a broader network of support across the three departments. We selected *Kappa University* as a focal institution for the present study in alignment with their NIC's focus on addressing rigor. Perhaps related to the NIC's identification of rigor as a change priority, Kappa is a highly selective institution where students and instructors alike expect difficult mathematics courses; Kappa students characterized the courses as "unnecessarily hard." As such, the Kappa NIC context serves as a fertile ground for reckoning with tensions between the perceived value, inherent ambiguity, and operationalized impacts of rigor.

The Kappa NIC was composed of four faculty affiliated with the introductory mathematics program, two graduate students who had taught in the introductory mathematics program, and two undergraduates who had taken classes within the introductory mathematics program. Research participants opted into the NIC with interests of contributing to equity-oriented change and were all equally paid by ACT UP Math. Faculty (Anna, Senna) were invited by the two NIC faculty co-leaders (Tiersa, Skylar), and the graduate (Parker, Kiara) and undergraduate students (Ricardo, Timothy) were purposefully selected out of an application pool. The NIC predominantly identified as white women, but included one woman of color and two men.

Data consists of journals and structured interviews from the eight NIC members, collected from Spring 2023 to Spring 2025. Journals were collected intermittently and prompted participants to reflect on their experience with the NIC, with some journal prompts asking specifically about participants' understandings of rigor and their progress towards addressing rigor in their undergraduate program. Interviews were conducted once per semester, typically within the latter half of the semester.

Data Analysis

We selected a subset of data for analysis by locating instances of the word "rigor," taken together with relevant context. We leveraged critical discourse analysis—a method that examines how ideologies related to societal power relations shape discourse, both implicitly and explicitly (Fairclough, 1989, 2013). Our multi-stage analysis proceeded as follows, methodologically aligned with reflexive thematic analysis, which generally includes six phases: familiarizing yourself with the dataset; coding; generating initial themes; developing and reviewing the themes; refining defining and naming the themes; and writing up the analysis (Braun et al., 2023). First, we read through all responses to the journal prompt "What does mathematics rigor mean to you?" as a basis for our preliminary codebook. The second stage consisted of developing our codebook using the subset of data which mentioned "rigor" and its surrounding context. As the codebook developed, each excerpt was coded by at least two authors, wherein different interpretations of an excerpt were reconciled within partner-to-partner or full group discussions. Multiple excerpts were coded with multiple codes. As we organized these codes into themes, we recognized the underlying CoP and organized codes according to the five characteristics of CoP to address our research question: *How do discourses around rigor reveal a culture of power in undergraduate mathematics education?*

Findings

To structure our investigation of rigor as imbued with implicit power in mathematics, we organize our findings according to Delpit's (1988) five characteristics, with brief empirical illustrations provided for each.

Issues of Power are Enacted in Classrooms

NIC members learned from student feedback on a survey and through a focus group that many students experienced Kappa mathematics courses as "unnecessarily hard." The NIC members attributed these perceptions of the course as unnecessarily hard to how rigor was enacted in classes, and led to the NIC's decision to explore rigor as their shared goal: "This idea of being unnecessarily hard… really informed that decision to interrogate rigor" (Tiersa). Given that rigor was a widely-held value in the department, including among members of the NIC, participants grappled with emphasizing rigor through their teaching. Tiersa commented that, "Instructors are feeling like 'rigor is the key component of my class', and students are feeling

like 'rigor is the thing in class that is destroying me,'" while recognizing that for students, the emphasis on rigor "can feel like gatekeeping." While participants recognized the power exerted by instructors in some cases, at other times power was implicit in their own values around rigor. For example, Skylar shared, "My dream would be to change the narrative of Kappa math, so that it is no longer perceived as 'unnecessarily hard.'" In desiring to change how students *perceive* rigor rather than the ways rigor is *enacted* in classes, Skylar left intact the assumption that rigor is inherently valuable and students must adjust themselves accordingly.

There are Codes or Rules for Participating in Power; That is, There is a Culture of Power

When discussing rigor, participants described many codes and rules associated with rigor, which were especially pronounced in relation to proof and notation. However, they also recognized these codes and rules were largely unrelated to students' academic development. For example, Parker noted,

> There are times where [rigor] is important when you're, like, writing up a proof because… you're publishing it. And someone on the internet is going to read it… [and] you won't necessarily be given the option to explain yourself later, and you want to be rigorous with how you write it up to do your very best at being understood correctly. But that's not necessarily why our students are learning math.

Parker frames adhering to written conventions related to rigor as important for mathematicians who may be publishing their work, but less important for students. In this way, codes and rules surrounding rigor can be seen as cultural values that arise from professional imperatives among mathematicians rather than conventions that are necessary to support students' learning. Supporting this view, Kiara suggested that adhering to rules and codes surrounding rigor may be antagonistic to goals of preparing students to apply their mathematical understanding to their major discipline when teaching Calculus II:

> Mathematical rigor at a course level sometimes loses sight of the point… to equip students with tools that they will hopefully use in whatever discipline they want to… it's not always most appropriate for us to go through proofs very carefully… On some level it does feel useful for students to see… what a proof looks like… to carefully check details starting from a definition and moving towards a proposition or a statement. And yet at the same time, maybe that's not the key skill that we want to be moving through.

Kiara's description references specific codes and rules associated with establishing rigor (e.g., "starting from a definition"). However, they perceive these codes as in tension with the goals of mathematics learning. This reinforces a view that the codes and rules of rigor are the product of cultural values within the mathematics discipline, functioning as a CoP.

The Rules of the CoP Reflect the Rules of the Culture of Those Who Have Power

Participants framed the adherence to rigor conventions as culturally rather than pedagogically motivated. Their discussions of rigor suggested, both implicitly and explicitly, that these cultural mathematical values aligned with racial and socioeconomic power differentials. For example, when discussing which marginalized group to focus on to guide instructional improvements, Skyler shared the NIC considered "students of color and students who come from… less rigorous high schools," because this population experienced "culture shock" when moving from schools that "didn't even offer calculus" to being in "classrooms with people who took linear algebra already." Given the tendency for 'rigor' in secondary schools to align with socioeconomic status (Palardy, 2013), Skylar's description draws an implicit correspondence between rigor and race and class inequality, suggesting those who value and are familiar with rigor constitute a racially

and financially privileged group.

Racial inequities were named infrequently but explicitly when participants discussed qualities of rigor. For example, pertaining to notation, participants discussed, without naming, the "worship of the written word"—a quality of white supremacy culture (Okun, n.d.) which can dismiss the perspectives of marginalized people due to syntax. NIC members questioned the precise grammar of rigor, claiming that instructors "making sure that they're getting the exact correct notation every time is not necessarily in their [students'] best interest" (Parker).

Being Told Explicitly the Rules of that Culture Makes Acquiring Power Easier

In line with Delpit's (1988) work, participants advocated for explicit teaching about rigor when rigor was deemed necessary. For example, when discussing notation, Tiersa considered changing the way she evaluated student work to validate "different dialect[s]" and to be explicit about expectations for notation when she could not.

> I don't want to be picky about notation, and I wanna make sure that I'm trying to understand what my student is saying, even if they're saying it in a way that's different from how I would say it, when I'm evaluating their work. And if I am gonna be picky about something, I better be really clear about whatever it is I'm being picky about.

Beyond the specific example of notation, participants challenged the rendering of rigor as an unquestioned, implicit expectation in calculus classrooms. As an example, Parker shared,

> I… tell my students… when it's okay to not be as rigorous… There's so much that we don't tell students, that we just say… "You have to learn this because it's important." …[I'm] taking that away a little bit… [at] times I'm like, "This is correct. I would like you to use this [notation], but I also understand if you don't"... showing a little bit more of that flexibility with the ultimate goal of them learning math… and put it together for themselves, instead of just doing what they've been told, because they were told "Do it."

Parker describes being explicit about when and why rigor was required, distinguishing between students' performance of rigor and their mathematical comprehension. These instructional aims recognize that explicit instruction helps students acquire rigor as a form of power in mathematics, while also decentering rigor as the "right way" to do mathematics. It is possible such explicit forms of instruction mitigate the racial and socioeconomic stratifications that arise through students' differential pre-college exposure to rigor.

Those with Power are Frequently Least Aware of Its Existence

Although participants occasionally acknowledged links between rigor and social power tied to race and class, more frequently they revealed a lack of certainty about rigor's relationship to broader inequities. As an example, Anna shares how "interrogating rigor [in the NIC]… was student driven" and that "if it were just [her] and [her] own silo, [she] would say 'I'm not looking at that [student work] because it's not rigorous enough'", which we interpret as maintaining rigor as a benchmark for evaluating hypothetical student work. She does recognize that she does need to "keep figuring out how to maintain [rigor] in the class while still keeping things accessible or making things more accessible and inclusive," implicitly contrasting rigor with accessible or inclusive classes. The NIC's tensions with recognizing potentially exclusionary aspects of rigor was also notable when Skylar brought a discussion topic to the NIC about possible connections between white supremacy and rigor, operationalized through rigid notation expectations.. Skyler noted that when they raised possible connections to white supremacy, the NIC "veer[ed] away from criticality," consistent with an avoidance of recognizing racial power—a common move among those who benefit from it (Bonilla-Silva,

2006).

Participants often expressed a lack of clarity and sometimes concern about how rigor and the team's explicit broader goals of advancing equity were related, particularly because they engaged a critical perspective that explicitly connected equity to identity. For example, commenting on students' common perception of rigor as "unnecessarily hard," Tiersa questioned, "what's the particular population or group that feels like things are unnecessarily hard?" After reflecting on how rigor relates to issues of power mediated through mathematical notation, they also shared,

> I don't know where the diversity, equity, and inclusion are in what I've just said…. I'm coming back to this 'for all' kind of language… I guess I'm not sure how that [notation] interacts with this idea of helping include people who haven't been well included.

Similarly, Skylar reflected "we really haven't talked much about student identity at all in this group, not even the sort of students with less rigorous high school experiences." Hence, although participants were attentive to power dynamics in the instructor-student relationship, they demonstrated a limited awareness of how rigor was tied to power in broader society. Participants' separating rigor from equity reveals their lack of awareness that rigor itself is part of the CoP they inhabit—and from which they benefit.

Discussion and Implications

Riley (2017) highlights the parallelism between the dual meanings of rigor—as both academic credibility and hardship—and of discipline—as both an academic field and corrective control. The CoP revealed through our findings demonstrates the confluence of these multiple meanings of disciplinary rigor, linking widely-held and seemingly-neutral mathematical values with the exclusionary impact of introductory undergraduate mathematics courses. While some work has importantly identified aspects of classroom practice that may contribute to racialized and gendered exclusion from STEM (e.g., Leyva et al., 2021), our analysis contributes to an emerging body of work that interrogates mathematical values as a root from which exclusionary teaching practices emerge (McNeill & Gresalfi, in press).

Delpit (1988) concludes by naming a number of ways to move beyond the limiting and exclusionary confines of the CoP within K-12 literacy education, including to give students opportunities to be authentic and creative in their writing while also explicitly teaching the cultural convention of writing. This resonates strongly with many current debates around modern pedagogical approaches within undergraduate mathematics and thus has implications for both our practice and future research. Mathematics educators seeking to improve student experiences by cultivating deep thinking and creativity within mathematics may see this as at odds with directly teaching mathematical conventions of rigor, similarly centering students who have already assimilated to the CoP within undergraduate mathematics. However, through the lens of CoP we recognize rigor as cultural capital, and thus see a need to make its value and form explicit, especially for students who have not yet assimilated to the CoP. We call for future research to take up and explore the role of rigor across undergraduate mathematics education to further theorize how instruction can move towards equitable mathematics learning within a CoP.

Student Experiences of Active Assessment in Undergraduate Mathematics

Sydney Belomy
California State University, East Bay

Anthony Chon

Simone Sisneros-Thiry
California State University, East Bay

Active-learning-based instructional practices are well-established in undergraduate mathematics. What it means to align assessment with those active learning methods is an emerging area of research and development. Here we present student experiences of "active assessment," assessment strategies grounded in the values and practices of active learning. As part of a larger study, we gathered undergraduate student responses to survey and semi-structured focus group interview questions about their experiences with various active assessments. Their instructors all were part of a year-long Assessment Community of Practice focused on active assessment. In this paper, we focus on student-identified benefits of active assessments, as well as student perceptions about how the assessments were equitable or potentially inequitable. We conclude with suggestions for instructors and discussion of considerations for moving forward.

Keywords: active assessment, active learning, student experience

What does it mean for assessment to be aligned with the values and practices of active learning? The benefits of active learning for students in college level mathematics courses are well-documented (Freeman, et al., 2014; Theobald, et al., 2020; Uhing, et al, 2021). However, little is known about how to align assessment practices with the methods promoted for active teaching and learning. *Active learning* has been defined broadly as instructional methods involving students in doing things and thinking about what they are doing (Bonwell & Eison, 1991). Our consideration of active learning includes Laursen and Rasmussen's (2019) four pillars of inquiry-based mathematics education (students engage deeply with meaningful tasks, students collaboratively process ideas, instructors inquire into student thinking, and instructors foster equity in their choices). Consonant with these methods, we have defined *active assessment* based on a consolidation of ideas including active learning, formative assessment, and alternatives to timed, high-stakes individual exams. Our working definition of active assessment was developed across a year of work by an instructor Assessment Community of Practice.

Active assessment captures student progress and facilitates growth in the journey through mathematics. Active assessment is a process that sets high expectations and supports meeting those expectations. The process is rooted in

- engaging student understanding more equitably,
- reinforcing communication, reflection, and collaboration, through mathematically rich tasks,
- valuing diversity in expression while being asset-minded, and
- giving students the opportunity to share, learn, and expand on ideas as a community.

Examples of active assessment include group projects and presentations, exams with a group or collaborative component, variations on standards-based grading, and portfolios. This paper presents student experiences of several of these forms of active assessment. The driving question for the larger project is: What are the benefits that students and instructors identify in the

implementation of specific active assessment strategies? Here we report on analysis of a subset of data aimed at addressing a particular question about student experience. *Research Question:* Among students who participated in at least one group-based active assessment, what did they identify as benefits and what did they point to as equitable (or not) in working with others to complete the assessment?

Conceptual Framing

We draw from Black and Wiliam's (2009) definition of formative assessment and Laursen & Rasmussen's (2019) definition of inquiry based mathematics education in framing this study.

Formative Assessment

Black and Wiliam (2009) give the following definition of formative assessment which highlights how teachers, learners and their peers are involved in formative assessment:

> Practice in a classroom is formative to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited.

They elaborate on this definition by introducing five strategies that were developed by crossing the three different agents (teacher, peer, learner) with Ramaprasad's (1983) three key processes for learning (see Table 1).

Table 1. Aspects of formative assessment from Black and Wiliam (2009).

<table>
<tr><th></th><th>Where the learner is going</th><th>Where the learner is right now</th><th>How to get there</th></tr>
<tr><td>Teacher</td><td>1. Clarifying learner intentions and criteria for success</td><td>2. Engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding</td><td>3. Providing feedback that moves learners forward</td></tr>
<tr><td>Peer</td><td>Understanding and sharing learning intentions and criteria for success</td><td colspan="2">4. Activating students as instructional resources for one another</td></tr>
<tr><td>Learner</td><td>Understanding learning intentions and criteria for success</td><td colspan="2">5. Activating students at the owners of their own learning</td></tr>
</table>

While elements of active assessment are formative, assessments also may serve as summative for a course or unit. Of particular interest to this study is strategy 4, *activating students as instructional resources for one another.* We explored the ways in which students are "activated" in this way by examining the elements of the active assessment process that students identified as beneficial, equitable, and potentially inequitable.

Four Pillars of Inquiry Based Mathematics Education

The Assessment Community of Practice was conceived in an institutional context that has a strong commitment to active learning. The active learning values of the departmental community were strongly aligned with the four pillars of inquiry based mathematics education (Laursen & Rasmussen, 2019). These four pillars are:

1. Students engage deeply with coherent and meaningful mathematical tasks.

2. Students collaboratively process mathematical ideas.
3. Instructors inquire into student thinking.
4. Instructors foster equity in their design and facilitation choices.

The four pillars did not originate in a context where assessment was considered explicitly. Nonetheless, they deeply influenced the ACoP's definition of active assessment. In this paper, we focus on the second and fourth pillars: students' reported experiences of how they collaboratively process mathematical ideas and their self-reports about perceived equity and inequity in the active assessment process.

Methods

Data for the study was collected through a two-stage process during the Fall 2023 through Fall 2024 semesters. In the 2023-24 academic year, we received a total of 278 survey responses from students in 13 different lower and upper division undergraduate mathematics courses, taught by 8 participating instructors who implemented active assessment strategies. This represented 59% of all students enrolled in those courses. Stage 1 data consisted of written responses to a survey administered during class time towards the end of the semester. Questions asked the students to share their experience with the active assessment strategy implemented in the class that they took, and to identify potential benefits or inequities of the strategy. Stage 2 data were from semi-structured focus group interviews with a subset of 18 of the 278 students who had completed surveys. At least one student from 9 of the 13 courses surveyed was in one of the four focus group interviews. The group interviews were completed across Spring 2024 (5 students and 2 students) and Fall 2024 (6 students and 5 students). Each interview lasted approximately 60 minutes. The interview questions were designed as follow-ups to the stage 1 survey and discussions focused on students' experiences with active assessment.

All data analyzed for this report were qualitative, from open-ended survey and interview prompts. The unit of analysis was a "student response." For the survey, this unit of analysis was the entirety of a student's answer to a survey question. For the focus group, a "student response" was everything a student said in response to a prompt (from the interviewer or from another student). Analysis of student responses was through the inductive constant-comparative method commonly used for qualitative data interpretation (Patton, 2014; Creswell & Creswell, 2018). The inductive hypothesis was that the categories for coding came from the prompts (e.g., the categories of benefits and equitable/inequitable experience). For the surveys, thematic coding was completed by three authors. Each person coded a subset of responses (about 20), then they compared and calibrated their coding. This cycle continued with larger subsets until all responses had been coded for the surveys. A different subset of three authors completed a similar coding and calibrating cycle for the transcripts of the focus group interviews. Next, key themes were identified across coding of student responses from the written surveys from stage 1 and the interview transcripts from stage 2. We report here on this analysis.

Researchers

All of the researchers have experiences of active assessment as students, in undergraduate mathematics courses, graduate courses and/or post-graduate professional development. In the context of undergraduate courses, some of the researchers have experience implementing active assessments as instructors of record and some plan to in the future. Our research team includes one faculty member and three current/former graduate students, each of whom worked on the project for at least one year and contributed to analysis for at least one of the stages.

Results

We present student experiences of active assessment strategies first from the survey and then from the focus group interviews. Students shared benefits and challenges about active assessments that involve collaborative group work, offering insight into how they saw these strategies as impacting their learning, confidence, and sense of equity. The key themes touch on collaboration, access, group dynamics, and equity, highlighting strengths and limitations of active assessment from the student point of view.

Student Survey Results

The two main survey questions we focused on for this report were:

1. Please give an example of something about the [assessment strategy] that you think is beneficial for students? and,
2. Please give an example of something about the [assessment strategy] that you think might be unfair or inequitable? Why?

Of the 268 responses to the first question, the most frequently identified benefit of an active assessment strategy was collaboration, with 85 student responses (31%) mentioning it. For example, one student wrote, "They allow students to share their knowledge and come together to solve problems. Multiple sources of input helps because maybe one section is particularly challenging." The next most frequently identified benefits were applications and reflection/review, each with 21 student responses (8%) mentioning these aspects as beneficial. Other identified benefits included less stress, building experience, feedback, and the opportunity for demonstrating knowledge. The vast majority of responses identified only one benefit, but several longer responses identified more than one benefit.

On the other hand, among those who responded to the second question, the most commonly identified potential inequity of the active assessment strategies was unequal work, with 76 responses (27%) identifying unequal work distribution as a potential source of unfairness. These comments were similar to the student who wrote, "With any group, there tends to be at least one person who doesn't do much work while there is someone who does too much." The second most frequently identified inequity was format/accessibility, with 23 student responses (8%), and the third most frequent response was group dynamics (not related to unequal work distribution), which appeared in 18 responses (6%). Other identified inequities included time/pacing and workload. Finally, 44 students (16%) said the strategy they experienced was not inequitable.

Student Interview Results

Students' perspectives were also gathered through focus groups. The interviews offered glimpses into how students defined equity, perceived the benefits of group-based assessments, and how they identified the assessments as equitable or potentially inequitable. Students also suggested improvements for future implementation. The following sections present key themes that emerged from the focus group interviews.

Student definitions of equity. During the focus group interviews we asked students to define equity in their own words. This gave additional context and meaning to their replies to later questions regarding the ways the assessment strategies they experienced were equitable or not. The common themes that arose in their responses were access and accommodations. As one student stated, "[Equity means] a level playing field for everyone." This was echoed by a student in a different focus group stating "The definition of equity is being able to allocate more toward those who are in need." In another group, a student said,

> I think equity has a lot to do with I guess access for me. Like, if you have access to these certain things or certain… Not learning strategies, like… Access to these different modes or these different styles and different learning. Different kinds of learning, right?

which was then backed by another student who said,

> For my definition of equity it would probably be, to be able to accommodate as large of an audience as possible. So pretty much not leave anyone out, be beneficial to everyone.

Students' definitions of equity provide a meaningful lens through which to interpret their experiences. Some students saw benefits as being an indicator of equity, and there was significant overlap in responses to questions about benefits of active assessments and what students indicated was equitable.

The beneficial impact of active assessment. A main theme that emerged from the interviews was the academic benefit of learning from peers. Students often described how working collaboratively exposed them to different ways of thinking.

> And also you could learn more from the group, because sometimes like you think you're doing it right, for example a lot of graphing for that one and you know sometimes it's just like those small things where someone could actually walk through it and be like, oh, actually I think this, you know, two brains are better than one, you know?

Another benefit students identified was the shift in students' mindset and confidence in problem solving. Rather than viewing assessments with anxiety or dread, some students reported that group assessments had changed their perspective to be more agentic:

> Students are not thinking of [math course] as like… it's a terrible exam. 'How am I going to do? What am I going to do?', that perspective changed to 'Okay, I'm going to figure it out. I got this exam.' So that change of perspective is what I observed within me, my friends in that class and all other people as well.

Group dynamics also played a positive role for many students. Several students emphasized how collaboration allowed for a safe environment to make mistakes and learn from them.

> When you do it in a group environment, you're allowing for that mistakes that happen. And with those mistakes, they get more confident in their answers, they're like, oh I know exactly what I'm doing now, I learned from my mistakes.

Furthermore, shared responsibility was reported as beneficial:

> I really found that effective uh because like for me as well as for others, because people... felt confident they feel comfortable in that setting and then that eventually helped them.

also serving to motivate students to engage more deeply with the material:

> I also observed that a few people from my group, they actually started putting more efforts in the group when they became a part of this… since everyone is answering questions, I need to put more efforts on myself. Maybe I need to study more so that even I can share answers or even I can help others to get solved and then maybe a few doubts which I have, others can help me with that.

These themes, exposure to other ways of thinking mathematically, an agentic perspective, increased support for risk taking, and the motivational benefit of shared responsibility captured what 14 of the 18 students (78%) said related to benefits. The students whose responses were not represented by these themes focused on reduced stress around grades, opportunities to "think outside the box" when demonstrating knowledge, and instructor support.

The inequities of active assessments. In addition to benefits, students also identified aspects of the assessment strategies that were potentially inequitable. Students identified challenges that raised questions about fairness, accessibility, and the burdens placed on certain individuals

within groups. One theme that arose was the shared responsibility of group work and having to rely on one's peers, particularly in groups where interaction was strained.

> For the project I did, a big barrier was not working well with team members, if they don't show up or you don't get along, it's hard to do the work. Unlike an exam where you rely on yourself, the main challenge here is working with others.

Another inequity that many students identified was the discomfort that group interactions might have for students with social anxiety.

> I've noticed that some people maybe they want to like, say their point of view out loud, but they just don't feel comfortable. Or, or yeah I guess they don't feel comfortable enough to talk about it as a group, maybe they might be afraid of how they might be judged. Maybe if it's wrong, they might overthink it and assume the entire group is gonna think they don't know what they're talking about.

Additionally, some students also acknowledged the potential to "ride the coattails" of their peers in a group setting.

> For mine, I like for sure rode the coattails of one of the dudes in our group, like I mean because math in like upper division takes a lot of time to study and some of these I feel like should be year long courses. So when I was able to study and prepare, I was contributing well.

These themes, interpersonal dynamics, discomfort and social anxiety, and unequal contributions to group work captured what 14 of the students (78%) responded in relation to inequities. While other concerns brought up included fairness of grading and time commitments, not all of the 18 students identified any inequities for their assessment strategy.

Student Suggestions for Next Time

As part of the survey, we asked students "If you could give advice to an instructor who was going to use this strategy in a future class, what would you want them to know?" Students identified areas of opportunity for instructors to combat the challenges that may arise with active assessment strategies. Student suggestions included:

1. Develop and communicate clear rubrics outlining specific expectations for active assessment tasks, as students noted that the unfamiliar nature of these strategies often introduced ambiguity in grading criteria compared to traditional assessments.
2. Integrate structured icebreaker activities to support the development of positive group dynamics and mitigate the social complexities associated with collaborative work.
3. Allocate additional in-class time for group collaboration, which students identified as a means to foster stronger peer connections and reduce the logistical challenges of coordinating meetings outside of class.
4. Incorporate a system of accountability within group assessments, such as peer evaluations and periodic check-ins with the instructor, to ensure equitable participation and sustained engagement.

In the focus group conversations and survey responses, student suggestions conflicted or students identified tensions in their preferences for how the active assessments were structured or implemented. For example, some students preferred randomly assigned groups while others said it "felt more comfortable" working with people they chose to work with. Similarly, some students preferred keeping the same group throughout a term, while others noted benefits from working with different peers. One-third of the focus group participants and about 9% of survey respondents indicated that they would like to be able to choose between assessment strategies (e.g. project or traditional exam for a particular unit).

The survey results indicate that despite the potential inequities they identified, students overwhelmingly preferred active assessments to timed, individual exams, with 79% of students stating that, given a choice, they would choose the active assessment compared to 16% who would choose a timed exam. Other students would choose both forms of assessment, or neither.

Discussion and Recommendations

While the majority of students reported meaningful academic and motivational benefits from active group assessment, their reflections also revealed important concerns. Despite the potential for deeper learning and confidence, experiences in collaborative settings were not universally positive. Student reflections highlight the complexity of group-based active assessments. Though some students reported finding them academically enriching and confidence-building, others encountered challenges that raised concern about equity. These tensions point to a need for thoughtful implementation, reflection, and ongoing improvement.

Some concrete suggestions from students to instructors look to alleviate the social complexity of working in groups and develop stronger relationships among peers. At the same time, students came to active assessments more familiar with individual assessments. Thus, their suggestions emphasized the importance of being graded for their specific contributions and being able to hold groupmates responsible for doing a fair share of work.

Not all challenges in implementing active assessment have straightforward solutions or recommendations. We note that different grouping strategies might work better for particular courses and contexts. Instructors may choose to poll their class to give the class more agency in determining group structures, or give some choice (e.g. choose one person you want to work with) within a more randomized system. Also, student preference for the option to choose among active assessment formats may raise additional concerns about equity in grading and opportunity.

A major ongoing topic of discussion for higher education is how to accommodate and support students who have extensive outside of class obligations or other personal reasons for being unavailable to engage in collaborative assessment activities that call for outside-of-class work. This is particularly relevant at our institution where many students work full time outside of the university, are nontraditional students, and commute to campus. The challenge of collaborating with peers who are not always present came up repeatedly for students, even as many of them found collaboration to be a primary benefit of active assessments.

Topics not raised by students in the interviews, but important for continued research and development of active assessments include: strengths and contexts of multilingual students, considerations for accessibility and accommodations, and adaptability to changing technology.

Each group of students is different. There is no one right way to make an active assessment perfectly equitable. Our conceptualization of active assessment is aspirational, and implicit in its definition is ongoing revision and response focused on making assessment equitable in a specific context. In the words of one student focus group participant: “Maybe it's impossible to have like, equitable classroom[s]. Lovely in theory, but it's just almost impossible to do. Okay. But I appreciate the efforts.” Student participants overwhelmingly preferred active assessments, though imperfect, and identified a number of benefits. This research suggests that active assessment has potential to imperfectly move toward equity.

PSTs' Symbolic Forms During Mathematizing: The Case of Mia and Ava and the Laundry Task

Afaf Bahajj
Utah State University

Sindura Kularajan
Utah State University

This study investigates the symbolic forms pre-service teachers (PSTs) drew upon while mathematizing a real-world laundry task. Drawing from Sherin's (2001) framework of symbolic forms, we analyzed how two PSTs, Mia and Ava, coordinated mathematical symbol templates with conceptual reasoning to model when clothes should be washed based on bacterial load thresholds. Our analysis identifies both singleton forms: threshold and exponentially growing, and networks of forms: rate, contributing factors, and exponential growth with a threshold. We end with implications for research on student cognition during modeling.

Keywords: symbolic forms, mathematical modeling, mathematizing, pre-service teachers, student thinking

Introduction

Mathematical modeling entails using mathematical structures and relationships to represent real-world situations. As such, modelers are required to engage in certain processes to have successfully modelled (Niss, 2010). Within the mathematical modeling (hereafter referred to as modeling) education research literature, the process of using mathematical structures to formulate a mathematical model for real-world situations is referred to as *mathematizing*. In essence, mathematizing is a process by which an individual uses mathematics to make sense of reality (Freudenthal, 1968). While there exist various modes of mathematical representations that can be used during mathematization, such as graphs, diagrams, and tables (Duval, 2006), modeling from first principles often requires modelers to represent real-world situations using symbols, expressions, and equations. When a modeler models from first principles, the goal is to align a mathematical representation with a scientific interpretation of the situation (Greca & Moreira, 2002). As mathematizing has been documented as notoriously challenging for learners of all levels (Stillman et al., 2010; Roan, 2024), many research programs have developed around the central goal of supporting students' mathematization. Examples of these research programs include theoretical frameworks for what it means to have successfully mathematized (Niss, 2010), how to support students through scaffolding to mathematize (e.g., Stender & Kaiser, 2015), identifying the blockages students' experience during mathematization (Klock & Siller, 2020; Schaap et al., 2011), and cognitive constructivist perspectives to construct accounts of students thinking around mathematizing, which is relevant to our study.

The primary goals of research programs that adopt a cognitive constructivist perspective to study students' mathematizing are to (a) build asset-based accounts of how and why a student did a certain mathematizing move, and (b) use those student-centric accounts to guide instructional design and intervention. In this study, we aim to contribute to the knowledge on goal (a). To do this, we adapt Symbolic Forms as a theoretical construct that is rooted in Knowledge-in-pieces (KiP) (diSessa, 1993). Particularly, in this paper, we contribute to the literature surrounding modeling and cognitive constructivist theories by documenting the symbolic forms our participants, pre-service teachers (PSTs), drew upon as they constructed a mathematical model for the Laundry Task scenario.

Theoretical and Empirical Background

Mathematizing

We situate our work within the cognitive perspective of modeling (Kaiser, 2017), where the focus is on investigating modelers' cognitive processes during model construction. Within this perspective, mathematizing is typically considered as transforming a real model (i.e., a modeler's idealized conception of the situation) into a mathematical model (i.e., a modeler's organization of their conception of the real-world in mathematical terms). While the process of modeling includes other competencies during modeling, such as understanding the situation, simplifying the situation by making assumptions, validating the process and results, and interpreting the results, the model construction process can be clustered into two major phases: pre-mathematization and post-mathematization (Niss, 2010). The compartmentalization of the modeling process, as before and after the model is formulated, implies the centrality of mathematization to modeling. For successful mathematization, it is suggested, modelers have to engage in both cognitive, meta-cognitive, and anticipatory meta-cognitive activities (Galbraith, 2017; Niss, 2010; Stillman, 2011). Yet, despite this centrality of mathematization to modeling, the process of mathematization has only been investigated to the extent of the kinds of mathematical approaches modeler's use during mathematization (e.g., Anhalt et al., 2018; Larson, 2013), the cognitive blockages students' experience during mathematization (e.g., Klock & Siller, 2020), and the modes of representations through which modelers externalize their mental representations (e.g., Duval, 2006). While this research illuminates important facets of students' mathematization activities, it does not attend to the cognitive resources (Hammer, 2000) that students draw upon during mathematization. Understanding these resources is critical for identifying instructional interventions that go beyond instructing students what to do to diagnosing students' blockages and prescribing ways where students can overcome the blockages to progress in their modeling. In this study, we focus on the cognitive resources PSTs drew upon to mathematize the real-world situation through equations.

Symbolic Forms

The fundamental premise of the KiP framework is that one's knowledge is a complex network consisting of knowledge ontologies and knowledge systems that work in coordination to make sense of a given situation (Swanson, 2025). One example of knowledge ontology—fine-grained knowledge elements that get activated when a situation is presented—that is particularly useful for mathematizing, is symbolic forms (Sherin, 2001). Symbolic forms build on the idea that scientific construction is an epistemic game in which the players' (or learners' or modelers') moves are guided by pre-existing knowledge templates (Collins & Ferguson, 1993). Thus, symbolic forms constitute both a symbol template and a conceptual schema. These constructs have been neatly illustrated by Jones (2013) with the following example. Consider the equation $V = V_0 + \Delta V$. This equation has the symbol template ■ = ■ + ■, and the conceptual schema associated with this template is total equals based plus change. At the same time, consider the equations $T = P + K$, where T represents the total energy of an object and P and K represent potential and kinetic energy of an object, respectively. While this equation also has the symbol template ■ = ■ + ■, it has the conceptual schema parts of a whole. In his work with students working on physics concepts, Sherin (2001) documented the various symbolic forms his students used while constructing equations to represent physical situations.

Few scholars have used symbolic forms and an analytical tool to construct explanatory models of students' mathematizing activities. For example, Roan and colleagues (Roan, 2024

Roan et al., 2025) used symbolic forms together with quantitative reasoning (Thompson, 2011) to explain the many meanings of multiplication students attribute to ■ × ■, while using it to model real-world scenarios such as interaction between species. The underlying premise is that symbolic forms blended with quantitative reasoning (Brahmia & Thomson, 2025; Roan, 2024) are powerful tools to go beyond describing what the students did to explaining why the students did what they did, providing prescriptive capabilities for educator intervention (Czocher, 2025). With this hope, in particular, we address the following research question: *What symbolic forms did the PSTs draw upon as they mathematized the laundry task?*

Methods

Participants and Setting

The participants were recruited from a mathematics content course required for K-8 pre-service teachers at a large public university in the western United States. All participants had completed prerequisite coursework in college algebra. A total of four students participated, working in two pairs. The research team met with each pair for 60 to 90 minutes for a total of ten sessions. Sessions were held in a quiet room on campus and were audio and video-recorded. The PSTs were given the freedom to conceive the task however they wished and use any mathematics they thought best represented their conception of the task. The researcher's role was to ask clarifying questions and probe the PSTs' thinking. In this paper, we focus on the symbolic forms of one pair of PSTs' (pseudonyms Mia and Ava) working on the Laundry Task. The Laundry Task is presented in Table 1. Mia and Ava's work on the laundry task was reminiscent of what Collins and Ferguson (1993) would call an epistemic game. First, the PSTs conceived that bacterial growth could either occur linearly or exponentially. Next, they modelled each linear and exponential growth, abiding by the "rules" of how each growth occurs. For this reason, we chose to explore Mia and Ava's work, the Laundry Task, for further analysis. In this paper, we report on a portion of those findings.

Table 1. The Laundry Task (abridged version). Task description taken directly from Smith (2023).

On January 10, 2023, TikTok user Allison Delperdang sparked a lively debate when she shared a video about wearing the same pajamas multiple times before washing them. The video garnered millions of views and countless comments, with some agreeing that frequent washing isn't necessary, while others argued it was unhygienic. Experts weighed in, explaining that how often clothes should be washed depends on several factors, including personal hygiene habits, activity levels, and the type of clothing. Dermatologist Dr. Anthony Rossi emphasized that our cultural norms often lead to "over-washing," even though not all clothes need frequent cleaning. At the same time, wearing hygiene clothes can cause skin infections due to bacterial overgrowth in the unwashed clothes. Research indicates that bacterial loads exceeding 1000 colony-forming units per square centimeter (CFU/cm^2) can pose a risk, particularly for pathogenic bacteria like Staphylococcus aureus. Develop a mathematical model for determining how long clothing can be safely worn before washing?

Data Analysis

The data were transcribed and analyzed using MAXQDA, a qualitative data analysis software, to support the identification of PSTs' symbolic forms. Our analysis proceeded in three stages. First, we used Sherin's (2001) framework on symbolic forms as a foundation to develop a shared criterion for identifying symbolic templates and their coordination with conceptual reasoning. We conducted an open reading of the transcripts, supplemented by repeated viewing

of video recordings to become familiar with the data while attending to moments where PSTs expressed their reasoning through both inscriptions and verbal utterances. During this round, we used Sherin's framework (see Sherin, 2001, p. 532–537) to identify any symbolic forms. For this analysis, we sought evidence of symbolic forms through (a) symbolic templates that were explicated either verbally or through notations and (b) PST's justification for their proposed templates. For example, when Mia and Ava wrote the expression $(c + h + a + s)^{\#days}$ as their model for exponentially growing bacterial load, we coded this as the symbol template ■▪. When the interviewer probed for justification for their representation, Ava stated, "I don't know if you need to put it to a power or something…I feel like when I've done exponential kinds of problems in the past…I mean I think it makes sense in the fact that as more days there's more growth." We took this as evidence of a growing exponentially conceptual schema. This is because the PSTs reasoned that the bacterial load grows "with some parameter that appears raised to a positive power in the exponent of the exponential" (Sherin, 2001, p. 536). Both authors independently coded the transcripts for such instances, marking segments where symbolic forms appeared and assigning them to one of Sherin's categories (e.g., *parts-of-a-whole*, *canceling out, exponent*). If there were any forms were not part of Sherin's framework, we created a new code based on the inferred PSTs' conceptual reasoning. We then met regularly to compare interpretations, discuss discrepancies, and refine the coding scheme together. Finally, the authors applied the refined framework to the entire video to ensure consistency.

Findings: PSTs' Symbolic Forms

Our analysis revealed that PSTs used a variety of forms as they worked on the Laundry Task. These forms fell into two categories: *Singleton Forms,* which involved the use of a single symbolic template tied to a conceptual schema, and *Network of Forms,* which reflected the coordination of multiple symbolic templates to organize the situation. Within the singleton forms, we identified the threshold and exponentially growing forms. Within the network of forms, we identified the rate form, the contributing factors form, and the exponential growth with a threshold form. Table 2 summarizes these symbolic forms, their associated templates, and the conceptual schemas that PSTs drew upon. Due to space constraints, we elaborate on the threshold, rate, and contributing factors in symbolic forms.

Table 2. Overview of PSTs' symbolic forms

Form	Template	Conceptual Schema
	Singleton Forms	
Threshold	■ < ■	One side cannot exceed the other
Exponentially growing	■▪	The amount is growing exponentially with time
	Network of Forms	
Rate	■/■ = ■	Instantiating a rate
Contributing Factors	■ = ■ + ■ + ■	Factors that contribute to a whole
Exponential growth with a threshold	■ ≤ ■▪	The amount that is growing exponentially with time cannot exceed the other

The Threshold Form

The threshold symbolic form consists of the symbol template ■ < ■ and the conceptual schema that one situational attribute cannot exceed the measure of another. For example, Mia and Ava reasoned that if the bacterial load reaches 1000 CFU/cm^2, then the clothes must be washed. The following conversation between Mia, Ava, and the interviewer illustrates this form.

Mia: I feel like one side of the equation would need to equal this, though [referring to the 1000 CFU]. Because that's a max that you can go.

Ava: Yeah, because that's a risk.

Mia: But like something equals 1000 colony for me. I don't know. *Interviewer:* What did you mean by that's the max we could go?

Mia: Because it says any bacterial loads exceeding this amount need to be washed basically, because they pose a risk.

Here, Mia and Ava reasoned that once the bacterial load reaches or exceeds 1000 CFU/cm^2, the clothes need to be washed, implying the bacterial loads on clothes must be less than 1000 CFU/cm^2, for the clothes to be safely worn. They initially mathematized the situation as $clothes < 1000\ CFU/cm^2$. Once the interviewer probed on what the PSTs meant by "clothes", Mia and Ava modified their model as shown in Figure 1. Mia and Ava's expressions, "$clothes < 1000\ CFU/cm^2$" and "$bacterial\ load\ on\ clothes/cm^2 < 1000\ CFU/cm^2$", and their reasonings reflect their organization of the Laundry Task scenario by drawing upon the threshold form.

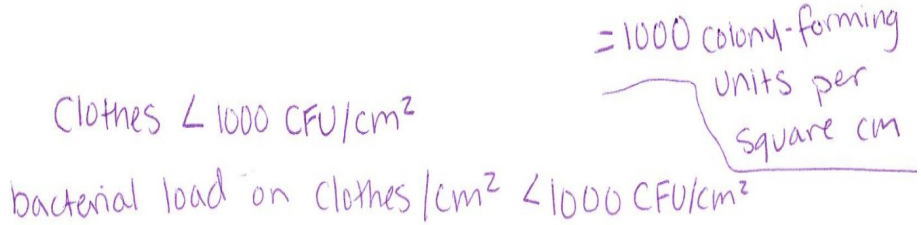

Figure 1. Mia and Ava's threshold symbolic form

The Contributing Terms Forms

Contributing terms symbolic forms consist of the symbol template ■ = ■ + ■ + ■and the conceptual schema that distinct quantities (left side of the equation) contribute to the whole (right side of the equation). This form is considered a network of symbolic forms because it integrates two key components of Sherin's forms: *parts-of-a-whole* form, which represents additive components (■ + ■ + ■) and the *balancing* form (■ = ■) which represents that both sides of the equation should be equal.

Mia and Ava demonstrated this symbolic form as they mathematized the factors that contributed to the rate of bacterial growth on specific clothing pieces. First, they began by identifying specific factors that influence bacterial load, such as type of clothing, personal hygiene, level of activity, and sickness (Figure 2). Mia justified the inclusion of sickness as a contributing factor to bacterial growth as "I just feel like when you're sick, it's like you're trying to get rid of all the germs, so you're trying to wash your clothes more." Next, they conceived that the rate of growth of bacteria per day is composed of the rate of growth of bacteria per day due to the contributing factors. Building on this reasoning about what might cause the bacterial load on specific clothing to reach the threshold of 1000 CFU/cm^2, Mia and Ava mathematized the

situation as shown in Figure 2. In this form, the overall rate of growth of bacteria is a whole composed of additive parts, for example, $rate\ of\ bacterial\ growth\ per\ day =$ $rate\ of\ bacterial\ growth\ due\ to\ Factor\ A\ +$ $rate\ of\ bacterial\ grwoth\ due\ to\ Factor\ B\ +$ $rate\ of\ \ bacterial\ growth\ due\ to\ Factor\ C.$

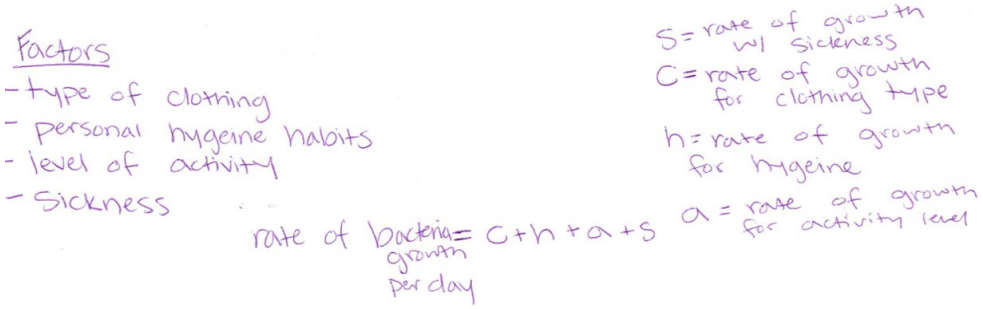

Figure 2. Contributing terms listed by Mia and Ava

The Rate Forms

The PSTs mathematized the number of days specific clothing could be worn as below:
$1000 \div rate\ of\ bacterial\ growth\ (measured\ in\ days) =\ days\ of\ wear$ (1)

We identified this mathematization as PSTs drawing upon their rate form. A rate symbolic form consists of the symbol template ■/■ = ■ and a conceptual schema instantiating a rate. We identified this as a network of forms as PSTs combined multiple symbolic forms simultaneously: (i) canceling form with symbol template ■/■ and conceptual schema that identical symbols appear in the numerator and denominator, and which represents the rate relationship, and (ii) balancing form with symbol template ■ = ■ and conceptual schema both sides of the equation are equal. We interpret that the PSTs drew on both these symbolic forms to mathematize the number of days one could safely wear a clothing piece before it needs to be washed. We elaborate on this interpretation below.

For the PSTs', one side of the equation was number of days. We make this conclusion due to the task prompt and the models PSTs constructed for this task. So, for the PSTs, the game was: *if one side of the equation was number of days, what should the other side be so that both sides are equal*. To attain this, as shown in Figure 3(a), the PSTs simplified the scenario by assuming that the total rate of bacterial growth was 100 CFU/cm^2 per day. Next, drawing on their balancing form that two sides of an equation should equal, the PSTs sought out what operation would produce number of days to balance the other side of the equation. Given that, 1000 CFU/cm^2 was the threshold bacterial load before the clothes required washing, to balance both sides of the equations to number of days, the PSTs drew on their canceling form and divided the threshold bacterial load by the bacterial growth per day to effectively cancel identical symbols. They verified their actions through considering different values for bacterial growth per day, such as 200 CFU/cm^2 (see Figure 3(b)). Finally, as shown in Figure 3Figure 3(c), the PSTs generalized their reasoning into equation ($1000 \div rate\ of\ bacterial\ growth\ (measured\ in\ days) =$ $days\ of\ wear$ (1).

We nominalized this form as a rate form because Mia and Ava purposefully operated on the threshold bacterial load, 1000 CFU/cm^2, and the bacterial growth per day, for instance 100 CFU/cm^2 per day, to yield the number of days. This operation mirrors Thompson's (1994)

notion of the quantitative operation instantiation rate. In a similar manner, we hypothesize, Mia and Ava constructed to a network of symbolic forms to mathematize their conception of the laundry scenario.

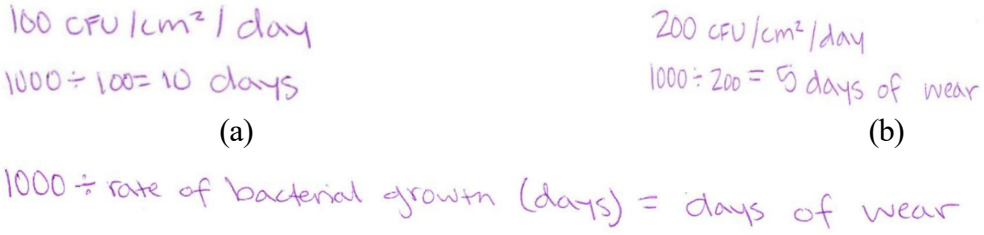

Figure 3. Network of symbolic form examples

Discussion

In this study, we found that our PSTs drew on symbolic forms in multiple ways, alone or in coordination as a network of forms. Our study is a first step towards building a repertoire of modelers' constructive resources (Sherin, 2000)—cognitive resources used by modelers as they mathematize real-world scenarios such as the Laundry Task. As mathematizing is not limited only to the construction of equations, our study's focus does not provide a complete picture of students' constructive resources for modeling. Researchers interested in modeling-centric cognition should draw on other representational forms, such as graphical forms (Rodriguez & Jones, 2024), to understand modelers' representational activities during modeling. Building such fine-grained accounts of modelers' knowledge enables educators and researchers to (a) diagnose the blockages modelers may experience during modeling (Roan, 2024), (b) provide modeling support that attends to and responds to modelers' cognition, and (c) develop modeling task characteristics from the perspective of the students (Roan et al., 2025). This repertoire of students' thinking can be used in modeling specific professional development programs to support teachers in designing and implementing modeling tasks that are guided by modelers' cognition (Franke & Kazemi, 2001).

Investigating students' symbolic forms and other constructive resources will pave the way to conceptualize modeling as a goal oriented, epistemic game, where students have the autonomy to choose their next move based on the resources available to them. In this view, modelers' actions are driven by "*I need to get X, what can I do to get X?*" For example, in the threshold form we illustrated, Mia and Ava's modeling actions were guided by the question, "*how can I mathematically represent that one side of an expression cannot exceed* 1000 CFU/cm^2." Similarly, in the rate form, Mia and Ava's actions were driven by "*what operations can perform to make one side of the equation the same as the other, which is number of days of wear*." Thus, adapting this perspective implies that facilitating students' modeling activities entails creating opportunities for students to activate certain resources, as well as designing learning ecologies that occasion the construction of certain resources which can later be activated for model formulation. Students' cognition during modeling is idiosyncratic and complex; we contend that using one theoretical framing alone is inadequate in capturing the intricacies in modelers' mathematics. Therefore, we call for more work in connecting multiple theoretical framings (Radford, 2008) that work synergistically to provide rich descriptions of modelers' cognition.

Connecting Multiplicative Structures Across Contexts: Students' "Product Layer" Reasoning in Water Pressure and Electricity Tasks

Olha Sus
Tufts University

Andrew Izsák
Tufts University

Students often struggle to interpret the multiplicative structure within integrals—what we call the "product layer" ($f(x) \cdot dx$)—when reasoning about applied problems. In this study, we analyze the reasoning of Melinda, an undergraduate in a calculus-based physics course, as she works on two tasks: estimating the total force on a tank wall (water pressure) and the total voltage across a capacitor (electricity). Using conceptual blending theory, we examine how Melinda connects symbolic, mathematical, and physical ideas when setting up integrals. Melinda frequently interprets integration as summation of small pieces or as area under a curve but struggles to coordinate multiplicative relationships among varying quantities (e.g., pressure· area, current· time). These findings suggest that challenges with product layer reasoning persist across contexts, highlighting the need for instruction that explicitly supports blended multiplicative reasoning.

Keywords: definite integral, conceptual blending, introductory physics, knowledge resources, product layer

Reasoning about integrals in applied contexts is central to success in mathematics and physics, yet students often struggle to connect symbolic procedures with physical meaning (Brahmia et al., 2016; Wilcox & Corsiglia, 2019). These difficulties are especially pronounced when interpreting the product layer—the multiplicative structure within an integral (Hu & Rebello, 2013a; Sealey, 2014). Applied contexts such as fluid mechanics and electricity require students to coordinate two simultaneously varying quantities and relate them to physical phenomena, rather than merely computing antiderivatives.

Despite its importance, students' reasoning about the product layer remains poorly understood, particularly across different contexts. The present study addresses this gap by examining how an undergraduate student constructs and coordinates symbolic, mathematical, and physical ideas when working with integrals in two applied settings. By comparing reasoning patterns across contexts, we aim to identify both persistent challenges and context-specific features that influence product layer reasoning.

This study is guided by two research questions:

1. *How do students reason about the product layer within integrals solving water pressure and electricity tasks?*
2. *How do symbolic, mathematical, and physical spaces interact across these contexts, and what roles do blended spaces play in shaping students' reasoning?*

Background and Literature Review

Students frequently struggle with applied integration, particularly in understanding the multiplicative structure of infinitesimal elements ($f(x) \cdot dx$), known as the product layer (Hu & Rebello, 2013a; Sealey, 2014). Mastery of this structure is critical for modeling quantities that depend on multiple varying measures, such as *pressure· area* or *current· time*.

Research consistently shows that students often interpret integrals as summing small pieces without attending to the multiplicative relationships among quantities (Jones, 2013; Sealey,

2014). These difficulties appear in a variety of physics contexts. In electricity, learners may fail to conceptualize $\lambda \cdot dx$ in continuous charge distributions, relying instead on memorized formulas (Nguyen & Rebello, 2011), while interpreting dq or dE requires coordination of symbolic, mathematical, and physical ideas (Meredith & Marrongelle, 2008). In fluid mechanics, students often decompose integrals into additive pieces, rarely interpreting *pressure* $\cdot$ *area* as a meaningful product, revealing fragile connections between notation, reasoning, and accumulation (Sus & Izsák, 2024).

Frameworks such as Multiplicatively Based Summation (MBS) (Jones, 2015) and Emergent Quantitative Models (Oehrtman & Simmons, 2023) describe productive ways of reasoning about integrals. Conceptual blending theory offers tools for understanding how students dynamically integrate symbolic, mathematical, and physical ideas (e.g., Hu & Rebello, 2013b). Despite these advances, the coordination of product layer reasoning across multiple applied contexts remains underexplored.

Theoretical Perspectives

In this section, we present theoretical perspectives and a methodological approach which best spans the results obtained in the study. It includes two components—the knowledge-in-pieces cognitive perspective and the modified dynamic conceptual blending diagram (Sus & Izsák, 2025), coming from the dynamic conceptual blending perspective (e.g., Van den Eynde et al., 2020).

The Knowledge-in-Pieces Epistemological Perspective

The perspective was first developed in science education on conceptual change (diSessa, 1993, 2006) and has since been applied to topics in mathematics, such as whole-number multiplication (Izsák, 2005), functions (Izsák, 2004; Moschovich, 1998), and integrals (Jones, 2013). It posits that reasoning is supported by diverse, fine-grained knowledge resources, which evolve from novice to expert through the construction, refinement, and reorganization of these resources. In this study, we focused on the knowledge resources students use when coordinating multiplication with a definite integral in physics contexts.

Conceptual Blending Perspective, Modified Dynamic Conceptual Blending Diagram

Fauconnier and Turner (1998) introduced conceptual blending to model how people create new meaning by combining information from different experiential domains. Studies (e.g., Bing & Redish, 2007; Hu & Rebello, 2013b; Wittmann, 2010) have applied this framework to describe students' use of mathematics in physics. In this study, we take the modified dynamic conceptual blending diagram (Sus & Izsák, 2025) to analyze Melinda's dynamic reasoning about the product layer in applied integration contexts. We construct the modified dynamic conceptual blending diagram (MDCBD) first by identifying and coding knowledge resources, listing selected resources in apparent order of activation, and assigning resources to one of four mental spaces—*mathematics* (mathematical concepts without new physical input, including drawings and equations), *physics* (physical concepts and quantities without introducing new mathematical input, including drawings), *symbolic* (technical roles of mathematics), and *blended* (combinations of symbolic, mathematical, and physical ideas, including equations and drawings). We then connect selected elements with coded links. Resources and connections are coded as more confident (e.g., "I remember") or more tentative (e.g., "I guess"), with more confident elements/connections shown as bold text/green solid lines and more tentative as regular text/green dotted lines. Activated/deactivated resources are marked with squared blue/red boxes,

while connections are marked with blue/red solid or dashed lines, respectively (Figure 1). By analyzing the elements and connections of these mental spaces, and their dynamic changes, we captured Melinda's moment-to-moment reasoning about the product layer as she blended ideas from symbolic, mathematical, and physical input spaces.

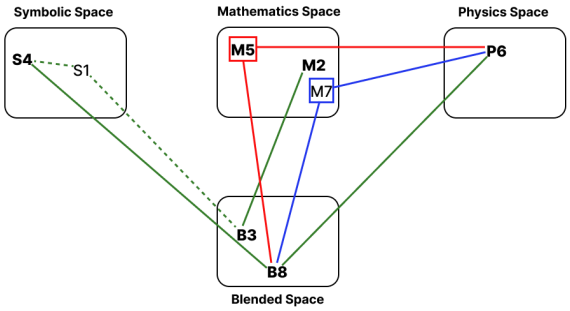

Figure 1. Schematic representation of MDCBD.

Methods

We conducted three 1-hour, one-on-one, semi-structured think-aloud interviews (e.g., Bernard, 1994; Ginsburg, 1997) with three students in a second-semester calculus-based physics course at a selective university in Fall 2023 to examine how they reasoned about integrals and constructed a product layer. The first interview focused on multiplication in applied problems that required summing products, without mentioning integrals. The second and third interviews explored connections between definite integrals and applied problems. Interviews were recorded with two cameras to capture both the student-interviewer interaction and the student's written work. We then synchronized the two videos, transcribed verbatim, and analyzed the knowledge resources students used in building the product layer.

Melinda was selected as an ideal case for studying conceptual blending and product layer reasoning across contexts. She reported an A- in Precalculus, a 5 on AP Calculus AB, and a 4 on AP Calculus BC, indicating strong preparation. In both tasks, she consistently attempted to link symbolic, mathematical, and physical representations, even when her reasoning was incomplete. In the Water Pressure task, she progressed from approximating sums to constructing integral notation, reflecting developing ideas of accumulation and infinitesimals. In the Electricity task, she articulated relationships among voltage, current, and charge, built expressions from definitions, and worked through integral and multiplicative relationships. Her thinking demonstrated productive strategies (e.g., visualizing contributions of small increments) alongside challenges in coordinating two varying quantities within an integral.

Results

This section presents an analysis of how Melinda reasoned about the product layer when calculating the total force exerted from the water pressure on a tank wall and determining the total voltage across a capacitor. The analysis focuses on how she constructed and coordinated symbolic, mathematical, physical, and blended spaces highlighting both productive reasoning strategies and challenges.

Water Pressure Task

Data. Melinda began by reading the problem aloud (Figure 2a) and paraphrasing the key details—the pressure increases with depth according to the law $P = 15x$, where x is the depth of the water—and described an approximation method using sampled points. Melinda then

produced work presented in Figure 3 and explained that she would add pressures at different depths to get a total pressure, not a total force, on the wall.

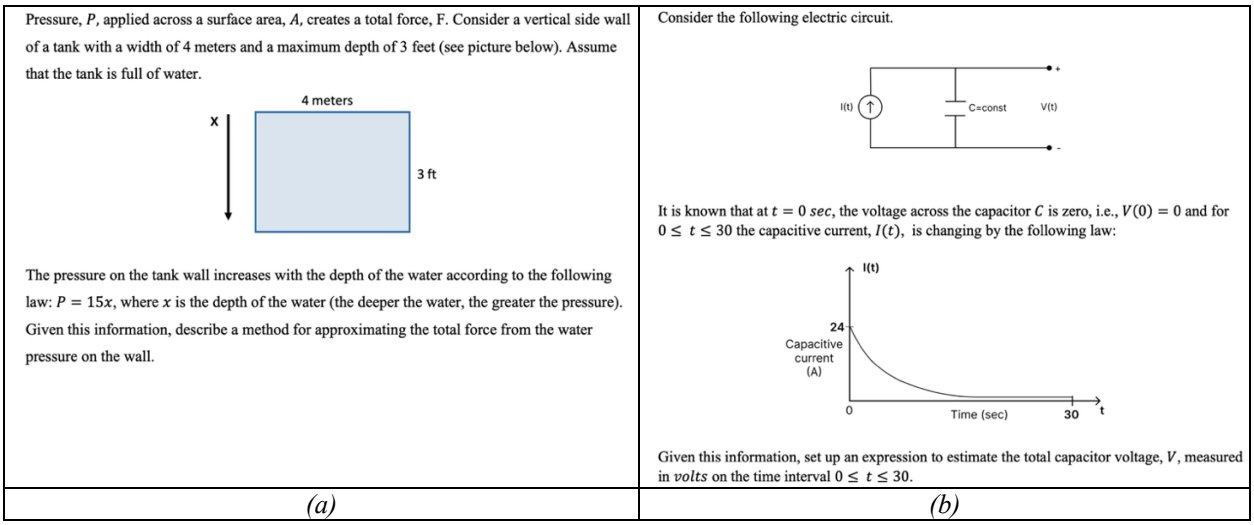

Figure 2. (a) Water Pressure task statement, Interview 2; (b) Electricity task statement, Interview 3.

Melinda then drew the red horizontal lines in Figure 3a that correspond to the red vertical lines in Figure 3b. She continued by stating that the area under the curve in Figure 3b represented the total pressure over the entire tank wall. Shortly after, she admitted uncertainty about finding the force from the pressure: "I don't really know how to get the force from the pressure though." She reiterated that to estimate the total pressure, one would sum all pressure values from 0 to 3 meters, represented by rectangles in Figure 3b.

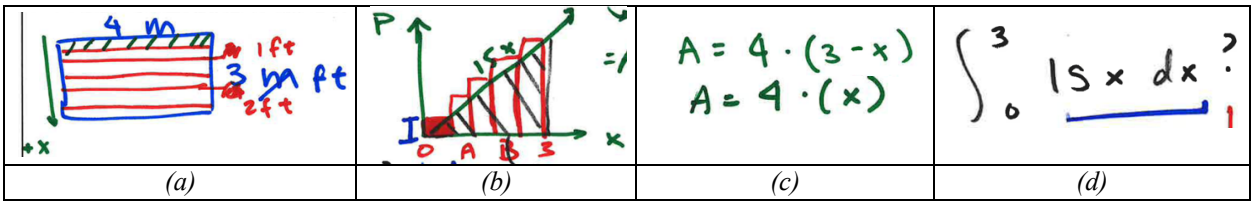

Figure 3. Melinda's reasoning about the definite integral structure in the Water Pressure task.

When asked to clarify her representation of the tank wall in Figure 3a, Melinda explained that she used the labels A and B on her diagram (erased red letters in Figure 3a) as arbitrary points along the depth rather than as areas. These letters A and B in Figure 3a correspond to letters A and B in Figure 3b. Melinda continued by explaining her interpretation of the surface area (Figure 3c):

> Surface area though … is like four, because the width doesn't change as you increase the depth, but the depth changes at three minus x because three is like the total three feet is the total depth minus wherever you are on the x axis or how far down you are.

The shaded green strip in Figure 3a represents the piece of area described by the first formula in Figure 3c. Melinda then changed labels A and B to $1ft$ and $2ft$ and corrected herself: "Your area would be four times x, you don't need the three minus. That's really counterintuitive actually." Ultimately, she represented the area at a given depth with 4 • (x).

Melinda produced two sketches during the task: one representing the tank wall with depths labeled at one-foot intervals (Figure 3a), and another showing pressure as a function of depth

(Figure 3b). She observed that both drawings share the variable x: "as you increase x, your pressure also increases. And here, as you increase x, your surface area also increases." She further suggested that the two quantities could be related by eliminating x: "If you do like $x = P/15$ and then $x = A/4$ and set them equal to each other, you could find the pressure as a function of area instead of x." Melinda clarified that the area of a shaded green strip in Figure 3a represented the surface area and was different from the area of a rectangle in Figure 3b where the height represents pressure.

As the discussion continued, Melinda reasoned about the integral notation $\int_0^3 15x\ dx$ (Figure 5d). She stated, "I kind of interpret it as from 0 to 3 … and you have the function of pressure as it relates to the depth, and then dx, which is like a super small amount of change in x." She explained further that the integral represented summing many small pieces: "Because you are taking the integral of it, the piece becomes like super small instead of like being as large." Finally, Melinda articulated the arithmetic operations involved in the integral expression:

> For the integral, I think it's like broken down into addition and multiplication.…you multiply like the height times the change in x, and then you add all of those like really small pieces together.

She related this multiplication to finding the area of a rectangle and recognized that the base and height corresponded to dx and $P(x)$, respectively."

Analysis. Melinda's reasoning included elements from four mental spaces (Figure 5a). She began by noting that pressure increases with depth (P1) and linking the $P = 15x$ relation (S2) to the physical behavior of the fluid. To quantify this, she approximated the total pressure by summing contributions at sampled points along the tank wall (B3) and interpreted the corresponding rectangles in Figure 3b as small pieces contributing to the total pressure, blending symbolic and physical understanding (B4). She clarified the calculation of surface area, noting the width of the wall is constant while the depth varies, so that area equals $width \cdot depth$ (P5). Using sketches, she visualized the tank wall and the pressure function, observing correspondence of the x-axis between the two (B6). She then expressed the integral symbolically $\int_0^3 15x\ dx$ (S7) and interpreted dx as a small change in depth (B8), describing the arithmetic operations involved: multiplying height by dx and summing contributions (M9).

Electricity Task

Data. Melinda began by reading the Electricity problem (see Figure 2b) and paraphrasing the key details, emphasizing that the voltage across the capacitor is zero at $t = 0$ and that the current varies with time. At first, she expressed uncertainty about how to connect the given quantities: "I don't really know how to relate voltage and current." Drawing on familiar ideas from resistive circuits, she considered Ohm's law but quickly dismissed it as irrelevant: "V equals IR … that really has nothing to do with the capacitor, that has to do with resistors."

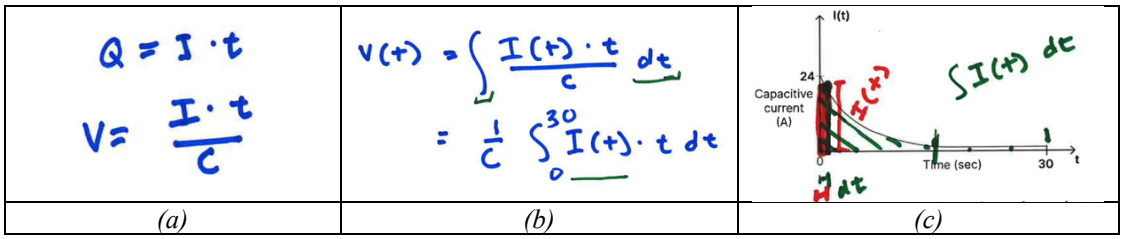
To move forward, Melinda recalled the capacitor equation, $V = Q/C$, and explained: "That means the voltage is equal to the charge that is pushed through … by the battery and then over the C, which is a capacity, like a property of the capacitor." She then attempted to connect current and charge, reasoning, "I don't know how to relate the charge Q, I current. Is it $I = Q/t$?" She elaborated, "I feel like the current is like the amount of charge that's moving through a wire at a certain time t," but admitted, "I don't know how Q, I, and t relate." She then tentatively expressed Q in terms of current and time and substituted into the voltage formula,

arriving at $V = \frac{I \cdot t}{C}$ (Figure 4a). She noted that both current and voltage depend on time, signaling awareness of the dynamic nature of the situation.

At this point, Melinda suggested integration as a tool to account for the varying current: "Then you could, to estimate the total capacitor voltage, you could take the integral from 0 to 30 seconds t …" (Figure 4b). She interpreted the integral of $I(t)$ only as the area under the curve of $I(t)$ (green shaded region in Figure 4c) and stated: "That would be the total current that passes through between the times of 0 and 30."

When asked about the visualization of the expression $I(t) \cdot t\, dt$ on the graph Figure 4c, Melinda responded that it was easier to visualize $I(t)$, the given line. She expressed uncertainty about the t term, which built on her uncertainty about $Q = I \cdot t$. Regarding dt, she said: "dt is like a small change in t" and indicated it on the drawing (Figure 4c). Explaining the full integral notation (Figure 4b), she stated: "The [green] shaded region would be the integral of $I(t)$ only. But I don't know how to multiply that if there is an additional t on the inside."

To interpret the expression $I(t)dt$, Melinda reasoned: "If this is dt, then $I(t)$ is here [width and height of the red rectangle in Figure 4c] … multiplying them together is like this little rectangle … that would represent the total current between zero and a small amount of t … then using that current you could, I guess, do like V equals I times t over C." Finally, she reflected on the meaning of the differential in the integral, noting: "dt would be in changing seconds because t is in seconds … dt kind of falls out of the equation when you take the integral" and added that the total voltage is measured in volts.



(a) (b) (c)

Figure 4. Melinda's reasoning about the definite integral structure in the Electricity task.

Analysis. Melinda's reasoning unfolded across four interrelated mental spaces—symbolic (S), physics (P), mathematics (M), and blended (B)—revealing both tentative explorations and confident connections (Figure 5b). Initially, she expressed uncertainty about how voltage and current were related, briefly recalling Ohm's law (S1) before dismissing it as irrelevant. This tentative symbolic recall illustrates her search for applicable prior knowledge. She then recalled the canonical capacitor relation, $V = Q/C$ (S2), and connected it to the physical property of the capacitor (P3), noting that C characterizes the capacitor's ability to store charge. Tentatively, she attempted to relate charge and current as $Q = I \cdot t$ (S4), combining this with the capacitor formula in blended reasoning (B5). To account for the time-varying current, Melinda proposed using an integral from 0 to 30 seconds (M6) to estimate the total capacitor voltage. She visualized the integral of $I(t)$ only (S7), not $I(t) \cdot t$, as the area under the current-time curve (B8), translating a dynamic physical process into a symbolic mathematical form. She interpreted dt as a small change in time (M9) and conceptualized $I(t) \cdot dt$ as a small rectangle representing current over an infinitesimal interval (B11), while expressing difficulty visualizing $I(t) \cdot t\, dt$ and its integral (B10). She also recalled the units for voltage (P12) and noted that after finding the total current, one could plug that value into $V = \frac{I \cdot t}{C}$ to compute voltage.

Discussion and Conclusion

This study examined how Melinda reasoned about the product layer—the multiplicative structure within an integral—while working on two applied problems. Across both tasks, Melinda demonstrated productive strategies, such as interpreting differentials as small changes and recognizing that integration involves combining contributions over an interval, but she also showed persistent difficulties in constructing the infinitesimal products that define the product layer.

In the Water Pressure task (Figure 5a), Melinda initially treated pressure values as directly summable and interpreted the area under the pressure-depth curve as "total pressure," overlooking the role of surface area. Although she later expressed the integral symbolically and described multiplication of height and a small change in depth, her interpretation remained primarily additive, with limited emphasis on how pressure and area together form an elemental force. In the Electricity task (Figure 5b), she represented $\int I(t)dt$ graphically as the area under a current-time curve and identified dt as a small change in t, but she struggled to connect this representation to the capacitor voltage formula.

These patterns indicate that interpreting the integral as summing contributions or finding an area does not guarantee an understanding of how multiple varying quantities combine within an infinitesimal element. The Water Pressure problem offered geometric anchors and visual cues that supported partial blending of symbolic and physical ideas, while the Electricity problem relied on abstract symbolic relationships and some visual representation, resulting in more tentative and fragmented blending.

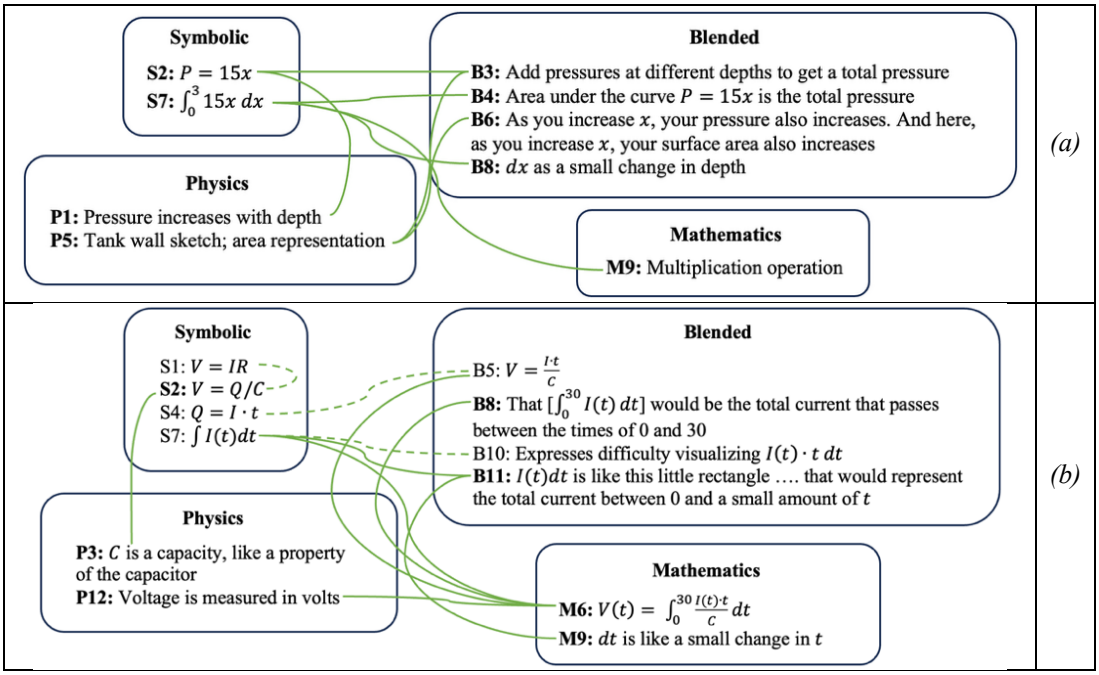


Figure 5. MDCBD representation for (a) Water Pressure and (b) Electricity tasks.

These findings suggest that instruction should explicitly foreground the blended meaning of the multiplicative structure in applied integrals and support students in coordinating symbolic, mathematical, and physical representations. Emphasizing how these quantities combine to form infinitesimal elements may enable students to move beyond additive interpretations toward a robust understanding of the product layer across contexts.

Acknowledgments

This research study was supported by the Graduate Student Research Competition Funding at Tufts University, Graduate School of Arts and Sciences.

Enacting Role Identities: Insights Into Mathematics Graduate Students' Professional Identity Development

T. Royce Olarte
University of California Santa Barbara

This study examined the professional identity devel0opment of six mathematics graduate students by exploring how they enacted and constructed meanings around five role identities: teacher, researcher, mathematician, mentor, and peer. Drawing on role identity theory, I highlighted the socially mediated nature of identity formation and the ways it was shaped by program structures, departmental cultures, and disciplinary expectations. Findings indicated that while graduate students identified the roles of teacher and researcher as most central to becoming mathematics faculty, the program offered more formalized opportunities for teaching than for research, suggesting an imbalance in preparation. This work contributes to understanding the liminal space between graduate student and professor, where multiple roles are navigated. The study points to the need for graduate programs to intentionally design structures that expand opportunities for development as researchers, mentoring, and community building.

Keywords: Graduate Students, Professional Identity, Role Identity

Recent scholarship on graduate students' professional identity development underscores the importance and impact of disciplinary and departmental contexts (Solari & Ortega, 2020; Tran et al., 2011). Graduate students' immersion in their fields can shape how they understand academic work (Clarke et al., 2013; Colbeck, 2008), with discipline-based cultures serving as a primary source of identity development and formation (Anderson & Louis, 1994; Clarke et al., 2013). In mathematics, the absence of laboratory work and the emphases on abstraction, correctness, and rigor (Gutierrez, 2017; Herzig, 2004) may uniquely shape students' roles and self-conceptions. While many experiences, such as teaching and research, are common across graduate programs, the meanings attached to these roles are shaped by departmental, sociohistorical, and personal contexts. Given that graduate students are deeply embedded within undergraduate mathematics education, understanding their multiple roles and identifying best practices to support their identity development has notable implications for postsecondary mathematics.

Across many mathematics departments, graduate students are often at the front lines of interacting with and supporting undergraduate students, meaning that their roles can directly influence undergraduate learning experiences, departmental climates, and students' sense of belonging in mathematics (e.g., Olarte et al., 2024; Herzig, 2004). Graduate students' pathways into faculty careers also mean that how they come to see themselves during graduate school has long-term implications for the practices, values, and representations that shape undergraduate mathematics education. Given the fragmentation of higher education and evolving institutional expectations (Nixon, 2006), graduate students' enactments and understanding of their roles may diverge from historical notions of the professoriate, raising questions about how graduate programs equip students for faculty careers (Austin & McDaniels, 2006; Zhang & Wang, 2024). In this study, I adopt a role identity perspective to examine how mathematics graduate students developed their professional identities through enacting and interpreting multiple roles, exploring which became most salient and how disciplinary and departmental contexts shaped these processes. The study is guided by the following research question: How did mathematics graduate students enact and make sense of their role identities as prospective faculty?

To examine graduate students' professional identity development, I draw on identity theory (Burke, 2003; Stryker, 1968; Zhang & Wang, 2024) and role identity theory (Colbeck, 2008; McCall & Simmons, 1978; Jazvac-Martek, 2009). These perspectives, aligned with sociocultural views of identity development, acknowledge the salience of others and context in shaping identity formation. Identity theory frames the "self" as constructed through performing activities and behaviors, while also emphasizing the meanings and expectations associated with the roles that individuals perform. Zhang and Wang (2024) wrote, "In identity theory, the core of an identity is the categorization of the self as an occupant of a role, and the incorporation, into the self, of the meanings and expectations associated with that role and its performance" (p. 353). For graduate students, navigating various roles such as teacher and researcher during graduate education contributes to their evolving professional identities as prospective faculty.

Role identity theory especially emphasizes how graduate students' internalized meanings of roles are shaped by social interactions, institutional contexts, and personal beliefs and values (McCall, 2003; Olarte & Street, 2025). Graduate students enact multiple roles such as researcher (Davis & Lester, 2016), teacher (Beisiegel & Simmt, 2012), and mentor (Brown & Sheerin, 2008), depending on situational demands, creating a salience hierarchy in which some roles become more central to their professional selves (Stryker, 1968; Zhang & Wang, 2024). When roles are affirmed through sustained enactment, peer recognition, or institutional validation, they stabilize and may anchor as enduring dimensions of identity. Alternatively, when affirmation is absent or roles conflict with personal commitments, tensions arise that disrupt identity development (e.g., Austin & McDaniels, 2006; Herzig, 2004). These negotiations underscore that professional identity is not a fixed construct but a continual process of (re)construction across multiple, and sometimes conflicting, role identities (Bale & Anderson, 2022; Olarte et al., 2024; Winstone & Moore, 2017). Understanding how graduate students navigate these dynamics provides insight into the interplay of personal, disciplinary, and institutional factors shaping their preparation for faculty careers. Figure 1 below visualizes this perspective and process of professional identity development through sustained and negotiated role enactments.

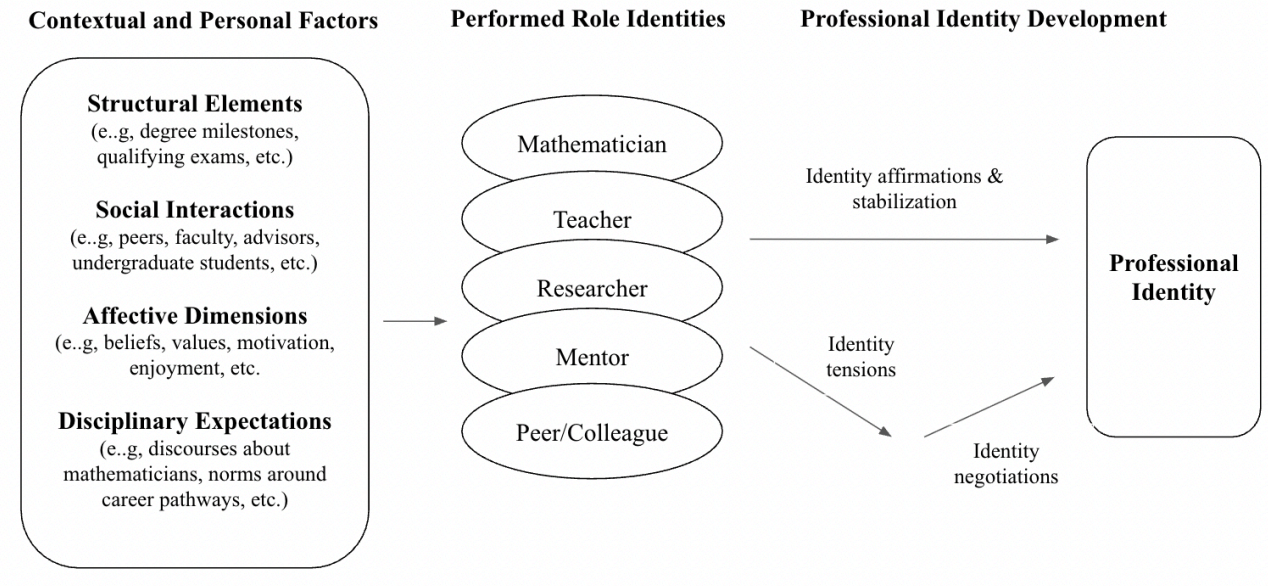

Figure 1. A Process of Professional Identity Development in Graduate Mathematics Education

Method

I employed a thematic analysis approach (Miles et al., 2020) that combined inductive and deductive approaches to examine the role identities that emerged from participants' narratives of graduate education.

Context and Participants

This study was conducted at Spruce University (pseudonym), a large, research-intensive university in the West Coast of the United States. The mathematics department at Spruce University confers graduate degrees (i.e., Master's and PhD) in applied and theoretical mathematics and completion of the doctoral program is expected to take about 5-6 years. The first two years of the program involves completing program requirements and graduate-level sequences for three content areas (e.g., Algebra, Analysis, etc.). Students take comprehensive exams (i.e., qualifying exams) for each area after the required coursework. After fulfilling these three area requirements, doctoral students select a focal research area, secure a dissertation advisor, and take an oral examination given by their respective doctoral committees to discern if the student can reasonably complete a dissertation on their proposed topic. This marks advancement to candidacy. At Spruce University, doctoral students are expected to advance to candidacy within four years of starting their graduate studies. The final milestone is to successfully conduct research and write and defend their dissertation.

I employed a convenience sampling (Miles et al., 2020) to recruit graduate students in the mathematics department at Spruce University in Spring 2023. 16 doctoral students completed a survey that elicited self-described or self-selected academic information (e.g., year in program, prior education, etc.), inclusive demographic information (e.g., gender, race, etc.), and career aspirations information. Then, purposeful sampling (Yin, 2016) was used to recruit students who indicated that they had considered or were actively pursuing careers as mathematics faculty. This study focuses on the six students who participated in an interview about their experiences. Their brief profiles are provided in Table 1 below.

Table 1. Participant Profiles

Participant	Year in Program	Gender	Race	Research area
Connor	3rd	Male/Masculine	White/Caucasian	Data-driven methods of learning dynamical systems
Kayla	1st	Female/Feminine	White/Caucasian	Geometric group theory, combinatorial group theory
Kendall	5th	Female/Feminine	White/Caucasian	Topology
Landon	2nd	Male/Masculine	White/Caucasian	Quantum topology
Martin	1st	Genderqueer/ Genderfluid	Latinx/Chicanx	Applied mathematics and math bio
Morgan	5th	Female/Feminine	White/Caucasian	Low-dimensional topology

Data Collection and Analysis

Data collection occurred within a 60-minute semi-structured interview (Rubin & Rubin, 2011), conducted over Zoom, about their experiences in graduate school, their understanding of the mathematics professoriate, the kind of faculty they hoped to be in the future, and key features of doctoral education. Some questions from this semi-structured interview included: (a) In what ways have you seen yourself as a mathematics professor or faculty while in graduate school?; (b) What aspects of your graduate education have most contributed to your development as a professional in higher education mathematics?; and (c) Tell me about your relationships with your peers in graduate school. Guided by Saldaña's (2013) system of open coding, I conducted multiple rounds of coding that involved close reading of the transcripts to identify emergent themes, actions, and meanings participants associated with their roles. In the first round, I coded for the roles and responsibilities participants reported enacting, such as serving as teaching assistants, collaborating with faculty on research, and engaging in mathematical work. The analysis was informed by existing literature identifying common graduate student roles (e.g., teacher, researcher, mentor), which served as sensitizing concepts. Codes were then organized into broader categories that reflected salient role identities and the contexts in which they were enacted, stabilized, or challenged. Using constant comparison (Miles et al., 2020), I examined similarities and differences in how participants enacted and made meaning of their roles, for instance, seeing teaching as both delivering mathematics content and supporting students' broader development. This process culminated in thematic findings that illuminated how graduate students enacted role identities during graduate school.

Findings

Participants' reflections of their experiences revealed five notable role identities that could qualitatively be organized in a salience hierarchy (Stryker, 1968; Zhang & Wang, 2024) based on the frequency and depth of their reflections on these role identities. I found that their identities as teachers and researchers were more central to their broader professional identities (See Figure 2).

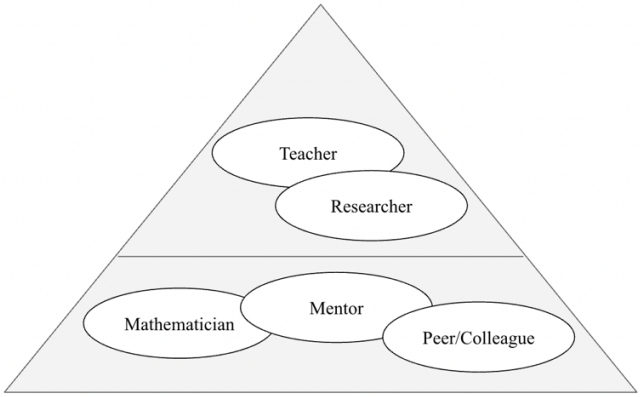

Figure 2. Participants' Salience Hierarchy of Role Identities

Teacher

The role identity participants most often enacted, and often most enjoyed, was that of *teacher*. All served as teaching assistants at Spruce University, with some, like Kayla and Morgan, also teaching as instructors of record at prior institutions, experiences that solidified this role identity. Teaching was not only central to how they envisioned the work of mathematics faculty but also a primary motivator for pursuing faculty careers. As Kayla shared, "I think I've

always known that I've wanted to teach, like that has been an unquestionable thing," while Kendall explained, "I still really love [teaching], and I don't want to stop. That's part of the reason why I want to pursue a career as a professor." Participants emphasized that positive classroom moments and relationships with students helped them see teaching as more than content delivery, but also about humanizing mathematics and supporting students' broader development. Kayla, for instance, described wanting to "make mathematics a more welcoming community" and be the kind of professor who both teaches math and "makes a difference in someone's life." Similarly, Connor said his goal was to be "approachable," while Kendall emphasized guiding students "in more of an emotional sense and a math sense." Many participants distinguished TA positions and instructor-of-record opportunities, with the latter providing greater agency and autonomy that deepened their sense of selves as teachers. As Morgan explained, "Sometimes over the summer, you're able to teach your own class, [and] that probably helps the most of preparing me to be a math faculty member." Overall, teaching was the role through which participants felt most connected to their career aspirations, grounding their professional identities in both pedagogical practice and relational commitments to students.

Researcher

For all participants, the *researcher* role identity, characterized by curiosity, agency, and independence, was understood as equally central to the professoriate as teaching. Many explicitly articulated the faculty role as a dual responsibility: teaching *and* contributing to the field through research. Morgan captured this duality, noting that being a math professor "means that you get to teach students pretty much during the whole school year," while also contributing through "researching and publishing papers." Kendall described research as "really hard, but super fun" while Landon particularly valued the freedom "to study whatever you want… and think about interesting problems all day long." Yet, unlike the role identity of teacher, which was formally structured early through TA positions, the formal path into conducting mathematics research was more fragmented, often depending on student initiative or chance faculty support. Kendall reflected on how a professor she "cold called" during her first year became a supportive mentor who "never made me feel stupid," and Connor shared how presenting in a faculty member's class led to a serendipitous advising relationship. Such mentorship and scholarly community were pivotal in affirming students' researcher identities, with Morgan emphasizing that "my advisor is super great… just a really good mentor." Across their accounts, being a researcher was not simply about producing results but about cultivating values of persistence, creativity, and collaboration, qualities that both grounded their sense of self in graduate school and shaped how they imagined themselves contributing to the field as future faculty.

Mathematician

While connected to teaching and research, the role identity of *mathematician* carried distinct meanings, often tied more to the process of engaging with mathematics than to producing publishable results. Participants characterized being a mathematician as involving deep thinking, intellectual exploration, and a love of learning mathematics for its own sake. Landon expressed this sentiment, saying, "I guess doing math seems like a really enjoyable way to use my brain's processing power, and I guess I kind of fit in, in that sense." Many participants said they saw themselves as "math persons" even before graduate school. Successes during their undergraduate years sparked curiosity and enjoyment that motivated them to pursue advanced study. Landon reflected, "There was never any doubt in my mind that I was going to study math, and taking college level math classes certainly didn't do anything to dissuade me from studying math." They

also associated being a mathematician with qualities like persistence, curiosity, and determination, especially in facing difficult problems without immediate solutions. Kendall noted, "I guess I don't give up very easily. That helps with being a mathematician….A lot of it is determination and resilience." This role identity was most often enacted during coursework, grappling with advanced concepts, and navigating qualifying exams, which became experiences that both prompted and challenged their identities as mathematicians. The qualifying exams, in particular, caused significant challenges and self-doubt. Several participants described this period as the most difficult time of their graduate careers. Morgan recalled, "It was definitely the qualifying exams. That's the only time where I've slightly wavered on, 'Is this [career] right for me?' That was the only time." These moments of uncertainty resulted in tensions with their mathematician identities, which were not grounded in research output but in a sustained connection to the discipline through learning and shared participation in mathematics.

Mentor

The *mentor* role identity captured how participants positioned themselves in relation to undergraduates, often describing mentorship as deeply fulfilling and distinct from teaching or research. Kendall shared, "Being a mentor to undergrads has always been a lot of fun… you basically get to be an advisor to them in some sense," while Landon framed it as "a great way to pay that forward in some sense and make that experience good for other people." Their approaches to mentorship were shaped by their own educational journeys, with many aiming to provide the support they had received, or wished they had, through structured opportunities like Directed Reading Programs (DRPs) and Research Experiences for Undergraduates (REUs). Landon described mentoring undergraduates in an REU as his "favorite thing to ever happen in math," and Morgan similarly shared that mentoring through a DRP and an REU affirmed her belief that "being a professor would be good." Notably, for the three women-identifying participants, mentorship also deeply intersected with gender identities and personal values. Kayla emphasized showing care and compassion to counter stereotypes of mathematicians as distant, while Kendall aspired to "be a woman in a field where I can make a trail for future girls." She shared that this commitment "was in the back of my mind for a lot of the time." Beyond formal programs, participants also viewed office hours and casual conversations as spaces where they could support students academically, emotionally, and personally. These meaningful interactions anchored their mentor identities and underscored the role of mentorship in shaping both their professional trajectories and more inclusive visions of undergraduate mathematics education.

Peer

Participants primarily enacted the role identity of *peer* through relationships with fellow graduate students, centering this identity on mutual support, peer mentorship, and advocacy. Grounded in values of collegiality and community, this role was often the most significant source of belonging in graduate school. Kendall summarized this sentiment: "I feel a sense of belonging in the field, but only because of the other graduate students, I feel a sense of belonging in my graduate students at Spruce." Rather than stemming from formal institutional structures, participants described informal spaces and social activities as essential to cultivating academic and emotional support. Connor shared, "Things like game night that we run have been really helpful in actually meeting friends in the math department. I was invited to go climbing with a couple of the math department people." These relationships then made it easier to ask each other for academic help, discuss challenges, and feel connected. For some, community was forged through shared identities. Morgan, for example, described bonding with a close group of women-

identifying graduate students, while Landon reflected on early social moments like playing video games and getting pizza with peers that helped ease his transition into graduate school. Peer mentorship across cohorts was another important facet of this role identity. Kendall noted how observing senior students navigate the job market helped her understand and anticipate future steps in her career: "Watching them, like older grad students, decide what to do and watch them apply to postdocs… Talking to older graduate students, talking to graduate students in my year and below, because you're all navigating the same career trajectories." This exchange of knowledge, support, and empathy was reciprocal and sustaining.

Discussion

Throughout graduate school, students deeply engage in learning, teaching, research, and academic life, while concurrently developing an understanding of themselves and the profession's values, norms, and practices (Clarke et al., 2013; Tierney & Rhoads, 1993; Trede et al., 2011). Participants' reflections revealed how their role identities were informed by program milestones, social interactions, personal commitments and affective dimensions, and the broader disciplinary expectations of higher education mathematics. Drawing on sociocultural perspectives of professional identity and role identity theories, I found five role identities that mathematics graduate students enacted: teacher, researcher, mathematician, mentor, and peer. While prior work has studied roles such as teacher (e.g., Deshler et al., 2015; Winstone & Moore, 2017) and researcher (Davis & Lester, 2016), the present work adds to this literature by examining how mathematics graduate students develop their professional identities within a specific departmental and disciplinary context. The findings revealed some of the meanings students associated with their roles, the ways departmental and institutional norms shaped professional identity development, and how pivotal doctoral program experiences impacted the salience of these identities. Interestingly, participants identified the roles of teacher and researcher as most central to what it means to be a mathematics professor, suggesting these dimensions were more strongly anchored (Mockler, 2011) and higher in their salience hierarchies (Stryker, 1968; Zhang & Wang, 2024). As Morgan noted, these were the "two aspects of being a math professor." Their prevalence indicates that Spruce University emphasized teaching and research as the most important roles for doctoral students, though the program's structure afforded more formal opportunities for teaching and fewer structured opportunities for research, creating an imbalance in preparation for the two salient roles communicated as essential for mathematics faculty.

Implications and Conclusion

This study offers both theoretical and practical implications for understanding professional identity development and preparing graduate students for faculty careers in mathematics by examining how students enacted and constructed meanings around five role identities. This work contributes to broader conversations about the multifaceted and dynamic nature of professional identity formation in graduate school (Clarke et al., 2013; Solari & Ortega, 2020; Trede et al., 2012). Moreover, the identification of critical experiences that support or hinder role enactments (Jazvac-Martek, 2009) points to the need for graduate programs to intentionally design structures, policies, and practices that expand opportunities for early research development, mentoring, pedagogical development, and community building. Ultimately, attending to graduate students' role identities provides valuable insights into how we might better support their growth within mathematics departments and the broader academic profession.

Math Anxiety Data Sources: Capturing Individual Differences Through Diverse Lenses

Amy Daniel
Montclair State University

Nina Bailey
Montclair State University

This multiple case study explores the affordances and limitations of four data sources: a validated math anxiety (MA) scale, written narratives about one's relationship with mathematics, semi-structured interviews, and recorded classroom observations. Analysis of three preservice elementary teachers revealed that each data source provides a unique and valuable perspective. Our findings demonstrate the need for researchers to leverage a diverse range of data sources to develop a more robust understanding of each individual's MA experiences, their MA triggers, responses to these triggers, and how these things may change over time.

Keywords: math anxiety, preservice teacher education, observational data

Identifying ways to reduce the math anxiety (MA) experienced by preservice elementary teachers (PSTs) is a persistent concern in education. Defined as "a feeling of tension, worry, and/or fear in situations involving math-related activities" (Bjälkebring, 2019, p. 1), MA is particularly prevalent among PSTs (Hembree, 1990), and is linked to a variety of negative outcomes for their future students (e.g., Mizala et al., 2015). Although relatively well studied, the vast majority of what is known about PST MA has been established through research conducted primarily using self-reported data sources. We aimed to investigate the affordances and constraints of three such data sources (a validated MA scale, written narratives about each PST's relationship with mathematics, and semi-structured interviews), as well as a fourth data source that does not rely on PST self-report, namely classroom observations.

Literature Review

Research on PST MA is primarily conducted using four data sources: validated survey scales, written narratives, interviews, and classroom observations. Validated survey scales are, by far, the most widely used data source, and therefore underpin most of what is known about PST MA. These surveys ask individuals to rate the amount of anxiety they associate with various mathematical settings, such as "listening to another student explain a math formula" (Alexander & Martray, 1989, p. 147). These surveys are easy to administer, take little time to complete, and can be helpful in identifying broadscale shifts in MA experienced over the course of a semester (e.g., Barrett, 2013). Despite their usefulness, these scales are limited to the situations referenced in the scale items, which tend to emphasize testing scenarios (Pizzie & Kraemer, 2019).

In contrast to surveys, written narratives give respondents the freedom to share about their MA experiences in their own words and to highlight the mathematical situations that are most relevant to them. Such narratives can help identify classroom aspects that either exacerbate or reduce individual PSTs' MA (e.g., Lipscomb & Lorenzen, 2023). Similarly, interviewing PSTs enables respondents to share about aspects of their MA that they believe are important and allows researchers to ask clarifying questions. This increases the chances that the researcher will build a nuanced understanding of PST's MA experiences and the kinds of scenarios that trigger their MA (e.g., Stoehr, 2017). The fourth data source, observational data, is rarely leveraged in published research; however, this data source has the potential to yield unique insights because it does not rely on PST self-report. That is, observational data can provide researchers with access to aspects of PSTs' MA that they are unaware of themselves (e.g., Daniel & Bailey, 2024).

Theoretical Perspective

We drew on Ramirez et al.'s (2018) *interpretation account* of MA because it acknowledges the individualized nature of MA by asserting that "students' development of MA is largely determined by how they interpret … previous math experiences and outcomes (rather than the outcomes themselves)" (p. 151). This perspective explains why certain situations, such as receiving a failing exam grade, might give rise to MA for some students and not for others. If a student interprets the failing grade as evidence that they have a fundamental inability to succeed in mathematics, that interpretation may provoke MA in future mathematical settings. In contrast, if the student interprets the failing grade as the product of their instructor's strict grading policies, this interpretation may give rise to anger instead of MA. We selected interpretation account because it centers the ways in which PSTs make sense of their own MA, the unique situations that elicit it, and the kinds of experiences that might help to alleviate it.

Leveraging the individualized focus of interpretation account, we define *MA triggers* as the unique mathematical situations and/or interactions that elicit tension, fear, or worry for an individual PST. Interpretation account suggests that MA triggers are unique to each PST because such situations and/or interactions will be interpreted differently by individuals. Although PSTs will write and speak about their MA triggers in a variety of ways, researchers have identified some MA aligned language commonly used by math anxious individuals. For example, Stoehr and Olson (2023) found that math anxious PSTs described their mathematical experiences using words or phrases such as *embarrassed*, *math is not my thing*, and *dreaded math class*. PSTs will not necessarily write or talk about all of their MA triggers (or even be aware of them); however, noting the commonly used MA-aligned language can help researchers to identify such triggers, thereby gaining a fuller understanding of each PST's unique MA experiences.

Because interpretation account asserts that the development and experience of MA is dependent on individualized interpretations of events, it also implies that MA experiences depend on a complicated tangle of factors, such as past experiences, personality, and culture. This suggests that multiple data sources are necessary in order to develop a robust understanding of the various ways in which MA is experienced by different PSTs within a single class. The primary aim of this work is therefore to explore what can be learned using four different data sources in characterizing the MA experiences of PSTs over the course of a single semester.

Methodology

The purpose of this multiple case study (Yin, 2018) is to understand the strengths and limitations of four different MA data sources: a validated MA scale (sMARS; Alexander & Martray, 1989), written narratives about each PST's relationship with mathematics, semi-structured interviews, and classroom observations. The three cases each consisted of a single PST enrolled in a terminal mathematics content course. Of 25 study participants, we selected three PSTs with high sMARS scores and different classroom dispositions; Mari was reticent, Eva confidently participated in class, and Velma was loquacious but appeared to lack confidence in class (all pseudonyms). We aimed to answer the research question: What do we learn about PSTs' MA using the sMARS, written narratives, interviews, and classroom observations?

Data was collected in Spring 2024 and included the sMARS (pre/post; Alexander & Martray, 1989), short written narratives about each PST's relationship with mathematics (pre/post), semi-structured interviews (pre/mid/post), and recorded classroom observations (pre/post). To characterize each PSTs' baseline MA, we used a priori theoretical coding for MA-aligned language (e.g., Stoehr & Olson, 2023) on the pre-narratives and interviews. We coded the pre-observation for evidence of their MA triggers and trigger responses and open coded the same

data for any additional MA triggers and trigger responses beyond the MA-aligned language. To track any MA changes, we performed descriptive statistics on the sMARS data and open coded the post-semester narratives, interviews, and observations for any changes in PSTs' MA triggers, responses, and potential rationale for those changes. After writing up case descriptions, we performed a cross-case analysis to answer our research question.

Findings

Our sMARS data showed that Mari and Eva reported notable decreases in their MA levels at the end of the semester (3.7 to 2.0 out of 5 and 3.6 to 2.9 out of 5, respectively). Velma's pre- and post-sMARS scores were nearly identical, with average item scores of 4.1 and 4.0, respectively. Considering these scores alone, it appeared that Mari and Eva had experienced a marked reduction in their MA levels, while Velma did not. However, considering the PSTs' written narratives, their interview responses, and our classroom observations revealed that all three PSTs' MA experiences had changed substantially over the course of the semester. Further, we observed that these changes were unique for each PST—not just in magnitude, but in nature.

Mari: "I can't figure it out on my own"

As identified in her pre-narrative and interview, Mari's baseline MA triggers were shaped by a belief that her peers were more mathematically capable than her: *working without support* and *peer comparison*. With respect to her first trigger, Mari expressed a desire to avoid working alone, writing in her pre-narrative that "I work better with a partner or in groups." In her pre-interview, she indicated that she not only felt more comfortable learning mathematics with her peers but believed that she *could not* do so without them. For example, Mari said, "I don't like doing stuff on my own. … I can't figure it out on my own." Despite her affinity for group work, Mari indicated that comparing her mathematical capabilities to theirs was also a source of MA. In her pre-interview, Mari was asked to clarify why she had scored the sMARS item *listening to another student explain a math formula* as eliciting more MA than *watching a teacher work on an algebraic equation on the board* (5 and 3 out of 5, respectively). Mari explained:

> When I hear another student, like, "oh, I did all of this to get this answer," I would just think, "I didn't even do it that way. I didn't even think the way she thought." … I get anxious thinking about that. But when I see a teacher doing it, it makes me feel better.

This explanation made it clear that, in addition to working alone without support from her peers, comparing herself to them mathematically was also a prominent MA trigger for Mari.

In the pre-interview, Mari described remaining inconspicuous as her primary response to an MA trigger. She stated that "I rather just sit quiet in math since I don't understand at all," and, when asked about sharing her thinking with the class, Mari said "I'd be deadly afraid to go up to that board and write everything down." Mari's pre-classroom observation was consistent with this characterization, as we saw her stay silent the entire class period, often engaging in behaviors that may have indicated anxiety (e.g., arms crossed, staring off, chewing her lip).

By Mari's mid-interview, we found emerging evidence that her levels of MA (connected to both MA triggers) were decreasing. This was most apparent when Mari discussed her experiences during the midterm exam and a subsequent email she received from her professor. Although the professor made it clear that students would have ample opportunities to correct any mistakes they made on the midterm, Mari reported that taking the exam was a stressful experience because she spent most of the exam comparing her experience to that of her peers:

> I heard everyone going, "Oooh!" like they under-, they said, "Oh!" out loud. I was like, what do you mean, "Oh?" I don't know what they're "oh"-ing about. … I was like, …

> maybe I'm not getting this. I was doing it … and I kept moving on. But then they're like, "Oh, I get it." And I was like, I'm not getting this … because I was not "oh"-ing.

Although her lack of having an "oh" moment made her fear that she had performed poorly, Mari reported that the professor sent her an email that had helped change her perspective:

> She sent me an email saying that I did really good in the midterm and that she was proud of me. And I was like, I did good on the midterm? … I just hoped that I passed, … but she was like, "You did really well. I'm so proud of you." … I was like, that means I should not think low of myself. I can actually learn this. So, next time … I could be like, hey, Mari, you can do this. You did well, … you can do it again now.

This suggests that this interaction with the professor helped Mari to make progress with respect to both of her MA triggers, as she seemed to recognize that she was capable of doing mathematics on her own, and that she had done so without "oh-ing" like her peers.

Mari's progress in overcoming her MA triggers appeared to continue throughout the semester. In her post-narrative, she wrote that her relationship with mathematics was "completely different now than it was before." She identified her realization that mathematical problems can be solved in multiple ways as a source of this change, which seemed to free her from her peer-related MA triggers. In her post-interview, she said, "Now that I know there's multiple other ways to do it, … if I can't do it one certain way, I could try another way to do it, because maybe that way works better for me than the other person."

Although Mari reported feeling much more comfortable in class during her post-interview, this change was only marginally observable. Mari was still mostly silent in her post-observation, and she did not share her mathematical thinking with her group or during whole-class discussions. However, we did observe her smiling and sharing a brief high school math experience with the whole class. For Mari, the observational data indicated some change in how she responded to her MA triggers but did not reveal the same profound MA transformation evident in her sMARS scores, written narratives, and interviews.

Eva: "It really was more dependent on the teacher"

Unlike Mari, Eva's MA experiences seemed unrelated to peer comparison or beliefs about her capabilities. Eva said early on that her MA was almost solely triggered by *teachers requiring particular solution methods* and *inadequate teacher support*. Eva wrote about her first trigger in her pre-narrative by describing a high school class: "I didn't like that I couldn't argue my point or think creatively in any sense. … I was frequently told I was wrong, even though I had gotten the correct answer, simply because of the method I chose to solve the problem." Similarly, in the pre-interview she described asking for mathematical explanations and being rebuffed: "No one could explain to me why things were the way that they were. … Like, two plus two equals four, just because two plus two equals four. There was no rhyme or reason." When asked whether the content of her high school math classes influenced how she felt about the class, she replied, "I think it's not so much the content that affects the math course … it really was more dependent on the teacher." Therefore, Eva's baseline data revealed that her MA was almost entirely dependent upon the classroom environment created by the course instructor.

Eva's pre-interview indicated that, in the past, she had responded to her MA triggers with disengagement. For example, she described disengaging after a teacher dismissed her question: "It was like, well, if you're gonna ignore me, then I'm gonna ignore you right back." However, such behavior was never witnessed during Eva's pre-observation. This was perhaps due to a lack of Eva's MA triggers in class; the course was specifically designed to emphasize the use of multiple solution strategies and the professor was attentive to students' questions.

Although Eva reported a decrease in her MA over the course of the semester, it was clear that this decrease was almost entirely instructor dependent. In her mid-interview, she indicated that the format of the course had improved how she felt about mathematics:

> The discussion element of [the course] really helps me out. And I think that is what the missing piece was when it came to my high school experience with math. So, I'm definitely feeling a lot better about it now.

Eva also stated that she felt supported by the instructor and her extensive assignment feedback: "She tells you what you're doing right and not just what you're doing wrong. Like, 'I love this thinking, can you just expand on this?' … At least I know I'm on the right track." In her post-narrative and interview, Eva suggested that her increased comfort with mathematics may not follow her into other mathematical environments. For example, she wrote, "I am not fully confident in my abilities, but I do have courage I could succeed given the right circumstances." When asked in her post-interview if her course experience changed the way she felt about mathematics more generally, she responded, "I have a better relationship with math, even though it doesn't really have to do with math, it has to do with the class."

All of Eva's observations showcased a mathematically confident student with no evidence of her identified baseline MA response of disengagement. Although this observational data appears to conflict with the MA decrease in her sMARS scores, Eva's narratives and interviews resolve this apparent incongruity. These data sources revealed that for Eva, MA was situational and dependent on the instructor's pedagogical practices. It is reasonable to assume that Eva's pre-semester sMARS responses were made referencing high school experiences, while her post semester responses likely referenced the current course environment. Eva's comfort with this environment perhaps meant that she rarely experienced MA in class during the study, fully explaining both her sMARS score decrease and the lack of observable disengagement.

Velma: "I'm just the lost person"

In her pre-narrative and interview, Velma repeatedly stated her belief that she was incapable of doing mathematics, a belief that permeated both of her primary MA triggers: *perceived mathematical inadequacy* (by self or others) and *having a wrong answer*. With respect to her first trigger, she stated in the pre-interview: "I'm not good at math. I still struggle to this day with my math. I constantly count on my fingers. … I can't do math." When asked to describe herself in her favorite class, history, she referred to her brain as a "sponge"; when asked to describe herself in math class, however, she described her brain as a "big blob."

While Velma did not self-identify a specific response to her first trigger, we observed a pattern of disengagement in class. When one of her groupmates expressed confusion, she quickly whispered "I'm confused too." When this groupmate later made progress and was praised by the teacher, Velma declared: "I'm just the lost person." After this exchange, Velma did not watch as her classmates shared their thinking in the whole group discussion and spent the rest of the class engaging in behaviors such as playing on her phone, ripping up paper, and doodling.

Her second trigger, *having a wrong answer*, emerged in the pre-interview: "I'm afraid of being wrong and being shunned for being wrong. I'm scared to be wrong. I'm embarrassed to be wrong." She then described responding to this trigger with silence: "I don't answer the questions. I don't like to answer the question in front of the class." Our pre-observation of Velma corroborated this response; she did not verbally contribute to either her group's collaborative thinking or to the whole group discussion.

Later in the semester, we found evidence of a shift with respect to Velma's second MA trigger (*having a wrong answer*), but not with respect to her first (*perceived mathematical*

inadequacy). We observed an increase in Velma's group participation, a change she identified herself in the mid-interview: "If it's not about something I like, I'm like, I can't do this. … I think [my group has] really helped get me out of that. They're like, 'Come on, you got the answer.'" Velma went as far as to say that "My group's really helped me just be less nervous and anxious." In the post-interview, Velma indicated that she had made further progress with respect to this trigger: "Now I'm like, okay, if I'm wrong, just tell me. I get it. I'm dumb sometimes, and I can't think. … Don't be afraid to tell me it's wrong. Like, teach me how I can fix it."

Despite this progress, her self-description as "dumb" and unable to think indicated that her first MA trigger, *perceived mathematical inadequacy*, remained consistent. In the mid-interview, Velma described her midterm exam experience: "I only got one and a half problems done. I got to the second page and … I couldn't get my brain around it." These self-disparaging descriptions persisted throughout the semester, with her post-interview rife with statements such as "I suck at math." Her post-narrative similarly contained statements such as "Basic math is simple but anything past that is too hard. My relationship [with math] remains the same."

Our post-observational data, however, painted a very different picture of Velma. We saw evidence of confident mathematical engagement that did not align with her own self-descriptions. As an example, consider Velma's contribution to a group discussion about the problem ⅓ divided by ⅙. Her groupmates arrived at different answers and were expressing confusion and frustration. Unprompted, Velma interjected: "It's 2. Because if you look, one sixth takes up half of the one third, and if you add another one it makes one whole, so [the answer is] 2." Velma did several things in this response that demonstrated confident mathematical engagement. First, she participated actively, sharing her thinking with her group without their encouragement. Second, she asserted her answer in a way that demonstrated certainty in her response. Finally, when sharing her thinking, she did so succinctly and in a way that made sense to her peers, starkly contrasting her representation of herself as "dumb" or unable to think.

Initially, Velma expressed confusion and frustration when working on fraction addition (e.g., "I'm just the lost person"), and rarely shared her thinking with her group mates or the whole class. By the end of the semester, and despite her expressed lack of confidence (e.g., "I'm dumb sometimes"), she participated in meaningful ways. Her contributions, both in small and whole groups, indicated that Velma was making progress with respect to *both* MA triggers, yet she only recognized improvement with respect to *having a wrong answer*. Consistent with the continued narrative that she believed herself incapable of math, she reported the highest sMARS score of the three PSTs both at the start and at the end of the semester, and her decrease was the smallest in magnitude. It was clear that Velma continued to view herself as incapable and was unaware of the shifts in confidence that we observed in her end of semester classroom observation.

Cross-Case Findings

As we looked across the three PSTs' MA journeys, the theme that emerged from comparing the data sources was that there was no single most insightful data source. In fact, the most insightful data source varied across cases. The sMARS provided insight into the existence of self-reported MA but failed to reveal how each PST's MA had changed. For example, the sMARS data showed a decrease in MA for both Mari and Eva but not the differing nature of their changes in MA; the sMARS missed that Mari's MA decrease was tied to a fundamental shift in how she viewed herself as a mathematical thinker, while Eva's was tied to a comfortable classroom context. These insights were revealed through their interviews and written narratives, through which we were able to characterize how they made sense of their MA triggers, responses, and the changes they experienced in these over the semester. Yet, the classroom

observations did not reveal any meaningful changes in behavior for either Mari or Eva. Observational data, however, was critical in understanding Velma's MA journey. The sMARS did not identify a change in Velma's MA, failing to register the shifts in how she responded to her MA triggers that were clearly evident in her interviews and second classroom observation. In fact, Velma's shifts in MA with respect to her first trigger would have gone undetected without the observational data. In conclusion, the cross-case analysis revealed that, consistent with the individualized nature of MA, each data source holds potential to reveal unique insights, though the nature of these insights will vary from person to person.

Discussion

We aimed to answer the research question: What do we learn about PSTs' MA using the sMARS, written narratives, interviews, and classroom observations? Our analysis revealed that each data source provided a unique and valuable perspective for each individual PST and presented its own affordances and limitations. For example, the validated survey scale helped us quickly identify high MA study participants and revealed some MA decreases. However, this data source could not identify the stark differences in the nature of these PSTs' MA decreases; it also did not identify the change in Velma's MA evident in other data sources.

Although our study was limited in size, each case illustrates how conclusions drawn in extant research may be enriched by analysis of additional data sources. Consider Barrett (2013), who used validated surveys (pre/post) to conclude that teaching PSTs to reason with manipulatives reduced their MA (a finding consistent with other studies, e.g., Gresham, 2018). If Eva was a participant reporting an MA decrease in this study, an interview may have yielded insight into whether this drop resulted from—or in spite of—the manipulative use. Without such data, it would be unclear if using manipulatives served as an instantiation of Eva's first MA trigger (*teachers requiring particular solution methods*) or if she viewed their use as a means to explore her own strategies.

Velma, in particular, illustrates how even the most robust data collection can fail to detect MA shifts if the study only employs self-reported data. Stoehr's (2017) study exemplified robust longitudinal MA data collection, showcasing the power of written narratives and interviews to reveal individualized aspects of PST MA. With three PSTs, Stoehr found that their unique MA coping mechanisms employed in learning mathematics carried over to teaching mathematics (e.g., working to conceal knowledge gaps). Despite Stoehr's extensive self-reported data and analysis, it is possible that a participant like Velma (who was sometimes unaware of how her MA manifested) may have presented a unique challenge to Stoehr's analysis. For participants like Velma, the absence of observational data likely translates into an absence of insight.

Beyond the value of varied data sources in MA research, the most commonly used data sources are often not utilized to their full potential, including in our own study. For example, the sMARS measures three dimensions of MA, *math test anxiety*, *numerical task anxiety*, and *math course anxiety* (Alexander & Martray, 1989). Though most validated MA surveys measure more than one MA dimension, few researchers utilizing these scales disaggregate their results by MA dimension, potentially ignoring readily available insights. Although we failed to consider disaggregated sMARS scores, our analysis suggests that, in addition to having a distinctive set of MA triggers and responses, each PST will also likely have a particular data source where changes in their MA are most evident. Because such evidence is not visible until data is analyzed, it is vital for MA researchers to utilize multiple data sources, including both self-reported and non-self-reported measures. This will honor the individualized nature of MA and ensure that MA research findings benefit a broad range of PSTs who struggle with MA.

The Structural and External Validity of Bold Problem Solving in College Math Students

Martha Makowski
The University of Alabama

Jim Gleason
The University of Alabama

Bold problem solving (BPS) describes an orientation towards mathematical problem-solving involving risk taking, inventiveness, and independence. Research establishing BPS is promising but requires more validity work to better position the construct. This study does so, exploring the factor structure of the BPS orientation scale, examining how BPS relates to risk taking, math identity and agency, and investigating if gendered differences in BPS orientations persist with more flexible gender measures than those used in earlier studies. Electronic survey data from 204 students enrolled in calculus or above at a single university were collected and analyzed using statistical methods. Results suggest that the BPS orientation scale has one dimension, but the measure can be improved. Risk taking and math identity have strong unique relationships to BPS. Gendered differences in BPS largely were non-existent using more flexible gender measures. Collectively, this work helps further the structural and external validity of BPS.

Keywords: bold problem-solving, mathematical risk-taking, scale validity

Participation in advanced math requires a great deal of independence, problem solving, and mathematical risk taking. A recent construct, Bold Problem Solving (BPS; Lubienski et al., 2021), is conceived as a socialized orientation towards math that involves inventiveness, independence, and risk-taking. Evidence from a different study suggests that BPS relates to advanced participation in math (Makowski, 2020). Although initial work by Lubienski et al. demonstrated that BPS differs from other orientations known to relate to math, this work left open many questions, including (1) a deeper investigation into the factor structure of the BPS orientation scale, (2) the relationship of BPS to related orientations not tested in the original work, and (3) whether observed gendered differences in self-reported BPS orientations persist when more flexible measures of gender are used. This report investigates these questions.

Theoretical Framings

BPS is a comparatively new construct and is still being validated. Flake et al. (2017) describe a three-part construct validity framework. *Substantive validity* is established by defining and linking a construct and its measure to existing literature and theories. *Structural validity* is established through statistical investigation into how the construct measure items perform together and individually. Lastly, *external validity* is established by examining how a construct measure relates to other, similar constructs and the measure's predictive power in relation to outcomes of interest. Here, we focus on the structural and external validity of the BPS orientation measure with an undergraduate students. In the sections that follow, we focus on the related constructs we test in our exploration of the external validity of the BPS measure.

Bold Problem Solving

Math problem-solving processes relate to the skills necessary for reasoning in advanced math (e.g., Furinghetti & Morselli, 2009; Savić, 2016). BPS was developed to help explore why girls underperform relative to boys in the top of the achievement distribution (Cimpian et al., 2016). Lubienski et al.'s study with high school students showed students' self-reported BPS related to, but was distinct from, both math confidence and spatial ability. The BPS measure also related to

the binary sex measure used: male-identifying students scored a full standard deviation higher on the BPS measure than did female-identifying students and it explained over half of the male advantage on a problem-solving test. Makowski (2020) showed that BPS orientation correlated with participation in advanced math: college students in non-STEM track math courses had lower BPS orientation scores than those in Calculus I or an introduction to proof class. Moreover, individuals with at least a Masters in math had higher BPS orientations than those in the more advanced math classes. Gender difference existed for students in Calculus I only.

The initial findings related to BPS are promising, but several important questions remain unexplored. First, Lubienski et al. (2021) hypothesized that their 10-item BPS measure might contain more than one dimension. Their investigation into this question concluded that the data did not support this structure, but their samples were small enough to leave the question open. Second, the relationship of BPS orientation to risk taking and independence was unexplored. Third, their use of a binary sex is misaligned with current understanding of gender.

Risk Taking

It is not uncommon to theorize that doing math involves risk. For example, Lampert (1990) noted that genuine mathematical activity is inherently risky, as it involves moving beyond what is known. Regier and Savić (2020) suggest that progression in advanced math requires comfort with risk taking. As hypothesized, BPS contains elements of risk-taking, but how it relates to BPS was not examined in the initial studies. Risk-taking might explain the gendered outcomes Lubienski et al. (2021) observed. Research from several fields suggests that females tend to be more risk-averse than are males (Byrnes et al., 1999). For example, in music, girls have been found to be less comfortable than boys with the improvisational nature of jazz (Wehr-Flowers, 2006). Similarly, in science and computing, boys were found to more often "tinker" with materials or tasks, while girls more often followed teacher directions (Jones et al., 2000).

Math Identity

Broadly, math identity captures the extent to which an individual sees themselves as someone who does math. In a recent study, Rothrock and Gay (2025) linked increased math identity in college freshmen with having high initial college math placements or having taken advanced math in high school. College students with stronger math identities are more likely to be interested in math related careers (Cribbs et al., 2020). As BPS correlates with participation in advanced math (Makowski, 2020), it seems likely that math identity may relate to BPS.

Sense of Agency/Independence

Sense of agency refers to the subjective experience of controlling one's actions and the subsequent outcomes. Students who perceive control over their learning and believe their actions directly affect outcomes are more likely to engage in exploratory problem-solving (Bandura, 1997). Agency in math is thought to serve as a gateway to creating a math identity (e.g., Boaler & Greeno, 2000) and deliberate efforts to create agency in math relate to increased interest and enjoyment of math for K-12 students (e.g., Sengupta-Irving, 2016). Thus, while BPS is hypothesized to relate to independence, a sense of agency may be an important prerequisite. We hypothesize that a positive sense of agency will relate to higher BPS orientation scale scores.

Gender

Gender identity is rooted in socialization and is not generally thought to be well-captured by the traditional binary categories used in research, including the original BPS studies. Lubienski

et al. (2021) found a binary sex difference in self-reported BPS orientations with K-12 students, which was also present for Calculus I students at the postsecondary level (Makowski, 2020). It is unclear whether more flexible measures of gender will continue to relate to BPS. On the one hand, the norms and practices of math are generally understood to replicate norms and interactions styles associated with white masculinity (Leyva, 2017). On the other hand, Alcock et al. (2014) found that personality had predictive power over and above binary sex for math achievement, suggesting that measures of personality might have a stronger relationship to BPS than binary sex while still tapping into gendered traits.

Methods

All data were collected via an electronic survey from undergraduate students enrolled at a single large southeastern university. Participants were recruited from multi-section math courses that are a standard part of a math major: Calculus I, Calculus II, Differential Equations, and Introduction to Proof. Students were eligible to participate if they were enrolled in one of these classes and their instructor allowed a researcher visit. The survey link was distributed during the research visit and again through an email distributed by the instructor.

Sample

In total, 264 students took the survey. Of these, 59 were removed for responding to an attention check incorrectly. One additional student did not provide their sex and was removed, leaving a final sample of 204. The number of students by course and binary gender are reported in Table 1. To bolster our sample size for the first research question, we supplemented the BPS orientation scale survey responses using data from 321 students enrolled in similar classes that were collected as part of a different study (Authors, in preparation).

Table 1. Sample Sizes and Percents by Binary Gender

Course	Men		Women		Total
	n	%	*n*	%	
Calculus 1	20	47.6	22	52.4	42
Calculus 2	37	67.3	18	32.7	55
Differential Equations	56	72.7	21	27.3	77
Introduction to Proof	15	50.0	15	50.0	74
	128	62.7	76	37.3	204

Survey Measures

The 15-to-20-minute online survey included questions about the student's course, their gender and racial or ethnic identity, and a battery of measures related to math attitudes and orientations. The order of the scales and the order of the items within each of the scales was randomized. We also included an attention check in the middle of the survey.

Bold problem solving. The 10-item BPS measure (Lubienski et al., 2021) was included. This measure has variety of items, some of which related to independence (e.g., "When I am stuck on a math problem, I usually play around with the problem for a while before examining worked examples or seeking help"), some to risk-taking (e.g., "I enjoy working on challenging math problems that do not have a set way of solving them"), and some to mathematical behaviors (e.g., "When solving math problems, I tend to use creative strategies"). Items used a 5-point Likert scale from "Strongly disagree" to "Strongly agree."

Risk taking. Risk taking was measured using the General Risk Propensity Scale, which is composed of eight positively worded items (e.g. "My friends would say that I'm a risk taker") and is shown to have very high internal consistency, fit a unidimensional confirmatory factor analysis model, and demonstrated predictive validity for samples of adults (Zhang et al., 2019). Items used a 5-point Likert scale from "Strongly disagree" to "Strongly agree."

Math identity. Math identity was measured using a single item asking participants to answer the question "On a scale of 1-10 (with 1 not very mathematical) how much do you identify as good at math?" While single item measures lack complexity, the large scale range and straight forward prompt provide a baseline for exploring how BPS might relate to math identity.

Sense of agency. To measure agency, which feeds independence, we used the Sense of Agency Scale, which has two subscales: Sense of Positive Agency (5 items) and Sense of Negative Agency (6 items; Tapal et al., 2017). We removed one item from the negative agency scale due to language issues and reduced the Likert scale response categories from seven to five to match the other instruments in the survey. A two-factor confirmatory factor analysis (CFA) model of the sample data suggests the reliability of the scale was still satisfactory with these modifications (RMSEA = .052, CFI = .934 with covariance of 0.308 between the factors and correlation between the subscale total of .441).

Gender. Given the relationship between gender and personality (Alcock et al., 2014), we included a measure of sex assigned at birth, two related measures of gender, and personality scale. The gender measures asked participants to rank on a typical day how masculine/feminine they felt (5 categories from "not at all" to "a great deal"). To examine personality, we used the BFI-10 (Rammstedt & John, 2007) measure, which was built based on research documenting five dimensions of personality (extraversion, agreeableness, conscientiousness, neuroticism, and openness). The 10-item scale assigns each of the five personality dimensions two items.

Analysis

Prior to the main analysis, data were cleaned and inspected for attentiveness and scale completeness. Reverse coded items were recoded to be on the same scale. Descriptive and reliability statistics were calculated for all scale items. For non-BPS measures we computed the scale score by taking the average of the responses on each item, with higher values associated with higher levels of the variable measured. The same was done for the BPS measure after the dimensionality of the 10-item scale was determined for Research Question 1.

Research Question 1: Factor Structure of the BPS Orientation Scale with Undergraduates

To assess the factor structure of the 10-item BPS orientation scale for the undergraduate student population, we used an exploratory factor analysis (EFA), examining the underlying dimensions of the construct and evaluating whether the items loaded consistently with the theoretical model of a unidimensional instrument. The analysis included tests of sampling adequacy (Kaiser–Meyer–Olkin statistic, Kaiser & Rice, 1974; Bartlett's test of sphericity, Bartlett, 1951) to ensure suitability for factor analysis. Reliability estimates, including Cronbach's alpha, were also calculated to examine internal consistency.

Research Question 2: Relationship of BPS to Other Related Constructs

To assess the relationship of BPS (using the factor structure determined in Research Question 1) to other related constructs, we performed a series of ordinary least square regressions using BPS as the dependent variable. Mimicking the original work of Lubienski et al. (2021), Model 1 assessed the baseline relationship between binary sex (entered as a binary indicator; students

who identified as female assigned a value of 1, males a value of 0) and the BPS measure. Model 2 included the other related variables (i.e., math identity, positive and negative sense of agency, risk-taking).

Research Question 3: Relationship of BPS to Flexible Gender Measures

To assess the relationship of BPS to more flexible measures of gender and personality traits, we first examined the correlations of the related measures with each other and to the BPS measure. For each of the three alternative gender-related variables (femininity, masculinity, Big 5 personality factors), we ran two models with the BPS measure as the dependent variable (6 models total). Model 1 included the gender or personality variable as the independent variable ("not at all" served as the reference category for the feminine and masculine cales). Model 2 added the other BPS-related independent variables tested in Research Question 2.

Results

All scale measures were inspected fit within standard parameters to be treated as normal in correlational analyses (±2 for skew, Tabachnick & Fidell, 2013; ±7 for kurtosis, Hair et al., 2010). These variables are thus treated as normal for the duration of the analysis. For brevity, we do not report descriptive statistics on these measures. Cronbach's alpha for the scales with more than two items ranged between .60 (sense of negative agency) and .81 (risk-taking). Cronbach's alphas were smaller for the two-item Big 5 personality measures (.26 to .75).

Research Question 1: Factor Structure of the BPS Orientation Scale with Undergraduates

Preliminary analyses indicated that the data were suitable for factor analysis. The Kaiser–Meyer–Olkin measure of sampling adequacy was .85, exceeding the recommended threshold of 0.60. Bartlett's test of sphericity was significant ($\chi^2(45) = 1489.3$, $p < .001$), indicating that correlations among items were sufficient to proceed with factor analysis. Individual MSA values for all items ranged from .75 to .90, suggesting items shared adequate variance to each other.

A parallel analysis suggested a three-factor solution was possible, with eigenvalues of 3.85, 1.34, and 1.11. EFA using principal axis factoring with a single-factor solution revealed factor loadings ranging from .26 to .76. The single factor solution accounted for 33% of the total variance (RMSEA =.12; Tucker Lewis Index [TLI] of .78). Internal consistency was strong (Cronbach's α =.81; .79 with analytic sample). Neither the two- or three-factor models were theoretically coherent. The three-factor model had strong fit indices (RMSEA = .05, TLI = .96), but a single item loaded onto the third factor and one item did not load onto any factor.

These results suggest that, consistent with the original theoretical model, the 10-item BPS orientation scale functions uni-dimensionally with this sample, with each item contributing to the overall factor. However, development of additional items and the use of cognitive interviews for response process validation are needed to create a stronger instrument.

Research Question 2: Relationship of BPS to Other Related Constructs

Table 2 displays the pairwise correlations of the various measures used. Here we only focus on the correlations between items 1 through 6. Notably, the BPS measure has a strong positive correlation with both risk taking and math identity. Consistent with prior research, the binary sex measure is also significantly correlated with the BPS measure. Neither positive nor negative sense of agency correlated with the BPS measure.

Table 3 displays the results of the three models. While female significantly negatively related to BPS (Model 1), this relation no longer held after the other covariates were added (Model 2).

Both risk taking and math identity significantly positively related to BPS (Models 2 and 3). This is interesting as risk taking and math identity were negatively correlated to each other. Neither positive nor negative sense of agency related to BPS. This makes sense as these measures were not correlated. Collectively, these results suggest risk taking and math identity together are more strongly related to BPS than binary sex.

Research Question 3: Relationship of BPS to Flexible Gender Measures

Table 2 displays the correlations between the BPS orientation scale and the flexible gender and personality measures. None of these correlations were significant. There were strong relationships between the binary sex (female) variable and the feminine and masculine 5-level categorical measures. Masculinity was positively correlated with risk taking.

Table 4 displays the regression results using the feminine and masculine gender measures in lieu of the binary sex variable. While identifying as feeling feminine "a lot" initially related to BPS, this relation was not strong and dropped once other covariates were added. Masculinity did not relate to BPS at the categorical level. We do not report the regression results using the Big 5 personality measures: the correlations between the personality measures and the BPS measure scale were not significant and the regression results reflected this pattern.

Table 4. OLS Regression Results Predicting BPS Orientation Using Flexible Gender Predictor Variables

Discussion and Conclusions

The analyses presented here builds on the work of Lubienski et al. (2021) and Makowski (2020), adding to the structural and external validity of the BPS construct. Research question 1 investigated the structural validity of the BPS measure, examining the dimensionality of the 10-item BPS measure. We found that for the undergraduate student population, the factor structure has the most evidence for a unidimensional structure. However, while this was the best solution, the fit statistics of the one-dimensional solution were not optimal, suggesting that developing and testing additional items is warranted.

Research question 2 examined the external validity of BPS, testing theorized relationships. Consistent with theory, BPS positively related to both math identity and risk taking. Curiously, these two variables were negatively correlated, suggesting that there might be something unique about the risk taking needed for math versus general risk taking that the BPS construct taps into. Neither a positive nor negative sense of agency related to the BPS measure, which is contrary to our hypothesis. This may be an effect of the fairly low reliabilities of the agency measures used. Alternatively, the particular measures used (which measured general agency) might be somewhat distinct from math agency. These relationships should be further probed using better, more targeted measures.

Research question 3 examined the external validity of the BPS measure, testing whether more flexible gender measures than those used in the original BPS studies still showed a relationship between BPS orientations and gender (Lubienski et al., 2021; Makowski, 2020). The results of research questions 2 and 3 together suggest that the BPS may be a "math socialization" construct that functions independent of gender. The gendered results of the initial studies may crudely measure and reflect the mathematical socialization that results from the male coded culture of math (e.g., Leyva, 2017). Measuring gender using more flexible reporting categories weakens the link between gender and BPS, while the relationship of BPS to other socialized affects remain strong. More work testing this theory should be the focus of future investigations.

Collectively, this study adds validity evidence to the theorization of BPS. However, the results are still inconclusive in important ways and additional work is needed to help understand bold problem solving in the undergraduate student population.

Targeting Conceptions of Derivative: Introducing Derivatives in Calculus With Inquiry

Hannah Freund[1]
Cal Poly San Luis Obispo

Chris Liu
Cal Poly San Luis Obispo

Morgan Raak
Cal Poly San Luis Obispo

Saba Gerami
Cal Poly San Luis Obispo

In this study, we leverage the Conceptions of Derivative (CoD) framework (Gerami et al., 2025) to analyze eight U.S. college calculus instructors' instructional tasks for introducing derivatives. During four task-oriented interviews, each instructor proposed up to eight tasks for introducing derivatives with inquiry in their calculus I courses. Based on Zandieh's (2000) process-object model, the CoD framework was used to reveal derivative conceptions that instructors were targeting in their tasks. We identified four components of derivative conceptions targeted in the tasks: contextual framing, epistemological approaches (limit-based, infinitesimal/differential-based, and instrumental/rule-based), mathematical representations, and process-object layers. While pure contextual frames and limit-based approaches dominated early instruction of derivatives for these instructors, some targeted physics and biology contexts as well as infinitesimal/differential-based and rule-based epistemologies. We discuss implications for research on calculus teaching.

Keywords: Derivatives, conception, calculus teaching, instructional tasks

While researchers have explored students' conceptions of derivatives for some time (e.g., Ferrini-Mundy & Graham, 1994; Feudel & Biehler, 2021; Jones & Watson, 2017), little research has examined how college calculus instructors teach derivatives and the conceptions they target during instruction. In this study, we investigate how college calculus instructors introduce derivatives by focusing on the conceptual opportunities they leverage in their instructional tasks. To reveal a broader range of conceptions of derivatives targeted within instructional tasks, we focused on instructors experienced with inquiry-based teaching, assuming they use a broader range of instructional tasks than those from conventional textbooks. We aim to address the following question: Which conceptions of derivative do eight college calculus instructors target in their instructional tasks when introducing the concept for the first time with inquiry?

Literature Review

Our search of the research on teaching of derivatives yielded nine studies. The first four studies were conducted with various motivations, yet they all examine non-intervention based teaching of derivatives by calculus teachers. The remaining studies (Borji et al., 2018; Hähkiöniemi, 2006; Hitt & Dufour, 2021; Kendal & Stacy, 2001) are intervention-based, as they investigate the efficacy of teaching interventions aimed at helping students make connections between multiple representations of the derivative to develop deeper conceptual understandings. Because our question revolves around teachers' natural ways of teaching derivatives, we delve deeper into the non-intervention based studies.

Park (2015) used a discursive approach to investigate how three university calculus instructors defined derivatives at a point, and on an interval (or as a function), and transitioned

[1] The first, second, and third authors contributed equally and are listed alphabetically.

from the former to the latter, given the challenges these concepts pose for students. Although the instructors used secant and tangent lines to graphically illustrate derivative at point, Park identified several disconnections. The instructors did not explicitly connect the graphical and the symbolic representations of derivatives, as they often referred to the slope of secant or tangent lines simply as 'secants' or 'tangents.' While they used graphs to illustrate the derivative at a point (via secants approaching a tangent), they did not use graphical representation to define the derivative at the function layer. Moreover, at the function layer, the instructors often showed derivative as a function with zero, positive, or negative values of derivative "rather than numerical values that change over an interval" (p. 248). Moreover, the transition from the limit to the function layer within the symbolic representation was only shown as changing the symbol for a point (x_0) to a variable (x), without addressing the reasoning behind the change of symbols. Park concluded that by not making these connections explicit, students were left to make some challenging connections on their own.

Within a study about one experienced college instructor's use of a calculus textbook in Norway, Randahl (2016) examined how the instructor introduced derivatives during a sequence of six lectures. The instructor closely followed the textbook's structure and content sequence, defining the following concepts through lecturing: 1) tangent line, 2) slope to the tangent line, 3) the difference quotient, 4) the slope of a curve at a point and the slope of the normal in this order, and 5) The derivative of a function defined using the limit definition. The definitions were presented on the board without further clarification or discussion, after which, the instructor assigned procedural exercises for group work, with some solutions discussed in front of the whole class. Because the instruction mirrored the formal introduction of derivatives in the textbook without providing additional explanations, Randahl concluded that the instruction likely did not enhance students' understanding of the abstract concepts associated with derivatives.

In a study examining teachers' views on differentiation and their knowledge of teaching it, Delos and Thomas (2003) investigated four New Zealand teachers' approaches to teaching derivatives. Although the authors found no common way of teaching derivatives across the teachers, they found that all teachers used graphical representations, particularly the approach of moving secants toward a tangent when finding derivative at a point. Despite their emphasis on graphical representation, the teachers expressed a desire for their students to develop a comprehensive conceptual understanding of derivatives, including understanding it as "a gradient function, as a rate of change, as a limit, and symbolically" (p. 56).

Lastly, in the fourth non-intervention-based study, Hitier and González-Martín (2022) identified the (in)consistencies in the use of derivatives in calculus and mechanics course, needed for solving one-dimensional kinematics tasks. As part of their broader investigation, the authors interviewed four college calculus instructors from Quebec, all of whom used Stewart's (2013) textbook to teach the course. The teachers described their ways of introducing derivatives similar to the textbook's, with interpreting derivative at a point as the slope of the tangent line. They also incorporated the symbolic limit definition both at a point and for a function and made connections with the graphical representations. Although the teachers mentioned using the four representations by Zandieh (2000) in their teaching, they expected students to heavily rely on symbolic calculations to solve derivative tasks about motion (i.e., within the physical representation of derivative).

In summary, these non-intervention-based studies on the teaching of derivatives focus on how teachers often define derivatives. They collectively suggest that instructors often utilize both graphical and symbolic representations, but that they may give less emphasis to physical

representations of derivatives. Among the intervention-based studies not reviewed here due to space, there appears to be agreement that using graphical representations for introducing derivatives is effective. However, it remains uncertain whether the physical representations, particularly those related to physics (as opposed to, for instance, population growth or decay), contribute to a better understanding of derivatives.

While these studies shed light on the importance of various representations of derivatives, they have focused exclusively on limit-based understanding of derivatives, reflecting the dominance of this approach in traditional calculus instruction. However, recent literature suggests that instructors may employ alternative epistemological approaches to derivatives that extend beyond the limit framework (Ely, 2021; Keisler, 2011; Samuels, 2017). The Conceptions of Derivatives (CoD; Gerami et al., 2025) framework, which we present next, addresses these gaps by incorporating multiple epistemological approaches and explicit attention to the physical manifestation of derivatives.

Theoretical Framework

The Conceptions of Derivatives (CoD; Gerami et al., 2025) framework extends the Zandieh's (2000) framework (Table 1) to include non-limit-based approaches to thinking about derivatives. Constructed as a cognitive model for students' understanding of the concept of derivative, the Zandieh's framework distinguishes between three derivative "process-object" layers—shown as *ratio*, *limit*, and *function* rows in the table—within four main representations/contexts of derivatives—graphical, verbal, physical, and symbolic. Relying on Sfard's (1991, 1992) notion of process-objects, Zandieh's framework uses "limiting" as the main process for deriving derivatives. The ratio layer is the average rate of change between two points: $\frac{f(x_0+h)-f(x_0)}{h}$. The limit layer is produced by *limiting* the ratio layer: $\lim_{h\to 0}\frac{f(x_0+h)-f(x_0)}{h}$, referred to as the derivative of the function at a point. Finally, the function layer is produced by using the same limiting process for all possible points to find derivative as a function: $f'(x) = \lim_{h\to 0}\frac{f(x+h)-f(x)}{h}$.

Table 1. Zandieh's (2000) framework for the conceptions of derivative

		Representations/Contexts				
		Graphical (Slope)	Verbal (Rate)	Physical (Velocity)	Symbolic (Difference Quotient)	Other
Process-Object Layer	Ratio					
	Limit					
	Function	.	.	.	.	

Tho CoD framework, shown in Figure 1 is more comprehensive, as it includes two other ways of thinking about derivatives: infinitesimal- or differential-based, and rule- or instrumental-based. The CoD framework has four distinct but interconnected components. *Contextual Framing* is the context through which we frame or interpret derivative problems. Common contexts in calculus are pure mathematics, physics, chemistry, biology, and economics. *Conceptual Epistemology* captures fundamentally different approaches to understanding what derivatives are and how they are derived. The framework identifies three distinct epistemologies: limit-based (traditional approach using limits of difference quotients), infinitesimal/differential-based (using infinitesimal quantities or differential reasoning), and instrumental/rule-based

(procedural approach using derivative rules). *Mathematical Representations* encompass the three primary ways derivatives can be expressed mathematically: graphical (visual representations), symbolic (algebraic expressions), and numerical (calculated values). *Process-Object Layering* maintains the hierarchical structure of derivatives from Zandieh's (2000) framework but adapts it to work across different epistemologies: 1) between two points (average derivative/rate of change), 2) at a point (instantaneous derivative), and 3) everywhere (derivative function). Unlike Zandieh's framework where layers are tied to limit processes, these layers can be conceptualized through any of the three epistemological approaches.

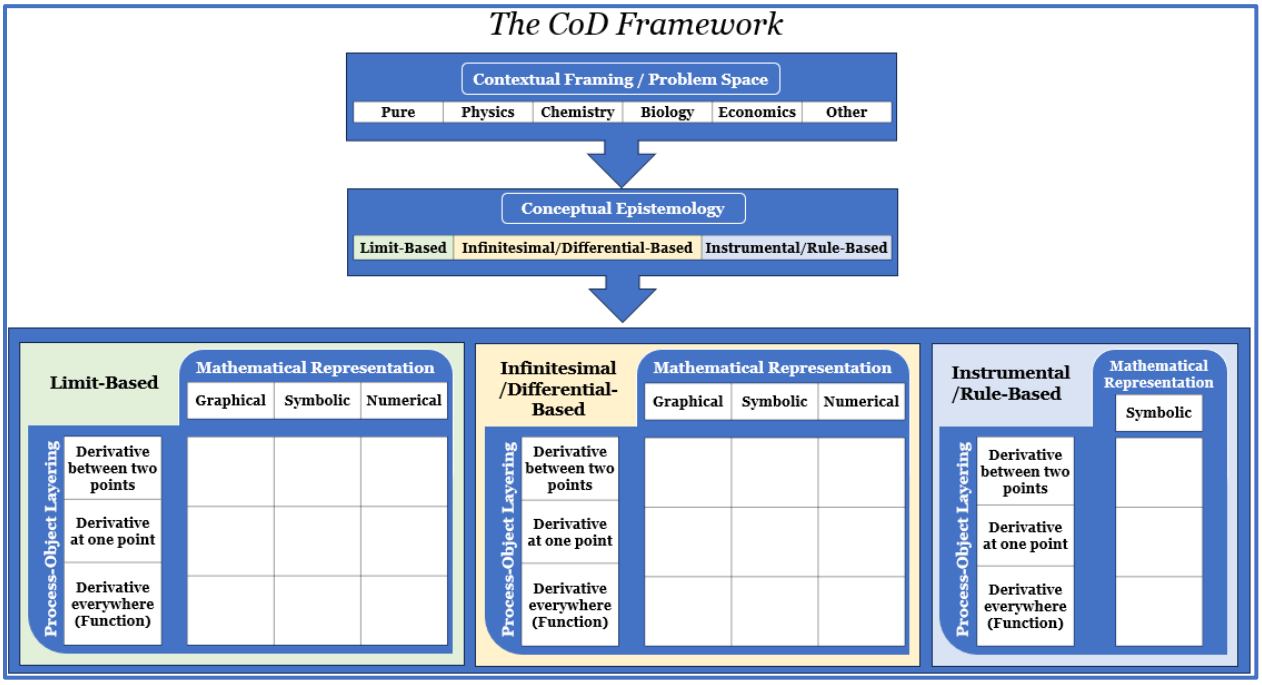

Figure 1. Conceptions of Derivative (CoD) framework

Methods

The data for this study comes from a larger study conducted to investigate calculus instructors' social and content-based framings of instructional tasks for introducing derivatives (Gerami, 2024). Eight instructors were purposefully selected via cluster analysis from a larger subset of experienced college calculus instructors who showed variety in their teaching with inquiry based on a survey (INQUIRE; Shultz, 2020). All using pseudonyms, the instructors were Adrian, Barry, Gopher, Justin, Matthew (he/him pronouns), Monica (she/her pronouns), Alex (any pronouns), and Max (they/them pronouns). The fourth author conducted four 1–2 hours long semi-structured interviews with each instructor. The interviews, organized by Zandieh's (2000) framework, asked instructors to propose up to eight tasks for introducing derivatives graphically, physically, verbally, and symbolically at a point (assuming students already knew about average rate of change), and as a function (assuming students already knew about derivative at a point).

However, the instructors often targeted multiple conceptions in their tasks, expecting students to use multiple representations of derivatives. This motivated us to analyze the conceptions of derivatives, including representations of derivatives, targeted in the tasks. Given that the proposed tasks often had multiple parts, the fourth author identified and separated the

smallest calculus-focused parts in each task to streamline the analysis; we call these calculus-specific task units (CTUs). Using the CoD framework and the qualitative software ATLAS.ti, all authors coded the four components of conceptions of derivatives targeted in each task: problem space (pure, physics, chemistry/biology), conceptual epistemologies (limit-, infinitesimal/differential-, or instrumental-based), mathematical representations (graphical, numerical, symbolic), and process-object layers (average derivative, derivative at a point, derivative everywhere/function). Problem space was coded at the task level, while the conceptual epistemologies, representations, and process-object layers were coded at the CTU level. Across the eight instructors, we analyzed 57 tasks containing 252 calculus-specific task units (CTUs). Table 2 shows the distribution of tasks and CTUs by instructor.

Table 2. Number of tasks and CTUs, as well as epistemologies used, by professor

	Instructor							
	Adrian	Alex	Barry	Gopher	Justin	Matthew	Max	Monica
Number of tasks proposed	8	8	8	8	4	6	8	7
Total number of CTUs across tasks	35	35	31	38	10	32	40	31

After coding the tasks independently, we met to compare our codes, discuss differences, and come to consensus. All final codes were agreed upon by all authors. To analyze patterns in conception targeting, we conducted chi-squared tests when possible (five or more CTUs) to determine whether individual instructors showed significant preferences for targeting specific process-object layers or mathematical representations, hypothesizing that instructors would target each layer (or representation) equally.

Findings

Contextual framing varied across instructors, as shown in Figure 2. Of the 57 tasks, 32 used pure mathematical contexts, 22 used physics contexts, and only 2 used biology/chemistry contexts. All instructors employed pure mathematical contexts, with Alex, Barry, Gopher, and Justin using them most frequently. Except for Justin, all instructors used physics contexts at least once, with Matthew, Max, and Monica using them more extensively. Adrian uniquely distributed tasks across pure and non-pure contextual frames, while being the only instructor who used biology/chemistry contexts.

Limit-based approaches dominated instruction across all instructors, appearing in 243 of the 252 CTUs (Figure 3). All eight instructors used limit-based epistemologies extensively. Infinitesimal/differential-based approaches appeared in only four CTUs, used exclusively by Gopher and Justin. Rule-based epistemologies were even less common, appearing in five CTUs across three instructors—Alex, Max, and Monica. While the instructors often targeted a single epistemological approach in their tasks, a few tasks incorporated multiple epistemologies within different CTUs.

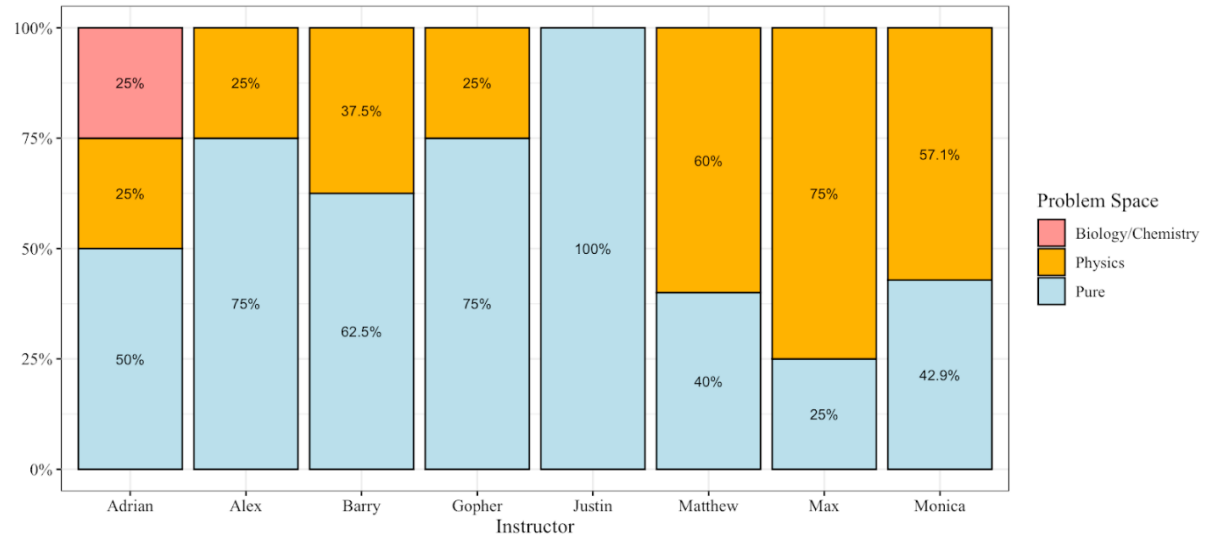

Figure 2. Distribution of contextual framing or problem space across instructors

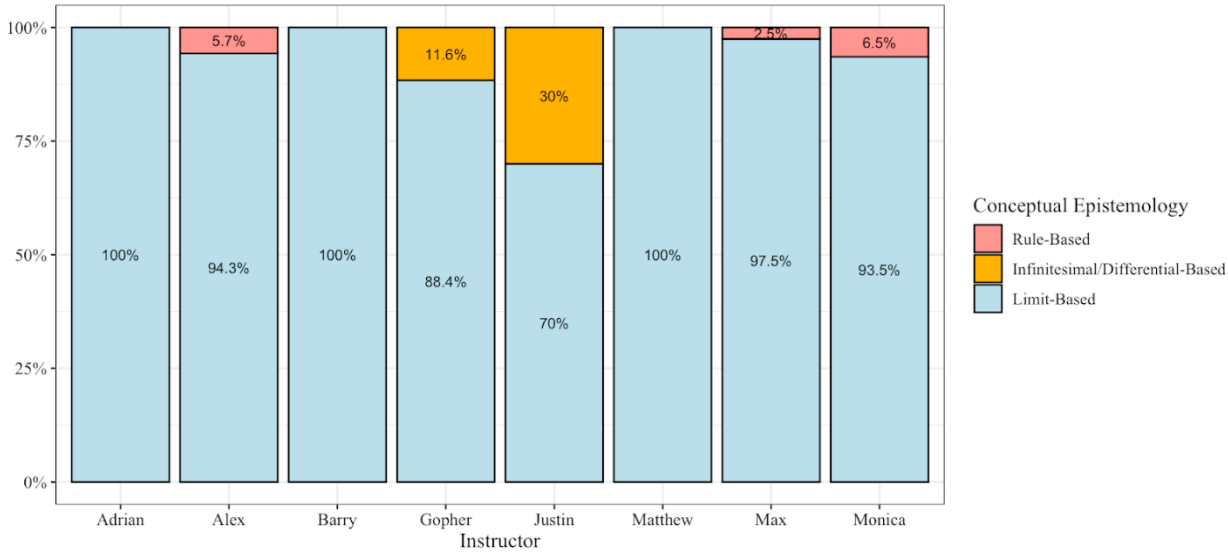

Figure 3. Distribution of conceptual epistemologies across instructors

Within the 243 limit-based CTUs, all instructors except Justin utilized the three mathematical representations and the three process-object layers, though with varying frequencies (Figure 4). Justin did not target the ratio layer or the symbolic representation. Statistical analysis of the rest of the instructors revealed that Gopher and Matthew significantly preferred targeting the limit layer over ratio and function layers ($\chi^2 > 5.99$, $p < 0.05$), while Adrian showed significant preference for symbolic over graphical and numerical representations ($\chi^2 > 5.99$, $p < 0.05$). While Justin's small number of CTUs did not allow χ^2 testing, the remaining instructors did not show significant preferences for targeting specific layers or representations.

The remaining epistemologies—Infinitesimal- or differential-based, and rule- or instrumental-based—were used infrequently. Infinitesimal/differential-based approaches appeared in only four CTUs from Gopher and Justin, exclusively at the limit layer and primarily using graphical representation (i.e., zooming in on the graph of a function to find the instantaneous derivative or the slope of tangent once the function becomes linear). Rule-based

epistemology appeared in five CTUs within tasks by Alex, Max, and Monica, all targeting the function layer with symbolic representation, reflecting the procedural nature of applying derivative rules.

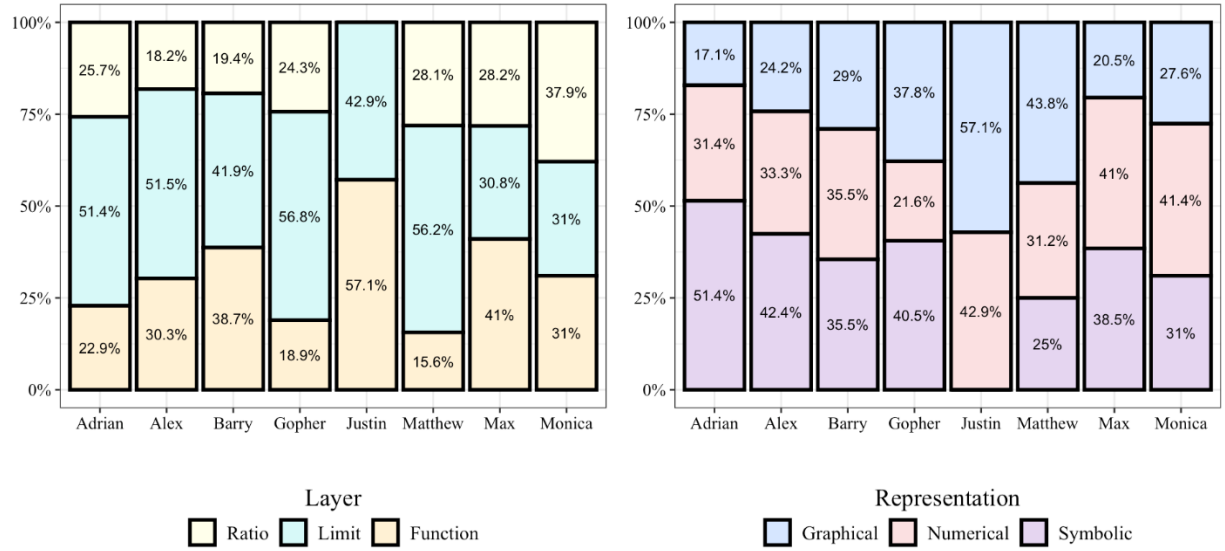

Figure 4. Distribution of process-object layers & representations within limit-based CTUs across instructors

Discussion and Conclusion

Our analysis of introductory derivative instructional tasks from eight experienced college calculus instructors showed that they predominantly targeted pure and physics contextual framing and limit-based epistemology within the conceptions of derivative laid out by the CoD framework (Gerami et al., 2025). However, the prevalence of limit-based epistemology may reflect both our sample selection and the study's original design around Zandieh's (2000) limit-based framework. Additionally, because we specifically asked instructors for tasks introducing derivatives, the focus on limit-based approaches may reflect the instructors' tendency to use this epistemology as the foundational approach when first teaching the concept.

These findings suggest several directions for future research. First, researchers could examine conception targeting across entire instructional materials, rather than just introductory instructional tasks, to capture how targeted conceptions might shift throughout the course. Second, future studies could use the CoD framework to map relationships between instructor targeting of specific conceptions and actual student conception development. Finally, given that colleges increasingly offer calculus courses designed for specific audiences such as biology and business majors, researchers might investigate whether intended student population influences instructors' choices of contextual framing and conceptual epistemologies when teaching derivatives.

Leveraging Universal Design for Learning to Scale Inquiry-Oriented Instruction on Sequences and Series

Kristen Vroom
Michigan State University

Tenchita Alzaga Elizondo
University of Texas at Rio Grande Valley

Although research has shown benefits of inquiry-oriented (IO) instruction for student learning, it has also been reported not to benefit all students equally. In this report, we illustrate how UDL can serve as a generative framework for (re)designing IO instruction in such a way that attends to the individual needs and strengths of students, working toward creating an equitable learning environment. We will also share UDL-aligned teaching practices for IO classrooms, including those fostering relationship-building, multimodal participation, and equitable assessment.

Keywords: Inquiry-Oriented, Universal Design for Learning, Equity

Research shows that inquiry-based (IO) instruction can support student learning, but it does not always benefit all students equally (Johnson et al., 2020). Without intentional instructional design, it may privilege certain voices or patterns of participation. For instance, Reinholz et al. (2022) showed women's (vocal) participation levels correlated with performance; when participation was equal, the gap disappeared. Other studies have similarly shown that IO classrooms can limit meaningful participation for students from groups historically marginalized in mathematics. For example, women can be excluded or dismissed during group work (Brown, 2018; Ellis & Alzaga Elizondo, 2023), and even when women offer valuable insights, their ideas may not surface in whole-class discussions (Ernest et al., 2019). Together, these findings suggest that although IO instruction holds great promise, it must be intentionally crafted to ensure that all students can participate in meaningful ways. Yet, what it means to intentionally craft this teaching remains underexplored.

One place where this issue becomes especially visible is in efforts to scale inquiry-oriented instructional materials. Research on scaling has made progress by focusing on the mathematical learning trajectory, resulting in streamlined task sequences (e.g., Larsen et al., 2013). However, this work has paid less attention to how to build in instructional supports into these materials that also address students' diverse strengths. As Armstrong (2011) notes, "classrooms are social environments, and all social environments are places where inclusivity happens—*or fails to happen*" (p. 53). Inquiry-oriented classrooms require careful attention to inclusivity, as they are structured around social interactions, which can promote inequities when not treated carefully (Battey & McMichael, 2021). Moreover, because IO instructional materials often originate from the work of a small group of students, if not intentionally designed to accommodate a broad range of learners, they risk privileging a narrow subset of the class.

Guided by Universal Design for Learning (UDL), we have been working to address these challenges to scale IO instructional materials on sequences and series in Calculus 2. In this report, we share our instructional (re)design decisions, informed by UDL principles and student interviews, as we scaled a task sequence that originated from the work of two students.

Theoretical Perspective

We engaged in design research (Cobb & Gravemeijer, 2014) to develop our IO instructional materials, following an iterative, cyclic process with three core components: (1) task (re)design, (2) implementation, and (3) data analysis. Each component informs the rest; the analysis of the

data collected during one implementation informs the redesign of the tasks that will be implemented (and subsequently analyzed) in the next. Traditionally, researchers have started with pairs of students and then scaled the tasks to a whole class setting once the tasks seem to appropriately support students in learning the content goals. However, the limited research on scaling the materials to a whole class setting has had a limited focus on streamlining the mathematical learning trajectory, rather than also attending to other social experiences that students might encounter with such learning environments. Because of this, we have adopted Universal Design for Learning (UDL) to help us also focus on other aspects of the environment. UDL complements the theoretical design frameworks that we have used to design the task sequence (e.g., Realistic Mathematics Education, Gravemeijer & Doorman, 1999; Gravemeijer & Terwel, 2000) by extending our focus from not only engaging students in meaningful mathematics but also other factors that might further support their engagement, representations, and strategic action.

We draw on UDL to support instructors to build environments that recognize and respond to the diverse identities, strengths, and needs of learners (Gargiulo & Metcalf, 2023). UDL is not a fixed set of techniques, but a generative framework for instructors that assumes from the outset that all learners are variable: in how they feel engaged in the content, how they communicate, and how they make sense of mathematics (Chardin & Novak, 2020; Tobin & Behling, 2018; Hall, 2012). Lambert (2024) outlined key elements of UDL-aligned math classrooms: (1) promoting engagement through meaningful tasks and supportive environments, and (2) supporting strategic action by helping students understand themselves as learners and offering equitable feedback and assessment, and (3) attending to mathematical representation by valuing multimodality and investing time in core ideas. (See Figure 1.)

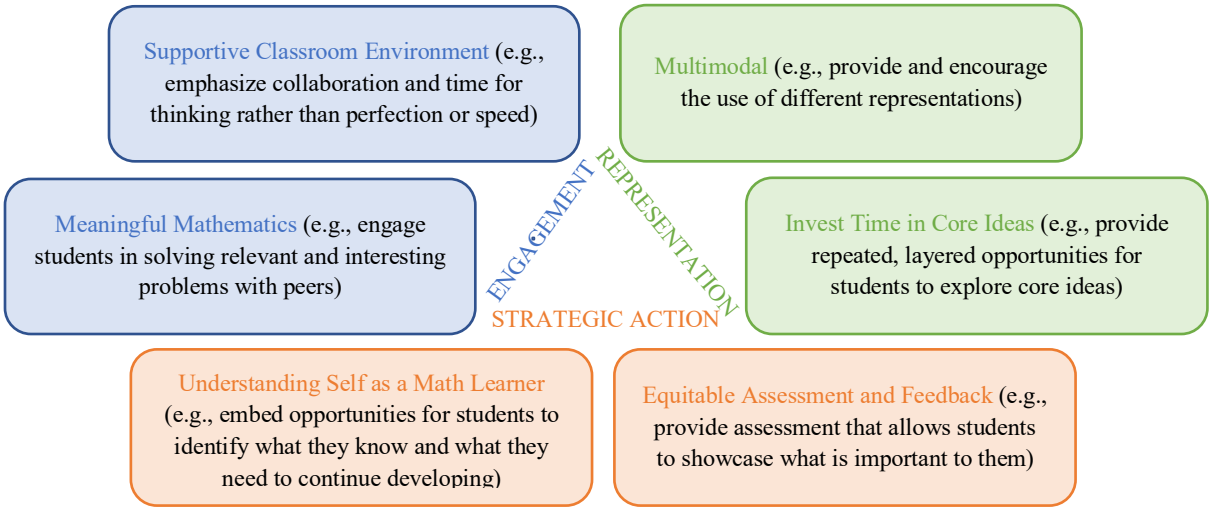

Figure 1. Key Elements of UDL-Aligned Math Classrooms.

We drew on UDL as an analytic tool during our analysis phase of the first whole-class design cycle. In particular, we wanted to (re)design teaching practices that recognize and respond to the diverse identities, strengths, and needs of learners. By teaching practices, we mean both the instructor's goal (i.e., task) and the observable actions taken toward accomplishing their goal (i.e., procedure) (Nachlieli and Elbaum-Cohen, 2021). When planning to scale the materials, we set out to test out the teaching practices that we anticipated would relate to UDL engagement,

representation, and strategic action goals. For instance, we planned to implement standard-based quizzes and portfolios instead of exams (procedure) to allow assessment to be more individualized (task related to understanding self as a math learner).

Together, we use these theories to investigate the following research questions: 1) *What are some UDL-aligned teaching practices for IO classrooms?,* and 2) *How can UDL guide instructional (re)design choices to develop such practices?* Answers to these research questions provide two main contributions. First, practical teaching practices that instructors can adapt to open up their classroom to serve a broader range of students. And, secondly, methodological suggestions for IO designers who want to scale up their materials in an inclusive way that takes into consideration the different strengths and needs of their students.

Methods

The data for this report comes from a larger project in which we are designing an IO calculus 2 unit on sequences and series. We have designed a set of tasks that, with the instructor's support, guide students to reinvent several key theorems of this unit: Monotone Convergence Theorem, all convergent sequences are bounded, and several tests for series convergence (Vroom et al., 2025; Vroom & Davis, 2024; Vroom & Alzaga Elizondo, 2025). Our design research to date has included implementing, analyzing, and revising the instructional sequence first with a pair of students in a laboratory design experiment (Spring 2022) and then in Vroom's calculus 2 class (Spring 2025). In this report, we focus on (a) some of our instructional design choices, informed by UDL and the previous paired-implementation, (b) the calculus 2 students' experiences with the instruction via interviews, and (c) redesigned instructional choices based on UDL and these experiences.

The primary source of data for this redesign relied on individual semi-structured interviews with students (13 of the enrolled 25 students in the Spring 2025 course), which were conducted a week after the course meetings ended. During these interviews, we shared our interpretation of some of the research findings on inequitable outcomes and experiences in IO classrooms (i.e., an elaborated version of the first paragraph of this paper). This was a purposeful decision to attempt to bring students into the conversation that our research aimed to address – to do research *with* the students rather than *on* them (inspired by Stinson, 2008). Following this reading, we discussed how, if at all, the research findings resonated with the students' experience during the sequences and series unit. We also asked students to share aspects (about the instruction, peer interactions, the course structure) that supported and discouraged their participation. See Table 1 for the participants self-reported identity markers (from a survey early in the semester).

Table 1. Self-reported identity markers.

Student	Gender	Race/Ethnicity	Sexuality
Aaron	Man	Chinese/White	Did not report
Alice	Female	White	Straight
Anna	Woman	White	Straight
Caleb	Male	White	Straight
Gabe	Male	Caucasian	Straight
Imran	Male	Indian	Heterosexual
Jack	Man	White	Did not report
Jason	Male	Asian	Straight
Micah	Transmasc/nonbinary	Caucasian	Asexual and Queer

Nina	Woman	White	Bisexual
Oliver	Male	White	Straight
Shaan	Male	Asian	Straight
Trevor	Male	White/Caucasian	Straight

Prior to the classroom implementation, we designed a set of teaching practices that we anticipated would align with UDL principles. For example, we planned to use Padlet, an online platform where students can post (anonymously if they choose), to provide multiple ways to participate. Following the implementation, we began analyzing these practices, initially focusing on interview transcripts from four students who identified with gender identities historically marginalized in mathematics (i.e., "woman," "female," or "Transmasc/nonbinary"). We prioritized these students' perspectives because our instructional design explicitly sought to respond to documented gender inequities in IO classrooms (Brown, 2018; Ellis & Alzaga Elizondo, 2023; Earnest et al., 2019; Johnson et al., 2020; Reinholz et al., 2022). In analyzing these transcripts, we first identified excerpts in which students referred to specific procedures associated with a teaching practice. We used these excerpts to refine our original list of practices. For instance, students commented on the practice of working in self-selected groups. Although the instructor typically uses this strategy to foster peer relationships, students' responses helped us recognize its potential alignment with UDL principles, even though we had not initially framed it that way. After identifying relevant quotes from the four transcripts, we compiled a table linking them to teaching practices. We then open coded the linked excerpts for how students perceived the practices' tasks, grouping responses to identify shared purposes. We compared these student-identified goals with our original intentions and revised (i.e., expanded, created, or maintained) practices accordingly. This process yielded a set of UDL-aligned teaching practices, which we then used to frame our analysis of the rest of the transcripts. We then read the remaining interview transcripts, coding for additional student references to these practices and incorporating their perspectives to elaborate and further refine them. Here we share a subset (eight) of these practices.

Results

Below we describe our (re)design choices. We organize this section by discussing practices that we 1) expanded, 2) created, and 3) maintained after the class implementation. In Table 2, we overview the redesigned teaching practices.

Table 2. UDL-Aligned Teaching Practices.

Revised Practice	UDL Reasoning
1. Incorporate anonymous discussion board to pose questions to provide an alternative way to participate	Representation: multimodal
2. Incorporate anonymous discussion board to create a safe space to take risk and mitigate perceived biases in discussion	Engagement: supportive classroom environment
3. Incorporate discussion board for students to increase peer engagement by providing a space for them to see or respond to each other's contributions	Engagement: supportive classroom environment

4.	Implemented standard-based quizzes and portfolios (instead of exams) to allow students to share *their* mathematics and what *they* find important	Strategic action: equitable assessment and feedback
5.	Implemented standard-based quizzes and portfolios (instead of exams) to support students to focus on their learning on their timeline rather than memorizing or their grades	Strategic action: understanding self as a math learner
6.	Allow students to choose groups that they will stay with throughout semester to build relationships	Engagement: supportive classroom environment
7.	Make sure everyone has a partner, preferable group of 2, to increase opportunities to contribute and reduce possibilities of exclusion	Engagement: supportive classroom environment
8.	Regularly share that the expectation is to share rough draft ideas (rather than perform polished ones) to normalize mistakes and emphasize growth	Engagement: supportive classroom environment

Expanding UDL-aligned teaching practices. Originally, we intended to *incorporate anonymous discussion board to pose questions to provide an alternative way to participate*. This was aligned with UDL in the sense that students would have options for how they shared their ideas so they could find a way that felt comfortable for them (*Representation: multimodal*). To do this, the instructor projected a class Padlet at the front of the room. We found evidence from the student responses that this task was realized as Anna noted:

> It's kind of an equal chance for everybody to share their ideas. Even with people, like me, that don't like talking in front of big groups of people. She kind of just let us post it on there to talk about it.

Additionally, we learned that the anonymous feature of the Padlet also supported students to feel comfortable taking risks in sharing their ideas (*Engagement: supportive classroom environment)*. For instance, Micah explained:

> I like how there's the option to be anonymous on it, and I think that takes away a lot of the fear that because of who you are, you might be perceived, or taken differently in you asking your question, and I think it gets rid of any opportunity for that, because then it's like, 'Oh. astounding chameleon asked a question'.

The students also shared that the Padlet increased peer engagement by providing a space for them to see or respond to each other's contributions (*Engagement: supportive classroom environment*). For instance, Trevor explained:

> I think the Padlets - those were helpful to me because I was kind of able to see like what other people were thinking rather than just my group members... It was helpful to see again other people's like opinions or ideas for a question.

For these reasons, we redesigned this teaching practice by expanding it to three different practices (see Table 2, lines 1-3).

In setting up the course, we decided to *implement standard-based quizzes and portfolios (instead of exams) to allow assessment to be more individualized*. This was aligned with UDL in the sense that it would give students more agency in demonstrating their understanding of what they knew and what they needed to learn (*Strategic action: understanding self as a math learner*). We found evidence that the assessment was more individualized in two different ways. First, similar to what we anticipated, it supported students to focus on their learning on their

timeline rather than memorizing or their grades (*Strategic action: understanding self as a math learner*). As Anna said:

> I'm not stressed out trying to... memorize it. Rather with this way, I feel like I could actually sit down and take my time and actually try to learn it rather than just trying to memorize everything in time for exams.

Second, it also allowed students to share *their* mathematics and what *they* find important (*Strategic action: equitable assessment and feedback*). For instance, Imran explained:

> [the portfolio was] showcasing your skills instead of doing a math test where it doesn't really show *you as a student*... [The portfolio] showed *our* understandings. It showed *our* interpretations of standards themselves. [emphasis added]

Thus, we redesigned this teaching practice by expanding it in two ways (see Table 2, lines 4-5).

Creating UDL-aligned teaching practice. One teaching practice that the instructor regularly uses in her courses was *not assigning groups in order to allow students to work with who they would like*. We were not attentive to this practice during our initial design; but, through our conversations with students, we realized that it was a practice that could align with UDL by supporting relationship building (*Engagement: supportive classroom environment*). Micah elaborated on how choosing the groups and staying with the same group was important to them:

> chosen groups versus assigned groups have it have a huge impact on what that group dynamic looks like ... there is a much, much lower chance of [exclusion] happening in chosen groups, and I think that sort of just adds another level of safety to it.

They continued to explain that staying with their chosen group helped them to "establish a consistent relationship" and that "made it so that it was a space where you guys were working together, not a space where you guys were forced together like you were actually collaborating, not just sitting next to each other doing your work." We also got insight from students about how the group size (partners vs groups of three or more) allowed (or prevented) individuals to contribute and reduced the possibility of exclusion (*Engagement: supportive classroom environment*). Students shared that it's easier to exclude yourself or others in groups of three. Shaan explained:

> in the third unit I didn't participate enough, but there was another new person who was talking to [my partner]. So, I was fine, like, I was not interacting. If ... it was just two of us, I would have like added more like to the conversation.

Trevor also explained that larger groups can lead to exclusion because he tries to find similarities with others to connect over:

> let's say we're in a group of three... And then there's two people who are more similar to each other. I think that those two people are gonna interact with each other more just because they're similar and maybe unintentionally exclude the person that's different from them.

However, when there is paired groupwork, "You gotta find, like the similarities between your partner [and] figure out how you can have... a functional group". Thus, in our redesign, we added two practices (see Table 2, lines 6-7).

Maintaining UDL-aligned teaching practice. Originally, we intended to *regularly share that the expectation is to share rough draft ideas (rather than fully formed polished ones) to normalize mistakes and emphasize growth*. This was aligned with UDL in the sense that such framing supports students to take mathematical risks by creating a safe and welcoming environment. (*Engagement: supportive classroom environment*). The students shared this

practice was realize, for instance, when Nina said, “I never felt like I had to be perfect in my understanding of everything in order to participate.” Similarly, Alice elaborated:

> I can actively give like not a fully correct answer and not feel ashamed of it. I feel like that really helps my learning. And when we worked in our small groups in class... we would all build off of each other, and we'd be... comfortable with each other not having the full answer.

Because of this feedback, we kept this practice in our redesign (See Table 2, line 9).

Discussion

Returning to our first research question, we crafted a set of UDL-aligned teaching practices for IO classrooms (see Table 2). Student feedback suggests these practices can help mitigate inequities documented in prior literature (Brown, 2018; Ellis & Alzaga Elizondo, 2023; Earnest et al., 2019; Johnson et al., 2020; Reinholz et al., 2022). We attribute this, in part, to the theoretical grounding UDL provided for scaling IO instructional materials in ways that attend to student experiences beyond the mathematical trajectory. For example, we reconsidered grouping not only in terms of mathematical productivity but also in relation to students’ comfort with taking risks and sharing emerging ideas. Similarly, UDL encouraged us to broaden what counts as participation. Although IO instruction often privileges verbal contributions, incorporating tools like Padlet helped us recognize non-verbal participation, thereby expanding whose ideas could be acknowledged and built upon. Although our insights arose from materials on sequences and series in Calculus 2, we see potential relevance across a range of IO contexts. We do not claim these practices work universally, but they may provide a starting point.

Importantly, and in response to our second research question, our work illustrates how UDL can serve as a generative framework for designing IO instruction. From the outset, UDL shaped the design of our practices by hypothesizing procedures that could accomplish a task related to UDL’s goals (engagement, representation, and strategic action). Post-implementation, we used UDL to analyze how these practices functioned, and student perspectives were crucial in this reflection. By inviting students into the research centering their perspectives, we were able to identify practices that supported them across the three UDL dimensions, practices that we at times did not even anticipate.

One notable point of divergence between our findings and the prior literature concerns group formation and size. Earlier research in mathematics education often recommends teacher-assigned groups of three or four to mitigate status differences (e.g., Cohen & Lotan, 2014). In contrast, our students emphasized that working in chosen, stable pairs reduced the risk of exclusion and fostered a sense of safety and collaboration. We interpret this difference as reflecting the distinct emphases of UDL. Whereas the groupwork literature often foregrounds managing status dynamics, our UDL framing foregrounded agency and supportive relationships. This suggests that grouping practices may be more context-dependent than the literature sometimes implies. For IO classrooms guided by UDL, chosen groups may offer advantages over assigned groups by fostering learning environments where students feel safe sharing emerging ideas, a key characteristic of IO instruction (Kuster et al., 2018).

This work takes initial steps toward scaling IO instructional materials in ways that extend beyond streamlining meaningful mathematical tasks. Future research could further examine how UDL interacts with specific IO practices across varied institutional settings, offering insight into how these practices might be refined and scaled sustainably.

Examining Online Mathematics Instructional Videos Through a Narrative Lens: The Role of Mathematical Questions

Mengqi Lin
University of Auckland

Ofer Marmur
University of Auckland

The increasing use of online videos in mathematics education has led to a need to understand what makes them captivating. This study applied Dietiker's mathematical story framework to online mathematics instructional videos (OMIVs), specifically analyzing several videos from a popular YouTube channel. Using a qualitative case study approach, we identified the central role of questions from a narrative lens and observed four open question types and three types of their closure. Findings also show how different question types may relate to the plot's characteristics and enrich the plot. This study is an initial exploration of mathematical stories in the context of OMIVs, providing new perspectives that would hopefully inspire further research and practical application in math education.

Keywords: mathematical story, online videos, complex Fourier series, plot, questions

The COVID-19 pandemic accelerated digital learning, making instructional videos more common in mathematics education (Alabdulaziz, 2021). Online mathematics instructional videos (henceforth called OMIVs) support engagement and understanding, and educators increasingly recognize their pedagogical value (Esparza Puga & Aguilar, 2023). Yet their quality varies, raising questions about why some videos are more engaging to the viewer (Jones & Cuthrell, 2011; Kolthof, 2021). A striking example is the YouTube channel 3Blue1Brown, whose creator Grant Sanderson argued that stories play an important role in engaging mathematical learners, with his widely spread videos deeply supporting his argument (TEDx Talks, 2020). Story, more broadly, has long been used as a pedagogical tool in mathematics for its capacity to guide emotions and foster meaning (Zazkis & Liljedahl, 2009). Building on this idea, Dietiker's (2015) mathematical story framework conceptualized mathematics lessons as unfolding events and has applied the framework to the context of lessons (e.g., Richman et al., 2019). This study adapts Dietiker's framework to analyze selected OMIVs, exploring how storytelling shapes math questions and their resolution to inform the design of more engaging instructional content.

Literature Review

Educators increasingly recognize the vital role of technology in mathematics education, as digital technologies continue to shape the current state and future of teaching (Borba et al., 2016; Darragh, 2021). With internet access and applications now available to much of the world's population, digital resources have become embedded in teaching and learning. More recently, the COVID-19 pandemic accelerated this trend, making online learning and digital products central to instruction (Ilmadi et al., 2020). The accessibility of digital devices enables learning beyond the classroom, and research highlights how such tools can enhance student attention, active engagement, and independent learning (Alabdulaziz, 2021; Fakhrunisa & Prabawanto, 2021). Moreover, compared to in-person teaching, online platforms reduce barriers of time and space and foster new forms of interaction among students and teachers (Ilmadi et al., 2020).

Whether lecture recordings or designed instructional videos, these have become a regular part of students' online mathematics learning. Researchers have examined the factors contributing to their effectiveness, such as video length, production quality, and instructor

presence, which could influence students' engagement (Acuña-Soto et al., 2018; Larkin, 2017). Equally important are pedagogical considerations: videos support students' conceptual understanding and sustained attention when they align with curricular goals, follow explicit learning objectives, and present sound mathematical explanations (Cardoso et al., 2014; Johanes & Lagerstrom, 2016). Visualization, such as animations, graphs, and text, can enhance comprehension when meaningfully aligned with learning goals (Ismail et al., 2017). In addition, recent research also highlighted that utilizing technology to transition between different realizations of mathematical objects could contribute to audience engagement in videos (Radmehr & Turgut, 2024).

While prior studies have explored technical and pedagogical aspects of OMIVs, to our knowledge, there has been less focus on their narrative and aesthetic dimensions. Researchers believe that narrative is central to mathematics learning, as it may bridge mathematics and students' experience, fostering cognitive and emotional engagement by grounding abstract mathematical ideas in familiar contexts (e.g., Toor & Mgombelo, 2015). Dietiker's (2015) mathematical story framework, developed to analyze curricula and lessons, offers a useful lens for evaluating such narrative structures. This study extends that work by applying the framework to OMIVs, aiming to illuminate how storytelling could play a role in their design and impact.

Theoretical Framework

Dietiker (2013, 2015) describes a *mathematical story* as the way mathematical content unfolds across a sequence of changes – that is, the progression of mathematical concepts. Building on this idea, Dietiker introduced four elements of a mathematical story: characters, actions, setting, and plot. *Characters* are mathematical objects, such as shapes, equations, or numbers, that may develop characteristics (e.g., a number being prime) or relationships (e.g., two functions intersecting). Character development occurs through *actions*, which mathematical actors, typically humans, perform. For example, in a video, a narrator may differentiate a function $f(x)$ – here, "differentiate" is the action on the character $f(x)$. The *setting* is the space where characters and their actions take place. Dietiker described it as the representations of the content that situate the story, which help the reader interpret the characters and their actions more clearly; for instance, $y = x$ appears as a line in two dimensions but as a plane in three. The *plot* refers to the aesthetic dimension of how readers encounter the story. Plot shifts occur when information changes, prompting readers to raise or answer questions, experience tension, and feel satisfaction or surprise.

Richman et al. (2019) further developed three characteristics of plot: density, coherence, and rhythm. *Density* concerns the number of open (i.e., unresolved) and closed (i.e., resolved or no longer under consideration) questions; and a plot becomes denser when more questions remain open. *Coherence* refers to how events connect and help learners anticipate or interpret what follows, producing responses such as pleasure or surprise. *Rhythm* is the pattern of opening and closing questions, shaping the story's pace. To interpret the overall plot, Richman et al. (2019) also introduced the idea of a *story arc*, which is the trajectory of a question and all the shifts it undergoes as it moves from being open to being resolved.

The Study

This study employs a qualitative case study to examine how OMIVs can be viewed through a narrative lens. Building on Dietiker and colleagues' work on plot analysis through opening and closing questions (2013, 2015; Richman et al., 2019), this study aims to extend this framework to video contexts. Specifically, we classify and characterize open and closed questions within the

mathematical narrative structure in OMIVs, and then examine how these question types connect with characteristics of the mathematical plot and contribute to its development. Guided by this framework, we seek to answer the following research questions:

1. What types of open mathematical questions and their closures appear in OMIVs?
2. How are these question types connected with the characteristics of the mathematical plot?

Data Collection

We collected the data from the YouTube channel 3Blue1Brown (3Blue1Brown, n.d.). As of August 2025, the channel had 7.57 million subscribers, 216 videos, and over 672 million views. Its creator, Grant Sanderson, has been recognized by the American Mathematical Society for his contributions to mathematics education (News from the AMS, n.d.). We selected this channel because of its wide reach and strong reputation in online mathematics education, and we note its pedagogical value has also been recognized in prior research (e.g., Radmehr & Turgut, 2024).

We analyzed four videos from this channel, chosen for their mathematical content, number of views, and the creator's identification of them as more narratively compelling. The videos are: V1 (3Blue1Brown, 2019c) on Complex Fourier Series within a sequence of videos on differential equations; V2 (3Blue1Brwon, 2017) on a Putnam problem and its solution; and V3 (3Blue1Brown, 2019a) and V4 (3Blue1Brown, 2019b) that constitute a two-part presentation that introduces and resolves a mathematical puzzle.

Data Analysis

We have reviewed each video multiple times and divided it into acts, defined by shifts in characters, actions, settings, or relationships (Richman et al., 2019). Acts varied in length depending on changes in focus, from under a minute to several minutes. We identified each mathematical question within each act, including explicit and implicit questions. To do so, we adapted Richman et al.'s (2019) framework by defining *explicit questions* as those posed directly by the narrator, and *implicit questions* as those that emerged from the unfolding plot in ways likely to inspire curiosity in the viewer. For example, "Perhaps you see the pattern here" could implicitly raise the question: "What is the pattern?". Also, following Richman et al. (2019), we grouped similar questions within the same act into a broader question to avoid artificially inflating question density.

For implicit questions, we included the questions we formed when watching the videos and questions we recognized that other audiences might form. Additionally, we assumed that the audience has a foundational understanding of the mathematics involved. Therefore, we focused on questions relevant to a level of knowledge that supports the understanding of the video.

Lastly, we coded the questions into story arcs and connected the story arcs to plot characteristics. Specifically, we explored the plot's density by examining the number of acquired and resolved questions across acts, analyzed its coherence by considering how arcs overlapped or linked, and traced its rhythm through the pacing of suspense and resolution. To contextualize narrative analysis with audience response, we compared the YouTube engagement graphs with plot features, offering insights into potential links between story elements and viewer engagement. The findings are presented below, with a primary focus on V1 due to word constraints.

Findings

Classification of Question Types

Types of open question. We observed four types of questions regarding how they were opened in the narrative. The first type is the *main question*, which introduces core mathematical content or ideas and serves as a central focus of the video. Progress on one main question does not necessarily contribute to a previous one. That is, while connections between main questions may exist, each relies on different knowledge. For example, in V1, the first question [Q1] was: "What is a complex Fourier series?". We classify this as a main question because it introduces one central idea without relying on earlier ones. Another example from V1 is: "How did the Complex Fourier Series create animation?". Although it seems to build on the first, we also treat it as a main question since its answer requires new knowledge rather than directly resolving the earlier one. Main questions may overlap, but each sustains its own distinct arc.

The second type is the *sub-question*, which relates to a previous question and helps make progress on it without altering its original conditions. Typically, a sub-question breaks a larger question into smaller, more manageable parts. For example, in V2, one main question is: "What is the probability that the center of the sphere is inside the tetrahedron [formed by four random points on the surface of this sphere]?". A related question is: "Which […] tetrahedra contain the sphere's center?". Because this question contributes to resolving the main question while preserving its conditions, we classified it as a sub-question.

The third type is the *helping question*. Like sub-questions, helping questions relate to a prior question, but they differ in that they modify the conditions to simplify the problem and enable progress. For example, in V2, for the same main question above, one helping question is: "What is the average size of the section that the fourth point could land if the other three points are fixed?". Fixing three points changes the conditions, making the problem more accessible. Helping questions, therefore, often serve as a bridge to solving the main question by reducing its complexity.

The last type is the *reformulated question*, which rephrases an earlier one with different wording or structure but preserves the same core idea. For instance, in V1, one question is: "Why don't we use 'vectors' instead of a 'complex number' in a complex plane?". Later in the video, the narrator revisits the same idea: "You'll notice I'm being a little loose with language, using the words vector and complex number somewhat interchangeably", which essentially asks, "Why are vectors and complex numbers used interchangeably?". Since both questions address the same underlying idea, we interpreted the latter as a reformulation of the former.

Types of question closures. We also observed three types of question closures. The first type is *normal closure*, which occurs when a question receives a clear and definitive answer, leaving no ambiguity. If a question has a normal closure, it has been fully addressed in the current context, enabling the audience to fully understand the explanation. Most of the mathematical questions in the videos fall into this category.

The second type is *inquiry closure*, in which the narrator deliberately leaves questions unanswered for further thinking or exploration. Inquiry closure occurs when the narrator poses a question and explicitly invites the audience to reflect or try solving it themselves. The purpose may be to promote active learning, deepen understanding, or develop problem-solving skills. For example, in V1, the narrator asked, "How do we find the coefficients in the step function?" and left the audience to think more about the question.

The third type is *deferred closure*, which occurs when the narrator postpones the full answer to another video or avoids giving it completely because the content is out of scope or irrelevant

to the main topic. For example, in V3, the narrator asked: "What is configuration space, or phase space?". He explicitly stated that further explanation would appear in the next video, and indeed, the following video continued with the same puzzle and expanded on this idea. Therefore, we suggest that this question exhibits a deferred closure because its scope extends beyond the current puzzle to broader areas of mathematics.

Question Types and Plot Characteristics

This subsection addresses RQ2 by examining how question types play a role in the plot's density, coherence, and rhythm.

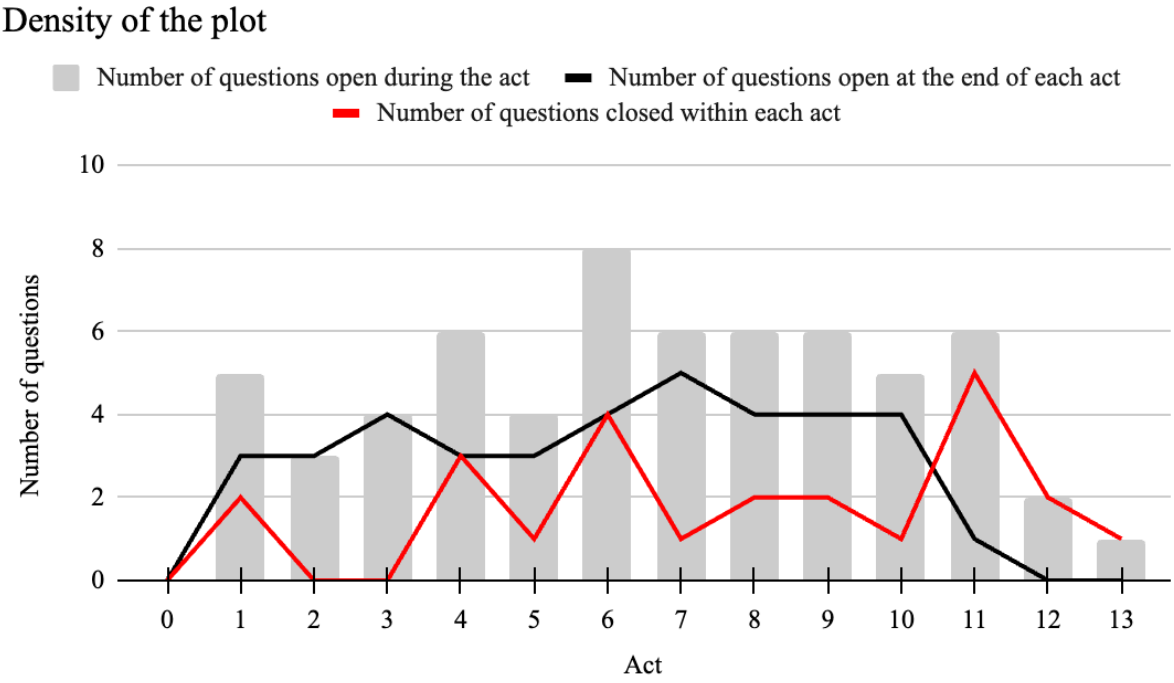

Figure 1: Density of the plot in V1

Questions and density. To recall, the density of the plot refers to how many mathematical questions remain open within a segment of the story (Richman et al., 2019). As Richman et al. (2019) explained, the plot becomes denser if more questions are left open, and a release in density occurs when the number of open questions decreases. Following the approach described in the Data Analysis section, we excluded reformulated questions when considering plot density because they do not introduce new issues, but merely re-express existing ones.

We observed a clear trend when considering how different open questions affect the density. Taking V1 as an illustrative example (see Figure 1), the density trajectory (see black line) first appears as a rising path marked by short periods of small release or sustained in between, then reaching a peak and holding steady for a time before undergoing a sudden release. Additionally, acts that open a new main question tend to generate a higher density for more than one act. The unfolding of complex mathematical concepts appears to be guided by a main question, which establishes the current topic within the narrative and where density accumulates. Supporting questions sustain and elaborate on this main question, causing the density to continue rising, reach a peak, and eventually release. This dynamic is visible in Figure 1, where peaks in density align with acts that open new main questions. For instance, Acts 1, 3, and 7 combine at least one new main question with more than one helping or unresolved sub-questions.

Figure 2: V1 engagement graph

Another perspective concerns the release of density. Figure 2 shows the engagement graph above the progress bar of V1, highlighting the most replayed moment in V1, which corresponds to Act 11. As Figure 1 illustrates, Act 11 involves a major release in density at the end of the act, with several previously open questions resolved at once. In contrast, the ends of previous acts (i.e., 8, 9, 10), show that the density remained relatively high for a while, indicating sustained tension. That is, the closures in Act 11 mark the resolution of a build-up maintained across earlier acts. The coinciding of this release and the peak of audience replays suggests that viewers are especially attentive when the accumulated tension is lifted. We therefore suggest that, rather than being drawn primarily to the opening of new questions, engagement appears concentrated at points where narrative pressure is released.

Questions and coherence. As a reminder, coherence refers to how different parts of the story connect. The classification of opening questions helps explain coherence because each type contributes a distinct way of linking ideas into the plot. In general, we suggest that main questions frame long story arcs, while sub- and helping questions sustain or clarify them, preventing the plot from fragmenting. In other words, sub- and helping questions may maintain coherence by breaking complex problems into manageable steps. For example, in V2, the main question "What is the probability that the tetrahedron formed by the four random points on a sphere's surface contains the sphere's center?" forms a long story arc that is resolved at the end of the video. Yet, it coheres with other sub- and helping questions, which develop supporting concepts and link back to the overarching narrative formed by the main question.

Closures also contribute to coherence, but in a more indirect way. We suggest that normal closures provide immediate clarity, possibly helping the audience build confidence to engage with longer arcs. Inquiry and deferred closures, in turn, may sustain coherence across videos by leaving questions open for later explanation and creating anticipation.

Questions and rhythm. To remind, rhythm refers to the pacing of the video, shaped by the pattern of how questions are posed and answered. We found that videos usually begin with more than one overarching main question in the first arc. This can create a slow rhythm, as the audience is generally unable to resolve them immediately in the same or next few acts, and they typically reach closure only in later acts. Also worth noting is that main questions are interspersed throughout the narrative but appear intermittently rather than at regular intervals. Yet most of their occurrence reinforce the video's narrative by either strengthening or shifting the focus through transitions in the main topic. This irregular pattern contributes to changes in pacing. In contrast, sub- and helping questions with normal closures maintain a steady pace by resolving smaller puzzles and advancing the narrative. The introduction of a new main question interrupts this steady rhythm, possibly breaking the audience's expectations and creating a new rhythm that may generate surprise.

For example, in V1, the rhythm begins with a consistent pace in Act 1, where two main questions have a long story arc, suggesting the story begins at a relatively slow pace. A recursive and steady pace follows, driven by shorter sub-questions that the narrators give answers to at a faster pace. However, this pace is then interrupted in Acts 6, 7, and 8, where the main question

comes into place and takes over. In Act 6, the main question, "What would happen if the heat equation solutions of the cosine waves were all added up?" initially builds up suspense. Still, the narrator answers this question at the end of Act 6, creating a sense that the next suspense would also be easily solved. However, what follows at the start of Act 7 is, "Why does the added complexity come up?", which cannot be answered within the regular pattern. After that, the pace returns to the previous in Acts 9 and 10, preparing for the changing of rhythm in Act 11, where most of the main questions get their closure. We propose that changing the rhythm, by intermittently shifting the focus at a steadier pace, can encourage students to think more, which may explain the small peaks in Figure 2.

Discussion

This study analyzed four OMIVs from the YouTube channel 3Blue1Brown to examine the role of mathematical questions in shaping mathematical narratives. We expanded Dietiker and colleagues' framework by identifying four types of open questions: main, sub, helping, and reformulated, which emerged at different parts of the story. Main questions introduced new concepts, while sub and helping questions extended them in ways that made the original idea more approachable. Reformulated questions rephrased earlier inquiries to reinforce their existence as unanswered questions. We also identified three types of question closures: normal, inquiry, and deferred. Normal closures resolved questions fully, providing clarity and closure. Inquiry closures left questions deliberately open, inviting independent exploration. Deferred closures postponed answers to the future, maintaining suspense and continuity across episodes.

The analysis of the videos showed that the type of question is related to the characteristics of the mathematical plot. It seems that main questions often bring higher plot density, slow down the development of the plot, enrich the plot, and accordingly may stimulate students' thinking. In contrast, the sub- or helping questions help the plot smoothly transition to the next stage by providing clear answers. The closure of questions, meanwhile, reinforces key mathematical concepts, providing the audience with an immediate sense of clarity and conclusion. Together, these forms of question openings and closures enrich the plot by alternating its pace, increasing and releasing density, and stimulating deeper reflection by creating connections between different parts of the story. This is in line with Richman et al.'s (2019) observation that alternating plot characteristics not only maintains students' interest but also improves the coherence and logic of the mathematics lesson.

Our classification of question types and their roles highlights the importance of a strategically structured narrative for maintaining engagement, as supported by previous research (e.g., Acuña-Soto et al., 2019). As noted above, the different question types shape the story's unfolding, contributing to the interconnected progression of the narrative. The findings suggest that an intentional use of questions in OMIVs aligns with the mathematical storytelling framework and points to the potential for future educators to apply this lens when designing OMIVs – by varying question types and strategically timing their closures.

In conclusion, this research demonstrates that questions play a central role in shaping mathematical narratives and provides a lens for digital content, which may also apply to classroom design. We suggest that by considering the type of opening questions and their closure, educators can design lessons that are logically coherent, as well as emotionally and cognitively engaging. While this study focused on a single YouTube channel and did not include audience feedback, future research could examine different OMIVs, contexts, or lesson formats, and investigate how coherence, rhythm, and density may be designed to shape learners' engagement.

Mathematics Graduate Teaching Assistants' Discourse in College Algebra: The Case of Anthony

Kayla Heacock
University of South Carolina

Graduate Teaching Assistants (GTAs) play a critical role in undergraduate mathematics, often serving as instructors of record with limited preparation for teaching. This paper examines the case of Anthony, a College Algebra GTA participating in a semester-long professional development seminar focused on anticipating student strategies, planning purposeful questions, and reflecting on teaching. Across three observations, Anthony's lessons shifted from lecture-heavy explanations to student-centered problem solving, supported by targeted guiding questions. Monitoring charts from Anthony's planning and post-lesson debriefs revealed how his instructional decisions were shaped by prior beliefs about student-centered learning and contextual pressures such as pacing demands and coordinator feedback. This case study provides insight into the tensions GTAs face in balancing explanation and inquiry and illustrates how professional development can support incremental shifts toward more student-centered mathematics instruction.

Keywords: Graduate Teaching Assistants, College Algebra, Professional Development, Student-Centered Instruction

Graduate Teaching Assistants (GTAs) play a critical role in undergraduate mathematics, often serving as instructors of record for introductory mathematics courses (Weidert et al., 2012). Despite their instructional responsibilities, GTAs often receive little to no preparation to teach (Judson & Leingang, 2016) and limited ongoing support for effective mathematics teaching (Rogers & Yee, 2018). Because GTAs teach thousands of students nationally, their instructional practices directly influence student learning experiences and retention in STEM pathways (Blair et al., 2018).

One key challenge GTAs face is facilitating student-centered instruction. GTAs often struggle to structure lessons in balancing task setup, group work, and whole-class discussion (Speer & Wagner, 2009). Yet, student-centered teaching practices, such as posing purposeful questions, monitoring student reasoning, and facilitating whole-class discussions, can support conceptual understanding and improved student outcomes (Conner et al., 2014; Smith & Stein, 2018).

Professional development (PD) programs for GTAs seek to bridge this gap by providing structured opportunities to plan tasks, anticipate student strategies, and reflect on instructional practice (Deshler et al., 2015; Maki et al., 2019). However, less is known about how GTAs' beliefs, contextual constraints, and PD experiences interact to shape their classroom practices over time.

This paper reports on one case study from a larger project on GTA professional development in College Algebra. Specifically, it focuses on Anthony, a second-semester master's student GTA enrolled in a semester-long seminar designed to support student-centered teaching. The research question guiding this study was: *How did Anthony structure his College Algebra lessons at the beginning, middle, and end of the semester, and how were these structures influenced by contextual pressures?* By examining Anthony's case, this paper illustrates how a GTA's instructional approach shifted during the semester and highlights the role of external pressures placed on GTAs in shaping the enactment of student-centered teaching.

Literature Review and Theoretical Framing

GTAs struggle to enact student-centered instruction (Speer & Wagner, 2009), challenges that stem not only from limited preparation (Rogers & Yee, 2018), but also from a tendency to reproduce the lecture-based instruction they experienced as students (Kung & Speer, 2009; Sofronas & DeFranco, 2009). Understanding how GTAs navigate these challenges requires attention to both the knowledge they bring to teaching and the contextual factors that shape their practices. This study is framed by Hauk et al.'s (2014) knowledge of discourse, which builds on Ball et al.'s (2008) Mathematical Knowledge for Teaching (MKT) framework.

The MKT framework differentiates between instructors' subject matter knowledge (SMK) and pedagogical content knowledge (PCK). Within PCK, knowledge of content and students (KCS) involves anticipating how learners may approach or misconceive a concept, while knowledge of content and teaching (KCT) focuses on sequencing ideas and instructional moves. Knowledge of curriculum concerns how mathematical topics fit within broader curricular progressions and instructional goals (Ball et al., 2008). This framing emphasizes the multifaceted nature of effective instruction and provides a lens for examining GTAs' instructional decisions.

Building on this model, Hauk et al. (2014) introduced knowledge of discourse to highlight the communicative dimension of teaching. Knowledge of discourse examines how instructors foster interactions among students, exchanges between students and instructors, and connections between classroom activity and broader mathematical communities. They linked this knowledge to three forms of instructor thinking: **anticipatory thinking**, which connects to KCS as teachers predict and prepare for a range of student responses; **implementation thinking**, which connects to KCT as teachers adapt instructional moves in real time; and **curricular thinking**, which connects to knowledge of the curriculum as teachers situate lessons within broader mathematical goals and trajectories. Later work reinforced that discourse is integral to both the enactment of mathematical tasks and the construction of collective understanding (Jackson et al., 2020).

Student-centered instruction in undergraduate mathematics has been consistently tied to opportunities for classroom discourse (CBMS, 2016; Yackel, 2002). Mathematics is not only a collection of procedures but also a way of reasoning, justifying, and engaging in argumentation (Conner et al., 2014; Sfard, 2001). Yet facilitating productive discussions is challenging, as instructors must guide students toward conceptual goals while maintaining space for exploration (Sherin, 2002). The five practices for productive mathematical discussion (Smith & Stein, 2018; Stein et al., 2008) provide a framework for supporting these instructional decisions: anticipating student responses, monitoring strategies during class, selecting contributions to highlight, sequencing them to build toward conceptual understanding, and connecting responses to key mathematical ideas. Questioning is central to each of these practices, both in assessing students' current thinking and in advancing their reasoning (Smith et al., 2017). However, research also shows that without targeted professional development, many GTAs continue to rely on procedural questions and extended explanation rather than orchestrating open-ended discourse, underscoring the need for sustained support (Paoletti et al., 2018; Roach et al., 2010). Thus, PD is essential in supporting GTAs from moving beyond procedural questioning toward facilitating mathematical discourse.

Although GTAs often possess strong mathematical backgrounds, content expertise alone does not ensure effective pedagogical practices (Begle, 1979; Musgrave & Carlson, 2017). PD programs vary widely and range from brief orientations to semester-long seminars (Deshler et al., 2015; Rogers & Yee, 2018). Sustained PD models emphasize iterative cycles of planning, instructing, and reflecting (Kung & Speer, 2009) as well as peer observation and mentoring

(Deshler et al., 2015). Recent recommendations highlight three priorities for GTA PD: fostering student engagement, developing knowledge of student thinking, and providing ongoing, sustained pedagogical training for GTAs (Maki et al., 2019). The seminar at the center of this study was designed with these principles in mind, engaging GTAs in planning cognitively demanding tasks, anticipating student strategies, and developing purposeful questions.

Methods

This paper reports a sub-study from a larger convergent mixed-methods investigation of GTAs teaching College Algebra. The larger project integrated qualitative (seminar recordings, reflective journals, interviews, planning monitoring charts, classroom transcripts) and quantitative (observation protocols, student surveys) data to examine GTA instruction and student perceptions. This paper focuses specifically on lesson structure across the semester using the Classroom Observation Protocol for Undergraduate STEM (COPUS; Smith et al., 2013) and a focal case analysis of one GTA, Anthony, a second-semester master's student. This was Anthony's second time teaching College Algebra. Other data sources are referenced to provide context for interpretation.

Context and Participants

This study was conducted at a large public university during one semester of a weekly professional development seminar, the Planning for Approaches to Teaching High-demand tasks (PATH) seminar, for GTAs serving as instructors of record for College Algebra. In that semester, twelve GTAs were assigned to teach College Algebra, and six volunteered to participate in this study. All participants were master's students in mathematics and were in their second semester of teaching. Each had previously completed a first-semester seminar on teaching mathematics, where the researcher was their instructor of record. Participation in the PATH seminar was voluntary, and GTAs who participated earned two credit hours and a $200 stipend provided by the mathematics department.

PATH Seminar Overview

The PATH seminar emphasized planning cognitively demanding, group-worthy tasks, anticipating student strategies, and crafting both assessing and advancing questions aligned with the five practices (Smith & Stein, 2018). Each week, GTAs engaged in a four-part cycle: (1) working through a focus task (adapted from Kuennen, 2021) as learners, (2) recording anticipated strategies and potential questions on a monitoring chart (Smith et al., 2020), (3) implementing the task the following week in one of their class sessions and (4) reflecting after implementation of the task on unanticipated student strategies. GTAs were expected to incorporate each focus task into their class the following week and share reflections during the subsequent seminar session.

Data Collection

Each GTA was observed three times during the semester, at the beginning (weeks 1–3), middle (weeks 7–8), and end (weeks 13–14), in their 80-minute College Algebra class. Observations were video recorded with the camera focused on the instructor and GTAs wore microphones to capture audio during student work. COPUS (Smith et al., 2013) was used to code observations minute-by-minute for both instructor and student actions.

In addition to the classroom observations, GTAs completed monitoring charts (Smith et al., 2020) for the seminar focus tasks. Monitoring charts asked instructors to anticipate a range of

student strategies, potential misconceptions, and plan assessing and advancing questions they might pose during instruction. The charts also included space to document which students used each approach and how to order student strategies in whole-class discussions. These documents provided a window into GTAs' planning and in-the-moment noticing of student thinking. A blank sample is provided in Table 1 to illustrate the structure of this planning tool.

Table 1. Sample Monitoring Chart

Strategy	Assessing Questions	Advancing Questions	Who and What	Order
Anticipated Strategy 1				
Anticipated Strategy 2				
…				

Finally, each GTA participated in three semi-structured interviews following their observed lessons. Interviews followed a common protocol designed to elicit GTA reflections on planning, classroom interactions, questioning, and student engagement.

Data Analysis

All classroom observations were initially coded with the full set of COPUS categories. For interpretability and comparison across lessons, codes were collapsed using the COPUS categories for instructors (Presenting, Guiding, Administration, Other) and for students (Receiving, Talking, Working, Other). Proportions were calculated for each category to generate a profile of lesson structure for each GTA across the three observations. For more details on these categories and individual codes, see Smith et al. (2013).

Monitoring charts were analyzed descriptively with attention to the strategies GTAs anticipated, the assessing and advancing questions they prepared, and the number of students noted for each approach. Particular attention was given to alignment (or misalignment) between GTA planning and classroom enactment.

Although COPUS and monitoring charts were collected for all six participants, this paper highlights Anthony's case. Anthony was selected because his trajectory illustrated both common challenges and noteworthy shifts in practice across the semester, making his case illustrative of the tensions GTAs experience in balancing instructional demands. The analysis traced changes across his three lessons, with attention to how his distribution of presenting, guiding, and student engagement shifted over time. To interpret these shifts, Anthony's interview reflections were triangulated with his monitoring charts and COPUS data, providing multiple perspectives on his planning, enactment, and instructional decisions.

Results

COPUS: Lesson Structure Across Observations

Table 2 summarizes the data for Anthony's three observations on the collapsed COPUS categories. With the COPUS data, multiple codes can occur within the same minute, so instructor and student percentages do not add to 100%.

Table 2. Proportion of Class Time for Anthony's Observations

Observation	Instructor				Student			
	Presenting	Guiding	Admin	Other	Receiving	Talking	Working	Other
1	73%	63%	5%	2%	73%	32%	27%	0%
2	71%	95%	7%	0%	73%	51%	27%	0%
3	17%	88%	5%	0%	2%	0%	98%	0%

Anthony's first two observations were dominated by presenting, with nearly three-quarters of class time coded as instructor presenting and students receiving information. Although guiding was coded relatively high (63% and 95%), this largely reflected procedural questions posed during lecture rather than student-centered activities. In contrast, Anthony's third observation reflected a shift in his instructional practices. He devoted only 17% of class time to presenting, while student work jumped from 27% to 98% of the class period. Guiding remained high (88%) in this lesson, which reflected his monitoring during group work and one-on-one questioning rather than procedural questions during lecture. Students' time receiving information dropped from 73% to 2%, highlighting the move from lecture-driven to student-centered instruction.

Monitoring Charts

Anthony's monitoring charts offered insights into how his planning aligned (or failed to align) with enactment. In his first observation, which focused on solving quadratics using multiple approaches, Anthony anticipated that "no help was needed," assuming that students would work through the task independently. However, his after-lesson notes indicated that students struggled to recall certain solution methods, and he had to provide additional support.

By the second observation, on graphing quadratics and generalizing transformations, Anthony anticipated that students would copy the x-values from $y = x^2$ (e.g., $x = -2, -1, 0, 1, 2$), and not focus on the vertex of other functions such as $y = (x-4)^2$. This did occur with some students, though in his reflections, he noted that limited time prevented many from reaching generalizations about parameters.

In his third observation, comparing exponential and linear growth models, Anthony's expectations narrowed, with his monitoring charts predicting that students would "get stuck". His reflection notes, however, documented a wider range of strategies than he had anticipated: students mistaking the exponential function for linear, attempting to compute initial population values, and experimenting with equivalent exponential functions. He also critiqued one of his planned questions, "How can we get the function?" as "terrible," noting that he revised in the moment, instead asking about patterns in the data, drawing on questioning strategies discussed in the PATH seminar the previous week. This shift illustrates both his persistent challenge in anticipating strategies and his growth in adapting questions in-the-moment.

Interview Reflections

Anthony's first interview sheds light on his rationale for lecture-dominated instruction at the beginning of the semester. Drawing on his experience, he explained:

> Last semester, the students actually were okay just reading the [ALEKS] explanation and trying to solve whatever they could. But I noticed not all of them would do that. Some of them just played on their phones or did other assignments, and that's not ideal.

As a result, Anthony saw explanations from him during lecture as "safe" structure: "Even if no one pays attention, at least they are hearing the solution… it feels like the safe side." While he

worried about being "too direct" at times, he valued the sense of security and coverage provided by lecturing.

Anthony's second interview revealed both his rationale for maintaining lecture at the start of class and reflected concerns about pacing and control: "I don't like them to start and not finish what they started… that's one of the reasons I decided to start explaining before giving them the paper." Yet, Anthony admitted that only "four or five" of the twelve students followed during lecture, while others "just ignore the lesson and try to work on something else." To address this, he focused his questions on computational struggles, like squaring negatives. He thought his questioning was a mix of single answers and explanations. Anthony tied his instructional decisions to coordinator and student feedback because he believed that this approach improved students' completion rates of the homework but constrained time for in-class exploration.

In his final interview, Anthony described a noticeable shift in his instructional approach. Having already lectured on prerequisite content in a prior class, he devoted nearly the entire session to the focus task on modeling exponential and linear population growth: "I wanted them to have the biggest chance to work on [the focus task] or figure it out." Although he was still uncomfortable with this and felt students might view his circulating as "lazy," but argued it was more demanding: "Maybe they think I'm lazy… but actually it's a lot more difficult, because you need to follow the students." He noted moments of unanticipated reasoning, such as when students connected exponential growth to the growth of world populations, or constructed different but equivalent exponential functions. He intentionally allowed them to pursue their own approaches before discussing alternatives: "Even if their ideas are really complicated, I like to let them approach the problem with the same idea they have in mind… after they are done, they will be happy because they were able to get it."

Taken together, the COPUS data, monitoring charts, and interviews illustrate Anthony's shift from lecture-dominated to student-centered instruction. Initially underestimating student needs and relying on his explanations, he gradually became more responsive, devoting more time to the focus tasks and adapting his questioning in-the-moment. At the same time, his reflections highlight ongoing tensions between content coverage and study inquiry, shaped not only by his own beliefs but also by coordinator and student feedback.

Discussion

This case study illustrates how Anthony's teaching was shaped not only by his developing knowledge of teaching but also by contextual pressures that influenced what felt possible in practice. Anthony's case demonstrates both growth and limits in his knowledge of discourse (Hauk et al., 2014). A central theme was the tension between Anthony's prior beliefs and his enacted practice. Early in the semester, he defaulted to lecture as a "safe" structure, believing that at least students would hear the solution even if they were not fully engaged. Additionally, Anthony struggled with anticipatory thinking, as seen in his first monitoring chart, where he assumed that "no help was needed." His enactment of discourse was also constrained by contextual factors. Coordinator comments about students disliking independent work and low attendance reinforced Anthony's perception that lecture was safer than leaving time for group work. These findings illustrate how contextual pressures can narrow the enactment of pedagogical content knowledge, even when instructors hold student-centered beliefs.

In the middle of the semester, Anthony attempted to integrate questioning but continued to focus on computational details rather than open-ended reasoning. His reflections about asking "mid-level" questions suggest some development in implementation thinking as he considered the role of the questions he posed. While he recognized questioning as a tool to support

engagement, orchestrating whole-class discussions remained difficult to sustain within pacing constraints. This highlights the ongoing challenge that ambitious pedagogy requires both time and tolerance for ambiguity, which Anthony felt constrained by (Stein et al., 2008).

By the final observation, Anthony's practice shifted more substantially toward student-centered instruction. Students spent most of the class working on the focus task while he circulated, adapting his questions in real time. This represented growth in implementation thinking, as he revised a planned question he later critiqued as "terrible" and instead drew students' attention to patterns in the data. His reflection that circulating was "more difficult" than lecturing reveals a developing awareness of the demands of facilitation. At the same time, his anticipatory thinking remained limited. Even in his third monitoring chart, he predicted only that students would "get stuck," failing to anticipate the diversity of strategies that later emerged. Thus, while Anthony demonstrated growth in adapting instruction in the moment, he still had room to grow in predicting and planning for a range of student strategies.

Taken together, Anthony's case demonstrates the interplay between knowledge of discourse and contextual pressures. While he developed greater responsiveness to student thinking across the semester, his ability to enact ambitious pedagogy was mediated by coordinator expectations, pacing demands, and concerns about student perceptions. This aligns with prior research showing that GTAs often struggle to align beliefs with practice when institutional forces pull in other directions (Deshler et al., 2015; Kung & Speer, 2009).

For mathematics departments, this case underscores the importance of supporting not only GTA pedagogical knowledge but also the contexts in which GTAs teach. Professional development should continue to emphasize frameworks such as the five practices (Smith & Stein, 2018) and knowledge of discourse (Hauk et al., 2014), while also explicitly addressing the institutional and cultural pressures that shape enactment. Coordinators should recognize how their feedback is interpreted and ensure that GTAs understand the broader pedagogical goals of the course. Without this alignment, GTAs may feel pressured to prioritize visible coverage over fostering mathematical discourse.

As a single case study, these findings are not generalizable to all GTAs or contexts. Anthony's reflections are shaped by his experiences, the particular coordinator he worked with, and the structure of his course. Nevertheless, the triangulation of COPUS data, monitoring charts, and interviews provides a rich account of the complex interplay between knowledge and context in GTA teaching. Future research could build on this case by examining how GTAs' practices evolve across multiple semesters of teaching, particularly on how they balance lecture with student-centered instruction. Additional studies might also investigate the pressures GTAs navigate, including departmental expectations, student feedback, pacing demands, and course structure, and how these interact with their development of anticipatory and implementation thinking. Such research could inform the design of PD and expectations that not only build knowledge of teaching but also alleviate the contextual constraints that can limit GTA growth.

Anthony's case underscores the complex reality of GTA teaching. While he entered the semester valuing student-centered learning, his practice was heavily mediated by contextual pressures. Only when schedule and content afforded greater flexibility did he more fully enact student-centered approaches. This finding highlights a broader lesson for GTA development: pedagogical knowledge cannot be understood in isolation from the institutional structures and feedback systems that shape practice. To support GTAs in enacting ambitious, student-centered teaching, PD must address both pedagogical tools and the contextual constraints that frame classroom decisions.

Insights into Student Perceptions of Learning Assistants in Calculus I: A Mixed-Methods Study Involving Survey and NLP Analysis

Rebecca Butler
Virginia Commonwealth University

Orly Buchbinder
University of New Hampshire

Increasingly, institutions of higher education utilize undergraduate Learning Assistants (LAs) to support students' learning in introductory calculus courses. Prior research has shown a promising impact of the LAs on students' success and retention. However, little is known about students' perceptions of LAs' roles or whether academic factors influence these perceptions. In this mixed-methods study, we analyzed 411 Calculus I students' survey responses. The results of statistical analysis indicate that, regardless of course performance or prior Calculus experience, students generally perceive LAs positively, with students who seek additional learning resources having even more favorable perceptions of LAs. Additionally, a natural language processing (NLP) technique– topic modeling—revealed two themes: Investigating Procedural Activities and Conceptually Framing Results through Collaboration. Findings support LAs' role in fostering meaningful engagement for a range of students and demonstrate the value of NLP in educational research, offering insights for LA support of active learning in Calculus courses.

Keywords: Learning Assistants, Calculus, Student Perceptions

Improving students' learning experiences in university Calculus courses has been at the forefront of many reform efforts by higher education institutions (Bressoud, 2020; Rasmussen et al., 2014). Some reform approaches involve studio course designs, group problem-solving, and personal response systems, all of which emphasize active learning. Active learning is broadly conceptualized as encompassing pedagogical approaches that center student contributions and are often viewed as the antithesis of lecturing (Freeman et al., 2014). The *Learning Assistant (LA) model* is one approach to implementing active learning that has been shown to support students' learning, engagement, and retention in the introductory STEM courses (Barrasso & Spilios, 2021). LAs are undergraduate near-peer tutors who have previously completed the course they LA for and receive pedagogical training. LAs are present in the classroom alongside an instructor and support students' learning and interactions in small groups (Otero et al., 2010).

While it has been shown that students in LA-supported courses have better content-related and affective outcomes than their peers without such support (e.g., Alzen et al., 2018), little is known about how students perceive the role of their LA within the classroom. Understanding students' perceptions of LAs' classroom roles can enhance our understanding of how to support student success in STEM courses, since students' perceptions of the course are closely linked to their persistence in STEM (Ellis et al., 2014). Recent studies have examined variation in LA-student interactions (e.g., Carlos et al., 2023) and LAs' reflections on these interactions (Butler & Buchbinder, 2023). However, students' perspectives of these interactions remain largely unexplored, including whether certain groups of students find LAs particularly helpful or not, in other words, "who benefits from interactions with LAs." Our study aims to address this gap.

Specifically, we investigate whether there are differences among Calculus students' perceptions of their interactions with LAs with respect to such variables as: final course grade, previous Calculus experience, and students' pursuit of extracurricular resources. We approach this topic through a mixed-methods analysis of Calculus I students' end-of-course survey responses about their classroom interactions with LAs. Our research questions are:

1. Do students' perceptions of their LAs differ based upon their final course grades, previous calculus experience, or utilization of resources outside of the classroom?
2. How do students describe their classroom interactions with LAs?

Prior to addressing our research questions, we conducted a psychometric analysis of the survey instrument to evaluate its validity, reliability, and overall measurement quality.

Theoretical Framing

We frame LA-student interactions within a Vygotskian sociocultural perspective on learning (Vygotsky, 1978). This perspective holds that substantial learning occurs through social interactions of individuals with a more knowledgeable other (MKO). We conceptualize LAs as MKOs since they have previously taken Calculus I at the institution of study and are tasked with aiding student learning through social engagement. This lends theoretical legitimacy to the notion that students' perspectives on their LAs' classroom roles may be distinct from how they perceive other university instructors due to differences in social and power dynamics involved.

To guide the design of survey items (described in the methods section), we utilized positioning theory and social support theory. Positioning theory attends to the ways in which individuals take up or reject broader social roles by describing the "types of rights and duties people draw on as they interact" (Herbel-Eisenmann et al., 2016, p. 103). Survey items were formulated with the aim of understanding how students perceive the "rights and duties" of their LAs within the context of a Calculus I classroom. Social support theory was utilized to further specify the specific "rights and duties" represented in these items. Social support is a well-established framework from psychology that describes one's perception that they are cared for by others (Taylor, 2011). Within the context of mathematics education, previous research has shown positive connections between levels of social support and learning-related constructs such as ability perception, self-efficacy, and grades across a variety of contexts (Monteiro, 2017).

Social support theory has been previously utilized to investigate students' perceptions of their interactions with LAs (e.g., Donis et al., 2024; Hernandez et al., 2021). These studies identified the types of social support that students perceive from LAs (emotional, informational, appraisal), and that this social support is positively related to student engagement.

Topic Modeling

To analyze open-ended students' responses, we used *topic modeling*, a natural language processing (NLP) method that utilizes unsupervised machine learning and statistical methods to categorize large corpora of text data, like open-ended survey responses (Finch et al., 2018). We utilize the Latent Dirichlet Allocation (LDA) approach to topic modeling, which generates collections of words, called topics, that frequently appear together (Chauhan & Shah, 2021). Each word within a topic has an associated probability indicating how strongly it is associated with a particular topic. From these probabilities, the proportion of each topic within each open response is determined. Thus, a single response may contain a mixture of topics, reflecting the complexity of natural language (Silge & Robinson, 2017). While the association of words with a topic is determined quantitatively by NLP, the themes underlying each topic are determined by the researcher qualitatively, considering the nature of the data (Hwang et al., 2023).

Topic modeling is a novel technique that has recently been applied in mathematics education research (Gökdağ & Özmantar, 2024; Copur-Gencturk et al., 2023). We illustrate how this novel technique can be used to analyze Calculus student survey responses.

Methods

Setting and Data Collection

This study was conducted at a large, public university in the northeastern United States. It is one component of a larger NSF-funded project that aims to transform introductory STEM courses in biology, chemistry, mathematics, and physics through active learning pedagogies. Within the mathematics department, these transformations began with the Calculus I recitations. Calculus I course follows a lecture-recitation format, where students attend a large lecture (~ 150 students) three times weekly and a smaller recitation section (~ 20 students) twice weekly. In the lecture, a faculty member presents information via traditional lecture methods. Recitations are facilitated by a graduate teaching assistant (GTA) and an undergraduate LA who jointly facilitate students' problem-solving activities in small groups. GTAs have a more authoritative role, as they are responsible for assigning groups, grading quizzes, and reviewing content.

To capture students' perceptions of the course, the research team developed a student survey and piloted it for two semesters. The items were adapted from the SEMINAL project's Student Postsecondary Instructional Practices Survey for Mathematics (Uhing et al., 2020). The survey comprises 35 Likert-scale items, scored on a 5-point scale, and six open-response items. Of those, ten Likert items and one open-response item specifically focused on students' perceptions of LAs' roles in recitations (Figure 1). Items 1-4 and 8 were sourced from Hernandez et al (2021); others were developed by the research team to capture nuances of LA-student interaction in Calculus recitations.

	Strongly Disagree (1)	Disagree (2)	Neutral (3)	Agree (4)	Strongly Agree (5)
1. My LA understands the challenges students face in this course.	○	○	○	○	○
2. My LA shares additional resources that help me be successful in this class.	○	○	○	○	○
3. My LA gives me helpful feedback on my work in recitation.	○	○	○	○	○
4. My LA encourages me to keep trying even when I am struggling.	○	○	○	○	○
5. My LA explains problems in ways that make sense to me.	○	○	○	○	○
6. My LA explains mathematical concepts in ways that I can easily understand.	○	○	○	○	○
7. My LA asks me questions more often than they tell me answers.	○	○	○	○	○
8. My LA helps me understand recitation activity instructions.	○	○	○	○	○
9. I ask my LA for advice about courses other than calculus.	○	○	○	○	○
10. I feel comfortable sharing my thoughts with my LA, even when I think I might be wrong.	○	○	○	○	○

How would you describe a typical interaction between you (your group) and the LA during recitations? Be as specific as possible.

Figure 1. LA-related Survey Items

The survey was administered during a recitation in the last two weeks of the course by researchers while the GTA and LA were out of the room. Data were collected for three semesters, across 37 different recitation sections staffed by 10 different GTAs and 7 different LAs. Of the 606 students enrolled in the course during these three semesters, 411 consented to have their responses analyzed (~68% response rate). The authors of this paper were researchers on the project and had no teaching or administrative roles in the courses studied.

Instrument Validity and Reliability

To determine the validity of these ten items as measuring the single construct of students' perceptions of LAs' classroom roles, we used exploratory factor analysis (EFA). EFA is a

multivariate statistical method that identifies latent variables in a set of directly measured variables (Finch, 2020). To ensure that this data set was suitable for the application of EFA, we conducted Bartlett's Test of Sphericity (showed significance at $p<0.001$) and the Kaiser-Meyer-Olkin Measure of Sampling Adequacy (returned values for each item above 0.89), indicating suitability of EFA (Shrestha, 2021). The EFA revealed that the instrument measures a single latent variable, with item loading factors ranging from 0.5 to 0.9, indicating moderate to strong loading (Batterton & Hale, 2017). The survey reliability was acceptable across measures, with Cronbach's alpha (0.90), split-half reliability (0.82), and McDonald's omega (0.94) all exceeding the recommended 0.7 threshold (Streiner & Norman, 2008). All psychometric analyses were conducted using the R packages *psych* and *GPArotation* (Revelle, 2017).

Analytic Procedures

A non-parametric approach was selected for this study due to the ordinal nature of the data and non-normal distribution of responses (see Table 1 in the Results section). A Bonferroni correction was applied to the Mann-Whitney p-value because multiple tests were run on the data, and to reduce the risk of Type I error (Armstrong, 2014). In the case of a significant difference ($p < 0.1$), Cliff's Delta was computed as a post-hoc test to determine effect sizes (Meissel & Yao, 2024). These statistics were computed using the R package rstatix (Kassambara, 2019).

Since some students in the sample had the same LA, both within and across the semesters, the sample could be considered as LA-dependent. However, after aggregating the data by LA, the mean difference between LAs across all ten items was 0.61, which is relatively minor for our Likert scale. This suggests that students' overall perceptions did not differ dramatically across LAs and that the sample can be considered holistically.

To perform topic modeling on the open-response item, we first conducted pre-processing, or text cleaning (Hvitfeldt & Silge, 2021). First, we removed stop words, which are parts of speech that typically carry little substantive meaning (e.g., a, the, did, or), using three R packages: *SpacyR*, *tidytext*, and *dplyr*. Next, we used the *SnowballC* package to reduce the remaining words to their root forms (Welbers et al., 2017), i.e., the words "explains", "explained", "explaining" are all reduced to their common stem, "explain." After text cleaning, we used the R package *ldatuning* to find the optimal number of topics in our dataset by selecting the number of topics that minimized the CaoJuan2009 metric (Nikita & Chaney, 2022). This resulted in two topics. We then used the R package *topicmodels* to construct the topic model with two topics and an alpha hyperparameter of 0.1 (Grün & Hornik, 2011). This low alpha indicates that topics are sparsely distributed across responses, aligning with our aim to capture features of LA-student interactions at the individual response level (Du, 2022).

Results

Likert Scale Item Analysis

For ease of communication, we refer to the set of 10 LA-related items in Figure 1 as the LA survey. Table 1 shows descriptive statistics for all items in the LA survey, indicating that students generally agreed with most survey items. This suggests that students' views of LAs' classroom roles were positively oriented. The exception to this trend is item 9, with a mean of 2.59 and a mode of 2, indicating relative disagreement with the statement: "I ask my LA for advice about courses other than calculus." Although this role was not explicitly required of LAs, the item was included in the survey to gauge whether LAs act as peer-mentors beyond the calculus course. Some students reported engaging with LAs in this way; most students did not.

Table 1. Descriptive Statistics of Student Responses to LA-Related Likert Scale Items

Item	1	2	3	4	5
					Mean	4.18	3.69	4.16	4.15	4.14
Standard Deviation	0.82	0.98	0.84	0.84	0.88
Median	4	4	4	4	4
Item	6	7	8	9	10
					Mean	4.09	3.52	4.04	2.59	3.98
Standard Deviation	0.86	1.07	0.83	1.29	0.90
Median	4	4	4	2	4

To explore whether students' perceptions of LAs differ by their final course grades, student responses to the LA survey were split into two groups: 238 high performers—students whose final course grade was B- or better, and 173 general/low performers—the remaining students. Mann-Whitney tests with a Bonferroni correction were conducted to determine whether these two groups responded differently to each of the ten survey items. No significant differences at the p=0.1 level were found, meaning that our data did not provide evidence that students' perceptions of their LAs varied by course performance.

To determine whether perceptions of LAs varied by previous experience with Calculus, student responses were divided into two groups: 174 students who self-reported having previous calculus experience and 237 students without such experience. Again, Mann-Whitney tests with a Bonferroni correction showed no significant differences between the groups at the p=0.1 level.

Next, we divided student responses into two groups based on their self-reported use of learning resources outside the course, such as the university mathematics tutoring center, online videos and other sources. There were 315 students who reported using such resources versus 91 students who did not. Mann-Whitney tests with a Bonferroni correction identified significant differences between these two groups only for items 2, 3, 4, 7, and 10 (Table 2). Since significant differences were found for these items, Cliff's Delta was computed post-hoc to determine the effect size. The results suggest that students who tend to seek outside help have more positive perceptions of LAs' roles, captured by these five items, compared to students who do not seek outside help. However, the effect sizes for all items are small (Meisel & Yao, 2024).

Table 2. Statistics for Students Who do and do not Utilize Outside Resources

Item Number	Mean Response from Students Seeking Help	Mean Response from Students not Seeking Help	Adjusted *p-value*	Cliff's Delta
2	3.77	3.42	0.00417*	0.231
3	4.21	3.97	0.0230*	0.195
4	4.2	3.96	0.0235*	0.195
7	3.61	3.22	0.00746*	0.224
10	3.82	4.03	0.0897**	0.171

Topic Modeling

Topic modeling of student responses to the open-ended question "How would you describe a typical interaction between you (your group) and the LA during recitations? Be as specific as possible" revealed two topics. Figure 2 shows the 20 words most strongly associated with each topic. For clarity, the words are displayed in full, rather than stemmed (e.g., solve instead of solv, easy instead of easi). The horizontal axis shows the probability of the word appearing within the topic; higher values indicate that a word is more strongly associated with a topic.

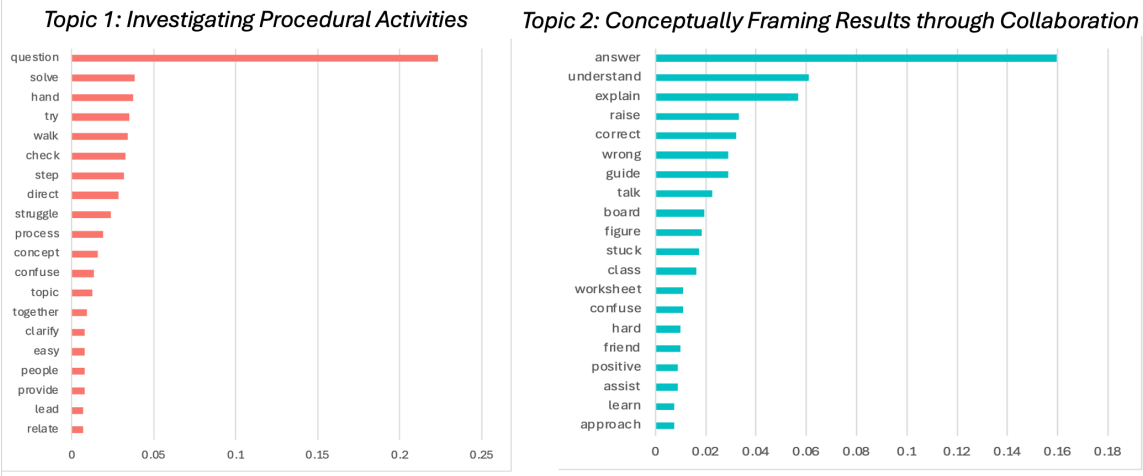

Figure 2. 20 Most Common Words in Each Topic

The first topic (Figure 2, left) includes words like *solve*, *step*, *process*, reflecting a focus on procedural aspects of Calculus. The word most strongly associated with this topic is *question*. Although it is unclear who is asking these questions (i.e., the LA or the student) or if it refers to questions on the worksheet, this word may indicate some procedural focus. The presence of words like *check*, *direct*, *provide*, *clarify*, and *lead* point to the utilization of the LAs' expertise to validate these procedural foci. The presence of the words *try* and *struggle* in this topic suggests some aspects of student difficulty or effort involved in these procedures. For example, in one response that is strongly associated with this topic, the student described "asking [LAs] specific questions when struggling or ask to have work looked over for errors and constructive criticism." Overall, the terms in this topic signal an engagement with the completion of mathematical procedures; thus, the topic was termed *Investigating Procedural Activities.*

The second topic (Figure 2, right) contains terms such as understand, explain, learn, approach, and figure (in the sense of a graph or a sketch), indicating a more conceptual focus within the topic, in contrast to the procedural focus of the previous topic. This topic also contains the terms answer, correct, and wrong, meaning that conceptual discussions were still centered on the correctness of mathematical outputs. This topic also contains words with a strong community orientation, such as guide, talk, board, class, friend, and assist, suggesting collaborative efforts during LA-student interactions. A sample response strongly associated with this topic is: "we work on a worksheet with groups and then we call [the LA] over if we are stuck and she guides us towards the right answer." We termed this topic Conceptually Framing Results through Collaboration since the frequent terms appear to represent outcome-oriented discussions between LAs and students.

Due to the nature of topic modeling, these topics are not necessarily mutually exclusive, meaning that students could describe their interactions with LAs as related to both topics. Our analysis reveals that there are two primary ways in which our students view their interactions

with LAs. Some aspects of interactions focus on dissecting specific procedural steps, while others are centered on communal engagement and understanding of outcomes.

Discussion

Statistical analysis of the LA survey revealed that across three semesters of data, *students had relatively positive perceptions of their interactions with LAs*, regardless of the LA. Also, there were no statistically significant differences between groups with high and general/low course performance, nor between groups of students with or without prior calculus experience. We consider this lack of statistical significance as *a positive result,* as it suggests that *all students viewed LAs' classroom presence as beneficial to them*: the struggling students, and the ones with a mastery of the material, those who encountered calculus for the first time and those with prior exposure to it. Statistically significant differences were only found for five Likert-scale items between students who do and do not report utilizing outside resources to aid their coursework. *Students who reported using such resources indicated slightly more positive perceptions of LAs' classroom roles*. This could be because students who seek additional learning resources tend to view LA as one such resource and were more comfortable with or proactive in obtaining LAs' assistance with their mathematical work.

The topic model indicated two primary ways in which students framed their interactions with LAs, which we termed *Investigating Procedural Activities* and *Conceptually Framing Results through Collaboration*. These two topics could provide insight into the reasons behind the often-reported student success in LA-supported courses (e.g., Alzen et al., 2018), specifically that LAs engage with both *students' procedural questions and conceptual discussion of mathematical results.* However, additional work is required to establish this connection.

Our findings align with the studies showing students' satisfaction with their interactions with LAs in large-lecture STEM classrooms (Donis et al., 2024; Hernandez et al., 2021). We extend this literature to the context of Calculus recitation sections led by GTAs. Since the instructional and power dynamics of this environment differ from those of a large lecture, establishing positive student experiences in this context is an important result. The results of this study are also relevant to the broader context of calculus reform, offering support for the LA model's impact as a transformation effort. Our results suggest that these efforts can reach students from a range of different mathematical backgrounds and achievement levels. Although focused on LAs, these findings also inform GTAs, especially those without prior pedagogical experience, by illustrating effective instructional practices. The identified themes—*Investigating Procedural Activities* and *Conceptually Framing Results through Collaboration*—offer concrete examples of valuable classroom support that can be highlighted in both LA and GTA training.

We also offer a *methodological contribution, illustrating the power of NLP tools in analyzing open-ended survey responses.* The use of topic modeling allowed us to broadly describe trends across a large volume of open-ended responses without manual open coding, but with the input and supervision of a researcher. As the use of NLP in education research continues to grow, developing best practices for the validation and interpretation of these automated analyses will be crucial to ensuring their appropriate use in understanding student experiences.

Queer Readings of Mathematical Proof: Appropriating Norms in the Pursuit of Epistemic Justice and Queer Joy

Catherine Davis (they/them)
Michigan State University

The enculturation of mathematics students into the mathematical norms of proof can be a source of epistemic injustice when personal, social, and cultural norms are in tension with those held by the mathematics community. This injustice can be addressed through students' conscious appropriation of these norms, and I argue that queer readings, a form of critical textual analysis originating in queer theory, offers relevant analytical tools for this appropriation. In this paper, I present findings from a study on queer readings of mathematical proof and illustrate how our queer appropriations of mathematical norms resulted in an epistemically just interaction with proof and invited queer joy into the proof reading process.

Keywords: Queer pedagogy, Epistemic justice, Proof, Proof reading

Many scholars have examined student and expert approaches to proof reading (Dawkins & Weber, 2017; Inglis & Alcock, 2012; Panse et al., 2018) in an effort to understand the "interactional accomplishment" (Weber & Mejía-Ramos, 2014, p. 90) between reader and text. However, this research often functions under an apprenticeship model where learners are expected to develop the same norms for proof as are held by professional mathematicians (Dawkins & Weber, 2017). As Tanswell and Rittberg (2020) explain, the enforcement of these norms during the learning process can create systemic disadvantages; "mathematics learners are not little research mathematicians and demanding that they operate in the same ethical order is a source of epistemic injustice" (p. 1209). Tanswell and Rittberg do not propose that the norms of proof necessarily need to shift, but that learners should "appropriate norms in order to experience the values these norms are intended to uphold" (p. 1207). In other words, mathematics students should be encouraged to explore and push back against norms of proof so that they may find when those norms are in tension with their personal background and understand why these norms are ubiquitous within mathematics. I argue that queer reading is a pedagogical method well suited to this appropriation. In this paper I investigate: [1] How do queer readings of proof encourage readers to interact with proof in epistemically just ways? [2] How does queer joy emerge during queer readings of proof?

Theoretical Perspectives

My work is grounded in the theoretical relationship between epistemic injustice and norms of proof as presented by Tanswell and Rittberg (2020), and in my conceptualization of queer readings as a proof reading strategy which encourages queer joy and epistemic justice.

Epistemic Injustice and Acontextual Norms of Proof

Epistemic injustice is a philosophical framework popularized by Fricker (2007) which exists at the intersection of epistemology, politics, and ethics. Epistemic injustice is used to discuss how systemic inequities, power dynamics and social relations negatively "affect humans…in their roles as epistemic agents" (Tanswell & Rittberg, 2020, p. 1200). For example, epistemic injustice highlights that when curricula fail to recognize Indigenous ways of knowing they discredit a culture's intellectual traditions (Pohlhaus, 2017).

Dawkins and Weber (2017) claim that norms of proof uphold four epistemological values central to mathematics. Of concern to Tanswell and Rittberg (2020), and therefore to this paper, is the second epistemological value proposed by Dawkins and Weber (2017) which states that "mathematical knowledge and justifications should be a-contextual and specifically be independent of time and author" (p. 128). Tanswell and Rittberg (2020) argue that the norms for proof upholding this epistemic value can perpetuate epistemic injustice in classroom environments by discouraging references to the agency of either reader or author and ignoring the collaborative and less formalized contexts in which proofs are frequently read and created.

Queer Readings of Proof

Reading strategies can be described as "goal-directed actions which are undertaken by readers for planning and monitoring their efforts in order to decode a text, understand words, and construct meanings of texts" (Alexander & Judy, 1988; Pereira-Laird & Deane, 1997; as cited in Yang, 2012, p. 309). The goal of proof reading is often proof comprehension or proof validation (e.g. Dawkins & Zazkis, 2021; Hodds et al., 2014; Yang, 2012) and proof reading strategies include self-explanation (Hodds et al., 2014), summarization (Davies & Jones, 2022), and attempting to prove a theorem before reading its proof (Weber, 2015). Given proof reading strategies include any activity which readers use to "decode a text" and "construct meaning" (Yang, 2012, p. 309), they can be extended to include annotation, construction and deconstruction. For this reason, I expand queer readings into the field of mathematics as a proof reading strategy.

Queer reading is a pedagogical practice originating in queer theory which intentionally explores the "interpretive performance" (Britzman, 1995, p. 222) between reader and text while attending to a text's hidden meanings, implicit messages, and cultural, political or societal norms (Björklund, 2018; Britzman, 1995; M. Morris, 1998). Common misconceptions of queer readings is that they require queer intentions on the part of the author and/or that they must center sexuality and gender. However, many queer theorists argue that queer readings "can be just as useful in analyses of how other norms are produced in texts" (Björklund, 2018, p. 9). Consequently, queer readings of proof may invite readers to critically examine the structure and nature of a proof's argument(s), address the implicit relationship(s) between reader, author, and mathematical content, and to critique and appropriate norms of proving.

Epistemic Justice and Queer Joy

As an extension of the argument by Tanswell and Rittberg (2020), I propose that epistemically just interactions with proof are those which allow learners to appropriate norms of proof valuing acontextuality by introducing social or mathematical context, referencing author and/or reader agency, and valuing casual language and collaborative efforts. Given queer readings are strategies that explicitly work to uncover hidden meanings, consider implicit messages, and monitor norms present within a text, my work is grounded in the theoretical idea that queer readings of proof provide opportunities for readers to appropriate proof in epistemically just ways. Additionally, I consider queer joy to be a source of epistemic justice specific to members of the queer community.

Queer joy counters narratives of oppression, abuse, and isolation that are common within discussions of the queer community (Morris et al., 2022) by promoting stories of resilience, joy, and power. In educational research, Duran and Coloma (2023) invite researchers to prioritize queer joy in order to "render LGBTQ individuals as complex vibrant beings, underscore the educational and lived conditions that accept and embrace them, and prioritize our happiness,

wellbeing, and the actualization of our full potential" (p. 122). In this project, I see queer joy as a form of epistemically just interaction with proof because it embraces the identity of the reader and invites them to contextualize their gender and sexuality alongside the mathematical content so that mathematics can "meet the learners half way" (Tanswell & Rittberg, 2020, p. 1208).

Methods

Data for this paper comes from a 2025 study conducted at a large university in the American Midwest. Data was created across three phases, all of which were methodologically informed by Jeong-eun Rhee's (2020) post-qualitative writings on rememory, my personal queer research aesthetics (Author, Year), and the knowledge that "queer lives can be addressed through a plethora of methods, and all methods can be put to the task of questioning normativities" (Nash & Browne, 2010, p.12). This paper's analysis is focused on phase two, a task based group interview (Goldin, 2012) where the queer readings took place. I describe my participants and outline my methods for preparing and conducting the task based group interview below.

Participants

Four participants took part in the study. Atticus (he/him) and Jeremy (he/him) were both completing their third year of a bachelor's degree in mathematics. Audrey (she/her) was a third year graduate student working towards her PhD in nuclear physics after earning a dual bachelor's degree in physics and mathematics. The fourth participant was myself (Author, Pronouns); I was a second year graduate student working towards a PhD in mathematics education and a master's in applied mathematics. All of us had completed at least two years of mathematics coursework and identified as queer. The choice to use queer participants stems not from a belief that only queer individuals can perform queer readings, but from a belief that queer methods of doing mathematics should originate from within the queer mathematics community.

Data Creation

Prior to the task-based interview, I conducted an unstructured group interview in which I used Rhee's (2020) rememory-based methodology as an access point to the social, political, and theoretical underpinnings of queer readings. This allowed us to collectively define our intended queer readings of proof as a way to "bridge the gap" (Jeremy) between theory and "what I can actually see going on" (Atticus), make proofs "explode" (Jeremy), acknowledge the queerness of proof's "funny little symbols" (Audrey), play with "what a proof can be" (Author), and "get the arts and crafts going" (Jeremy) so that proof does not seem "so far away" (Author).

Two proofs were selected for the task-based interview on the basis that they are present in other studies on proof reading. The majority of our time was spent reading the proof taken from Mejía-Ramos et al. (2012) (see figure 1) and all findings shared are in reference to this proof.

(1) **Theorem:** There are infinitely many triadic primes.

(2) **Proof:** Consider a product of two monadic numbers: $(4j+1)(4k+1)$
(3) $= 4j \bullet 4k + 4j + 4k + 1$
(4) $= 4(4jk + j + k) + 1$

(5) which again is monadic.
(6) Similarly, the product of any number of monadic numbers is monadic.
(7) Now, assume the theorem is false, so there are only finitely many triadic primes, say $p_1, p_2, \dots, p_n$.
(8) Let $M = 4p_2 \dots p_n + 3$, where $p_1 = 3$
(9) $p_2, p_3, \dots, p_n$ do not divide M as they leave a remainder 3, and 3 does not divide M as it does not divide $4p_2 \dots p_n$.
(10) We conclude that no triadic prime divides M.

(11) Also, 2 does not divide M since M is odd.
(12) Thus all of M's prime factors are monadic, hence M itself must be monadic. But M is clearly triadic, a contradiction.
■

Figure 1. Proof of infinitely many triadic primes. Line numbers included for readability of findings.

During the interview we had access to multiple copies of this proof as well as a variety of art supplies. The interview took place in a queer community center, lasted approximately ninety minutes, and was filmed from multiple angles to ensure that facial expressions, body language, and any manipulation of the proofs would be visible. At the start of the interview we reviewed our discussion from the unstructured group interview and agreed that even if we "don't know what it's going to look like" (Jeremy) we were ready to begin our queer readings based on the desires and guidelines we had previously co-created.

Data Analysis

In order to analyze the second task-based group interview I immersed myself in the data through repeated relistening and rewatching. This strategy of data immersion was inspired by the work of post-qualitative researchers who describe data analysis not as a "recipe" or "process" but as a form of experimentation grounded in the theoretical underpinnings of the work (St. Pierre, 2018, p. 604). For me, this meant inviting the data into my life outside of the academy by consciously relistening and rewatching the data while cooking, driving, and participating in my favorite hobbies; by the end of this phase of data analysis I estimate that I had relistened/rewatched the second task-based interview upwards of fifteen times.

Having built a strong internal relationship with the data, the next step of data analysis took the form of externalizing my noticings. For the purpose of this paper, I reviewed the task-based interview again, this time pausing to take notes when I observed moments where we interacted with the proof in epistemically just ways. For example, moments in which we contributed contextual annotations (e.g. "p_1 must be 3!", "b/c primes") represent an epistemically just interaction by appropriating norms valuing acontextuality. I also noted moments when we experienced queer joy while conducting the queer reading, as evidenced by our laughter, facial expressions, and implicit or explicit connections between our identities and the proof. After collecting these notes, I watched the interview again and selected specific instances of epistemic justice and queer joy that I felt most clearly demonstrated how the queer reading process was conducive to the emergence of these moments. I then began drafting my findings with the knowledge that the act of writing is another phase of analysis which allows the writer to explore their findings through the externalization process (St. Pierre, 2018).

Findings

During our queer readings of mathematical proof, the participants and I were inspired to physically deconstruct and reconstruct part of the proof for infinitely many triadic primes by cutting apart the existing proof (figure 1) and rearranging it onto a poster while adding our own context, notes, definitions, arrows, and other forms of annotation (figure 2). Through this de/reconstruction we were able to engage in proof reading in epistemically just ways by reintroducing agency and context to the mathematical text. This de/reconstruction of proof and the appropriation of proof norms also invited moments of queer joy in which we saw our queer experiences mirrored in mathematical proof and proving. Given my understanding of queer joy as an extension of epistemic justice, these findings are shared in the second subsection. However this ordering does not imply that our experiences of queer joy are secondary in importance.

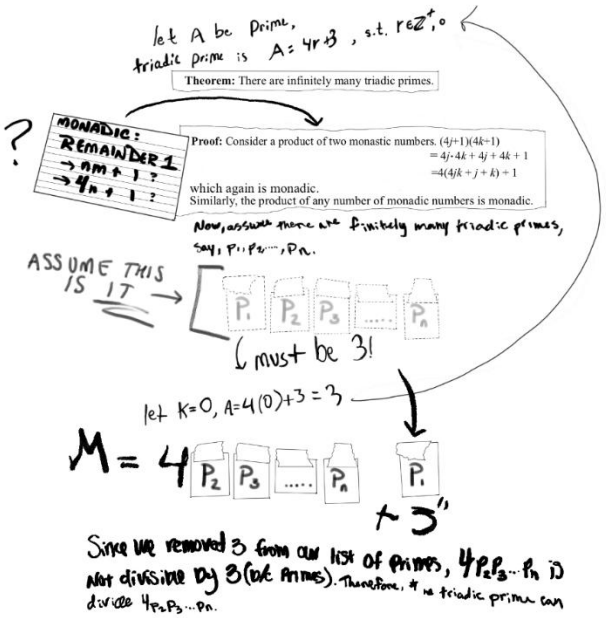

Figure 2. Partial proof de/reconstruction; digitally rendered for legibility

Moments of Epistemic Justice in the Queer Reading Process

One moment in which we experienced epistemic justice through appropriating proof norms valuing acontextuality was while discussing the assertion in line 7 and its relationship to line 8 and the overall proof by contradiction.

Audrey: So, the $p_1, p_2,$ all the way to p_n …are we assuming that *those* are the triadic primes? [she makes a chopping gesture with her hand] Are we assuming that that's all of them?

Author: Yeah, like if there was finitely many, that's it. That's our—like we could create a list and then this would be the list.

Audrey: Okay, okay. So, this is [her hands make a large sweeping gesture] all of them.

Author: All of them. [Laughing] We've done it. We've found them all.

Audrey: [She laughs and then frowns] What's the point of M though?

Author: Um…[Everyone is quiet for a moment]

Audrey: I think they're just trying to show that you can create a new triadic prime using the ones you've already created in the finite list?

Jeremy: Ohhh…

Audrey: You prove that that new product is a triadic prime…

Jeremy: Oh…okay, no I understand what you're saying.

Author: Right so it can't be finite.

Jeremy: Cause we already assumed it was finite, [He adopts a sassy tone and holds up his pencil] but actually, there's one more!

In this interaction we discuss line 7, emphasizing the proof's certainty that the list is finite while knowing that this assertion will quickly be disproven. In this way, we are acknowledging our agency as readers; we are not bound by the proof's linearity because we are able to look forward to line 12 as we read line 7. This allows us to find humor and curiosity in line 7's assertion, contextualizing the statement as it relates to the proof by contradiction. During our de/reconstruction of line 7 for our poster, Atticus, likely recalling the conversation shared above,

suggested that we emphasize the finiteness of our p's with an annotation. I wrote "ASSUME THIS IS IT" to the left of the list of p's as a playful reminder of the upcoming contradiction.

Shortly after this discussion, and as part of our de/reconstruction of line 7, I was drawn to create a physical representation of the p's, cutting out $p_1, p_2,$ etc. and taping them on our poster. This resulted in Audrey reaching out to physically move the p's from line 7 into the equation for M on line 8 as we progressed in our de/reconstruction. Her choice to physically relocate the p's to line 8 demonstrates her understanding of their equivalency and her sense of agency as a reader. Our queer reading method of de/reconstruction invited her to treat the elements from line 7 as tangible constructions which she is capable of manipulating and redefining, giving her agency over the proof in tangible ways.

Later, during our de/reconstruction of line 9, we felt the need to contextualize the conclusions being made about the terms within the equation for *M (*defined in line 8) which are central to the proof by contradiction.

Atticus: So what is it [line 8] even saying?

Audrey: Okay okay okay…so it's two [she raises her hands in a grasping gesture and then frowns, dropping her face in her hands] what's it called when things are…? [she perks up and holds her hands forward again] Terms, yes! Two terms! So we have to prove both are not—cannot—be divided by three.

Jeremy: Okay. [He uses his pinky to poke at the first term in the equation for *M*] And this one can't because we already pulled three out [he slides his pinky to the second term].

Author: And this one [I gesture to the first term for *M*] is just four and a bunch of primes.

Jeremy: Okay.

Author: So if this is four and a bunch of prime numbers…

Audrey: Yeah.

Atticus: [Slowly, while rubbing his chin] Right…then they're only divisible by four and the same prime numbers. Not three.

Jeremy: Exactly. [He leans forward and writes: Since we removed 3 from our list of primes, $4p_2p_3 \ldots p_n$ is Not divisible by 3]

Author: That makes sense to me.

Jeremy: I'm gonna say…[he adds the parenthetical (b/c primes) to the poster, and we all laugh]

In this excerpt, we discuss why the first term in the equation for M in line 8 is not divisible by three, a discussion which Jeremy summarizes by rewriting line 9 with additional mathematical context and consideration for the reader. His choice to add the phrases "since we removed 3 from our list of primes" and "(b/c primes)" demonstrate a preference for casual narrative language which guides readers towards the line's main idea and explicitly addresses the logical jumps which were implicit in the original proof. This appropriation of norms valuing acontextuality allowed us to reconstruct the proof in a manner that was more comfortable for our reading process and more closely resembled our conversations surrounding the topic.

Moments of Queer Joy in the Queer Reading Process

As our queer readings led us to de/reconstruct the proof for infinitely many triadic primes, we paused to consider the separation we felt was visible between lines 2-6 of the proof and lines 7-12 of the proof.

Author: So we have a piece of the proof that feels unrelated?

Jeremy: We need a better transition for sure

Author: [Referencing those who identified as transgender (trans) within the group] Don't we all want a better transition? [Everyone laughs]

Atticus: [Emphatically] Yes! Yes, I do!

The word transition can refer to the narrative flow between lines of text, but it is also used by the trans community to refer to the actions and experiences of modifying one's gender presentation in gender affirming ways (e.g. cutting one's hair, changing one's name). This play on words which was evoked during our queer de/reconstruction of the proof allowed us to connect to the proof on a more personal level; we were able to see our identities as relevant in a mathematical context in which acontextuality frequently disguises the existence of queer readers and queer authors of mathematics.

Other examples of queer joy were visible in our discussion of broader mathematical concepts relevant to the proof. At the start of our de/reconstruction Audrey noted that primes as a mathematical concept felt queer to her, saying "primes are queer…they're special and there are infinitely many of them." As she spoke, she smiled and wiggled side to side in her seat. I remember feeling briefly emotional about this concept; delighted that, like primes, queerness extends into an infinity of experiences within an infinity of individuals. Similarly, Jeremy pointed out that proof by contradiction is a queer way to prove a theorem, laughing and gesturing at the proof as he exclaimed "like, we said there are infinitely many of them…JK!" Again, this moment of humor represents a deeper connection between our identities as queer doers of mathematics and the mathematics itself. This identity-forward interaction with proof is evidence of an epistemically just interaction with proof since it values the context and the community that we bring with us as proof readers.

Discussion

In order to uphold epistemic values of acontextuality, norms of proof discourage reference to time, place, reader or author agency, and the realities of proof as a human creation, and these norms perpetuate epistemic injustice for students (Tanswell & Rittberg, 2020). Queer readings, a practice which celebrates reader agency and invites the deconstruction of texts for the purpose of critique, exploration, and personal meaning-making is a pedagogical tool that encourages the subversion of these acontextual proof norms. And by subverting these norms, students are able to interact with proof in epistemically just ways, which for queer students, can include epistemic justice through the cultivation and acknowledgement of queer joy.

Much of the existing literature discussing proof reading focuses on student's cognitive behavior and/or the quantifiable outcomes of specific proof reading strategies such as improved proof comprehension or proof validation (e.g. Lew et al., 2024; Mejía-Ramos et al., 2012; Panse et al., 2018; Weber et al., 2012; Yang, 2012). But in recent years researchers and educators have begun considering the humanization of proof instruction (e.g. Contreras et al., 2025; Dahlgren, 2024) and how one might incorporate equitable pedagogical practices into proof based courses (e.g. Melhuish et al., 2024). I present queer reading as a supportive critical tool in advancing these agendas, as well as an enticement for students to experience joy and justice in proof classrooms. As Atticus expressed in his reflection exercise, "this process was so, so healing for me and my math soul! I feel like I can embrace looking deeper into proofs, and even rewriting them so they make sense to me."

There is still much to conceptualize about the practice of reading proofs queerly and how it might support students of mathematics, and I plan on continuing this work with the belief that queer pedagogy can be critical, subversive, and uplifting for students regardless of their identity (Author, Year). As we continue to ask ourselves how undergraduate mathematics education might become more equitable, just, accessible, joyful, and humanizing, I offer queer pedagogies as complementary frameworks deserving of continued study.

Designing Activities About Definition Values Through Collaboration and Attention to Professional Obligations

Seth Ricarte
Michigan State University

Kristen Vroom
Michigan State University

Rachel Rupnow
Northern Illinois University

Because many mathematics instructors rely on lectures as their primary mode of instruction, change efforts should engage with and build on instructors' existing values and practices rather than attempt to replace them. We report on the first year of our project, where we take a collaborative approach to improve instruction surrounding definitions through activity design and implementation. Constructing narrative cases, we explored how our collaboration aided participants in navigating alignments and tensions between their professional obligations and their activity. We found our collaboration succeeded in guiding our participants, but it required careful examination of reasons as to why instructors may not institute instructional change.

Keywords: Professional Obligations, Instructor Collaboration, Values, Definitions

Many mathematics faculty continue to rely on forms of lecture that prioritize efficiency and content coverage, both in Calculus (Kirin et al., 2017; Vroom et al., 2022) and proof-based courses (Johnson et al., 2018). Dawkins and Weber (2023) argue that such instructional choices may persist because they fulfill instructors' perceived commitments, such as ensuring mathematical precision, preparing students for advanced coursework, and managing time constraints. This suggests a need for instructional change efforts that engage with and build on instructors' existing values and practices, rather than seeking to replace them. In this study, we focus on one context where values play a central role – the teaching of mathematical definitions. We collaborated with mathematics faculty to design classroom activities that communicate the nature of mathematical definitions, hypothesizing that attending to instructors' values could support them in adopting more interactive teaching strategies while remaining aligned with their professional obligations. This focus is particularly important given evidence that mathematicians and students understand definitions differently (Edwards & Ward, 2004; Fernández-León et al., 2021; Martín-Molina et al., 2020).

Theoretical Grounding

We draw on Herbst and Chazan's (2011) theory of *practical rationality*, assuming that instructors' practices are rational within the context of their available resources and perceived professional obligations. Herbst and Chazan theorize four such obligations that instructors weigh as they make instructional decisions: (1) disciplinary, to represent mathematics authentically; (2) individual, to attend to students' needs; (3) interpersonal, to manage classroom interactions as social spaces; and (4) institutional, to meet the expectations of the schooling system. For instance, Johnson et al. (2025) exemplify such decision-making. The mathematicians they studied were hesitant to adopt active learning approaches that might limit content coverage because they wanted to avoid upsetting the department chair if their section deviated from others (institutional obligation), aimed to adequately prepare students for graduate school (individual obligation), and wanted to have time to cover all the essential topics according to their disciplinary expertise (disciplinary obligation).

Our collaborative work aimed to foreground the instructors' disciplinary obligations, as we suspected these would provide a compelling rationale for implementing an instructional

innovation. In particular, through collaboration, faculty developed activities to treat mathematical definitions in ways aligned with the mathematics community's values. By *activity*, we mean any part of an instructor's lesson that solicits some artifact of how students think about a value (e.g., a discussion, individual exercise, exit ticket). We conceptualize values, mirroring Dawkins and Weber (2017), as a community's shared goals or orientations (*values*). Rupnow and Randazzo (2023) identified two values that guide how mathematicians treat definitions: the *communication value*, emphasizing clear and unambiguous expression, and the *freedom value*, emphasizing flexibility and creativity when using or creating mathematical definitions.

As the instructors planned and enacted activities, we noticed that these activities often aligned with, but at times came into tension with, their professional obligations. For instance, a think–pair–share activity that asks students to consider multiple, conceptually distinct definitions may align with instructors' disciplinary obligation to highlight the freedom value while also supporting their individual obligation to engage students in meaningful mathematics. At the same time, such an activity might create tension with their institutional obligation to follow the textbook's chosen definition and to cover material efficiently. Recognizing and navigating these alignments and tensions proved central to the design process. Thus, we view the development of activities that either aligned with or productively responded to instructors' obligations as an advantageous goal for the activities to be realized and sustainable in the instructors' classes. In this study, we investigate: *In what ways do instructors' professional obligations align or come into tension with activity design and implementation around mathematical definitions? How can collaboration help surface and respond to these alignments and tensions?*

Methods

Our data comes from the *Supporting Mathematical Instruction around Definitions through Values-Centered Collaboration* project. We focus on the first year of the project during which participants engaged in a series of focus groups (FGs) (four total meetings) and completed surveys before or between meetings (five total surveys). We also recorded any activities that the instructors implemented in their class. We recruited ten instructors in Fall 2024 and six instructors in Spring 2025 across two PhD-granting Midwestern universities. Four FGs were held each semester.

We began the FGs by introducing instructors to the framework we used for mathematical definition values (Rupnow & Randazzo, 2023) and discussed messages that instructors may send to students about them. We (the researchers and instructors) also discussed examples from our teaching in which we aimed to share definition values with students. Author 2 shared a Real Analysis activity in which the students analyzed an informal definition for increasing sequences and used it to formulate a more formal and unambiguous version. Author 3 shared two activities: one from Abstract Algebra that engaged students in defining "prime," and, later, one in Linear Algebra where students reflected on the name "orthogonal complement" and the conceptual insight it conveys. After these discussions, instructors brainstormed activities that communicated a chosen value (and norms that uphold them) and, in the subsequent meeting, they presented these activities and exchanged feedback. After the instructors implemented their activities in their course, we debriefed and reflected on their implementations. The surveys collected demographic data, perceptions on the role of definitions in mathematics, reflections on the values discussed in FGs, descriptions of their classroom activity, and feedback from their involvement. We drew on these survey responses between FG sessions to revise our initial plan for the following session.

In this study, we highlight two cases of working with two mathematicians, who we refer to as Julian (computational mathematician) and Drew (algebraic combinatorialist). We selected these two cases because we thought both seemed like successful collaborations but in different ways. Based on our experiences with them, we thought that our collaboration with Julian supported alignment in his professional obligations and his activity whereas we thought that our collaboration with Drew supported him in responding to tensions between his obligations and his activity design.

Our data analysis involved constructing narrative cases (Auerbach & Silverstein, 2003) of our collaborations with Julian and Drew. Our narrative writing was guided by the following questions: (a) How, if at all, did [mathematician] feel obligated to share the communication value in his teaching? The freedom value?, (b) How did [mathematician's] activity align and/or come into tension with their professional obligations? (c) How, if at all, did our collaboration with [name] contribute to this alignment or tension? We developed the narratives using an iterative process. First, we re-read faculty's survey responses and answered the guiding questions, interpreting their responses through a professional obligation lens. We then discussed our interpretations until we reached an agreement. Next, we drafted what we noticed related to the guiding questions, referencing any relevant quotes from their surveys. With this first draft, we watched the FG recordings and read the corresponding meeting transcripts to test and refine our emerging claims and enrich the narrative with contextual detail. Once satisfied with the narrative, we engaged in member-checking by inviting the mathematicians to read their narratives and provide feedback, which we subsequently incorporated.

Results

In what follows, we share two abbreviated narratives that highlight our collaborations with Julian and Drew, attending to how their professional obligations aligned or came into tension with activity design, and how collaboration helped surface and respond to these obligations.

Julian's Activity: Aligning Design with Obligations

Julian's Disciplinary Obligations. Julian had an obligation to uphold the communication value in his teaching, particularly through the way he used and presented mathematical definitions in his Differential Equations class (*disciplinary obligation*). Since the course placed little emphasis on proof, he explained that the role of definitions was primarily about "communicating ideas to the students and giving something a name." In this context (and in mathematics more broadly) he explained that definitions serve key communicative purposes: they make concepts "easier to reference and talk about," help ideas "be memorable to others," and clarify "what something is and what it is not." Julian emphasized that modeling clear communication was essential because "we want our students to be clear as well when they're doing their written work- we would like them to try to emulate that."

Julian did not feel as obligated to uphold the freedom value in his teaching as compared to the communication value. While he acknowledged that definitions can also be used in the creation/discovery of concepts, he emphasized this was "mostly done in research" and not typically relevant to his classroom teaching. He explained one tension between sharing this disciplinary value and an obligation to the course to present definitions a certain way to maintain consistency for students (*individual obligation*) - "If we're using a certain textbook… I feel like I have to use whatever the textbook is using." Still, Julian shared that he exercised the freedom value in small ways in his teaching prior to the project. He shared that he sometimes replaces a traditional term with one he thinks will resonate more with students (e.g., "linear independence"

as “no redundancy”) with the caveat that he introduces the conventional term as well: “I still feel that I'm required to teach them the usual term as well, because I don't want to send them out into the world with a misunderstanding of, you know, what something is called.” That is, Julian also used traditional concept names to fulfill his obligations to students and to the discipline to promote consistency in concept names.

Activity Design. Because Julian felt obligated to uphold the communication value in his teaching (especially in comparison to the freedom value), we aimed to collaborate with Julian to design an activity that would showcase this value. At the time, he hoped to develop an activity around the Laplace Transform, one of the remaining key definitions in the course. However, he was unsure how to connect this definition to the communication (or freedom) value. In particular, he noted that in the initial teaching case studies shared, we had used the definitions of “prime” and “increasing,” which are intuitive subsets of familiar sets (primes within the natural numbers) or relate to their everyday meaning, whereas the Laplace Transform did not fit that mold. During the following focus group, we supported Julian in several ways to develop his activity so that it would better align with his desire to share the communication value. First, Author 3 shared an example from her Linear Algebra course in which she asked students to reflect on the name “orthogonal complement,” surfacing the communication value. Second, we paired Julian with another instructor who was also designing a Laplace Transform activity, to provide new perspectives during the discussion. Additionally, we encouraged both instructors to reflect on the concept name. We noted that while “Laplace” (a person’s name) may not provide much conceptual insight, the term “transform” points more directly to the heart of the concept, and what Julian described as the important part of the definition. Ultimately, Julian created an activity in which he asked students to discuss: (1) Why is it useful to give the Laplace Transform a name?, (2) Why do you think we call it a “transform”?, and (3) What are the ways that the Laplace Transform transforms something into something else? These collaborative supports helped Julian recognize ways to align his disciplinary obligation to uphold the communication value with the design of his Laplace Transform activity.

Alignment with Professional Obligations. Julian reflected on several ways that implementing the activity fulfilled his professional obligations. He emphasized that the activity elevated a potentially new obligation to himself as an instructor and to his students to make the course more interactive and fun (*interpersonal obligation*). He reflected, “it was surprising, the class kind of erupted in discussion.” He later added: “it was the best part of the class. The rest of the class felt kind of dry and boring compared to that because... I think the students had fun, I had fun.” Julian also explained how his activity supported other professional obligations. He recounted one student’s insight as he explained it fulfilled his obligation to share the communication value (*disciplinary obligation*)*:* “One student said something which I thought was interesting. He said, ‘well, if we didn't give things like this a name it would be like none of us have names and then we would just have to refer to each other, you know, without names, which would be really difficult.’ So I thought that was really a good answer.” The activity simultaneously addressed Julian’s obligation to support students in deepening their understanding of the concept itself (*individual obligation*)*.* He said, “I think the students will remember the Laplace transform and its properties more deeply now - like it'll be something that they've actually thought about. And it may help them in the future when they recall what is the Laplace transform and they'll think, ‘oh, yeah, that's that thing that transforms all sorts of things into something else that's useful.’”

Because the activity aligned with multiple obligations (*disciplinary, interpersonal, and individual*) Julian expressed a commitment to implementing similar activities in future courses. In particular, he noted that such designs would be "super easy to incorporate" when the name of a concept is chosen to convey meaning (e.g., Laplace Transform, complementary solution).

Drew's Activity: Responding to Tensions between Design and Obligations

Drew's Disciplinary Obligations. Drew desired to share different aspects of the communication value in his teaching (*disciplinary obligation*), depending on the context and audience. Across all his teaching contexts, he explained that definitions are "to get [students] to understand and reason about a concept." He distinguished between two kinds of definitions: "the short but less useful version of a definition and then the more intuitive, less precise version," using the epsilon-delta definition of a limit and its informal counterpart as examples. His choice of which version to teach depended on the course context and the needs of the students (*institutional* and *individual obligations*). In some undergraduate settings, he felt it was important to teach both: "And I try to impart to them that this is a formal thing we have to do it for these reasons, but here's maybe the useful thing that you do instead that is in itself some kind of definition, just not the usual mathematical kind, perhaps." He felt formal definitions "need to be supplemented with the informal stuff - to get students to the point where they can appreciate what the formal definition was for." In this sense, he felt a consistent disciplinary obligation to showcase how more intuitive versions of the definitions communicate conceptual meaning, and in contexts where formal definitions were expected (such as proof-based courses), he also felt obligated to the discipline to connect that meaning to formality.

While Drew felt consistently obligated to share the communication value through his teaching across different levels of courses (albeit in different ways), he sometimes felt obligated to share the freedom value, but mostly in upper-division courses. He shared an instance while teaching Abstract Algebra prior to his involvement on the project when he felt this obligation. The course textbook defined rings as not having an identity element. "And that was sort of very new to me," he reflected. "I gave them a little five-minute discussion of like, here's why we're doing it this way. These are the advantages. Not everyone does it this way. It's sort of arbitrary what the word can mean." In this instance, he felt obligated to convey to his students that definitions are choices and that there is freedom in how mathematical objects are defined.

Activity Design. Because of his professional obligation to the discipline to share the communication value, Drew wanted to develop, with our support, a classroom activity that would highlight this value. He especially wanted students to see definitions as a packaged way of expressing the main idea. He expressed interest in this after we shared a teaching scenario in which Author 2 supported her students to notice the idea of "increasing" first, and then supported the students in recognizing how precision supports clear articulation of that concept. Drew remarked, "I thought it was cool, this [activity] got the students to think about the level of precision in language that they're taking in and the way they're thinking compared to the way a textbook reads."

Drew initially began designing an activity for his current Calculus I course, centered on the definition of Riemann integration. He explained that he wanted to show his students the velocity graph for a car and then ask how far it went. He thought this would get them to "confront their intuition for like distance – time times speed equals distance – just doesn't work here because there's a curve". He then intended to support students in visually seeing how partitioning the interval could make better approximations, and then connecting this process to the definition by supporting them to see that this process "is a limit," but just one that "looks very different from

the limits we've done throughout the course." He wanted to further develop this activity to share the communication value in the sense that "this definition is a catchall uniform way to talk about the different ways of doing the same thing" and that it "[wraps] these different choices of how you might do this area approximation into one definition".

Tensions with Professional Obligations. However, Drew experienced several tensions between his task design and his professional obligations. First, he explained that he typically avoids rigorous definitions in this course, keeping things "very pictorial and heuristic-based." His students, who were primarily first-year engineering majors, wouldn't "appreciate too much rigor" (*individual obligation*). Yet, Drew thought sharing this aspect of the communication value would require linking the visual and intuitive work to a formal definition (*disciplinary obligation*). Without this connection, he felt the activity would not align with the value he was trying to promote. With this connection, he felt he would not fulfill his obligation to his students to provide meaningful coursework for them. Additionally, Drew had an obligation to stay in step with the course's tight coordination, and he did not feel free to change the pacing or topics (*institutional obligation*). From Drew's perspective, continuing to develop this activity would not fulfill his obligation to the coordinator and other instructors to offer a uniform experience for their students.

Responding to Tensions. For these reasons, we encouraged Drew to shift his focus to an activity for his upcoming Abstract Algebra class in which he felt (a) a greater sense of obligation to share the formal versions of the definitions with his students (*disciplinary obligation*) and (b) a greater sense of freedom in the content, pacing, and structure of the course (*institutional obligation*). This suggestion seemed to constructively respond to this tension as he shared, "I'm definitely more excited about not shoving something into calculus" and "I was trying to squeeze something into calculus where it maybe doesn't quite fit." In this case, collaboration did not eliminate tensions but instead supported Drew in recognizing a more fitting context where his obligations and design could be more aligned.

His abstract algebra activity focused on the concept of group isomorphism. Drew described his plan: "My tentative plan is to give them an informal definition of group isomorphism as two groups being fundamentally the same but looking different." He would begin with similar things from other math contexts such as congruent geometric shapes, different factorizations of polynomials or integers, or games like tic-tac-toe versus choosing three numbers that sum to 15. He planned to give students pairs of isomorphic finite groups and ask them to explain why they thought the groups were isomorphic. He anticipated that students would come up with the idea of pairing elements, and then he would then ask them to try write a formal definition. Finally, he would present a formal definition and discuss why it takes the form that it does. This activity appeared promising because it might allow Drew to meet several of his teaching obligations. It supports the communication value by illustrating how a formal definition can precisely capture the central idea of isomorphism – that two groups behave the same way – while also supporting the freedom value by allowing students the experience of crafting a definition (*disciplinary obligation*). It also aligned with his obligations to students, especially his desire to support their understanding: "I think it will get them to think more deeply about the concept of isomorphism and experience a line of thinking they don't usually get to" (*individual obligation*). Drew remained excited and hopeful about implementing the activity in the following semester.

Discussion

Through sustained, instructor-centered collaboration, our project aims to improve undergraduate mathematics instruction. By applying a practical rationality lens and attending to

the professional obligations that shape instructors' choices, we note our collaboration with Julian and Drew successfully supported them in navigating the alignments and tensions between their professional obligations and the design of their activities. However, this navigation required careful examination and explication of the factors that could explain why instructors are not willing to implement certain types of instructional change. In our case, this meant consideration of our participants' professional obligations and their course learning goals and contexts. Julian's case was an example of a co-designed activity where his professional obligations were aligned with his course learning goals. Further, Julian's experience with both our collaboration and his activity resulted in a commitment to continued activity implementation post-intervention. In contrast, Drew's initial activity resulted in tensions with his obligations and thus caused reluctance to implement his activity. We renegotiated the design with Drew to situate the activity in a context that aligned with – rather than put in tension – his professional obligations.

Moreover, we echo Johnson et al.'s (2025) note that professional obligations depend on the context of the particular course. Our work points to how this can be the case in two different ways. First, tight course coordination and time concerns deterred deviation from pacing and content coverage. While research on coordination has positioned it as a means to support professional development (e.g., Martinez et al., 2021), our findings show that in some cases, coordination may stifle instructional innovation. Second, as we anticipated when entering the project, the instructors did perceive the values related to definitions to be important to the discipline of mathematics. However, consistent with Rupnow and Randazzo (2023) we note that valuing something within one's discipline does not imply instructors find it necessity to share it in teaching across all levels. This raises questions about how mathematics is portrayed and how mathematicians want to portray mathematics – if instructors commonly wait until students are in upper-division courses to share notions of freedom, students who persist in the math major may expect and desire less freedom and be uncomfortable when given more, just as students who desire to think flexibly and creatively may leave mathematics before that creativity is incorporated.

Why Pursue Graduate Studies in Mathematics? Insights Into Motivation From Personal Essays

Sophia Towle
University of New Hampshire

Orly Buchbinder
University of New Hampshire

Deciding to pursue graduate study is a pivotal step in students' academic and professional trajectories. However, limited research exists on the motivations for applying to mathematics graduate programs. To address this gap, we analyzed 74 personal statements, in which applicants articulate their motivations, goals, and experiences, submitted as part of applications to master's and doctoral programs in mathematics and statistics at a mid-sized research-intensive university (2015–2024). Using qualitative coding with AI-assisted analysis, five key themes emerged: pursuit of knowledge, research aspirations, career advancement, growth as a teacher, and appreciation of mathematics. Most applicants expressed multiple, overlapping motivations, often linking professional goals to disciplinary growth and research. A distinctive finding was the prominence of appreciation of mathematics, where applicants described joy and fascination with the subject as central to their decision-making. These results expand understanding of mathematics graduate decision-making and carry implications for recruitment, advising, and program design.

Keywords: graduate studies in mathematics, motivation, personal essays, AI-assisted coding

The decision to pursue graduate education in mathematics is a significant milestone in an individual's academic and professional journey. While there is a growing body of literature examining motivations for graduate studies in general, much of this work has focused on broad patterns across disciplines or within professional fields, and relatively little is known about this decision-making process in the context of mathematical sciences. Previous research has identified both internal and external factors that shape an individual's decision to pursue an advanced degree. For example, individuals are often motivated intrinsically by intellectual fulfillment and self-satisfaction (Incikabi, 2013; Kowalczuk-Waledziak et al., 2017). External motivations include career advancement, prospects of financial gain, and job security (Hinkle et al., 2014; Ivankova & Stick, 2007). Mathematics-related graduate programs prepare individuals for diverse roles in academia, research, and industry, yet little research has examined the factors influencing students' decisions to apply to these programs.

This study seeks to address this gap by examining the personal essays written by applicants to graduate programs in mathematics and statistics at a mid-sized public university with a high level of research activity in the Northeastern United States. By analyzing how applicants articulate their motivations, goals, and aspirations, this research aims to provide deeper insights into the factors shaping students' decisions to pursue advanced mathematics degrees.

Literature Review and Theoretical Framing

Research on pursuing higher degrees is extensive across fields; however, fewer studies focus specifically on mathematics. This review first draws on the general literature on motivations for advanced study, then turns to factors shaping decisions to pursue graduate mathematics.

Motivations for Pursuing an Advanced Degree

Motivations for pursuing an advanced degree are multifaceted, shaped by both internal and external factors (Incikabi, 2013). Internal factors influencing the decision to pursue graduate

degrees often center on personal fulfillment, such as intellectual challenge, self-satisfaction, and a sense of achievement (Incikabi, 2013; Kowalczuk-Waledziak et al., 2017; Teowkul et al., 2009). Students are also often motivated by research interests and prior academic success (London et al., 2014; Wiegerová, 2016). Additionally, self-efficacy, influenced by both internal and external factors, is critical in this decision-making process. Positive self-efficacy—bolstered by support from faculty, peers, and family—strengthens confidence in one's ability to succeed academically and professionally (Gibbons & Schoffner, 2004; Sherman, 2021).

External motivations typically center on professional gain, career advancement, job security, and higher salaries (Hinkle et al., 2014; Ivankova & Stick, 2007; Ng et al., 2011; Teowkul et al., 2009). Advanced degrees are typically required for entry into academia and some industry fields (Basalla & Debelius, 2014). Hence, career alignment is a strong predictor of graduate enrollment (Tennant, 2004). Additionally, different social pressures, including family expectations, peer influence, and mentor encouragement, often shape the decision to pursue graduate education (Brailsford, 2010; Hinkle et al., 2014).

Factors Influencing the Decision to Apply to Graduate School in Mathematics

While the literature on pursuing graduate studies in mathematics is limited, previous research has shown that this decision is shaped by a set of academic, social, and structural influences. These influences interact with broader demographic and social dynamics—such as race, gender, and socioeconomic status—to shape who ultimately pursues graduate study in mathematics. For example, students from minoritized groups face financial barriers, such as application fees, and underrepresentation in mathematics departments, contributing to feelings of isolation (McEldowney et al., 2024; Posselt, 2016). Gender and socioeconomic status similarly shape opportunities and have been shown to encounter systemic challenges that limit access to graduate mathematics (de Brey et al., 2021; Nevill et al., 2007).

Institutional and relational factors also play a key role. For instance, students at research-intensive universities are more likely to pursue graduate study due to greater access to resources and research opportunities (Zhang, 2005), which strengthens confidence and research identity (Hathaway et al., 2002; Willis et al., 2013). Faculty mentorship, supportive advising, and inclusive teaching practices further encourage persistence and application to mathematics graduate programs (Blaney & Wofford, 2021; Mu & Fosnacht, 2019).

Methods

The primary data consist of personal statement essays submitted as a part of the application process for mathematics or statistics graduate programs at a mid-sized public research university in the Northeastern United States. These personal statements are carefully composed essays in which applicants articulate their motivations, long- and short-term goals, and relevant research or professional experiences, offering insight into the factors shaping their decision to pursue advanced study. To recruit participants, we contacted applicants from 2015 through 2024. For those who consented, the second author—who serves on the admissions committee and has access to applications from these years—extracted their statements along with background information on gender, year of application, program, and citizenship status. Race/ethnicity was an optional field on the application and could not be collected consistently for all participants.

Participants and Data Collection

The participant pool for this study comprised 74 individuals who submitted applications to graduate programs in mathematics or statistics during the academic years 2015-2024. The data

set includes applicants that fall into four groups: (1) current students at the university (N=14), (2) graduates of the university (N=11), (3) individuals whose application was rejected by the university (N=20), and (4) individuals who were accepted but chose not to attend or who started their studies but withdrew prior to graduation (N=29). The degree programs (referred here as "mathematical sciences") included both doctoral and master's programs in Applied Mathematics, Statistics, and Pure Mathematics, a doctoral program in Mathematics Education, and a Master of Science for Teachers (MST). The breakdown of the participants' data by program is specified in Figure 1 in the Results section. Out of these participants, 41 identified as male, 32 as female, and one did not specify. Additionally, 46 were U.S. citizens, 25 were not, two had dual citizenship (one of which was the U.S.), and one did not specify.

Data Analysis

We employed qualitative methods to identify applicants' motivations for pursuing graduate education in mathematics or statistics. The data analysis was completed in two stages: codebook development, followed by AI-assisted coding (Butler & Buchbinder, submitted; Dunivin, 2024), which aided in handling the large volume of qualitative data.

Codebook development. First, we manually developed a codebook of participants' reasons for pursuing advanced study in mathematics. The first author used open coding and the constant comparative method (Patton, 2002; Strauss & Corbin, 1998) to analyze a subset of 16 essays (21.6%) and generate preliminary codes for explicit and implicit motivations in the personal essays. These codes were refined into broader categories with clear definitions and illustrative quotations. This process yielded five themes: Knowledge Pursuit, Career, Research Aspirations, Growth as a Teacher, and Appreciation of Mathematics (Table 1).

Table 1: Thematic codes, definitions, and examples of applicant motivations.

Code	Description of Code	Example
Knowledge Pursuit	Applicants emphasize intellectual growth, expressing a desire to expand their mathematical understanding or develop specific skills, whether theoretical, problem-solving, or applied.	"Upon admission, my primary goals would be to understand the methods by which mathematics is applied and then utilize those methods in my study of physics."
Research Aspirations	Applicants describe motivations centered on engaging with the research process in graduate studies, such as designing studies, investigating questions, or contributing to scholarship.	"My immediate goal in continued graduate work includes gaining more research experience, as I currently have less experience than I would prefer."
Growth as a Teacher	Applicants aspire to become stronger educators, inspire students, address mathematical anxiety, or improve pedagogy. This code is more focused on instructional development rather than obtaining a teaching position.	"I want to get a PhD in Math Education to find techniques to assist a larger number of students to enjoy and appreciate the beauty of mathematics."
Career	Applicants explicitly tie graduate study to professional outcomes or a job goal, such as becoming a professor, researcher, or analyst.	"Becoming a professor has been a goal of mine for a long time, and that is the ultimate goal of getting a PhD for me."

Appreciation of Mathematics	Applicants express joy, fascination, or admiration of mathematics—highlighting its beauty, creativity, or elegance. Points to affective and aesthetic dimensions of engagement with the discipline.	"My biggest motivation for pursuing a graduate degree is my love and appreciation for mathematics. This subject has pushed me out of my comfort zone and has given me an outlet to demonstrate my creativity."

AI-assisted coding. Following the development of the initial codebook, an AI-assisted coding workflow was utilized (Butler & Buchbinder, submitted; Dunivin, 2024). For ethical considerations and in accordance with IRB approval, a temporary feature of ChatGPT was used. This means that the data was not used to train a large language model and is automatically erased from the system after 30 days. All essays were anonymized before the analysis. This use of AI was included in the participant consent form.

First, we designed a preliminary AI prompt, instructing AI to apply the codebook deductively to the 16 statements (21.6%) that the first author had already manually coded. We compared the AI-generated codes to the researcher's original codes. Based on the results, we corrected the prompt and reapplied it to the same data. This iterative process of prompt refining and applying to coded data continued until a satisfactory level of agreement between the human coder and AI was achieved, with a Cohen's Kappa of 0.83, representing a strong level of agreement (McHugh, 2012). With this level of intercoder reliability established, we applied the finalized prompt to have AI code the remaining personal statements with the five codes (Table 1). Then, the researcher blindly coded another 16 statements (21.6%) coded by AI and compared the results. There was almost perfect agreement between AI and manual coders, with a Cohen's Kappa of 0.89 (McHugh, 2012). In both manual and AI-assisted coding, each theme was counted only once per essay, regardless of how many times it appeared. This allows us to associate each applicant with the set of themes in their essay, and each theme with the number of applicants who mentioned it in their essay.

Results

Analysis of the 74 personal statements resulted in a total of 252 codes across all essays. On average, each essay was coded approximately three of the five codes, indicating that applicants typically cited multiple reasons for pursuing a graduate-level mathematics degree. All five themes were present across applicant types, degree levels, and programs, though the prevalence and emphasis varied. Results for each code in each major are represented in Figure 1. We turn now to summarizing each theme. Due to space constraints, the results section focuses on the context of each code across all essays rather than on detailed subgroup analyses.

Across the essays, the *knowledge pursuit* code was the most prevalent motivation (24.6% of total codes) across most programs, as shown in Figure 1, appearing in 62 personal essays (~84% of applicants). Some applicants with this code shared eagerness to deepen their theoretical foundations, often citing specific advanced coursework, such as abstract algebra, set theory, and analysis (e.g., "I would like to continue my education in Bayesian Statistics as well, which is one of the many reasons that I am seeking admission.") While other applicants framed their learning as open-ended exploration, curious about topics they had not yet encountered (e.g., "My long-term objectives are to expand my knowledge, likely in ways I have not yet imagined.") Overall, the knowledge theme highlights applicants' view of graduate study as an opportunity to expand and deepen their understanding of mathematics.

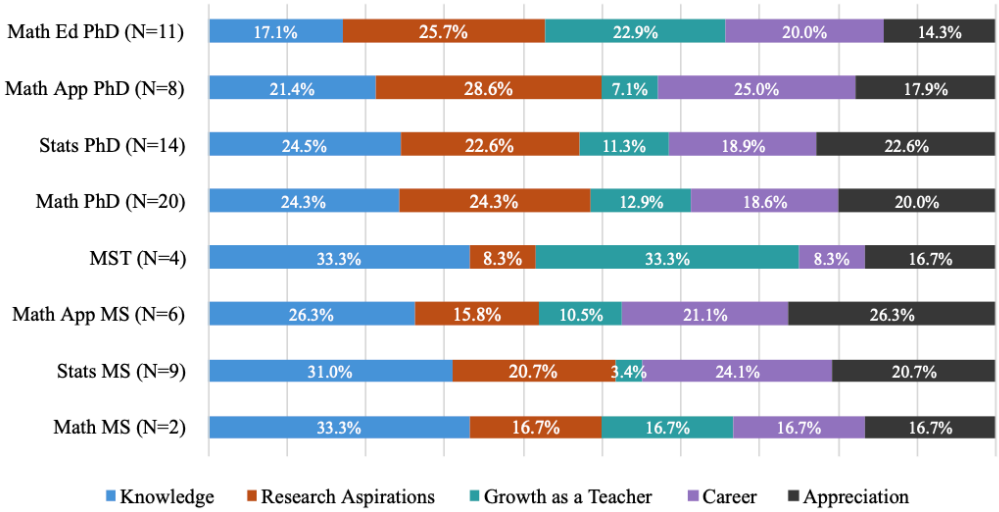

Figure 1: Distribution of codes by program (MS and PhD).

The next most common theme was *research aspirations* (22.6% of total codes), present in 77% of essays, but more prominent in doctoral applicants (Figure 1). Several applicants described a strong desire to engage in research in graduate studies, some referencing prior independent or guided projects and expressing intentions to continue such work in graduate school. For example, one applicant wrote, "I would very much like to continue research in mathematics." In contrast, others emphasized their goal of gaining new experience with research in a specific area, either emphasizing a broader ambition to contribute meaningfully to the field (e.g., "My long-term objectives are to discover and contribute to meaningful work and to do my best to offer something special to a field full of great thinkers,") or citing specific questions or area of interest. For example, one applicant stated:

> The experiences that I have from tutoring, teaching, and researching have sparked my interest in studying and seeking to improve math education. I am interested in answering questions like: Should the learning of probability and statistics be given more emphasis in high school? How can we improve students' mathematical discourse, in particular, oral communication? How much should we value our students' mathematical discourse? How can we improve students' mathematical reasoning?

Overall, this theme underscores applicants' curiosity and proactive engagement with mathematical inquiry.

In the personal essays, several applicants (~68%) also expressed a desire to pursue a graduate-level degree to achieve specific career goals. The *career* code captured applicants' descriptions of their long-term professional aspirations and represented 19.8% of the total codes. For example, one applicant wrote, "My long-term objective is to be a tenured professor of mathematics at a university so that I can conduct research alongside other mathematicians and encourage young people to engage with mathematics," implicitly highlighting how graduate study serves as a stepping stone toward this goal. Many applicants aimed for academic careers that combine research and teaching at the college or university level. Others emphasized particular fields they hope to enter and how the degree would equip them with the expertise needed to be successful (e.g., "This [MS in Statistics] will provide the foundation I need to contribute to development of soccer analytics.") Across essays, several applicants framed graduate school as integral to their broader professional goals, providing the skills, knowledge,

and experiences necessary to make meaningful contributions to their chosen field, as one applicant noted: "I firmly believe that a PhD program will enable me to delve deeper into the field, expand my knowledge, and become a successful university professor."

The *growth as a teacher* code appeared least frequently (13.1% of total codes) in applicants' personal statements, present in 44.6% of them, yet still represented in nearly half of the sample. Applicants with this code expressed a commitment to improving pedagogical practice, inspiring students, and addressing barriers such as mathematics anxiety during their graduate studies. Many reflected on past teaching experiences and the challenges they faced. For example, one applicant described the difficulty of motivating students who were held back by fear of mathematics:

> Over the years of teaching, the biggest challenge has been motivating the students to understand the lessons and see the importance of mathematics. I have seen many intelligent students who I know can be good with math but are afraid of math...I aim to find methods to reach as many students as possible. It is important to me to find teaching techniques to at least lessen the fear of math for those who are afraid.

Other applicants emphasized broader teaching goals, such as making mathematics more inclusive (e.g., "My personal teaching goal in all of my math courses is to make math accessible to all students.") Some focused on strengthening their own mathematical knowledge to better support students (e.g., "I believe [the MST program] will be beneficial for my students, in that I will have a deeper understanding of topics I present to them.") Overall, this theme was most prominent in Mathematics Education-focused programs (MST and Mathematics Education PhD), as seen in Figure 1. However, it was present across all programs, as many applicants viewed graduate study as an opportunity to develop as educators capable of creating supportive, engaging, and effective learning environments.

Similar to the career code, the *appreciation* code appeared in 67.6% of personal essays and accounted for 19.8% of total codes, across all program applicants (Figure 1). While many applicants discussed professional goals, several emphasized a deep, sustained enthusiasm for mathematics itself. They described formative experiences that sparked their interest in mathematics—from early problem-solving activities to noticing mathematical patterns in nature and art—highlighting the intellectual stimulation and challenges the discipline provides. For some applicants, this appreciation served as a core motivation for graduate study, as they explicitly linked their pursuit of graduate education to this passion (e.g., "My biggest motivation for pursuing a graduate degree is my love and appreciation for mathematics.") Others conveyed it more implicitly. As in one essay:

> I feel mathematics brings out some of the qualities I admire most in myself. I am captivated and thrilled by the constant challenge math provides and I experience a profound curiosity from within that demands the understanding of a concept, solving a problem, or writing of a satisfying proof.

These expressions of intellectual curiosity and motivation illustrate how a genuine appreciation for mathematics can drive applicants' decisions to pursue advanced study.

Discussion and Conclusion

This study provides insights into the under-researched topic of the motivations of individuals for pursuing graduate studies in mathematical sciences. Across 74 personal statements of individuals applying to master's and doctoral programs, five primary reasons for applying to graduate school emerged: Knowledge Pursuit, Research Aspirations, Career Goals, Growth as a Teacher, and Appreciation of Mathematics. These themes align with and extend prior research.

Consistent with existing literature, applicants' essays reflected both internal and external motivations. The prominence of *knowledge pursuit* and *research aspirations* suggests that mathematics applicants tend to frame their decisions around intellectual growth and scholarly engagement (e.g., Teowkul et al., 2009). *Research aspirations* as a reason for applying to graduate school was more prominent in PhD applications compared to master's, underscoring the appeal of academic research but also the differences in future professional trajectories (e.g., Wiegerová, 2016). As in other fields, *career* motivation was also frequently mentioned (Incikabi, 2013; Kowalczuk-Waledziak et al., 2017). However, in our study, the applicants often described career goals as integrally tied to knowledge pursuit and research aspirations rather than a stand-alone objective. Many applicants envisioned careers in academia, highlighting the link between mathematics graduate education and pathways into teaching and research (Tennant, 2004).

The theme of *growth as a teacher*, though less frequent, was apparent. Consistent with previous findings, applicants described a desire to improve their pedagogical practice (Kowalczuk-Waledziak et al., 2017). While this theme was most prominent among applicants in education fields, such as the Master of Science for Teachers and PhD in Mathematics Education, it appeared in applications across all disciplines, with the lowest being Statistics MS (Figure 1). Many individuals articulated a goal of addressing classroom challenges they had encountered in either formal or informal settings, and expressed a commitment to making mathematics more accessible. This suggests that for some applicants, graduate study is not only about advancing their own expertise but also about transforming their role as educators.

The novel emergent theme was a*ppreciation* of mathematics. Although prior research has identified intellectual curiosity (London et al., 2014; Teowkul et al., 2009) and personal fulfillment (Kowalczuk-Waledziak et al., 2017) as drivers of graduate study, these constructs only partially overlap with the present findings. Applicants who expressed appreciation often framed mathematics as a source of "beauty" and intrinsic value. This deep-seated passion frequently co-occurred with other motivations, indicating that research engagement and career planning are often interwoven with an enduring appreciation for the discipline itself.

Our findings help broaden understanding of applicants' decisions to pursue graduate degrees in mathematical sciences, showing that these decisions are driven by a complex interplay of reasons. Applicants view themselves as future professionals and members of a disciplinary community tied to knowledge, research, teaching, and appreciation of the field. Understanding these motivations can inform targeted recruitment, advising, and mentoring strategies. In practice, these results can guide admissions committees, advisors, and program designers by illuminating the values and aspirations students bring into their graduate studies.

Some limitations should be acknowledged. First, the dataset is drawn from a single mid-sized public research university, which may limit the generalizability of the findings across institutional contexts. Applicants' personal statements also reflect self-presentation strategies shaped by the admissions process; motivations expressed here may be idealized or selectively emphasized. Our study is ongoing, as we continue to investigate how these motivations differ across demographic groups and programs. Future research should also examine how these motivations shift as students progress through graduate school.

Additionally, we aim to understand the types of past experiences—whether positive or negative—described by the applicants in our study that shape their decision to pursue graduate studies in the mathematical sciences. Furthermore, investigating how mathematics identity interacts with these motivations may provide deeper insight into the pathways that lead students into advanced study in the discipline.

Ontology—the recognition or erasure of ways of being—is a justice issue in mathematics, intersecting with race, gender, sexuality, and disability. Despite growing scholarship on liberatory ontologies in mathematics education, little is known about how such paradigms might be enacted in postsecondary contexts, or how trans mathematics-doers experience ontological tensions uniquely. We address this gap by analyzing a mathematical representation of trans experience created by a transfeminine, graduate student of color in mathematics, and the ontological tensions it draws from us as trans mathematician-researchers. Our findings identify ontological erasure, disembodiment, and categorization as features of mathematics that conflict with trans ways of being. We propose ontological possibilities for postsecondary mathematics that affirm trans and other marginalized realities, and invite further exploration of postsecondary mathematics as a site for ontological justice.

Keywords: ontology, trans mathematicians, gender, equity, embodiment

Ontological Justice in Mathematics Education: Literature Review and Research Aim

Settler colonial paradigms embrace dualist framings, such as mind/body, human/nature, and man/woman (Kovach, 2021). These dichotomies may perpetuate justice issues related to ontology (how ways of being are recognized or erased). For example, settler colonial dichotomies related to sex and gender have historically framed Indigenous diversity in sexuality and gender as primitive (e.g., Morgensen, 2010) and been used to punish Black people through violations of their gendered and sexual self-definition (e.g., hooks, 1981).

Settler ontologies underpin dominant views of math, reinforcing marginalization by race, gender, sexuality, and disability (Butler, 2024; Gutiérrez, 2017; Martino & Cumming- Potvin, 2018; Westby, 2021). For example, math is framed as an intellectual pursuit, which is valorized in the hierarchical dichotomy of mind and body. Societal portrayals of Black people as primal and hypersexual rather than intellectual (McNeill & Jefferson, 2024; Strings, 2020) enact the mind/body and human/nature dichotomies, shaping dehumanizing conditions in math education, the educational outcomes of which perpetuate Black dehumanization. (McNeill & Jefferson, 2024; Joseph et al., 2019). Cultural ways of being can also be marginalized through engagement with math content. For example, since math is often construed as intellectual, its teaching can sideline physical and spiritual presence that is vital to Indigenous ways of knowing (Gutiérrez, 2017). Similarly, binary parities in math can naturalize cisheterosexuality to alienate queer students whose being is implicitly construed as mathematically illogical (Leyva et al, 2022).

A growing body of research theorizes diverse ontological possibilities in mathematics (e.g., de Freitas & Sinclair, 2013; Gutiérrez, 2017, 2022). For example, seeking to honor materiality and embodied knowledge in school mathematics, de Freitas and Sinclair propose teaching the number line as an elastic line that can be grabbed and stretched "so that it brings forth an infinitude of numbers that were imperceptible a moment earlier" (p. 465-466). At the postsecondary level, emerging scholarship in mathematics (e.g., Ardila-Mantilla, 2016; Paton,

2025; Cheng, 2025) integrates mathematical and relational ways of being and knowing to advance equity. For instance, Paton challenges both the mathematical and social value of equality, framing category theory as a paradigm for equivalence that embodies equity. These emerging disruptions of dominant mathematical ontologies reflect a demand for liberatory ontological possibilities in postsecondary mathematics education research.

Ontological tensions can be particularly salient for trans[1] people, as we navigate gendered societal assumptions and expectations that are often incongruous with our internal realities. However, research knowledge about trans ontologies in mathematics is limited. Two studies of trans experiences in mathematics exhibit ontological themes, but report on social dimensions of undergraduate contexts (e.g., gendered assumptions of mathematics ability, positive experiences in collaborative learning environments; Cassiday, 2019; Kersey & Voigt, 2021). For example, Kersey and Voigt asked students to create graphs of their trans mathematics experiences with axes representing masculinity/femininity and cisgender non/conformity. However, they did not examine how students' trans being shaped their engagement in the mathematical task.

Ontological tensions can be a generative and powerful informant for liberatory ontological possibilities in mathematics education and beyond (Anzaldúa, 2002; Gutiérrez, 2012, 2016; Myers et al. 2023). Towards theorizing ontological possibilities, we draw from a study of trans mathematicians' experiences, centering AT, a transfeminine graduate student of color. We analyze a mathematical representation of her intersectional experiences as a trans mathematician, queering the researcher–participant boundary by examining resonances with our own ontological experiences (Heckert, 2016; Nash, 2016; Rooke, 2016) as trans mathematicians. We pursue the research question: How does AT's representation illuminate, and invite us to collectively inhabit, generative ontological tensions between mathematics and transness?

Theoretical Perspectives

We ground our work in gender theory (Butler, 2011), queer theory (e.g., Muñoz, 1999) and new materialist ontologies (deFreitas & Sinclair, 2013). Queer theory critiques and destabilizes sex and gender binaries in culture, society, and politics to "offer alternative ways of thinking and performing in the world" (Voigt, 2022, p. 4). However, alternative, liberatory ways of performing gender are not free from embodied and political realities. Addressing common misinterpretations of "gender performance" (Butler, 2002) as independent from corporality, Butler (2011) prompts us to consider how the sexed body is socially constructed. Bodies "only appear, only endure, only live within the productive constraints of certain highly gendered schemas" (Butler, 2011, p. x) and become intelligible only under certain conditions. The act of imposing intelligibility to the body as either male/man or female/woman creates a category of being which is unintelligible by dominant society, fueling (trans) oppression through limited social and political recognition (Butler, 2011; The White House, 2025). This societal exclusion from intelligibility defines "foreclosures and repressions that constitute the discontinuity and incompletion of the [trans] subject" (Butler, 2011, p. 141), framing some bodies as "unthinkable, abject, unlivable bodies" (p. x). Relationality between the body and society also extends past gender: its interconnections with race, in particular, structure which bodies (often white ones) are rendered legible in their rejection of cisnormativity, and which (often non-white bodies) might *disidentify* with a politicization of gender that presumes whiteness as normative (Muñoz, 1999). We leverage these ideas of gendered, raced, bodily intelligibility to consider how trans ontology may resist governance by political-mathematical cisgender binaries, especially as experienced by

[1] We use *trans*, abbreviated from transgender, to reflect language used within trans communities.

AT, a trans mathematician of color. Drawing from Muñoz's (1999) disidentification as "productive interventions in which politics are destabilized" (p. 102), we name this ontology as a gendered experience in a perpetual state of flux between (dis)embodiment and (dis)identification.

We engage new materialism to deepen our exploration of mathematics as a dis/embodied, dis/identified gendered experience. New materialism frames matter and agency as intertwined and cocreated (deFrietas & Sinclair, 2013). Providing both non-human and human examples, deFrietas and Sinclair contend that the uncertainty principle in quantum physics demonstrates that "indeterminacy is intrinsic to matter" (p. 460) and similarly "the [human] body is…[not] passive matter upon which culture is inscribed... it is centrally implicated in the constitution of itself and society" (p. 460). So too is matter's relationship to mathematics. The body can be viewed as "an assemblage of human and non-human mathematical concepts" (p. 453) that, in turn, resonates with and extends mathematical ideas. Recognizing how the body both creates and is constituted from mathematics provides a bridge between queer theory, mathematics, and ontology, creating mathematics and trans being as together fluid, ambiguous, and queer.

Methods

In alignment with the study's aim of legitimizing trans ways of knowing and being in mathematics education, our inquiry drew from queer and embodied methodological paradigms.

Context, Researchers, and Participants

This analysis comes from a larger study of trans mathematicians' experiences, inclusive of those who completed at least one year of a U.S.-based doctoral program in the mathematical sciences. In early 2025, we recruited participants through professional mathematics organizations that centered marginalized identities (e.g., Spectra, Lathisms, Sines of Disability). We selected 20 participants, prioritizing those with multiple marginalized identities. Our research team consists of five white trans people (two faculty, two doctoral students, and an undergraduate).

We selected our focal participant, AT (she/they/it), because their mathematical representation was uniquely evocative in its interplay between mathematical and trans ways of being. AT is a transfeminine graduate student of color who holds additional marginalized identities. AT was consulted about identifiability risks, and a draft was shared for her review.

While data were collected by the full team, analysis and writing were completed primarily by the first three authors. These authors identify as mathematicians, spanning graduate to faculty experience in mathematics. Queer methods embrace researcher subjectivity and blur boundaries between researchers and participants, establishing credibility through reflexivity (Heckert, 2016; Nash, 2016; Rooke, 2016). We leveraged our lived experiences as mathematicians to occupy this researcher-participant boundary. McNeill (they/them) is a femme trans man with a history of mental illness and disability. Davis (they/them) is a neurodivergent, nonbinary transmasculine graduate student. Black (she/they) is a queer, transfeminine, neurodivergent, able-bodied graduate student. The team acknowledges racial power dynamics inherent in white scholars drawing analytic conclusions from narratives shared by a participant of color. Informed by analytic autoethnographic methods (Anderson, 2006), we make our positionalities transparent throughout the study to acknowledge our subjective influence on the knowledge it produces.

Data Collection

Participant Data Collection. We conducted, recorded, and transcribed two 90-minute interviews over Zoom. The first interview explored participants' trans and mathematics histories. Afterwards, participants engaged in an open-ended, reflective exercise—to create a mathematical

representation of their intersectional experiences as trans mathematicians. The second interview asked participants to narrate their representation, and probed further into connections between mathematics, transness, and intersecting identities. We present AT's representation in Figure 1.

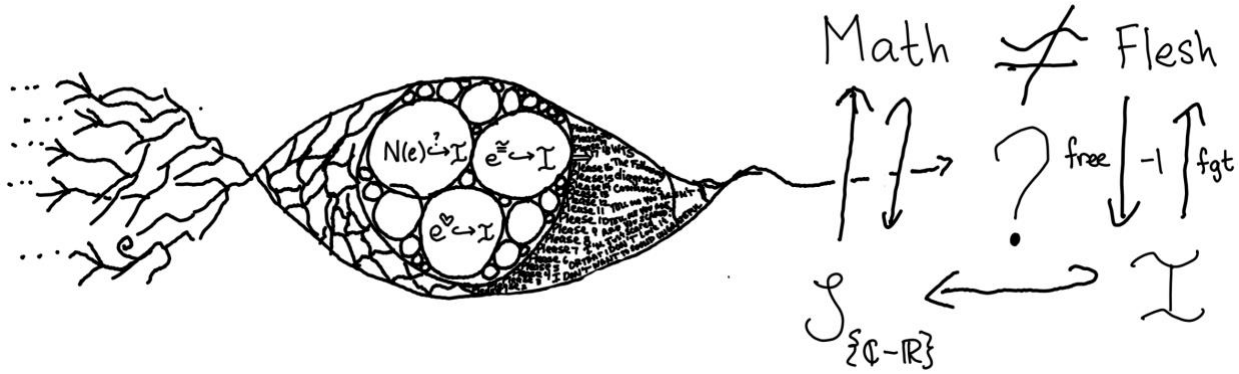

Figure 1. AT's mathematical representation of their intersectional experiences as a trans mathematician. AT's handwriting has been replaced by McNeill's to retain authenticity while protecting AT's anonymity.

We briefly explain AT's representation to contextualize later findings. The right side is a (potentially) commutative diagram. AT uses *I* to represent the self and conceptualizes the self as flesh with extra structure. There is a "free" map that includes the flesh into the self, and the forgetful functor maps the self to the flesh. The self is mapped injectively into an imaginary (the complex numbers without the real line) realm. Math is also included in the imaginary. On the left side is an eye, whose iris contains circle packings. The large circles pose possible injections of semi-mathematical objects (e.g., $e^{\heartsuit}$) into the self. Lines branching from the eye on the left represent both nerves and eyeliner. The right side of the eye contains the words "WTS [wish to show] The Following diagram commutes. TELL ME YOU AREN'T. ARE YOU FLESH? TELL ME YOU ARE. ARE YOU SCARED? I'M Just Scared. OR THAT I DON'T Love it. I DIDN'T WANT TO SOUND UNGRATEFUL" (capitalization in original). The right side of the iris is lined by 20 numbered instances of "Please."

Researcher Data Collection/Analytic Note-Taking. The last stage of data collection and first stage of analysis consisted of (embodied) analytic note-taking. The first three authors each read AT's transcripts alongside its representation. In alignment with our research question about ontological tensions we collectively inhabit, we each recorded our embodied experiences of engaging with AT's data (e.g., emotions, physical sensations), and the personal experiences and stories to which these embodied responses were attached, through in-line analytic note-taking. We intentionally brought awareness to our racial experiences and observations to mitigate race-evasive interpretations of AT's experiences. As empirical inquiry (Richardson, 1994; Richardson & St. Pierre, 2005), this writing externalized our thinking, fostering "adventure and experimentation" and bringing forward 'the unintelligible' (St. Pierre, 2018, p. 605) that conventional forms of data analysis often miss. We combined our notes into one document, AT's transcript augmented with researchers' reflections placed in their original locations. We color-coded each person's contributions to preserve the distinctness of our perspectives.

Data Analysis

Guided by queer and embodied methodologies' attention to researcher subjectivity, we conducted a reflective thematic analysis (Braun et al., 2023). To address the research question about how AT's narratives illuminate, and invite us to collectively inhabit, ontological tensions

between mathematics and transness, we first coded the augmented transcript for connections to ontology. We then identified collective thematic tensions. Guided by our positionality, we selected themes that were salient in AT's narrative rather than those driven mainly by researchers' reflections, preserving the intersectional complexity of AT's ontological tensions even when intersectional dimensions were not mirrored in the researchers' realities.

Findings

Analysis revealed three collective ontological tensions between mathematics and transness: mathematics is construed as real while trans people are construed as imaginary, mathematics is positioned as disembodied while trans people are made especially aware of their bodies, and mathematics is categorical in nature while trans self-understandings are often anti-categorical.

Imaginariness: "Weird Nonsense that has Implications… with a Capital 'I'"

AT's maps of the self and mathematics into non-real, complex numbers suggests a parity between the imaginariness of her being and mathematical truth. However, she witnessed a social validation of mathematics as real that she did not experience in relation to their own existence. Its sense of "not being real…, being imaginary, just that sense of unreality or being invisible" was sustained by the marginalization it experienced as a woman, trans person, and religious minority in a largely cisgender, male, secular field. They described frequently being "talked over" or having their bodily needs neglected through professional mathematics structures (e.g., conferences where they could not safely use the restroom, speaker dinners during religious observances). Interactions reinforcing this ontological erasure were largely unintelligible through a dominant mathematical lens, which failed to connect such experiences to AT's identities: "you can't repeat the social interaction in a double-blind exam or anything." Our resonances with AT's invisibility communicated implicit pressures to legitimize transness in math, questioning "What aspects of [my gender presentation] do I need to erase" (Davis) and noting that the lack of recognition for non-binary identities "positions me as non-real on both sides" (McNeill).

This gendered invisibility contrasts the invisibility of mathematics. AT recognized much of mathematics as "abstract nonsense" that was widely legitimized. Black noted, "to be not real in a mathematical sense carries a sort of intriguing depth,... vision, and excitement; meanwhile, to feel not real as a person… carries a mournful and sad heaviness,... disassociation or… disconnection." This represented a double standard, as McNeill commented:

> A lot [of] mathematics… prov[es] the existence of… things [that] are… not tangible… Things that are tangible, like the body, paradoxically, do not really exist in mathematics. The supposed objectivity of mathematics renders the subjectivity of the body invisible.

This double standard materialized through experiences of misogyny. AT described a traditional view that "mathematicians are discovering secrets of the universe," which evokes a sense that "math [i]s this higher power or perfect form of knowledge and logic" (Davis). AT characterized mathematicians holding this view as "super misogynistic… they're like, 'Yes, I'm better than you.'" This power imbalance renders mathematics as real and trans existence as imaginary. Yet, she described the field as "moving away" from this view: "the gays" in mathematics often said, "look at this weird little thing I have made… Can I show you my arrows?"—a framing that presents mathematics as a human endeavor and may open more ontological possibility.

(Dis)embodiment: "Does Everyone… Think about Flesh… as Much as… a Trans Person?"

AT's ontological tensions with the disembodied framing of mathematics stemmed from the interplay of three factors: her need for positive connection to her racialized, transfeminine body,

the abstract nature of her subfield, and her recognition that mathematical language often borrows flesh-related terms. Category theory uses many flesh-related words, which tempted her to force a mathematical understanding of her own body, as evidenced in AT's mathematization of their embodiment, considering the self as "flesh with extra structure in a monoidal category".

AT's reconciliation of (dis)embodiment in mathematics was both playful and poignant. For example, in their representation they denoted the "heart of a category" with the symbol ♡. They also described playing a game with non-category-theorists: "Is this a math word or am I bullshitting you?" using "body-related things" like "hearts", "skeletons", "cores", and "nerves." Black felt especially "tickled" to learn of category theory's "Theorem of the Heart". Despite these linguistic connections, AT's embodied experience remained mathematically unintelligible. Considering the heart of a category, she questioned, "[Are] these structures inside of me?" and lamented how "math isn't helping [her]… in terms of understanding [her] relationship to the flesh." Resonating with AT's sentiments, the authors noted that "I can touch a knitted sweater in a way that I can't touch my math homework" (Davis), which contributed to ontological disconnection as mathematicians who "experience the body only through metaphor" (McNeill).

AT's sentiments illuminate liberatory ontological possibilities of welcoming the body's subjectivity in mathematics. AT perceived that mathematicians' appeal to the body is neither a coincidence nor an accident. For example, they argued that ♡ is "much more indicative" of the essence of the heart of a category than the "abstract instructions" of the formal definition ("...the truncation above by zero and the truncation below by zero…"). Furthermore, AT noted that "people in math… lov[e] going on hikes and rock climbing… they're also connecting to their bodies even if they're cis[gender]," which she conjectured might represent a universal need among mathematicians to be more connected to their physicality. Moreover, McNeill noted that embodied subjectivity is inherent to mathematical thought: "I think with a piece of meat. We all do. How objective can meat be?" We collectively considered the political possibilities of recognizing such subjectivity. For example, AT noted that mathematics is "heavily funded by the NSA," an organization that placed their community under heightened surveillance. A more embodied mathematics might resist such forms of dehumanization.

Categorical (Un)Intelligibility: "This Doesn't Make Any God Damn Sense"

AT's visual references to math, flesh, and mathematical "unreality" illustrate its desire to categorize its world, identity, and mathematical experiences in logical ways. By representing itself in a commutative diagram, its intersectional trans experiences are described through sources and targets. This presents an ontological tension between what can be categorized and her intersectional trans experiences which defy logical structure and categorization.

For example, while discussing the non-equivalent relationship between mathematics and the flesh represented in her commutative diagram, AT explained "math is not flesh, it is sort of different… [I'm] trying to think about how I'm structuring my life." AT's attempt to "structure" her life category theoretically led to her questioning whether her diagram (and therefore herself) "commute up to a higher homotopy." Such sentiments represent AT's impulse to mathematize and categorize her body, self, and mind, which were shared by the authors. For example, Davis described a desire for gendered coherence, expressing frustration at not being categorized correctly in social interactions. They noted that their androgyny "doesn't read for people," which led them to wonder, "what cues am I missing?" In our trans experiences changing names, appearance, or pronouns also reflected the pursuit of intelligibility by cisgender society.

AT's attempts to categorize their existence, however, were in tension with the fluidity they embodied as a creative and gender-transgressive person. Later in the interview, she abandoned attempts to categorize herself, explaining that the difficulties of trying to represent herself mathematically resolved when she chose to treat the commutative diagram as poetry and to "not [be] super worried about the math." However, she recognized this approach opposed accepted approaches to mathematics: "if an actual category theorist saw this, they'd be like, what the fuck have you written?" AT's playfulness and creativity with conventional categorization was also reflected in her nonbinary gender expression where "ambiguity is some part of the point for me." For example, she described dressing in a more feminine way in mathematics contexts where "girliness is not allowed." Similarly, when discussing her pronouns, she described picking different pronouns to use on different days, or inviting fellow trans people to use he/him/his pronouns to refer to her exclusively when "it's funny", saying "If I'm wearing a ball gown, that's a 'he.'" The authors shared AT's desire for incoherency. McNeill expressed a desire to "live apart from the cisgender world," a nod to unintelligibility as freedom from dominant binary categorization (in mathematics). AT's abandonment of the rigor of her commutative diagram, thus, represents our collective search for mathematical freedom and unintelligibility as a tool for self-expression. Overall, AT's attempt to describe itself through the systems of category theory illuminates ontological tensions between its embrace of life as an unintelligible system and its desire for a life that can be described systematically through their field of mathematics.

AT's desires to use mathematics in ways that defied standard mathematical coherency illuminate ontological possibilities for trans affirmation. McNeill noted that "there is something delightfully metaphorical about questioning the existence or coherence of the self in relation to mathematics at higher dimensions" and compared this to aspects of physiology, such as the placebo effect, that "escape understanding." Black also highlighted how, as trans people and mathematicians, there is a "persistent push to interrogate and challenge and wonder about whether or not our existing models of the world are working for us." When existing models fail, we, as mathematicians and trans people, ask "what perceived limitations or assumptions do we have that we need to forget?" These desires explore the possibility of unintelligibility as a mathematical value, resolving ontological tensions between conceptualizations of mathematics as structure and trans realities that often revel in nonconformity and unintelligibility.

Discussion & Conclusion

AT's representation offers a pathway toward trans ontological justice in mathematics, extending theories of liberatory ontologies to reveal new possibilities in postsecondary contexts. Scholarship on ontological justice in mathematics education often seeks to disrupt settler colonial paradigms by contextualizing mathematical ideas within ecological and social imperatives (e.g., Gutiérrez, 2017). Yet, abstract mathematics, such as category theory, defies contextualization. AT's representation offers new directions for disrupting settler colonial, binary paradigms, reminding us that the materiality of the body—and the political contestations that shape its social signification—are ever present in mathematical inquiry. By recognizing "pure" mathematics as a social construction, AT positions mathematics as a flexible human creation whose ways of knowing and being can expand through embodied and social experience, revealing situated and partial truths; mathematics need not be an absolute truth to which our humanities must yield. AT's experiences also highlight that transness marks avenues for *dis*identification from settler knowledge production, illustrating ways of doing and teaching mathematics with decolonial intent. We call on mathematicians and researchers to explore how attending to students' ontological affirmation in mathematics can generate new and diverse educational possibilities.

Shore to Shore: Students' Progressive Mathematization of Null Spaces

Zachary Bettersworth
Western Kentucky University

Jessica Smith
Utah Valley University

Matthew Mauntel
Tarleton State University

This study explores how undergraduate students develop reasoning about the relationship between a matrix and its null space through progressive mathematization within an inquiry-oriented linear algebra context. Using a playful hallway map task, students engaged in a paired teaching experiment to investigate how modifying the number of rooms and hallways affects the dimension of the null space. We drew on a river journey metaphor to examine students' movement along and between shores of contextual or formal symbolic reasoning. Findings reveal a dynamic interplay between contextual reasoning and formal symbolic representations, as students moved fluidly between the realistic hallway context and matrix-based interpretations. Through successive horizontal and vertical mathematization, students gradually developed reasoning that approached a reinvention of the rank-nullity theorem. The results highlight the complexity of this journey and suggest further research into providing supports for instruction.

Keywords: Progressive Mathematization, Student Reasoning, Linear Algebra, Null Space

Inquiry-oriented instruction (IOI) is a student-centered teaching approach where the instructor investigates students' reasoning (Kuster et al., 2017). One source of materials for IOI is materials designed using Realistic Mathematics Education (RME) because it leverages realistic contexts, promotes the instructor acting as a guide, and is designed to take students from reasoning about a context to formal mathematical activity (Gravemeijer, 1999). Sometimes this transition might be seamless, where students might have developed a robust enough understanding within a context to begin reasoning outside of the context to general cases. Other times, students might bring in prior mathematical experiences on the topic and this transition might be messier. In these cases, students go back and forth between contextual and formal symbolic ways of reasoning to consider more general cases (Rasmussen et al., 2005). The result of discussing these different paths is a rich interplay where students can build off each other's knowledge taking them on a complex journey that traverses between developing understandings of realistic contexts and formal symbolic perspectives.

In this paper, we detail one such journey in a playful mathematics task designed to supplement the Inquiry-oriented linear algebra (IOLA) task sequence about subspaces (Andrews-Larson et al., 2023). The goal of the activity was to help students develop ways of reasoning about the relationship between a matrix and its null space by drawing on intuition developed in the context of school hallway maps. We present the results of a paired teaching experiment with students and highlight their complex journey of going between contextual and formal symbolic reasoning which ends with students approaching a reinvention of the rank-nullity theorem.

Theoretical Framework and Related Literature

The task sequence used in this study was developed drawing on RME design heuristics. Of particular interest are heuristics related to students' reinvention of concepts and the purposeful use of realistic contexts (Gravemeijer & Doorman, 1999). In such tasks, students move between a realistic context and formal symbolic reasonings through progressive mathematization. Treffers' (2012) progressive mathematization consists of two types of activity: horizontal mathematization and vertical mathematization. For Treffers, *horizontal mathematization*

involves "transforming a problem field into a mathematical problem" (p. 247), where *vertical mathematization* involves making progress within symbolizing more general notions of a concept. In this case, the ultimate goal is to move "from the world of life to the world of symbols" (Freudenthal, 1991, p. 41).

Oftentimes, however, students' progressive mathematization is more complex than simply developing intuition within a realistic context, transferring that to mathematical symbols, then formalizing concepts through those symbols. Unlike Treffers' conception, horizontal mathematization can also present itself as students going from formal symbolic ways of reasoning back to reasoning within a realistic context (Rasmussen et al., 2005). For instance, students could learn row reduction and how to interpret its results and then use this method to reconsider a previously examined context. Similarly, vertical mathematization can take place within a realistic context and is not unique to reasoning within formal symbolic mathematics.

Considering horizontal and vertical mathematization in these ways instead highlights how students can move between horizontal and vertical mathematization within and out of a realistic context. Students do not have to solely work within a given context then shift to and stay within formal symbolic reasoning for progressive mathematization to occur. Rasmussen and Keene (2019) used a river metaphor to highlight "places (islets) where students pause to engage various ways of reasoning…as they explore the river and progress in their mathematical journey." We expand on this metaphor by adding shores to the river which represent the realistic context and formal symbolic mathematics. As students progress down the river, students may choose to work within the context or formal symbols. Perhaps a student is trying to vertically mathematize on the formal symbolic shore but hit an obstacle stalling progress. That student can go back to the other side of the river, or back to reasoning within the realistic context, to anchor what they were trying to formalize within the context. These stopping points along or close to one shore act as opportunities for students to cross the river and horizontally mathematize a concept, where vertical mathematization occurs along one shore. This gradual movement down the river between and along the shores represents students' progressive mathematization.

In this paper, we focus on students' progressive mathematization of the relationship between a matrix and its null space. Research regarding null space specifically is limited, especially research focusing on students' concepts or understandings of null space. Two studies touch on student reasoning about null space, but mostly for other purposes. Wawro (2015) details one student's interpretation of the Invertible Matrix Theorem. This study is not about null space alone but does involve the student describing relationships between null space and other attributes of matrices or collections of vectors. Caglayan (2019) examines undergraduate students' classifications of subsets of various vector spaces as either subspaces or not. One of those subsets was the null space of some given vector space. There has been recent work exploring students' conceptual resources while reasoning about null space (Andrews-Larson et al., 2022) and the ways students are positioned while reasoning about null space in the context of the hallways task (Andrews-Larson et al., In Progress; Smith et al., 2025). Because student reasoning about null space is understudied, we use this topic as the subject of this research study. More specifically, we are interested in the ways students move between reasoning about null space within the realistic hallway map context and formal symbolic reasoning about null space. Our research question is: how do students develop their reasoning about the relationship between a matrix and its null space through progressive mathematization?

Methods and the Hallways Task

Methods of Data Collection

During Summer of 2024, our research team conducted a five-day paired teaching experiment (PTE; Steffe & Thompson, 2000) over Zoom with three participants enrolled in a differential equations course. The third author acted as the teacher-researcher for all five interviews, while the first and second authors took turns acting as the observer-researchers. While the teacher-researcher was engaged in the in-the-moment interactions with all three participants, the observer-researcher was taking field notes, or asking clarifying questions when needed.

When initially designing the study, our research team was curious if participants would position each other differently based on perceived experience with the content (Smith et al., 2025). This was relevant because two of the three participants (Henry and Tyler) previously completed linear algebra before the first interview. We focus our attention on discussions between Henry and Tyler because they represent two different journeys down the river of progressive mathematization. By the start of the fifth day of the PTE, all participants had completed the subspaces unit of the IOLA curriculum, which we refer to as the hallways task.

The Hallways Task

The hallways task has three parts (See Wawro et al., 2013). The first involves the notion of closure under linear combinations of camera data vectors, where 5D vectors represent paths from classrooms in the hallway map pictured in Figure 1. Participants reasoned about the set of camera data vectors that emerge from sending participants from room C back to room C as a set closed under linear combination. Participants referred to these paths as "loops", which became a common contextual term for this set of vectors. In Task 2, participants began to associate camera data vectors with room population change vectors by considering how many people move past certain cameras between each period. This association often led to a discussion of how a system of equations can be represented by a coefficient matrix. The span of the "loop" vectors resulted in a set of vectors that resulted in no change in population because they corresponded to a path that started and ended in the same room. Finding all the "loops" became a way for participants to conceptualize the null space. Finally, in Task 3, participants were provided with a 5 by 7 matrix and asked to create a new one-way hallway map that would correspond to this new coefficient matrix.

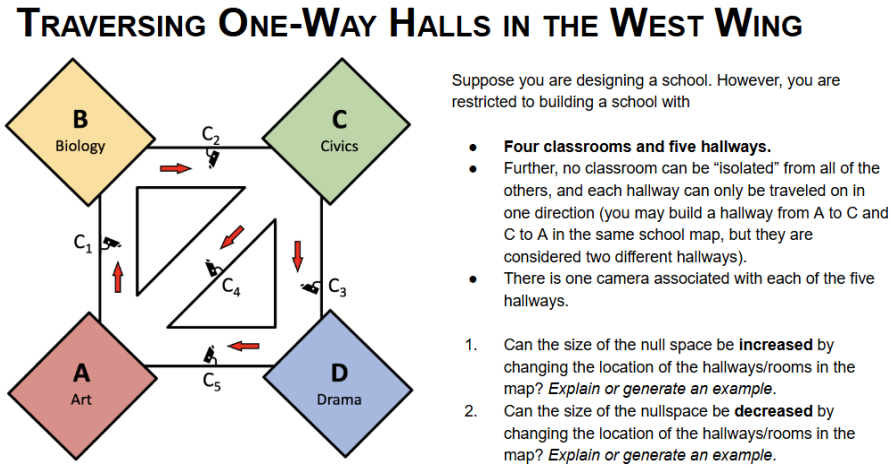

Figure 1. The hallway map from the hallways task sequence with the first Day 5 task statement.

Our team designed an additional task as a follow-up to the hallways task sequence stated at the right of Figure 1. Our initial design was related to the development of a playful math task (Ellis et al., 2024), where participants first attempt to change the dimension of the null space of the original coefficient matrix associated with the hallway map. Then, participants became "structural engineers" tasked with developing a new map where they could change the number of rooms and hallways to determine the impact this had on the dimension of the null space of the associated matrix.

Methods of Data Analysis

Our initial analysis of the data involved reviewing the Zoom recordings as a whole team. We began by noticing instances of collaborative reasoning between the pairs of the three participants. We then highlighted these specific excerpts as examples of collaborative reasoning individually, then coded these excerpts in pairs to develop our collaborative reasoning actions (Smith et al., 2025). We examined the ways participants made space for, acknowledged, or leveraged each other's ideas. For this paper, we reanalyzed the video data from the fifth day, focusing more on participants' mathematical reasoning. We noticed Henry and Tyler were both horizontally mathematizing (i.e., going between reasoning within the realistic hallways context and the more formal matrix representations) and looked to further explore what started this movement and what happened because of this movement. Note that we use the term "realistic context" to represent the context chosen by the designers of the task sequence. We examined two more salient shifts between realistic context and formal mathematical symbols, adding context by noting the catalyst for and results of these shifts. By doing this, we studied Henry's and Tyler's progressive mathematization.

Results

Part 1: Keeping the Number of Rooms and Hallways the Same

At the beginning of Day 5, participants were trying to change the dimension of the null space by generating a different hallway map with four classrooms and five hallways. Tyler was the last to share his hallway maps after some individual working time. Tyler's first map demonstrated his attempt to increase the dimension of the null space by increasing the number of loops:

> Unless I violated a rule I'm unaware of, I think I was able to decrease it by just decreasing loops, but I was not able to increase it. I thought I did, but then I noticed two of the loops just added together to be the third one. So…it's not actually a third independent vector…so I haven't really increased the span at all.

Tyler realized that he had not "increased the span" since the camera data vector that represented the "new loop" was a linear combination of the original two (e.g., <1, 1, 0, 0, 0> + <0, 0, 1, 1, 1> = <1, 1, 1, 1, 1>) as pictured in Figure 2. Next, Tyler described his success in decreasing the dimension of the null space by decreasing the number of hallway loops from two to zero:

> There's no loops here on the right. I just want to make sure this didn't violate any things…does there have to be one main loop? Do you have to be able to go throughout the school? Cuz obviously here you kind of get stuck at D, which that's no good. So, I don't know if that's against what we're doing here. If I changed any of them, I would get a loop…. I'm more confident in my inability to increase the null space.

Tyler's continual attention to the "rules" of the task, and his concern with violating them was an indication of his care in contextualizing his mathematical reasoning. It is interesting to note that the task states that students would be able to get from one room to any other room, but as Tyler said, "you're gonna get stuck" in room D. If one were to row reduce the coefficient matrix

associated with Tyler's map, there would be two free variables associated with loops that travel backwards on hallways, which is also "against the rules" of the task.

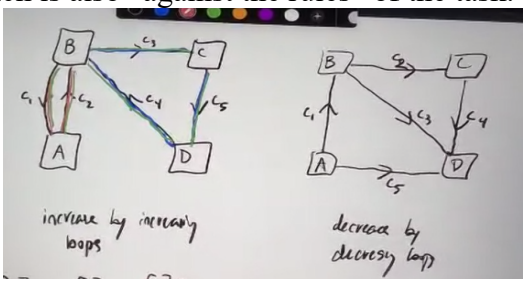

Figure 2. Tyler's maps with two loops (left - 2D null space) and no loops (right - 0D null space).

Tyler's contribution led to Henry discussing the number of rows and columns of the coefficient matrix, as represented by the number of classrooms and hallways in the map:

> I think I agree with Tyler, because if you think about the matrix representation then the most amount of linearly independent variables you can have is the number of rows that you have which corresponds to the room distributions. Since you have four rooms, then that means that you can only have four linearly independent variables. Then the amount of free variables would be the number of weights minus the number of independent variables. If we have five weights, then the most linearly independent variables you could have is four, then that would have at least one loop or something like that…I think that assumes though that it has to be onto, in which case, if it doesn't have to be then you could add more and more zeros.

Henry's approach of using the greatest number of pivots by comparing the number of rows to columns was accurate. However, when re-presented with Tyler's hallway map with no loops (see Figure 2), Henry struggled to reconcile the initial statement with his context-based interpretation of the dimension of the null space as a number of hallway loops. Henry went on to say, "I don't have a solution to my original problem, but the largest possible free space you can have is five, so you would have a 5D null space." This led to a discussion of a contextual interpretation of a matrix of all zeros, with Henry stating, "I'm not sure how to reconcile the matrix representation with the physical layout." Tyler goes on to respond:

> I think this is all just connecting to my sort of lingering interest in how we're actually making these things from matrices. Because it seems sort of convenient whenever there's like a -1 and a 1, like those pairings to just draw it like that. But I don't see what's like absolutely making us do it like that. Like I'm sort of thinking. Based on how we've been doing that would be no rooms and no, well not even. It would be like…a bunch of hallways to nothing.

Tyler appeared to be leveraging a zoomed-out perspective of coefficient matrices to question the impact of the restrictions placed on the entries of the coefficient matrix by the task sequence (e.g., the -1 1 pairs within each column). The group continued to consider what a matrix of all zeroes would represent in the context of a hallway map before working on the second task.

During this part of the task, we saw Tyler start his journey by reasoning within the hallways context, then horizontally mathematized by crossing the river to formal symbolic notation. This horizontal movement took the form of Tyler trying to generalize what he was noticing within the hallways context. Henry, however, started on the formal shore but could not make sense of Tyler's findings in relation to his more formal reasoning

Part 2: Changing the Number of Rooms and Hallways

For the second task, participants were positioned as structural engineers and allowed to make edits to the map (e.g., adding rooms or moving and removing hallways) and determine the impact this alteration had on the dimension of the null space. After Henry presented his initial map, he presented two more maps that had five classrooms instead of four:

> Tyler said something about adding rooms and I thought was interesting. So, thinking back to the matrix, I thought that would increase the amount of rows that you have…so then I drew the pentagon because that was the simplest geometry in my head to draw. So, then I was thinking about what would happen if you had no null space. So then according to this, you have five hallways and five rooms so then you have a square matrix, so then you could make something with no null space, so then I made the thing on the right.

Henry appeared to be saying that to have a 0D null space you need to have the same number of rows and columns to ensure there is a pivot in every column, which corresponds to the same number of hallways and classrooms, as indicated in Figure 3. However, it should be noted that Henry's second map emerged from a discussion about a contextual interpretation of the zero matrix. A hallway map with no null space would have no loops, meaning that there is no way to keep the population of each room fixed between class changes. A coefficient matrix with all zeros, would have a 5D null space since it would collapse all camera data vectors to the zero vector. So, even though Henry said the right-hand map in Figure 3 would have no null space, we interpret him to mean this was his attempt at constructing a map that had an associated coefficient matrix of all zeros since, "you get stuck in the room you start in."

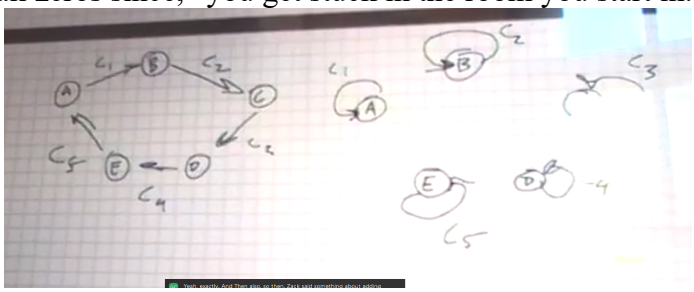

Figure 3. Henry's second set of maps demonstrating 1D null space (left) a no null space map (right).

Similarly to Henry attempting to determine the limits on the possible values of the dimension of the null space, Tyler also attempted to generalize the relationship between the number of rows and columns to determine the dimension of the null space:

> [I] added an additional pathway between C and D going back up. I think that acts as an additional linearly independent vector, so increasing the null space to three. But…I looked at my old one, and sort of realized, I mean yeah if this one has already reduced the null space, then I can just get rid of any of the classrooms or any of the pathways and I can't ever make more loops by reducing, by getting rid of things I already have, so I just said hey I'll start where I'm at and I can remove things to show…you can do either and I've reduced the null space…I'm trying to find out like a rule of thumb for this. But it was sort of confusing because I got there was six columns, and four rows equals two…[I'm] trying to sort of figure out how can we, say we wanted to like minimize how many hallways and things that we're using, how could we do that.

As seen in Figure 4, Tyler was attempting to generalize the relationship between the number of rows and columns and what this meant for the dimension of the null space. However, the difference in the number of rows and columns was not equivalent to the number of loops Tyler

generated with his new map (pictured on the left side of Figure 4). The participants ran out of time to completely finalize their thoughts at the end. However, we view Tyler and Henry's progress in investigating the relationship between the number of rooms, hallways, and loops and the number of rows, columns, and dimension of the null space of the associated coefficient matrix as progress towards reinventing the relationship between the dimension of the null space and the number of rows and columns of the that coefficient matrix.

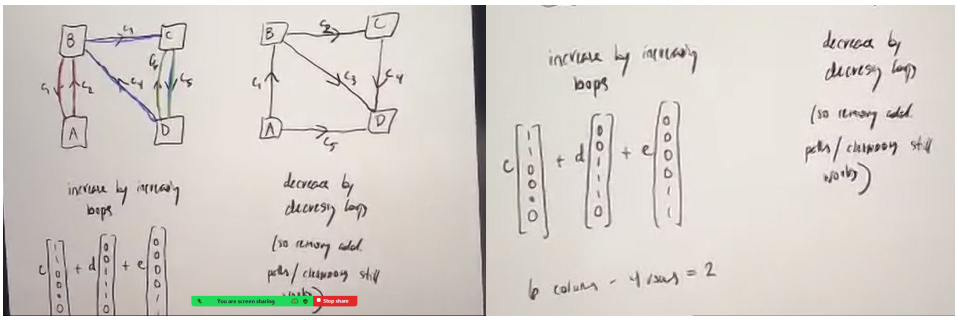

Figure 4. (Left) Tyler's second set of maps with three loops and no loops. (Right) Tyler's attempt at formalizing the relationship between the number of rows, columns, and loops.

Here we see Tyler horizontally mathematize to again cross the river to the formal symbolic side to generalize the relationship between the number of columns, rows, and loops. Henry, on the other hand, horizontally mathematized back to the hallway maps to demonstrate a map that corresponded to his largest value of the null space being five dimensions.

Discussion and Conclusion

In this work, we found that Tyler and Henry had two different approaches to the playful math problem. They were each vertically mathematizing, but on different "shores". The rich discussion between the two resulted in horizontal mathematization, generating connections between shores. For example, Tyler and Henry linked adding columns to adding hallways and adding loops to increasing the dimension of the null space. At the end of the conversation, they were close to understanding how altering the map or matrix impacted the dimension of the null space. For Tyler and Henry, their discussions resulted in successive horizontal mathematization which led to vertical mathematization along both shores of the concept of null spaces.

As both designers and IOI practitioners, we believe that students should be encouraged to revisit and create connections between their formal mathematical experiences and a variety of contextual experiences. This approach paves the way for two new avenues of research. From an IOI instructor's perspective, what are the asset-based approaches to navigate conversations between students who are approaching tasks from opposing shores of the river? From an RME designer's perspective, attention should not only be paid to appropriate entry points but also how frequently the context can be revisited throughout the course and how well these ways of reasoning support the mathematization of later concepts. For example, the hallways context can used to support the guided reinvention of null space as well the rank-nullity theorem.

While this study was limited in number of participants, it charts the start of a journey to a guided reinvention of the rank-nullity theorem. It also highlights the complexity of student reasoning and progressive mathematization down the river. The result of this journey is not only a deep understanding of formal mathematics, but also a rich context from which students can refer to considering new ways to reason about related ideas. Future research will focus on developing this additional activity to supplement the IOLA curriculum.

Acknowledgements

The authors wish to thank Western Kentucky University for providing funding for the participants in the study. In addition, we wish to thank Michelle Zandieh, whose discussions with the authors helped refine the task.

Utilizing Discourse Analysis to Explore the Merits of Nonverbal Communication in Higher Education Mathematics Classrooms

Tabitha Mingus
Western Michigan University

Discursive interactions have been of great interest to researchers studying students' sense of belonging in the classroom. The study of discourse helps us understand positions of authority and agency, as well as creating a common language to describe expected social roles in student-teacher and student-student interactions (storylines). Positioning theory provides the groundwork for understanding how our beliefs about social roles influence how we express ourselves. In each of these areas, verbal communication is typically studied directly, with nonverbal communication used as confirmatory or add-on illustrations. This study centers on instructor nonverbal communication, using empirical data from an observation of a higher-education mathematics classroom across two class sessions. We seek to identify how the instructor's use of classroom space (proxemics) and body movement (kinesics) demonstrates the assignment and shifting of power structures, as well as the enactment of storylines.

Keywords: Positioning theory, discourse analysis, nonverbal communication

Mathematics, as a discipline, is notorious for creating the unfortunate dichotomy of "math people" versus "non-math people" in the classroom. Identifying oneself as a "non-math person" engenders a lack of confidence, a high incidence of math anxiety, and a significant impact on the rate at which students pursue STEM careers (Beilock, 2019; McDermott-Murphy, 2022). According to a study by Bressoud (2015), Calculus 1, a course required for most STEM and some non-STEM majors, had significantly higher drop/fail rates and lower levels of student confidence. One possible finding Bressoud identified was in the connection between student confidence, enjoyment, and a desire to continue mathematics as related to "good teaching" (Bressoud, 2015).

"Good teaching" and "ambitious teaching," according to Bressoud (2015), include qualities such as eliciting student thinking, holding frequent whole-class discussions, helping students become better problem-solvers, and providing time for student thinking. Each of these qualities positions students as co-contributors to classroom knowledge, sharing authority between teacher and student, creating a narrative of "teacher as facilitator of learning" and "teacher as participant in learning" (Drageset & Ell, 2024).

In this study, we follow one instructor, Kim (pseudonym), to examine how he positioned students and the messages he conveyed through verbal and nonverbal cues. After determining the importance of Kim's nonverbal communication through an initial analysis of verbal communication, the research question we sought to answer was: How does nonverbal communication demonstrate the assignment and shifting of authority and the enactment of storylines?

Few studies exist in mathematics education discourse research that describe communication acts beyond gestures. Therefore, this study lays the groundwork for understanding the relationship between verbal and nonverbal communication and examines the merits of nonverbal communication in mathematics education. We first consider the theoretical frameworks employed to understand the verbal and nonverbal communication in Kim's classroom discussions. We then describe our process for analyzing instances of verbal communication,

which led to the discovery of the central role of nonverbal communication. Lastly, we will discuss the implied messages conveyed by Kim's nonverbal communication acts and their impact on student engagement.

Theoretical Framework

Communication is a collection of socially constructed verbal (words, tone, pauses, and inflection) and nonverbal (gestures, gazes, movements) cues that deliver messaging consistent with our contextual understanding. Researchers in mathematics education have studied discourse extensively as common phrases used in the classroom (Biber & Barbieri, 2007; B. Herbel-Eisenmann et al., 2010), as constructors of relationships of power and authority (Langer-Osuna & McKinney de Royston, 2017; Wagner & Herbel-Eisenmann, 2014), or as indicators of social roles and inherent responsibilities (Davies & Harré, 1990; Drageset & Ell, 2024; B. A. Herbel-Eisenmann et al., 2015).

Discursive analysis, using positioning theory, can be applied to both verbal and nonverbal communication to ascertain the subject's beliefs and attitudes. Most discursive analyses have focused on verbal communication (words, utterances, intonation), while using nonverbal communication (gestures, facial expressions, movement) as an add-on to provide further depth to their findings. In this analysis, verbal communication analysis led the research team to a deeper conversation about nonverbal communication. Therefore, we will begin with a discussion of the theoretical basis for our verbal analysis, followed by a discussion of the nonverbal frameworks.

Analysis of Verbal Communication

Categories. Teachers' utterances can be classified into seven distinct statement types based on their intended purpose. For example, bookend statements summarize a previous activity and serve as a springboard to the following activity. Norm-setting and “math talk” center mathematics within the social and contextual setting. Other categories include affective discourse, technical tools, discursive moves, organization, and information. Identifying the purpose of teacher statements allows for comparison across disciplines, instructors, or class periods (Knott et al., 2008).

Positioning Theory. Discourse comprises a collection of communication acts that convey messaging about our perceived roles and the roles we attribute to others. In a classroom setting, for example, a teacher may see themselves as a facilitator of discussion, with students as primary consultants who provide the necessary dialogue to engage with and interact with other students. Students may expect to be the recipients of the knowledge that the teacher provides. In this case, they may perceive themselves as passive observers, whereas the teacher is the subject-matter expert. Both sets of expectations *position* students and teachers into roles based on their individual understandings of the storyline of student/teacher interactions. These roles are negotiated constantly and can change from moment to moment (Davies & Harré, 1990; Drageset & Ell, 2024; B. A. Herbel-Eisenmann et al., 2015).

Analysis of Nonverbal Communication

Several types of nonverbal communication are identified in disciplines such as linguistics, sociology, psychology, and social anthropology. For this study, we focus on two: proxemics and kinesics.

Proxemics. The distance in a conversation varies with the relationship between the speakers. For example, if two strangers are talking, they tend to naturally stand further apart than siblings. Farsani and Rodrigues (2021) highlighted four distances commonly used in discourse: intimate

space (up to 45 cm), personal space (up to 120 cm), professional space (up to 370 cm), and public space (more than 370 cm). In a classroom setting, for example, teachers speak at the front of the class using public space. When speaking with small groups of students, teachers may step closer, into the professional space, or into personal space in more relaxed settings (Farsani & Rodrigues, 2021).

Kinesics. Body position, movement, and facial expressions are all examples of kinesics (Khan et al., 2025). This includes movements such as folding the arms, leaning forward or back, shrugging the shoulders, or using a rolling hand gesture to indicate that the topic continues (or should continue).

Methodology

As part of a larger study, one algebra instructor, Kim (pseudonym), at a Midwestern university was observed twice within two weeks at the end of the Spring 2025 semester. The class was being conducted using the Building Thinking Classrooms methodology (Liljedahl, 2021). In the first observation, the tables were arranged in rows, with some rows near the side walls, leaving little room for movement. In the second observation, tables had been moved into clusters and away from the walls. In both class periods, vertical whiteboards were affixed to the walls, with students clustered in groups around each board. Kim was selected for analysis because of his approach to teaching in higher education, changes in furniture arrangement, and his use of technology to decenter the classroom.

At the front of the room was a table with a technology station, next to which was the screen for the overhead projector. Kim had his laptop set up and alternated the overhead display between a Desmos (now known as Amplify) activity on the laptop and an Apple TV setup connected to his iPad. In this way, he could walk around the classroom, taking notes on his iPad visible to the students, and, during large-group discussions, he would sometimes hand the iPad to a student to operate the technology without walking to the front of the room.

Swivl Robot technology used a recording device on a lanyard to capture audio/video recordings that followed Kim's movement around the room. Four additional recorders were placed at tables around the room to pick up student voices during small-group discussions. These additional recorders could be enabled and disabled during analysis to improve transcript accuracy.

Data Analysis

Following the observation of each class, the resulting audio/video recording was used to create a transcript. During the cleaning process, special attention was paid to nonverbal communication. The transcripts were independently coded into categories and positioning acts by each member of the research team.

The research team then convened to compare their individual coding of the transcripts. When interrater discrepancies occurred, the researchers relied on the context of the instructor's statement to reach an agreement. This involved listening to the instructor's statement in the recording while attending to tone, phrasing, nonverbal cues, and student reactions.

During these deliberations, the research team realized their reliance on nonverbal cues to more accurately categorize the instructor statements in question. While the team had previously noted common hand gestures, the researchers began using more subtle physical movements to gain a deeper understanding of the instructor's statements. This included how the instructor positioned himself among the groups, how he leaned toward or away from a speaking student, and shifts in posture that drew attention to other groups.

To supplement their understanding of these nonverbal communication acts, the research team created a map of teacher movement in 20-minute segments at the beginning, middle, and end of the two observed classes. To do so, a two-dimensional scale of the classroom was created for each observation because the furniture was moved between the two observed class sessions. Researchers then watched the recordings and manually traced the instructor's physical movements through the classroom using different colors to represent the "trips" that occurred during the 20-minute segments. A "trip" was considered to be the path that Kim took before returning to a given starting point, typically the front of the classroom or the podium. Researchers then noted specific patterns that emerged in Kim's movements.

Results

The research team identified four primary categories of nonverbal communication consistently used by Kim: position in physical space, gestures, movement, and pacing. We will discuss the patterns identified for each of these categories before addressing their implications.

Position in Physical Space

Across both observations, Kim used the classroom space differently during small-group and large-group discussions. During the first observation of large-group discussions, Kim spent most of the teaching time at the front of the classroom, asking students in their groups questions and using the vertical whiteboard. In the second observation, Kim used technology to teach from the center and the back of the room, with only a brief period of instruction from the front.

During small-group discussions, Kim adopted several physical positions in relation to the groups. When providing students time to brainstorm and collaborate on ideas, Kim primarily positioned himself in the circle created by students around the vertical whiteboards, as in Figure 1. However, as time progressed and Kim shifted to more direct teaching, he tended to stand behind the groups, either speaking directly to them or over their shoulders as they continued working on their boards.

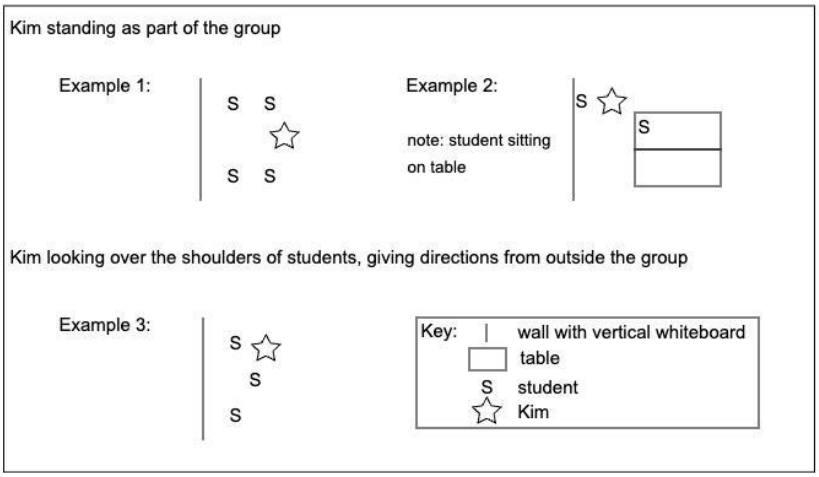

Figure 1. Kim's physical positioning around small groups.

Gestures

Physical movements were used to help students differentiate among ideas and to aid memory recall. When discussing the concept of "balancing," Kim alternated raised hands to indicate the rising and falling of opposite sides of a balance beam, as opposed to the leveling of a bar chart,

demonstrated by a line drawn in the air. Kim repeated these movements with each group toward the end of the small-group discussion, connecting the gestures to the two ideas.

Pointing was consistently used to convey three distinct ideas. Kim used pointing to indicate the person he was directly addressing, often accompanied by a lean inward as if sharing a secret. He also used pointing to signal when he wanted to capture a statement, thereby validating the response. Lastly, he used pointing to direct the students' attention to either another group, a computer, a vertical whiteboard, or the class notes projected on the screen.

One notable use of gestures to direct student attention occurred when Kim crossed his arms, set his shoulders beside a student, and leaned back as if they were both reclining on a couch. The student then followed his gaze and shifted again when Kim moved. This movement had a more lasting impact than a simple point to shift focus.

Another method Kim employed to direct attention was general arm sweeps, such as when he asked a speaking student to "tell them," motioning to the other students in the class. The student looked up and followed Kim's arm around the room before speaking again, a little louder than before.

Movement

A class norm that had clearly been established was to look at other whiteboards when a group became stuck. After conversing with one group, Kim suggested they ask another group, then turned and walked toward the group. The students followed, and when Kim stepped back, the group continued in the desired direction.

In large-group discussions, Kim would turn his body to face the projection screen while students discussed their work, thereby providing a model posture for students to emulate. Student gaze would then shift from Kim to the board, following his gaze and posture.

This happened again when in a large-group discussion, shortly after Kim had been teaching from the middle of the classroom. Kim had asked a student to show the class their ideas on the iPad. The student took the iPad and moved to the center of the classroom, mimicking Kim's movement.

Pacing

During shorter conversations, Kim moved and talked very quickly, setting the tone for the classroom discussion. In small groups, Kim quickly provided validation or correction after an idea was shared. He moved away briskly after a group began discussing his answers to their questions. When releasing the class to their groups, he gave directions and then issued a curt "Let's go" to signal that the students should act quickly. Occasionally, this fast pace meant that he spoke over students as they tried to voice their thoughts. An interesting consequence occurred during a large-group discussion, when a student spoke over him, picked up the iPad, and provided an answer before Kim was ready to relinquish authority. In this case, a student appeared to take on the role Kim demonstrated.

However, this was not always the case. When students were working in small groups, Kim would saunter around the room along a set path, such as a circle in the middle of the room, listening to conversations, reading the students' vertical whiteboards, and then checking online for their responses in the Desmos activity. At these times, he provided opportunities for students to think, collaborate, and formulate their own responses. Maps of these moments showed dark paths along which Kim repeatedly moved in the same direction.

Each of the nonverbal cues discussed above (position in physical space, gestures, movement, and pacing) conveyed messages directly to students, sometimes overriding verbal messages. In

the following section, we discuss the implications of this messaging on the classroom environment and the direct impact on students.

Discussion

In response to our research question, two primary areas of analysis were examined directly: the assignment and shifting of authority and the enactment of storylines. One unintended result became apparent as well: agreement (or lack thereof) between verbal and nonverbal messages.

Assignment and Shifting of Authority

Authority figures are participants who direct attention, whose ideas are taken up, and who have control over the situation (Bishop, 2012). In analyzing nonverbal communication, we can observe the student and teacher posture, physical position, and classroom/group attention to identify authority at each moment. In this study, the shifting or sharing of authority was most clearly identified with shifts in student focus and with students mimicking Kim's behavior.

The researchers found that Kim shifted students' attention solely through nonverbal cues, altering his posture and gaze toward their work. The student mimicked these movements, thus accepting the directional shift without any verbal acknowledgment from Kim. Their change in physical position followed his direction without explicit verbal direction.

On another occasion, he taught from the center of the classroom. When a student offered to answer a question, he handed the iPad to the student and stepped back. Without verbal prompting, the student took Kim's place in the center of the classroom to speak. The authority shifted to the student as Kim stepped aside, de-centering himself.

Storylines

In verbal communication, we talk about storylines of "teachers as providers of insight," "teachers as facilitators of learning," or "teachers as participants in learning" (Drageset & Ell, 2024). When examining Kim's observation recordings, we observe elements of the first two at various points during the class periods.

At times, Kim joined the student groups, standing alongside them in a circle. In these moments, he leaned in when asking questions, gesturing to the student or to the board. As he listened to students, he turned his whole body toward them, frequently with his head tilted to the side. Between groups during this time, Kim circled the classroom at a distance and observed students' conversations. These movements suggested that he participated in the discussion, in which students were the providers of collaboratively constructed knowledge. Our interpretation was validated by his verbal communication acts, which included soliciting students' thinking, highlighting key concepts articulated by students, and encouraging collaboration within and between groups.

At other times during the two observations, Kim took a more direct approach to teaching, standing behind groups to talk over their shoulders and sometimes pointing through students to the board. Listening to his language use, he was providing more direct instruction in these moments, enacting a storyline of "teacher as provider of insight."

While the two storylines were both present, they do not necessarily indicate conflicting messages. Teachers frequently move between storylines during a single class period, taking on different roles and shifting their expectations of student behavior (Drageset & Ell, 2024).

Agreement (or Lack of) in Messaging

In analyzing nonverbal communication through verbal communication, the research team hypothesized that the two would align. Before the observations, Kim stated that he intended to use students' thinking to create a productive learning environment. Classroom norms were established that students would work together, with Kim facilitating their discussion and occasionally providing input. Students were encouraged to try new things, take chances, and participate collaboratively.

During student group work, when Kim followed a set path around the room, observing conversations and reviewing students' work on boards, he created space (both physical and metaphorical) for students to collaborate. At times when students asked for help or when he noticed students were stuck, he facilitated discussion by asking questions and requesting that students provide feedback to one another. These are the moments he moved to a physical position directly in line with the students in the group. When responding to questions, he validated correct responses by pointing to the student who provided the proper response and leaning in toward them. Leaning toward a student in this manner reduces the distance between Kim and the student, shifting from personal to intimate space. All of these verbal and nonverbal cues indicate a shared space between the student and teacher. Students are encouraged to provide information, and the teacher serves as a facilitator.

However, there was a significant period during which the nonverbal cues conflicted with the established classroom norms and occasionally with the verbal cues. During the observations, Kim began to speak over students, moving the conversation along at a quicker pace. He began walking briskly and visiting groups for shorter periods. When he visited groups, he spoke to them over their shoulders and, occasionally, pointed at their board between their shoulders. The faster pace and Kim's removal from the groups led to a shift in the storyline and a new expectation that students respond quickly and accurately, which conflicted with the class's explicit and implicit norms. Although student perceptions were not measured in this study, some students were hesitant to speak in the groups at this time, and many looked to one another while he was speaking, which seemed to indicate some unease.

Identifying conflicting messages provided a mentoring opportunity for Kim, who was unaware of the change in his behavior and its impact on student engagement.

Conclusion

Discourse analysis is an effective method for gaining insight into classroom interactions. While it is tempting to focus primarily on verbal communication, nonverbal communication provides a wealth of information that can highlight hidden messaging or infer interpretations of messaging.

The limitations of a study such as this, however, are that perceptions of nonverbal communication acts differ across cultures, making international classrooms difficult to analyze. Future research may include the cultural contexts of the ethnicities represented by the teacher and the students present. Also, obtaining the teacher's intended messages and the students' perceptions of these communication acts could be helpful.

A Social Network Analysis of Race/Ethnicity and Gender in Inquiry-Oriented Linear Algebra

Minah Kim
Northern Arizona University

This study investigates mechanisms of equity in active learning by examining student networks in an Inquiry-Oriented Linear Algebra (IOLA) classroom through social network analysis (SNA). Drawing on the sociopolitical perspective, particularly the dimension of power in equity, the research analyzes how race/ethnicity and gender shape students' peer nominations. Data were collected from an IOLA class of 64 students at a Southeastern U.S. university, using discussion board "shout-outs" and replies to track social networks. Findings reveal strong patterns of racial and gender homophily and highlight that women of color occupied disproportionately central positions within the network. While these positions suggest potential empowerment, they may also reflect additional labor on the part of women of color to sustain visibility and influence. The study underscores the need to frame equity in active learning not as inherent but as contingent on power dynamics, solidarity, and segregation within mathematics learning communities.

Keywords: Inquiry-oriented instruction, equity, social network analysis, women of color

Equity in postsecondary Science, Technology, Engineering, and Mathematics (STEM) education remains an urgent issue due to systemic barriers. Interventions often focus on "helping" or "fixing" students, yet such approaches rarely address the structural issues of racism, sexism, and microaggressions that persist in STEM classrooms (McGee, 2020). Mathematics is widely recognized as a gatekeeper in STEM (Battey et al., 2022; Leyva, 2021), where narratives of innate ability and deficit views of minoritized students contribute to inequity. These conditions call for research that investigates how equity is enacted or constrained.

Active learning has emerged as a reform strategy by shifting the focus from lecture to participation, collaboration, and inquiry. Evidence shows that active learning can narrow achievement gaps for historically underrepresented students in STEM (Theobald et al., 2020). However, equity is not automatically guaranteed in active learning. This highlights the need to examine not just whether active learning works but also how equity operates within it.

In light of this necessity, Social Network Analysis (SNA) offers a promising quantitative methodology. By mapping classroom relationships through nominations and interactions, SNA makes visible the patterns of influence that shape student participation (Grunspan et al., 2016). When tied with the critical perspective and the quantitative approach on equity, SNA allows researchers to interrogate how race, gender, and power intersect in active learning classrooms. This study fills the research gap in the intersection between equity, active learning, and SNA.

This study focuses in particular on women of color. Black and Latina women remain significantly underrepresented in STEM fields and often face the "double-bind" of racism and sexism (Ong et al., 2011). Asian women occupy a paradoxical position: while Asian students are frequently stereotyped as overrepresented, Asian women encounter gendered racism that renders them invisible or devalued in STEM spaces (Castro & Collins, 2021). These complexities make the experiences of women of color crucial to understanding equity in mathematics classrooms.

Accordingly, this study investigates "What is the student social network in an inquiry-oriented linear algebra class, and how do race and gender relate to these networks?"

Literature Review and Theoretical Perspective

Equity in Active Learning: Not Automatically Equitable

Active learning refers to a pedagogical approach that promotes students' active involvement. Active learning commonly entails student-centered learning, in-class activities, small group discussions, and challenges to lecture-based and instructor-focused teaching (Freeman et al., 2014; Theobald et al., 2020).

Several studies state that active learning can aid equitable learning. The meta-analysis result by Theobald et al. (2020) shows that active learning courses in undergraduate STEM have lower achievement gaps on historically marginalized groups of students than do traditional lecturing STEM courses. Similarly, Laursen et al. (2014) found that Inquiry-Based Learning (IBL) eliminates a gender gap, based on their quasi-experimental design that compares student outcomes across four universities with over a hundred IBL and non-IBL courses.

However, equity is not inherent in active learning. According to Theobald et al. (2020), one-third of active learning courses in the meta-analysis data had wider achievement gaps in active learning versus passive learning. Also, Johnson et al. (2020) reported a gender gap in inquiry-oriented abstract algebra, with men outperforming women. Additionally, undergraduate mathematics classrooms that implemented small-group work and whole-class discussions involve inequitable experiences reported by women and/or racial minority groups of students, such as microaggressions or sexist and racist events (Ernest et al., 2019; Leyva et al., 2022).

The Sociopolitical Perspective: How to Frame Equity

Given the issues of underrepresentation of historically marginalized groups in STEM education, sociopolitical concepts and theories highlight the critical perspective on underrepresentation and marginalization in mathematics education (Gutiérrez, 2013; Gutiérrez, 2009; Adiredja & Andrews-Larson, 2017). From a sociopolitical perspective, mathematics and mathematics education are political because they involve issues of power and have the potential to challenge or reproduce existing deficit narratives about underrepresented groups of students (Gutiérrez, 2017; Adiredja, 2019).

Specifically, Gutiérrez (2009) suggests framing equity in four dimensions: *achievement*, *access*, *identity*, and *power,* and this study focuses on the ***power*** dimension, one of the dimensions of the critical perspective on equity, beyond gap-gazing. Because of the political attributes of mathematics and mathematics education, power can be measured across various components of mathematics learning, such as voices in the classroom—who gets to talk, who decides the curriculum, and opportunities for students to engage in mathematics learning (Gutiérrez, 2009). Given the need to investigate the mechanisms of equity in active learning, this study suggests a focus on students' power in such settings.

The Social Capital Perspective: How to Interpret SNA

The social capital perspective is adopted in this study to interpret SNA and students' power measures. According to Knaub et al. (2018), social ties are resources such as knowledge, material, and social actors like humans, and there is no free will, so social actors strategically and purposefully seek out others and generate ties. Thus, knowing people is more than just knowing people; it is a matter of privileges and marginalization among students. Particularly, students from historically marginalized groups may have fewer social ties than they want, or may not have them, because they strategically access social ties as coping strategies to engage more actively in class.

Methods

This study was conducted in a 4-credit-hour Linear Algebra course, which used the IOLA setting; 64 students were enrolled, taught in Fall 2023 at Gauss University (the pseudonym), a 4-year public Southeastern predominantly White institution in the United States. The instructor is a tenured White cisgender woman at Gauss University, an experienced IOLA instructor who understands the nature of inquiry-oriented instruction and equity in mathematics education.

Except for two students under 18 and one who opted out, 61 students consented to the use of their written work for research purposes. Then, among 61 students, 38 consented to self-identify their race/ethnicity and gender on the consent form. These 38 students are referred to as "network participants" in this study. Figure 1 shows the race/ethnicity and gender of the network participants. Note that there is no Black woman among the network participants, even though there seem to be some Black women in the classroom, from the classroom observation.

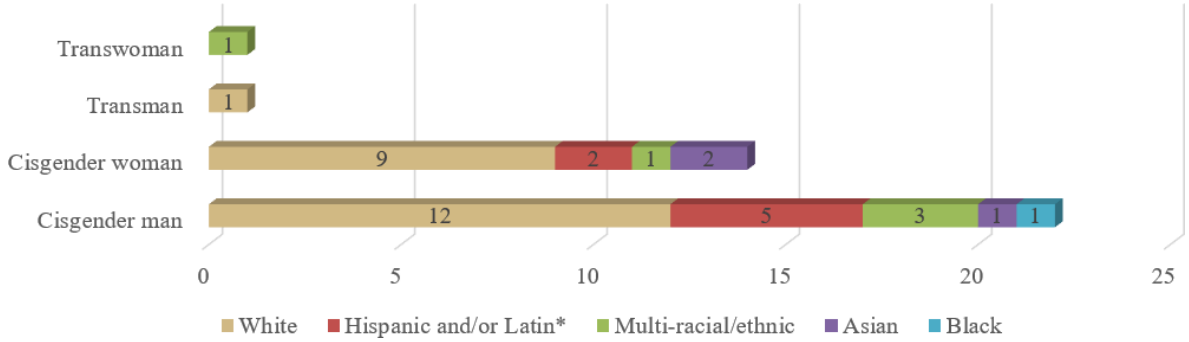

Figure 1. Demographic Information of the Network Participants
Note that students "of color" refer to "non-White," that is, Hispanic and/or Latin, multi-racial/ethnic, Asian, and Black. Latin is an inclusive term intended to recognize the presence and identities of people across the gender spectrum, including gender-nonbinary people of Latin American descent.*

The collected data sources are, first, discussion boards, where students submit online as part of their graded assignments; a survey that asks about students' prior experiences in mathematics; and self-reports of race/ethnicity and gender. The author also attended the IOLA class to observe and take field notes regarding notable patterns of social interactions.

In this study, "nomination" refers to the student nomination assignments on the discussion boards by either "shout-out" or "reply." "Shout-out" means that students nominate other students' names for those most influential in their learning, corresponding to IOLA content topics. Also, students had the option to "reply" to classmates who were helpful with their understanding, and in that case, those replies were considered the same as a "shout-out." There were 14 discussion boards assigned in the semester; 11 of them asked students to "shout-out," and three did not require a "shout-out" but allowed "reply".

SNA was conducted with "Gephi," an open-source graph and network analysis software. The first step of SNA is converting student nominations to matrices. Each matrix represents one discussion board, and students in the network are represented as numbers in the row and column matrix. For instance, for 64 students, each is represented as S01, S02, …, S64, and one discussion board is represented as a 64×64 square matrix. For one discussion board per day, entries in the matrix are either 0 or 1, where 0 indicates no nomination between two students and 1 indicates a nomination. Then, by summing the matrices across days, it shows accumulated networks throughout the semester and allows visualization of the entire network in Gephi.

Then, the number of nominations is analyzed using mean values and standard deviations, box-and-whisker plots of degrees in race/ethnicity and gender, and the Mann-Whitney U-test. Hypothesis tests were also conducted in "DATAtab," an online statistics tester using artificial intelligence. Also, ***homophily*** —the measure of patterns of who relates to whom in terms of similarity in attributes—race/ethnicity and gender —was tested using chi-square.

This study measures four types of centralities to find who is the most central in the network. The first measurement on the social network is ***degree centrality***, which identifies the most nominated students, as it represents the total number of connections. Next, ***Betweenness centrality*** measures how often students bridge paths between two other students. So, a student with higher betweenness centrality is a broker in student groups. ***Closeness centrality*** measures how students connect to others in the entire network, unlike degree centrality, which focuses on direct connections. Therefore, if a student has a high closeness centrality, that student is indirectly connected to other students through nominations, potentially influencing the whole class. Lastly, the ***eigenvector centrality*** measures how much students are networked to well-connected neighbors. So, if a student has a high eigenvector centrality, then that student has access to well-connected student neighbors.

Findings

This part addresses the social networks in an IOLA class and how race/ethnicity and gender relate to those networks generated from student nominations. The social network diagram (See Figure 2) illustrates how students nominate one another.

Who Received and Sent More Nominations? Descriptive Results of Mean Values and Standard Deviation

Note that this part uses the binary groups in race/ethnicity and gender. The racial/ethnic groups are non-White and White, and the gender groups are women, both cisgender and trans, and men, both cisgender and trans. On average, IOLA students received nominations from 3.86 (SD = 2.26) students 7.64 (SD = 5.32) times and sent nominations to 3.86 (SD = 2.66) different students 7.83 (SD = 4.13) times. Regarding gender, on average, women received 10 nominations from around 5 people, which is about 1 more than men did. Women and men sent nominations to around four people, but women sent nominations around ten times, more than men did. This comparison between non-White and White students indicates that non-White students received nominations from around one more person. Still, both groups received slightly more than nine nominations. White students sent nominations to 0.36 different people. However, according to the Mann-Whitney U-test, there is no statistically significant difference between the Non-White and White groups, and between women and men, in how often or how many different people they receive and send nominations to.

Does the Network Have Homophily? Chi-Square Test Results in Race/Ethnicity and Gender

From here, "target" refers to nodes that send nominations, and "source" refers to nodes that receive nominations. Figure 3 shows the Sankey diagrams of the homophily in race/ethnicity and gender. A Chi-square test was performed between the Source Race and the Target Race. All expected cell frequencies were greater than 5; thus, the assumptions of the Chi-square test were met. There is a statistically significant relationship between the Source Race and the Target Race ($\chi^2(1) = 42.39$, $p = <.001$, Cramér's $V = 0.4$). The calculated p-value of <.001 was lower than the defined significance level of 5%. Hence, the Chi-square test was significant. This means that the tendency for White students to nominate White students and non-White students to nominate non-

White students is statistically significant. Also, according to the Chi-square test, a statistically significant relationship exists between the Source Gender and the Target Gender. ($\chi^2(1) = 61.78$, $p = <.001$, Cramér's $V = 0.48$) The calculated p-value of <.001 was lower than the defined significance level of 5%. Therefore, the Chi-square test was significant. This means that the tendency for men to nominate men and for women to nominate women is statistically significant.

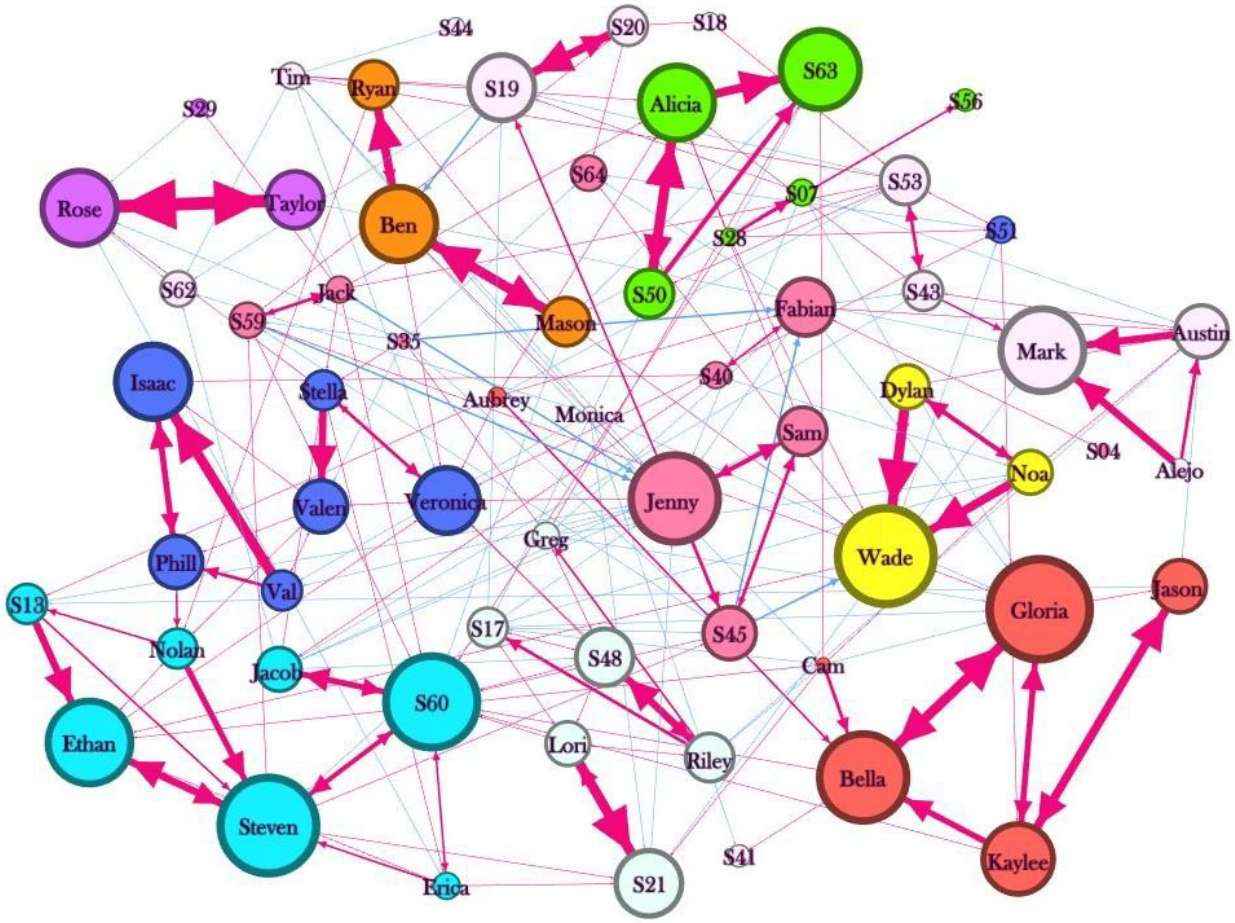

Figure 2. Social Network of the Number of Student Nominations in the IOLA Class at Gauss University.
Note: Circles with pseudonyms are network participants, and circles with codes are students who did not identify their race/ethnicity and gender. Node size represents weighted in-degree—how often the student receives nominations, regardless of redundant people. Node colors represent the small communities of the network determined by nominations. Pink arrows mean nominations by shout-outs, and blue arrows mean nominations by replies.

Who Were the Most Central? Results on Centralities Regarding Race/Ethnicity and Gender

With a comprehensive analysis of the four different centralities, the students of higher centralities include two women of color, who are disproportionately more represented in terms of race/ethnicity and gender in the class. Considering the intersections of the top 6 students (10% of the classroom population) of in-degree, betweenness, closeness, and eigenvector centralities, there are three students among the highest centralities: Jenny, Veronica, and S60. Jenny, a Chinese American cisgender woman, and Veronica, a Hispanic and/or Latina cisgender woman, are women of color. Hence, S60, Jenny, and Veronica not only received nominations from a greater variety of students (in-degree centrality) but also were able to reach other students more

closely (closeness centrality), build bridges with different classmates (betweenness centrality), and connect to other well-nominated students (eigenvector centrality).

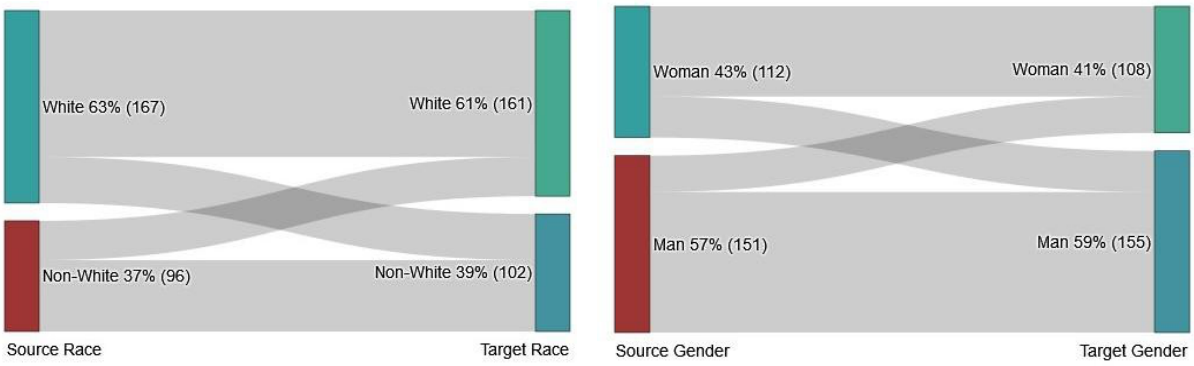

Figure 3. Sankey Diagram in Race/Ethnicity and Gender

Discussion

Limitations of This Study

This study has the following limitations. First, this study could not include Black women as network or focal participants, though Black women were observed attending the Applied Linear Algebra course at Gauss University. So, this study could not document how Black women would have social networks and experience the IOLA setting class. Second, the written works from discussion boards, including student nominations, are collected from only some classrooms because, of 64 students, two are minors and one opts out. Thus, the social network generated by nominations might miss some information. Also, since the network participants are 38 students out of 64, the SNA results related to race/ethnicity and gender might not represent the entire groups of some racial/ethnic or gender in the class.

The IOLA Class Could Imply Equitability

Considering the social capital perspective on the SNA, the results indicate that women of color could construct more empowerment. The rationale for this is that, first, women of color were disproportionately represented among the students of the highest centralities. From a social capital perspective, higher centrality indicates greater social capital, which means greater empowerment. Also, these high centralities mean that women of color could be exposed as influential students in others' learning. This implies that the linear algebra learning community could provide women of color more opportunities to be identified as influential. Additionally, the results showing no significant difference in the number of nominations between men and women, and between White and non-White students, indicate that the IOLA classroom may be where classmates perceive other students as influential. This perception would be reasonably similar across race/ethnicity and gender.

Then, was the IOLA class inherently equitable? Was the IOLA class disproportionally supportive of women of color? The response to this study remains "no." The next part addresses the reason the IOLA class was not necessarily equitable for women of color.

Potential Interpretation of Additional Labor of Women of Color

This study also interprets this potential equity in the IOLA class as resulting from additional ***labor*** by women of color. ***Labor*** refers to how students from historically marginalized groups process and respond to discouraging experiences (Battey et al., 2022). This study found that

Jenny and Veronica had the highest in-degree, betweenness, closeness, and eigenvector centralities in the class, indicating that they may need to put in additional effort to participate in linear algebra. For instance, regarding in-degree centrality, Jenny and Veronica were nominated by the most diverse peer groups in class. In contrast, White students with the highest weighted in-degree centrality were usually nominated by redundant classmates. Additionally, Jenny's and Veronica's higher degrees mean that they had quicker accessibility to the entire class (closeness centrality), made bridges between different classmates (betweenness centrality), and possessed connections to other well-nominated students (eigenvector centrality) and these measures can be interpreted as Jenny and Veronica being exposed to relatively more peers, implying they may need to work on additional labor.

How to Interpret Racial/Ethnic and Gender Homophily: Solidarity and Segregation

There is strong homophily in student nominations regarding race/ethnicity and gender in the social networks in the IOLA class. This study suggests two contrasting interpretations of this homophily: ***solidarity*** and ***segregation***. The first view is to see homophily as the solidarity of minoritized groups of STEM students. That is, the tendency for women to nominate other women and for students of color to nominate other students of color can be interpreted as solidarity within the linear algebra classroom community. The second view is to interpret homophily as segregation between minoritized groups and non-minoritized groups in STEM. More specifically, the tendency of White and/or cisgender male students to nominate each other segregates female, non-cisgender, and/or students of color in a linear algebra learning community. These two perspectives contrast yet possibly coexist. That is, solidarity within minoritized groups of students and segregation between them and non-minoritized groups can occur simultaneously in a mathematics class. For instance, a group of racially diverse cisgender men would be racially inclusive but also might be exclusive from women and women of color, thus segregating them. Also, a group of White women and White non-cisgender students can be interpreted as a community where students stand in solidarity regarding gender inclusivity.

Conclusion and Suggestion for Future Work

This study demonstrates that active learning is not inherently equitable but is shaped by classroom power dynamics. In an IOLA course, women of color held central positions in peer networks, reflecting both empowerment and additional labor. Strong racial and gender homophily suggested overlapping patterns of solidarity and segregation. These findings emphasize the need for intentional design to ensure equity in mathematics. Future research should extend SNA across broader contexts and include groups not represented here, particularly Black women, to better understand how equity is enacted and sustained in active learning.

Exploring Attentive Behavior While Reading Mathematics Textbooks

Aaron Weinberg
Ithaca College

Emilie Wiesner
Ithaca College

Textbooks remain central in undergraduate STEM education, yet little is known about how readers distribute attention across the diverse elements of extended mathematical texts. This study investigates how mathematics majors, non-mathematics STEM faculty, and non-math majors read a four-page excerpt from a standard calculus textbook. Using eye-tracking, we compared participants' attention to expository prose, worked examples, figures, and a highlighted formula. Exploratory analyses suggested differences between the groups' distributions of attention. However, a compositional data analysis did not reveal statistically significant group-level differences. These findings point to the importance of disciplinary literacy frameworks in interpreting attention patterns and raise questions about how readers' identities shape engagement with mathematics texts.

Keywords: Mathematics Textbooks, Reading, Didactical Disciplinary Literacy, Eye-Tracking

In STEM education, pedagogical texts, such as textbooks, are central curricular resources; they provide a basis for content and sequencing as well as serving as learning resources for students. In conjunction with increased interest in pedagogical formats such as "flipped" classes (e.g., Maxson & Szaniszlo, 2015), educators and researchers have highlighted the "need for greater attention to reading in mathematics instruction" (Doerr & Temple, 2016, p. 6).

Despite the central role played by textbooks, detailed evidence about how readers distribute attention across extended expository passages in pedagogical texts remains limited. Eye-tracking has been used extensively to study reading and learning across educational contexts (Holmqvist et al., 2011; Rayner, 1998), and mathematics education researchers have begun to apply it to understand students' attentive practices (e.g., MacKay et al., 2025; Zhang et al., 2025). Still, there are relatively few studies that examine how readers engage with longer instructional texts.

The goal of the present study is to extend this line of work by investigating how different groups of readers allocate their visual attention when reading an excerpt from a calculus textbook. Building on prior research contrasting students' and experts' engagement with calculus texts (e.g., Shepherd & van de Sande, 2014; Weinberg et al., 2023; Wiesner et al., 2020), we examine how mathematics majors, non-math majors with calculus experience, and non-mathematics STEM faculty attend to prose, worked examples, figures, and highlighted equations in a common calculus text (Stewart, 2016). In particular, we ask how attention patterns vary across these groups, and how these patterns can be interpreted in relation to readers' disciplinary and didactical literacy practices.

Literature Review

Reading in Educational Contexts

Pedagogical texts are situated within disciplinary genres with conventions that require readers to engage in particular reading practices (e.g., Rezat, 2006; Rezat & Rezat, 2017). Mathematics textbooks are highly multimodal: they integrate prose, formal definitions, theorems, examples, and diagrams (Fan, et al., 2013; Lemke, 1998; O'Halloran, 2005; Pepin & Haggarty, 2001). Prior research has shown that novices tend to read superficially, focus on worked

examples, and under-utilize expository text (e.g., Mesa, 2010; Randahl, 2012; Shepherd et al., 2012; Shepherd & van de Sande, 2014; Weinberg et al., 2012). While design elements like boxed formulas or diagrams can scaffold learning (Lai et al., 2012), they may also constrain attention to salient but less integrative features.

Some of these results have been investigated using eye-tracking (ET) methods. ET measures like fixation times and scan paths have provided insight into how readers select and integrate multimodal information (e.g., Coskun & Cagiltay, 2022; Lai et al., 2013; Liu & Cui, 2025), although most of this work has been descriptive rather than theoretically grounded. Studies suggest that readers selectively attend to various text components (e.g., diagrams or highlighted equations), and that this varies by reader characteristics (knowledge, motivation, and disciplinary identity) and task context (e.g., Drexler et al., 2019; Hochpöchler et al., 2013; Ögren et al., 2017; Panse et al., 2018; Schnotz & Wagner, 2018; Schnotz et al., 2014; Tóthová & Rusek, 2022). Such findings underscore that reading mathematics texts is not uniform between readers, and that readers' attention is shaped by knowledge, task demands, and textual design.

Disciplinary and Didactical Disciplinary Literacy

The perspective of disciplinary literacy was introduced to examine how reading and writing are tied to disciplinary values, norms, and reasoning practices (Moje, 2007; Shanahan & Shanahan, 2008; 2012). Disciplinary literacy is socially situated within intellectual communities (Boaler, 2002; Bishop, 2012; Moje & Luke, 2009). Thus, knowing mathematical content cannot be separated from knowing how to engage with the texts where that content resides.

Mathematics texts encode conciseness, formal justification, and multimodal coordination (Morgan, 1998; Doerr & Temple, 2016; Lee & Spratley, 2010); and mathematicians' disciplinary literacy complements these features. In a comparison between mathematicians, chemists, and historians, Shanahan et al. (2011) found that mathematicians use the structure of the text to support understanding; reconcile the text with their own knowledge to focus attention; emphasize accuracy; view graphics as an integral component of the prose itself; and engage in intensive rereading. In contrast, historians viewed graphics as potentially ancillary to the text; chemists demonstrated more subtle differences, such as viewing graphics as alternative forms of overlapping information.

Textbooks, which are "pedagogically prepared for classroom use" (Kling et al., 2017, p. 2), differ from research texts in both style and function (Fauvel, 1988; Richards, 2002). Weinberg et al. (2023) extended disciplinary literacy to account for texts specifically written for instructional purposes by introducing the concept of didactical disciplinary literacy (DDL), which involves practices such as framing the text as a product of authors; referring to instructional purpose; attending to teaching-related structures in the text; and expressions of authority in teaching and learning (Weinberg et al., 2023). Readers' meaning making depends on both disciplinary background and sensitivity to pedagogical design (Wiesner et al., 2020; Fulmer et al., 2022).

Gaps and Research Question

Comparative ET research in mathematics rarely juxtaposes novices and experts, despite evidence from other fields (Harsh et al., 2019) that expertise mediates attention. Furthermore, ET work often lacks integration with disciplinary literacy frameworks, limiting interpretation of gaze measures (Andrä et al., 2020). In addition, the intersection of disciplinary literacy, DDL, and attention allocation remains underexplored, especially in the context of mathematics texts. The present study addresses these gaps by examining how STEM faculty, mathematics majors, and non-majors allocate attention to expository text, figures, examples, and highlighted equations.

Our research question is: How is a reader's distribution of attention across different types of text (examples, text, figures, and equations) in a standard calculus textbook excerpt related to their positioning in the mathematics and school community?

Theoretical Framework

The core of our framework is the idea that readers actively select components of the text to focus on as they read, that this selection is guided by disciplinary norms and their own content knowledge, and that their eye fixations reflect their attention.

Reading Attention and Eye Movements

Researchers in mathematics education have increasingly begun to use eye-tracking to study how readers attend to texts, solve problems, and engage with multimodal representations (Schindler & Lilienthal, 2019). As Schindler et al. (2025) point out, most eye-tracking work operates based on the eye–mind hypothesis (Just & Carpenter, 1980; Rayner, 1998), which proposes a positive connection between visual fixations and cognitive attention, and in which, as König et al. (2016) note, gaze patterns are seen as indicators of higher mental processes such as perception, memory, problem solving, and abstract reasoning.

Gaze data are not inherently self-explanatory. For example, several scholars (e.g., Andrá et al., 2015; Hartmann et al., 2015; Holmqvist et al., 2011; Jacob & Karn, 2003) have proposed that readers' cognitive behavior might not match what their eyes are fixated upon, and some research (e.g., Schindler & Lilienthal, 2019; Thomaneck et al., 2022) has demonstrated evidence of such mismatches. Despite these limitations, numerous researchers (e.g., Alemdag & Cagiltay, 2018; Deubel & Schneider, 1996; Remington, 1980; Scheiter & Eitel, 2017; Schindler & Lilienthal, 2019; Thomaneck et al., 2022; van Gog et al., 2014; Wang et al., 2019) have found that eye movements are generally linked to attentional foci.

Disciplinary and Didactical Disciplinary Literacy

As Barton and Hamilton (2000) described, literacy practices are "the link between the activities of reading and writing and the social structures in which they are embedded" (p. 7). Disciplinary literacy refers to the specialized ways of reading, writing, and reasoning that are characteristic of each academic field (Fang & Schleppegrell, 2010; Rainey & Moje, 2012). In mathematics, this entails precision with notation, logical structure, coordination of representations (symbolic, graphical, verbal), and orientation toward proof and generalization (Morgan, 1998; O'Halloran, 2005; Rezat & Rezat, 2017). Readers engage not just with words and symbols but with the epistemological norms and values of mathematics itself.

Didactical disciplinary literacy (DDL) extends disciplinary literacy to the context of instructional texts (Wiesner et al., 2020; Weinberg et al., 2023). It involves readers' ability to recognize and interpret instructional scaffolds such as boxed definitions and worked examples; critique texts as instructional artifacts; and navigate their positionality within institutional settings and norms, among other skills and habits. DDL highlights how readers' practices are simultaneously disciplinary, didactical, and situated within relations of power.

Methods

Participants and Materials

The study is structured as a comparison between three groups expected to bring a range of literacy practices and content knowledge to the reading experience. The first group consisted of

five students who had declared either a major or minor in mathematics and had completed at least the first two semesters of college-level calculus and a semester of linear algebra with a grade of at least C-; we hypothesized that students in this group had developed and refined literacy practices for reading didactical mathematics texts and would also have sufficient knowledge to learn new calculus concepts by reading a textbook excerpt.

The second group consisted of five students who had completed a single college-level calculus course with a grade of at least C- in the previous semester. We hypothesized that these students had developed sufficient calculus knowledge to learn a new concept but were less likely to have developed sophisticated DDL practices for mathematics.

The third group comprised five faculty members (biology (2), chemistry, environmental science, and physics), all with PhDs, at least four years of undergraduate teaching experience, and active research agendas. As a result, they were skilled in interpreting disciplinary texts and using textbooks pedagogically. All had taken calculus; but, except for the physicist, none had used calculus in over a decade. We expected the group to have less calculus knowledge than the student groups, but disciplinary literacy practices similar to those of mathematicians (as supported by the findings of Shanahan et al., 2011).

Participants were recruited via email from lists of all students and faculty who met the above criteria. Participants were selected from among the respondents based on whether they continued to respond to scheduling emails and their availability during scheduled interview time slots.

We sought to have all participants read for the same purpose—namely, to learn a new concept. We selected the section "Newton's Method" from a widely used calculus textbook (Stewart, 2016). This four-page excerpt included expository prose, a formula (presented inside a blue box) for obtaining the n+1st approximation from the n^{th} approximation of the root of a polynomial, three worked examples, and seven figures. At the beginning of the reading session, all participants were asked about their familiarity with Newton's Method, and all indicated they were not familiar with the concept.

Data Collection

During each interview, the textbook excerpt was displayed on a computer monitor, and the participant was able to navigate between the pages using the computer keyboard. Participants were asked to read the excerpt "to learn about the concept of Newton's method" at their own pace, while the interviewer worked independently at a separate desk. They were provided with a pen and paper and told they could take notes as they read. The participant's eye movement was recorded with a Tobii X2-60 eye tracker mounted below the monitor and calibrated according to manufacturer guidelines (Tobiipro, 2019).

AOI Construction and Data Processing

We created a rectangular Area of Interest (AOI) around each section of expository prose, figure, example, and the formula in the blue box. The AOIs were grouped by type: blue box formula, example, figure, or text. This choice of grouping was made to reflect the ways in which mathematics disciplinary literacy practices differ from those in other disciplines by tightly integrating the interpretation of expository prose, graphics, and formulas, with the goal of enabling us to (1) explore ways in which these elements might be approached by the different participant groups and (2) the extent to which the didactical nature of the text might lead to different attentive patterns.

We restricted the set of eye movements to fixations, created a variable to indicate which AOI each fixation was contained in, and then computing the total duration (in seconds) for which each

participant had fixations within each AOI. We then computed the total fixation duration for each type of AOI for each participant. One participant (one of the biology faculty members) had long stretches with no valid fixation data, so we omitted their data from our analysis.

Results

Participants distributed their attention across the different types of text in a wide variety of ways. For example, one non-math major spent approximately 60% of their time looking at the examples and 20% in each of text and figures, while one math major spent approximately 55% of their time looking at the figures, with 20% looking at the examples and 25% at the text.

The percentages for the blue box formula were uniformly small (approximately 2% among all participants). Thus, we examined the distributions of the other AOI types using the ternary plot shown in Figure 1. In this plot, the three colors (red, green, and blue) indicate data from the three groups (MM, NMF, and NMM). Each group's dots are connected by a convex hull, and the large black dots are the hull centroids, which represent group averages. From the centroids, we can see that the math majors tended to spend a larger proportion of their time reading the expository text; the non-math majors tended to spend a larger proportion of their time looking at the examples; and the non-math faculty tended to spend a larger proportion of their time examining the figures. Although there is some overlap between the hulls, visual inspection suggests that the three groups exhibit relatively distinct distributions of attention.

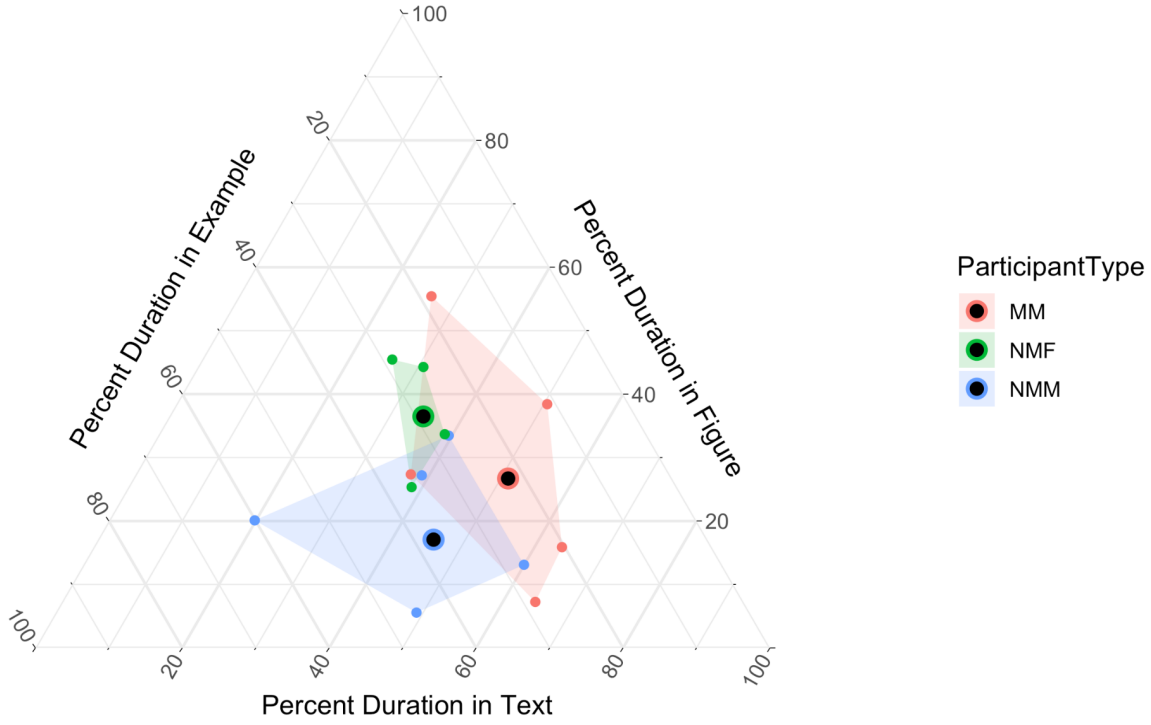

Figure 1. Ternary plot of participants' proportional durations in the example, figure, and text

Within these global patterns, however, there was a relatively considerable amount of variation among the participants within the MM and NMM groups compared to the NMM group, as demonstrated by the large areas of the hulls. In addition, the separation between the three hulls does not occur along a single axis, suggesting that between-group differences might not align with the three AOI types.

Compositional Data Analysis

Our data are non-negative and multivariate, with values that only carry relative meaning and, within each individual and group, must sum to a fixed value (in this case, 100%). This constant-sum constraint violates assumptions of independence in standard statistical methods. Thus, compositional data analysis, which uses logarithms of ratios of values, is the most appropriate statistical tool.

To conduct this analysis, we began by transforming our data using an orthonormal basis of log ratios of parts, which maps the data into a set of orthogonal components and eliminates collinearity. This isometric log-ratio (ILR) transformation is: $ilr(x) \coloneqq V^t clr(x)$, where $clr(x)$ is the centered log ratio that expresses each component relative to the geometric mean of all parts, and V is an orthonormal basis of the clr plane. We then compared the resulting three (now independent) ILR coordinates across groups (MM, NMM, NMF) using a permutational multivariate analysis of variance (PERMANOVA; Anderson, 2001). The analysis, based on Euclidean distances with 999 permutations, indicated that participant type did not significantly predict variation in the duration data ($F(2, 11) = 0.89$, $R^2 = 0.14$, $p = 0.50$). Thus, when considering all three ILR coordinates jointly, our data do not provide evidence of a significant overall difference in the distribution of attention across the stimulus types between groups.

To follow up this non-significant result, we conducted a principal component analysis (PCA) on the CLR-transformed duration data to investigate the potential for more complex relationships between factors. Four components were extracted, with PC1 accounting for 65.1% of the variance and PC2 for 18.9% of the variance. Loadings indicated that blue box (0.61) and figure (−0.79) duration loaded strongly on PC1, whereas example (0.53) and text (0.45) loaded on PC2. A plot of the first two components is shown in Figure 2.

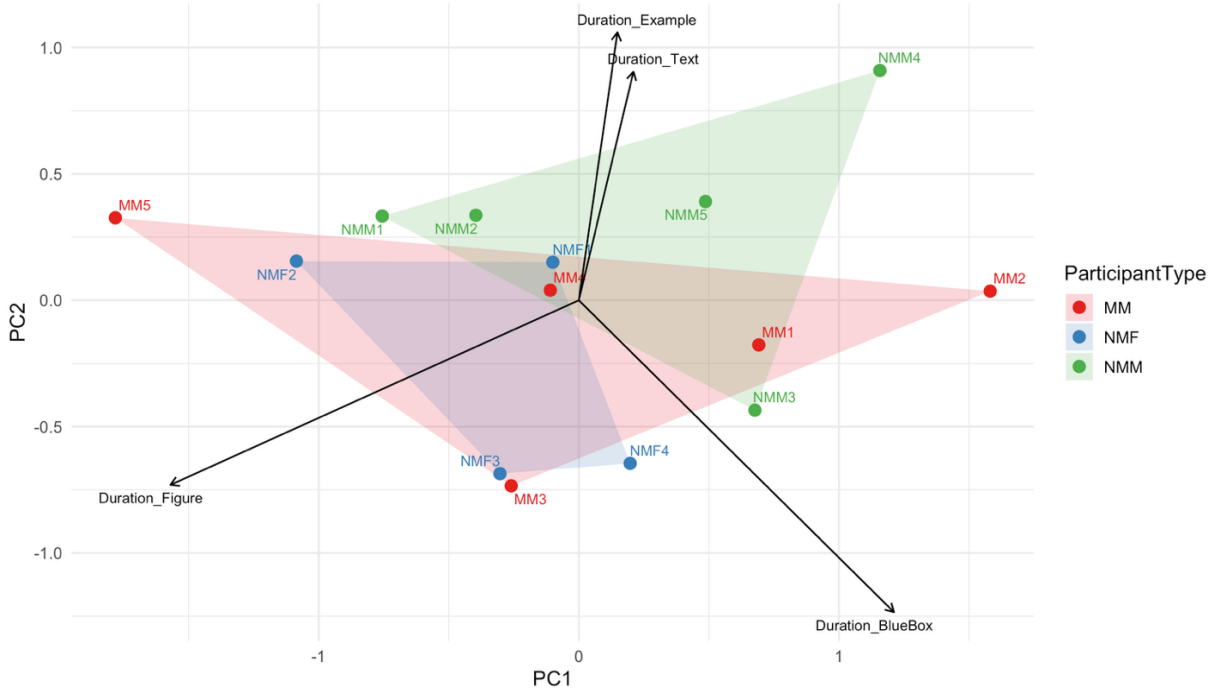

Figure 2. PCA biplot of duration variables.

In this plot, the arrows represent the contribution of each stimulus type to the principal components; these arrows suggest that the figure and blue box components most strongly influence PC1, while example and text primarily play a role in PC2.

Each point in the graph represents one participant's score along the PC1 and PC2 axes. The points are connected by colored convex hulls to highlight similarities and differences within and between groups of participants. In the green hull (NMM), four of five points had relatively higher PCA scores along PC2. The blue (NMF) and red (MM) hulls occupy roughly the same range along the PC2 axis, suggesting a similar balance between text and example durations. However, the MM hull suggests that some MM participants spent relatively more or less time on blue box and figure compared to others, whereas the clustering of NMF along PC1 indicates more uniformity in their distribution of blue box and figure attention. However, these group-level interpretations are exploratory and not inferential.

Discussion

The initial EDA revealed differences in how the participant groups allocated their attention across types of text. The faculty members distributed their attention roughly evenly among the example, figure, and text, while the math majors tended to focus on the expository prose and the non-math majors focused on the examples. One explanation for these patterns could be the participants' disciplinary literacy practices. The faculty members were all scientists, and one disciplinary literacy practice in science is to view different text elements as alternative forms of overlapping information (Shanahan et al, 2011); this might have led faculty members to attend equally to the different types of text. Similarly, the math majors might have focused on the expository text to closely read the derivation of Newton's Method because understanding derivations is an essential mathematical practice. In contrast, the non-math majors' focus on the examples could be interpreted from a perspective of what it means to know mathematics, in which understanding a concept is viewed as equivalent to being able to perform a procedure.

The perspective of didactical disciplinary literacy provides a slightly different set of explanations for the participants' distribution of attention. One DDL practice involves attending to the textbook authors' instructional purpose. In this textbook excerpt, the figures played the role of providing an intuitive explanation of more formal aspects of the text. The faculty members might have recognized this purpose and, consequently, focused their attention on the figures, while the math majors' attention was still guided by the disciplinary focus on the formal symbolic derivation. In contrast, the non-math majors' focus on the examples could be explained by their identity as students and their anticipation of being asked to solve similar problems.

The permutation MANOVA did not reveal a statistically significant difference between the groups' distribution of attention. One explanation for this is that there are no significant differences between the groups. Another possible explanation is that there is significant variation within each group, and the small sample size didn't provide sufficient statistical power to identify the differences. The PCA biplot suggests yet another explanation: There might be differences between the groups, but these differences exist on more complex combinations of groups of variables, such as contrasting figure + formula with text + examples.

By examining how different reader populations allocate attention across types of text, the present study offers one of the first attempts to link measurable patterns of attention with theoretically grounded models of literacy. Future work could include combining AOIs along other dimensions, such as mathematical content or pedagogical purpose, to further examine relationships between DL, DDL, and participants' attentional distribution.

Investigating Students' Ways of Reasoning When Estimating an Unknown Population Parameter

Claire Miller
University of Georgia

To examine the forms of reasoning novice statistics students employed when reasoning about sampling distributions, I used Charles S. Peirce's three classic forms of inferential reasoning—deduction, induction, and abduction—defined by case, rule, and result. In this paper, I report on a subset of these findings by describing and comparing the reasoning of seven undergraduate students. I engaged each student in a statistical task that I designed to investigate their reasoning in a repeated sampling environment when given a population with an unknown parameter. Findings indicate that abductive reasoning was powerful in making inferences from sample data to the unknown population.

Keywords: statistics education, reasoning, sampling distribution

Data are everywhere. Data are often reported in the form of polls, medical studies, and advertisement information. Introducing students to the basic language and fundamental ideas of statistics will help them develop statistical reasoning skills to evaluate data-based claims, enabling them to become better educated, well-informed members of society (Bargagliotti et al., 2020; Ben-Zvi & Garfield, 2004; GAISE College Report ASA Revision Committee, 2016). A major component of statistical reasoning is inferential reasoning, or drawing conclusions from data. Noll and Hancock (2015) noted that inferential reasoning is "a fundamental skill for participation in a global, technological, and data-driven society" (p. 362). Inferential reasoning includes many statistical ideas, such as repeated sampling, variability, and randomness. Understanding these ideas is important for improving students' statistical literacy and productive citizenship (Franklin et al., 2007; Saldanha & Thompson, 2007).

Despite the importance of understanding these statistical ideas and being able to reason inferentially, research suggests that students struggle with these ideas (Saldanha & Thompson, 2002, 2014; Sotos et al., 2007). For example, many students may be able to carry out the calculations involved in formal inference procedures, such as confidence intervals and hypothesis tests, but they often struggle to understand the underlying process and logic behind statistical inference (Chance et al., 2004). One reason for this difficulty stems from the complex and abstract concept of sampling distribution, which requires students to coordinate multiple ideas such as sample, population, distribution, variability, and repeated sampling (Chance et al., 2004; Kadijevich et al., 2008; Noll & Shaughnessy, 2012; Saldanha & Thompson, 2002, 2007). Another source of difficulty is that the forms of reasoning that are expected and highlighted in statistics differ from those that are standard in mathematics (Groth, 2015).

Theoretical Framework

Definitions of reasoning include some process of transforming given information to develop a conclusion or make an inference (e.g., Galotti, 1989; National Council of Teachers of Mathematics, 2009). Deduction, induction, and abduction are three classic forms of inferential reasoning. I adopt the definitions of deductive, inductive, and abductive reasoning from Peirce (1878) and others (e.g., Reid & Knipping, 2010). *Deductive reasoning* is the process of drawing logically valid conclusions based on stated assumptions or rules and is thought to be the only form of reasoning that establishes a conclusion with certainty. *Inductive reasoning* involves

generalizing a rule from several observations. *Abductive reasoning* starts with an observation and involves *hypothesizing* what rule might lead to that particular observation.

Peirce (1878) defined deduction, induction, and abduction in terms of a triadic structure involving a *case*, *rule*, and *result* that are linked in a particular order. Reid & Knipping (2010) interpreted Peirce's definitions and defined a *case* as a specific observation that a condition holds. A condition describes an attribute of something, or a relation between things. A *rule* is a general proposition that states that if one condition occurs then another one will also occur. A *result* is a specific observation, similar to a case, but referring to a condition that depends on another condition linked to it by a rule. The order in which one links a case, rule, and result determines the kind of inference needed to gain more knowledge about the situation. In deductive reasoning, a rule and a case conclude a result. In inductive reasoning, a case and a result (or often, many cases and many results) lead to a rule. In abductive reasoning, a result and a rule infer a case. Consider the different ways case, rule, and result can be linked using Peirce's (1878) original example about a pile of beans found on a table: (1) If I know that all of the beans in the bag on the floor are white (the rule) and that a pile of beans on the table is from the bag on the floor (the case), then I can *deduce* (with certainty) that all of the beans in the pile on the table are white (the result); (2) If I know that a pile of beans on the table is from the bag of beans on the floor (case) and that all of the beans in the pile on the table are white (result), then I can *induce* that (probably) all of the beans in the bag on the floor are white (rule); and (3) If I know that all of the beans in the pile on the table are white (result) and all of the beans in the bag on the floor are white (rule), then I may *abduce* that (possibly) the pile of beans on the table is from the bag of beans on the floor (case).

In both mathematics and statistics, we see all three forms of reasoning. Conjectures and generalizations through inductive reasoning occur in both mathematics and statistics. Abduction occurs in both mathematics and statistics when hypotheses are constructed to explain some observation or event. Although mathematics and statistics share similar forms of reasoning, the emphases in each field differ. In mathematics there is an emphasis on deduction and proof, arriving at conclusions with certainty. The emphasis in statistics is on reasoning with uncertainty, a feature of both inductive and abductive reasoning. This paper reports on a subset of my findings from a larger project in which I investigated how novice statistics students understand sampling distributions. For this paper, I studied the research question: When given a population with an unknown parameter, what forms of reasoning (i.e., deduction, induction, and abduction) do novice statistics students employ when making inferences from one sample outcome to the population from which it was drawn, and what do these forms of reasoning reveal about their understanding of sampling distributions?

Methods

Participants for the larger study were 11 undergraduate students from a large university who had recently completed an introductory statistics course. I engaged each student in two clinical interviews, each 60-75 minutes in length. Across both interviews, the context was about the true population proportion of intended business majors at two large universities. North University's website states that 20% of their undergraduate students are intended business majors while South University's website does not have this information posted. In the first interview, students reasoned about sample outcomes drawn from North University, a population with a known parameter. They made predictions for sample outcomes, physically drew samples from a large box of beads with proportions corresponding to the population of interest, and simulated drawing many samples using a web-based applet (Rossman & Chance, 2021). Throughout the interview,

they updated their predictions for sample outcomes as they continued to draw more samples. In the second interview, I tasked students with estimating the unknown population parameter at South University based on the result of one sample outcome. They drew one sample from a box of beads that modeled the population of interest, made an initial prediction for the unknown parameter, tested and refined their prediction using the web-based applet, and ultimately provided a range of plausible values they believed captured the true population proportion. This paper reports on data collected from the second clinical interview.

Primary data for this paper include the interview transcripts. After checking and timestamping interview transcripts against the audio and video recordings of the interviews, I adapted Simon's (2019) three-level approach to analyzing qualitative data. In the first level, I analyzed the interview transcripts line-by-line and identified segments of data in which students provided an explanation or a justification. Taking a convergent approach (Clement, 2000) in the second level of analysis, I applied Peirce's (1878) case-rule-result framework to each segment to infer the form of reasoning students used. This involved identifying what the student used as a rule and how they either applied the rule to a particular case (deductive reasoning), developed the rule from multiple cases (inductive reasoning), or hypothesized a rule to explain a particular case (abductive reasoning). In the third level of analysis, I identified emergent themes that provided additional insight into students' understanding of sampling distributions beyond the three broader forms of reasoning.

Results

This paper reports on a subset of the findings of the larger study. By describing and comparing the reasoning of seven students, I highlight a critical difference in two forms of reasoning. All seven students used the applet to continually make and test predictions for the unknown population parameter. In addition, all seven students used the likelihood of their sample outcome to assess their predictions for the unknown population parameter. However, only three students related one or more sampling distributions that they constructed using the applet to a hypothetical population. These three students reasoned abductively by hypothesizing multiple populations that could have produced their one sample outcome. In contrast, students who did not consider a hypothetical population developed a rule—using the likelihood of their sample outcome—to deduce a range of plausible values for the unknown population parameter. I identified a subtle yet critical distinction in students' reasoning across these two groups; those who reasoned abductively coordinated two levels of distribution—population distribution and sampling distribution—and those who reasoned deductively did not show evidence of this coordination.

Abducing Plausible Values for the Unknown Population Parameter

Three students related one or more sampling distributions that they constructed using the applet to a hypothetical population that could have produced the collection of sample outcomes. These students abduced a range of values based on the likelihood of the outcome of their one random sample that they drew from the box of beads that modeled the South University context. They repeatedly predicted and tested multiple values for the unknown parameter and assessed the plausibility of each value by considering how often their sample occurred in the many samples they drew using the applet (see Figure 1). Each time they determined that a hypothesized value was plausible, they abduced a case from a result and a rule. Starting with their one sample outcome (result), they hypothesized a value for the unknown population parameter, then constructed a sampling distribution using the applet with the probability of

success equal to the hypothesized value and drew many samples. Because their sample outcome was likely to have occurred under the hypothesized value (rule), they abduced that their sample could have been drawn from a population whose parameter was equal to the hypothesized value (case).

For example, when testing her prediction of 60% for the unknown population parameter, Lorraine drew 500 random samples with the applet using a probability of success of 0.6 (see Figure 1). Using the results of her simulation, Lorraine assessed the likelihood of her sample outcome of 52% when the probability of success was 0.6. She said,

> It looks like 52 would be reasonable…it looks like there's a pretty significant number of results that are…52. And then past that is where it tends to kind of taper out. So maybe if the true proportion were 60%, the lower bound would be like 48 or so.

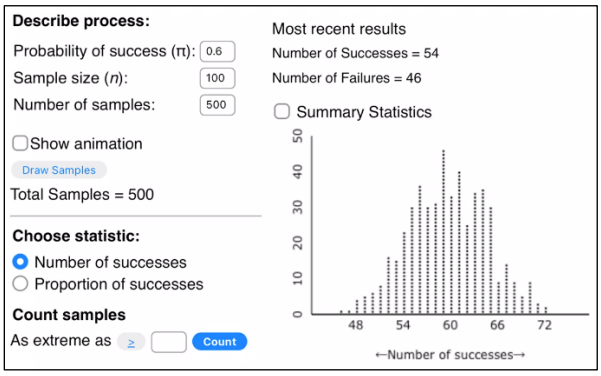

Figure 1. The Result of Lorraine's Simulation When Testing 60%

Given her sample outcome of 52% (result), Lorraine assessed the likelihood of her sample outcome, determining that her sample outcome "would be reasonable" "if the true proportion were 60%" (rule). She abduced that her sample outcome could have come from a population whose true parameter was 60% (case) and included 60% in her range of values for South University's true parameter. Lorraine related the sampling distribution she constructed to a hypothetical population with a "true proportion" of 60%, indicating she understood that the sampling distribution represented the outcomes of 500 random samples drawn from a population whose parameter was 60%. Lorraine continued to use the applet in this way to abduce multiple values that were plausible for the true percentage of undergraduates at South University who were intended business majors, ultimately providing a range of 42% to 62% for the unknown population parameter.

Like Lorraine, Eric and Lyla repeatedly predicted and tested multiple values for the unknown population parameter, assessing the plausibility of each value based on how often their sample outcome occurred. Furthermore, both showed evidence of relating one or more sampling distributions they constructed using the applet to a hypothetical population that could have produced that collection of sample outcomes. When Eric tested his prediction of 40%, he explained that the 40% represented "the assumption that if South University had their proportion online…that proportion is 40%. It's like the 20% from North University," indicating that he related the sampling distribution he constructed with a probability of success of 0.40 to a hypothetical population whose true parameter was equal to 40%. To assess the plausibility of his prediction, he considered the likelihood of his sample outcome under this assumption. He said, "If you say it's 40, then 50 could be a possibility," pointed to a sample outcome of 50 on the dot plot, and said, "So we could say, oh, that one [sample] that I drew was that one." When Lyla

tested her prediction of 50%, she explained that she "made a distribution based on this 0.5" and looked for "the probability of drawing 46 students in a sample of 100 from this larger population." She related the sampling distribution she constructed with a probability of success to a "larger population" and considered the likelihood of her sample outcome of 46. Like Lorraine, both Eric and Lyla repeatedly reasoned in this way, abducing a case from a result and a rule. They abduced that their sample outcome (result) could have been drawn from a population (case) whose parameter was equal to their prediction (rule).

The conclusion of this abductive inference is that the one random sample these students drew could have been drawn from a population with some parameter, *p*. Without connecting a collection of sample outcomes to the population from which they were drawn, this conclusion is not possible. Without this connection, considering the likelihood of the outcome of the one sample can be used as a procedure to deduce a range of values for the unknown population parameter. This was the case for Tami, Tyra, Mindy, and Corrina.

Deducing Plausible Values for the Unknown Population Parameter

Four students used the likelihood of their sample outcome to assess the plausibility of multiple values for the unknown parameter, without relating each sampling distribution they constructed to a hypothetical population that could have produced those outcomes. Rather than hypothesizing what population could have produced their sample outcome, they used the likelihood of their sample outcome as a rule to determine whether they should include their prediction in the range of values for the unknown population parameter. These students reasoned that if their sample outcome occurred often when the probability of success was equal to *p*, then *p* should be included in their range of values, without connecting the collection of sample outcomes to a population whose parameter is equal to *p*. This connection is the subtle yet critical distinction between the abductive inference I described in the previous section and these four students' deductive inference. By considering the likelihood of their sample outcome each time they constructed a new distribution using the applet, they understood that the distribution they constructed represented a collection of sample outcomes to which they could compare their one sample outcome. However, they did not show evidence of understanding that each sampling distribution they constructed with some fixed parameter, *p*, represented a collection of possible outcomes from a population whose true parameter was equal to *p*.

Corrina's reasoning is representative of the group. When testing her prediction of 40%, Corrina considered the likelihood of her sample outcome of 51 (see Figure 2a). She said, "It's kind of on the higher end. It's not as likely, but it totally could happen" and included 40% in her range of values for South University's true parameter. When she tested 60%, she said, "Yeah, so that 51, again, is kind of on the lower end, but still likely, so I think it could be 60" (see Figure 2b) and, again, included 60% in her final range of 38% to 62% at the end of the task.

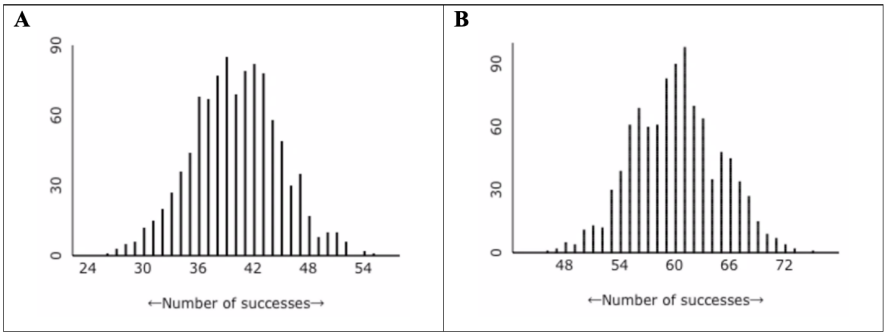

Figure 2. The Results of Corrina's Simulations When Testing 40% and 60%

Corrina applied a general rule to each of her predictions to deduce whether she should include the prediction in her range of values for the true parameter at South University: If my sample outcome occurred in a large collection of outcomes when the probability of success is equal to *p*, then *p* should be included in my range of values. She applied her rule to her prediction of 40% and reasoned that because her sample outcome of 51 "could totally happen" when the probability of success was equal to 40% (case), then 40% was a plausible value for the unknown parameter (result). Similarly, because her sample outcome of 51 was "on the lower end, but still likely" when the probability of success was 60% (case), then 60% was a plausible value for the unknown parameter (result).

Students' Summaries

At the end of the task, students summarized how they determined their range of plausible values for the true percentage of intended business majors at South University. These summaries provided additional evidence of the difference in students' understanding across the two groups. Table 1 shows the summaries of a subset of students who are representative of each group.

Table 1. Students' Summaries

Form of Reasoning	Summary
Abductive	Lorraine: If I put in the probability of success as 42, or if I put 0.42 in the center, that would be the proportion of business students. Then it'll tell me, or it won't tell me, but I can guess how likely it is that I would pull the result that I pulled (motions to her sample of 100 beads on the scooper) from that [box of beads]…If it was likely enough that I could pull a sample of 100 students where 0.52 was 52 is the percent that were business majors, then it would be likely that that number could be within the range of the actual proportion…It's kind of a messy way to explain it, but since we put in 0.42 and 52 was a reasonable, or it wasn't an uncommon result, yeah, it wasn't significantly high or significantly low, then it's likely that this [0.42] could be the actual proportion. So, it should be included in the range.
	Lyla: We started by drawing a sample of undergraduates without knowing the true proportion of students that are intended business majors, which my value was 0.46. And then I just made a prediction what the true population may look like based on this sample. I didn't stray much from the 0.46, I did 0.5 and then made a distribution based on this 0.5 and saw where the probability of drawing 46 students in a sample of 100 from this larger population fell on that success rate. And then based on that, tried to find values where drawing 46 was the very furthest extremity and then the lowest extremity to try to find cases in which it seems nearly impossible to get 0.46, both it being the smallest number and the largest number. And from that, knowing the proportions in which it was basically impossible to get the number 46, we know where it is possible to have 46.
Deductive	Corrina: So, when looking at the dot plot, I would put in our prediction of maybe it's 50% and then look for that 51 on the dot plot. And then just obviously we looked at the other numbers, but if you were really looking for, is it this or not, you could just kind of look at 51 and see how likely that happened. So, normally I would just kind of go straight for that 51 and see on this one it's this teeny tiny dot, but on one of the other ones it was the most probable thing on there…Just kind of where 51 was sitting on the scale. The number that we put in here (points to the probability of success on the applet) kind of is usually towards the middle, just kind of how close it's getting to this sample [outcome of 51] was kind of deciding whether or not it ends up in the scale.
	Mindy: So, this [first] one was just kind of a random prediction, because it's super close to 49. And then we plugged in different ranges, and I determined whether or not 49 would fall on the graph. And because of that you can kind of determine whether or not you think 20 or 30 would actually be in the range…When we saw 20, 49 wasn't super likely to show up.

There are two important differences between the summaries of students who reasoned abductively and those who reasoned deductively. First, those who reasoned abductively mentioned the context of the problem multiple times when they referred to "business students," "business majors," "a sample of undergraduates," and "a sample of 100 students." Second, they related the context to a hypothetical population when they referred to "the proportion of business students," "the true proportion of students that are intended business majors," and "students in a sample of 100 from this larger population." In addition to the explicit connections these students made to a hypothetical population in their explanations when testing multiple predictions, these key differences in their summaries provide additional evidence that this group of students coordinated two levels of distribution: population distribution and sampling distribution. In contrast, students who reasoned deductively referred to "the dot plot," "this teeny tiny dot," and "the graph," without ever referring to the context of the problem or using words or phrases that suggested they were thinking about a hypothetical population in relation to the samples they drew using the applet.

Discussion and Implications

This study examined the forms of inferential reasoning seven novice statistics students employed when reasoning about sampling distributions. When given a population with an unknown parameter, students used abductive or deductive reasoning when making inferences from one sample outcome to the population from which it was drawn. Those who reasoned abductively hypothesized multiple populations (and corresponding parameters) that could have produced their sample outcome. In doing so, they reasoned about the multi-tiered repeated sampling process (Saldanha & Thompson, 2002) and considered multiple levels of distribution in their reasoning—a critical understanding to reason productively from sample data to the population from which it was drawn. In contrast, students who reasoned deductively used the likelihood of their sample outcome in their rule for determining whether to include a particular prediction in their range of values for the unknown parameter. These distinct ways of reasoning have important implications for research and teaching.

Using Peirce's (1878) framework illustrates how these three broad forms of inferential reasoning are useful in distinguishing between the critical aspects of statistical reasoning and mathematical reasoning. In particular, I defined statistical inference in terms of abductive reasoning, which enabled me to understand how students coordinated multiple levels of distribution to draw inferences from sample data to a larger population. This approach of using Peirce's (1878) forms of inferential reasoning could be adopted by other researchers to investigate students' understanding of other important statistical concepts and statistical reasoning more broadly.

The focus of many introductory statistics courses at the undergraduate level is on statistical inference, whether informal or formal. The results of this study showed that abductive reasoning was powerful in making inferences from sample data to a larger population. Providing students with opportunities to reason abductively can support them in understanding the underlying logic and processes in estimating an unknown population parameter. For example, designing tasks that provide students with opportunities to continually hypothesize multiple populations from which a sample may have been drawn can promote abductive reasoning. Engaging with simulation tools can promote these critical forms of reasoning, but more research is needed to understand the meanings students construct when using these tools.

Interpreting Components as Coordinates in Two Coordinate Systems

Inyoung Lee
Utah Valley University

This study explores how linear algebra students reason with a novel coordinate system, the COSLA system. As part of a larger study, individual clinical interviews were conducted with three students, and their work was analyzed through the ReNaming and ReLocating framework (Lee; 2023, 2024). Findings include various approaches in interpreting n-tuples and vector notations and different ways to reason about a displacement vector. This paper also presents challenges students may face with non-Cartesian systems and suggests future implications for teaching change of basis.

Keywords: student thinking, change of basis, n-tuples, vectors, coordinates

Introduction and Literature

Coordinate systems are widely used in undergraduate mathematics. In precalculus and calculus, students work with various coordinate systems, such as the Cartesian and Polar coordinate systems. They use n-tuples to denote point locations on plane or to express the results of component-wise operations. In linear algebra, students also work with non-traditional linear coordinate systems generated by basis vectors distinct from the Cartesian unit vectors, where vector notation is typically employed.

Several studies have reported on student thinking about vectors in n-tuple form. Students often interpret vectors as a particular string of numbers, independent of any coordinate systems (Hillel, 2000). Similarly, students may conceive the image of a vector under a linear transformation as a string of numbers rather than as a vector representation relative to a basis. (Hillel & Sierpinska; 1994, Sierpinska et al; 1999) More recently, Selby (2016) found that linear algebra students could answer change of bases questions by memorizing formulas, however, often neglected to reason about what is accomplished through the process. To support students in learning change of basis, he proposed a change of basis project emphasizing physical interpretations.

A few other studies have focused on developing instructional materials in the context of change of basis. Wawro et al. (2013) developed a task sequence to support students in reinventing matrix diagonalization, $A = PDP^{-1}$ by working with a non-traditional coordinate system which uses y=x and y=-3x as the new axes. Zandieh, Wawro, & Rasmussen (2017) identified four types (S1-S4) of linear algebra students' symbolizing evolution found in their class the reinvented matrix diagonalization curriculum was applied to. Levenberg (2015) developed a task for pre-service teachers that involved reading values from axes labeled with non-numerical quantities. He found that such activities prompted logical thinking because the relationship among the non-numerical values were directly tied to their associated meanings.

Conceptual Framing

ReNaming and ReLocating

I developed a framework that describes how students reason when identifying locations within a single coordinate system and across multiple coordinate systems. Also, the framework details how they represent numerical values as locations within one or more coordinate planes

(Lee; 2023, 2024). The framework, referred to as the coordinate system framework, includes four distinct components: Naming, Locating, ReNaming, and ReLocating.

Naming describes how locations or shapes in a coordinate plane are assigned names, such as ordered pairs and equations, while Locating describes the reverse process, how ordered pairs or equations are placed into a coordinate plane.

ReNaming refers to when a location or shape, initially measured in one coordinate system, is assigned a new name in a second coordinate system laid atop the first. For example, a circle centered at (1,0) with radius 1 can be named as $(x-1)^2+y^2=1$ in the Cartesian coordinate system and renamed as $r=2cos\theta$ in the polar system (Figure 1. Left).

ReLocating, on the other hand, occurs when an existing name creates two different locations or shapes in space, depending on the coordinate systems being used. The new one may appear different from the first, but they share the same name. For instance, the polar curve, $r=2cos\theta$, can be sketched in the Cartesian coordinate system (Figure 1, Right).

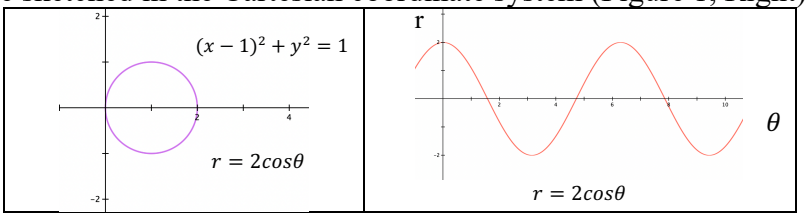

Figure 1. ReNaming Circle with Two Systems (Left), ReLocating $r=2cos\theta$ into Cartesian System (Right)

Coordinates Not the Same as Components

Coordinates are not always identical to the components in n-tuples (Lee, 2024). Coordinates represent relative sizes with respect to the units employed by a coordinate system, whereas components are the number values listed in an n-tuple or a vector notation. This distinction may not be apparent when considering a point's coordinates within the Cartesian coordinate system, however it becomes salient when reasoning with non-Cartesian coordinate systems. For example, when a student attends to the components of a point's ordered pair (1,2) in the Cartesian coordinate plane, s/he may think of it as "over 1, up 2". His/her interpretation may not have much problem to view (1,2) in terms of the Cartesian basis vectors as such "1 of $\begin{bmatrix}1\\0\end{bmatrix}$ and *2* of $\begin{bmatrix}0\\1\end{bmatrix}$" because the calculation $1\begin{bmatrix}1\\0\end{bmatrix}+2\begin{bmatrix}0\\1\end{bmatrix}$ becomes the same as $\begin{bmatrix}1\\2\end{bmatrix}$. However, when thinking of a point viewed in another coordinate system, things get different. For example, there is a point named as (2,1) relative to the basis $\boldsymbol{B}=\{\begin{bmatrix}1\\-1\end{bmatrix},\begin{bmatrix}0\\2\end{bmatrix}\}$, which would mean "2 of $\begin{bmatrix}1\\-1\end{bmatrix}$ and 1 of $\begin{bmatrix}0\\2\end{bmatrix}$". The location of (2,1) is being represented as a linear combination of the two vectors, $\begin{bmatrix}1\\-1\end{bmatrix}$ and $\begin{bmatrix}0\\2\end{bmatrix}$, that is $2\begin{bmatrix}1\\-1\end{bmatrix}+1\begin{bmatrix}0\\2\end{bmatrix}$ in the new system. Figure 2 illustrates the location of coordinates (2,1) in the new black system.

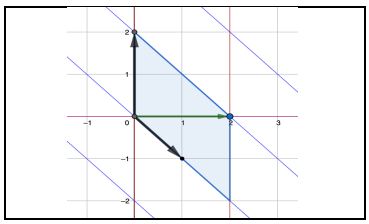

Figure 2. (2,1) in the New Black Coordinate System

While (2,1) is represented as the green vector in the plane, it is also represented as (2,0) relative to the Cartesian basis. In other words, 2 and 1 in (2,1) are the *coordinates* of the location because they are defined relative to the basis $\{\begin{bmatrix}1\\-1\end{bmatrix}, \begin{bmatrix}0\\2\end{bmatrix}\}$, while 2 and 0 in (2,0) are the *components* if it is the calculated result from $2\begin{bmatrix}1\\-1\end{bmatrix} + 1\begin{bmatrix}0\\2\end{bmatrix} = \begin{bmatrix}2\\0\end{bmatrix}$ with no attention to the basis.

This proposal reports on student reasoning with a novel coordinate system, the COSLA system, to address the research question: How do students interact with the novel coordinate system and how they interpret components and coordinates- are these interpretations distinct?

Methods

As part of a larger dissertation study, this proposal draws on data from individual face-to-face clinical interviews (Clement, 2000). At the time of interviews, participants were STEM majors who had completed Calculus 1 or 2 as prerequisites and had taken an inquiry-oriented linear algebra course at a large public university in the United States. Both their written work and interview conversations were video recorded. Written work was archived as pdfs, and conversations were transcribed into spreadsheet. Student reasoning was coded line by line on the spreadsheet using the ReNaming and ReLocating framework. All the names used in this report (Hann, Wilson, Jeraldo) are pseudonyms.

Description of the Task

I designed my dissertation task protocols in three packets each called clinical interview, teaching experiment 1, and teaching experiment 2. This proposal focuses on a task administered at the end of clinical interview (Figure 3, Left). The task was designed to explore how students interpret and use a novel coordinate system, referred to as the COSLA system, in which the unit vectors, C_1 and C_2, do not have length 1 relative to the rectangular system, and the origin is not located at (0,0). Prior to this task, students participated in clinical interview tasks themed around Gulliver's Travels, set in an experientially real place, Cocos Island, including a treasure hunt task. Students worked with multiple coordinate systems, such as the Gulliver (slanted) system (Figure 3, Middle) and the Rock (rectangular) system (Figure 3, Right). This series of tasks was developed according to the central idea of Realistic Mathematics Education (RME) informed by Freudenthal (1991). During the clinical interviews, students approximated the location of the Treasure on the Rock's coordinate system as roughly (10, 6.6) or (9.8, 6.6).

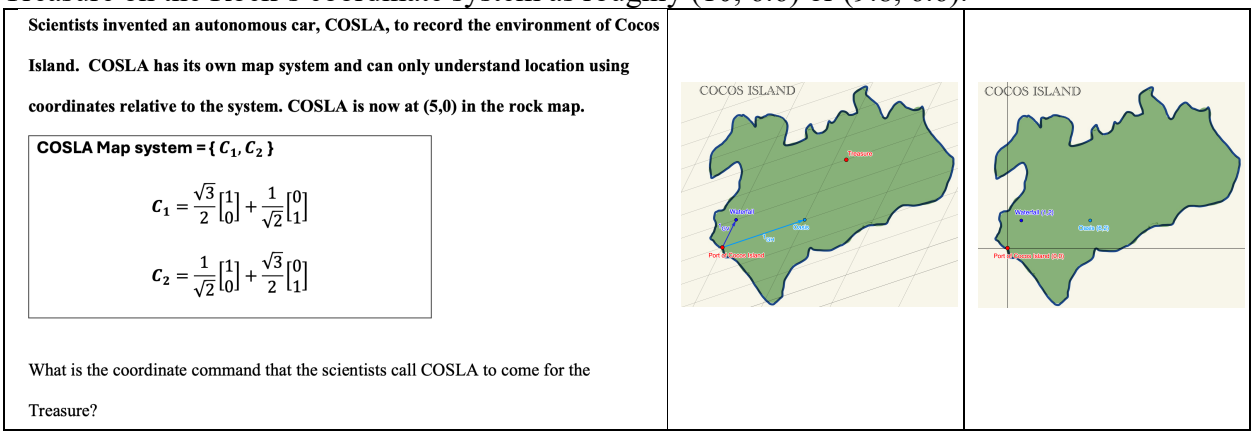

Figure 3. The COSLA Task (Left), Gulliver System (Middle), Rock System (Right)

In the COSLA Task, two coordinate systems are used: the COSLA system, which employs C_1 and C_2 as unit vectors, and the Rock system, which is identical to the rectangular system. Scientists, as inventors of the car, have access to both systems and represent components in C_1 and C_2 in terms of the rectangular coordinate system. That is, $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$ are the standard unit vectors, and $\frac{\sqrt{3}}{2}$ and $\frac{1}{\sqrt{2}}$ are relative sizes to the '1'in the standard rectangular system. The car, COSLA, can only interpret commands expressed relative to its own unit vectors, C_1 and C_2.

Results

This section reports how two participants progressed in their search for the coordinate command in the COSLA task. It also examines how components in an ordered pair or a two-dimensional vector came to be understood as coordinates in their reasoning.

Interpreting Components as Coordinates in ReLocating Unit Vector

A participant, Hann, began by interpreting vectors as relative to a coordinate system.

> "We have this definition of our map system[COSLA system]. Okay, so I'm going to interpret these vectors [pointing to the $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$ in C_1 and C_2] as being expressed in relation to the rectangular coordinates. So, this one zero, zero one is in rectangular."

He clarified $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$ inside C_1 and C_2 as vectors within the rectangular system, and then continued: "What does that [pointing to C_1 and C_2] tell me? …Okay, so we have C_1 which is one zero, C_2 which is zero one (Figure 4)."

He went on to conceptualize C_1 and C_2 as unit vectors relative to the COSLA system and represented them again as $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$. The $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$ appearing inside C_1 and C_2, and the $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$ representing the exact C_1 and C_2, although numerically identical, were distinguished by Hann through coordination with their respective coordinate systems. The two pairs of $\begin{bmatrix}1\\0\end{bmatrix}$ and $\begin{bmatrix}0\\1\end{bmatrix}$ thus came to indicate two distinct locations, which I categorize as ReLocating. To Hann, the components of ones and zeros in each vector were interpreted as coordinates of ones and zeros relative to their respective coordinate systems.

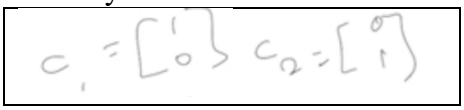

Figure 4. ReLocating Unit Vector to COSLA system

Interpreting Components as Coordinates in ReNaming Unit Vector

Hann next simplified C_1 and C_2 component-wise into vectors and related them to the COSLA unit vectors, saying: " that [COSLA unit vectors] should equal square root three over two, one over square root two in rectangular coordinates…(Figure 5)"

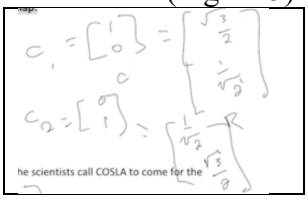

Figure 5. ReNaming COSLA Unit Vector

He placed equal signs even though the entries in the vector notation do not equal their respective components. Here, the equal sign was used to indicate the same physical unit length, despite the unequal components. These are two names for the COSLA unit vector C_1 and C_2, which I categorize as ReNaming. Hann interpreted components in $\begin{bmatrix}1\\0\end{bmatrix}$, $\begin{bmatrix}0\\1\end{bmatrix}$, $\begin{bmatrix}\frac{\sqrt{3}}{2}\\\frac{1}{\sqrt{2}}\end{bmatrix}$, $\begin{bmatrix}\frac{1}{\sqrt{2}}\\\frac{\sqrt{3}}{2}\end{bmatrix}$, as coordinates relative to their respective coordinate systems.

Interpreting Components as Coordinates in ReNaming Displacement Vector

Hann continued his search for the coordinate command by identifying the displacement vector from (5,0) to the Treasure location in the rectangular system. Drawing his earlier work in the clinical interview, he used the Treasure's location (10, 6.6), and again clarified both points, (5,0) and (10, 6.6), as well as the displacement vector from one point to the other, all expressed in rectangular coordinates.

> "What I think I'm looking for is a vector from five zero to the Treasure which is 10 and 6.6. Again, these are rectangular coordinates, and I need this vector to be expressed eventually in terms of the car [COSLA]…We can just do like the head minus the tail, so it's going to be rectangular coordinates. Now, I have the rectangular vector for this command (Figure 6)."

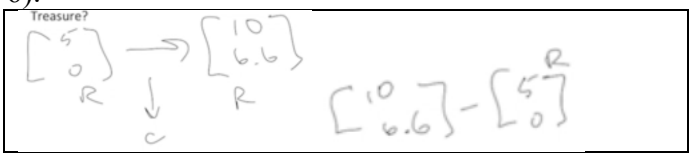

Figure 6. Naming Displacement Vector in Rectangular System

To rename the displacement vector relative to the COSLA system, Hann set up a matrix equation.

> " I need to convert it into the COSLA system, which I think I will need another matrix to do that… You want to multiply it [the matrix with A B C D in it (Figure 7)] by the COSLA coordinates that's one zero, and that will give me my square root numbers [wrote 'C→R' under M (Figure 7) to clarify COSLA to Rectangular]."

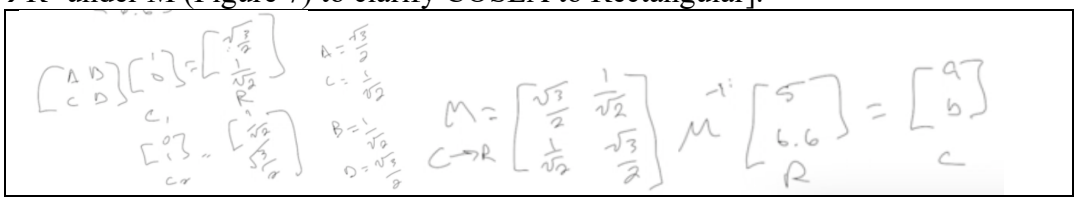

Figure 7. Matrix that Renames Vector

He continued: "to get the coordinate command we're looking for, we need to do M^{-1} times our coordinates we found before…that'll give us our car coordinates. Inverse because we're doing the opposite of what this matrix does. So, M goes from the car to the rectangular, and I want to go from rectangular to the car so taking the inverse."

Hann indicated that the coordinate command is $\begin{bmatrix}a\\b\end{bmatrix}$ (Figure 7) as a result of inverse matrix multiplication, without performing the operation by hand. The vector, $\begin{bmatrix}5\\6.6\end{bmatrix}$, is renamed as $\begin{bmatrix}a\\b\end{bmatrix}$, representing the same displacement vector, which I categorize as ReNaming. Hann interpreted components in these vectors as coordinates relative to their respective coordinate systems.

Interpreting Components as Coordinates in Rectangular System

Wilson, another participant in the interview, approached the same task in a different way. His primary reasoning was to visualize a path that connects the initial location of COSLA to the Treasure as a linear combination of vectors (Figure 8. Left), rather than as a directed displacement vector. In this approach, he did not coordinate between two coordinate systems, but instead interpreted all vector components within the rectangular system. He simplified C_1 and C_2 component-wise into vectors (Figure 8. Middle top), approximated them with decimals (Figure 8. Middle bottom), and used them as a pair of travel vectors. All components were thus expressed relative to the rectangular system. Wilson searched for the COSLA coordinate command as the coefficients a and b attached to each travel vector (Figure 8. Right).

> "The treasure in the rocks map [rectangular map] is 9.8 and 6.6… [he found the Treasure coordinate earlier as (9.8, 6.6)] what I'm trying to find …is how the commands for COSLA would put the treasure to that span… coordinate command… that's what my initial thought is the command for the coordinates to travel this path to the treasure."

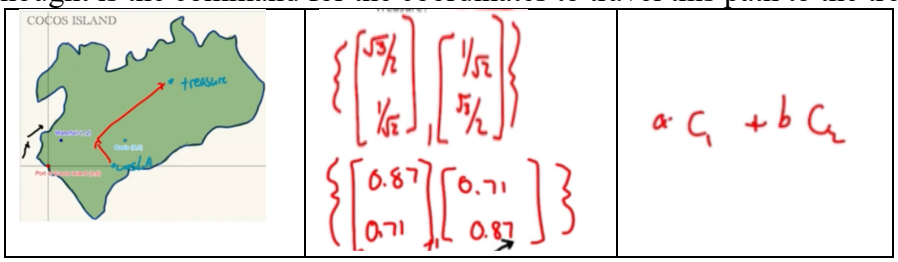

Figure 8. Path from COSLA (5,0) to Treasure (9.8, 6.6)

He continued: "I'm going to expand them [C1 and C2] out… Now that those are C1 and C2 fleshed out (Figure 8. Middle), I guess that's how those set of vectors can get to the point 9.8 6.6."

Wilson then marked travel vectors on the map as multiples of each vector from COSLA to the Treasure (Figure 9, Left) and expressed the path as a vector equation from the initial point (5,0) to (9.8, 6.6) (Figure 9. Right). His drawing and equation reflect an interpretation of the displacement vector as a journey from the initial to the final location. He then spent considerable time plugging whole numbers into a and b in the equation to approximate the Treasure's location as closely as possible.

> "Creating a path from the origin or from a point within a coordinate system to a point that isn't outright just noticeable …How many of these combination of vectors would be used as the coordinate command within this problem."

Rather than ReLocating and ReNaming the units, Wilson expanded every component of the new units and interpreted them relative to the rectangular system. In other words, he treated the components in the vectors C_1 and C_2 as coordinates within the rectangular system.

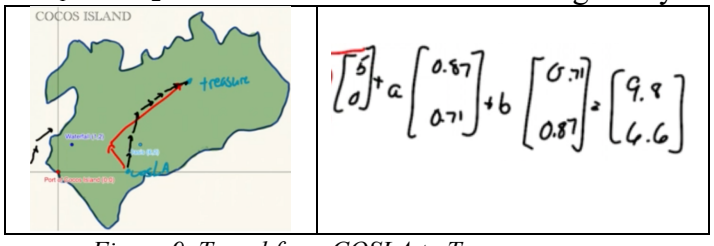

Figure 9. Travel from COSLA to Treasure

Another participant in the interview, Jeraldo, approached the task another way. Like the other two, he began by simplifying C_1 and C_2 component-wise into vectors. He then voiced the need of a transformation matrix to rename coordinates from one system to the COSLA system. Rather than relating the rectangular units to the COSLA units directly, he decided to use the landmarks on the map, the Oasis and the Waterfall, to set up a matrix equation (Figure 10).

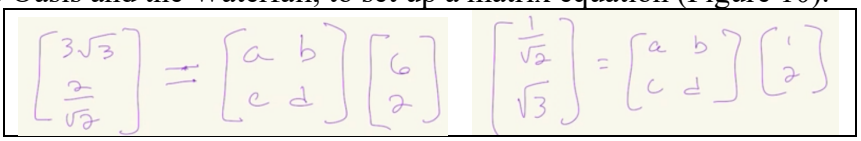

Figure 10. ReNaming Oasis (Left) and Waterfall (Right)

The Oasis is at (6,2) and the Waterfall at (1,2) relative to the rectangular system. From his matrix equations, Jeraldo appeared to assume that the two systems, rectangular and COSLA, shared the same origin at (0,0). This suggests either that he have not yet had the opportunity to distinguish the two, coordinates and components, or that he did not consider such a distinction necessary, or that he simply did not fully understand the problem.

Discussion

Similar to what Moore et al. (2013) and Zazkis (2008) noted, students express locations or equations within the system in which they have developed thinking- that is, the Cartesian coordinate system. Consequently, when they encounter another system, they tend to think of the new system in terms of an old familiar system. In many curricula and textbooks, components in an n-tuple and vector notation are by default interpreted relative to the Cartesian system, making it compelling for students to view numerical values as corresponding to the Cartesian units. To support students' flexibility in moving and expressing between coordinate systems, it is helpful to include instructions on conversions between non-Cartesian coordinate systems, independent of the Cartesian system.

As noted in the literature section, many of linear algebra studies have emphasized the importance of incorporating more realistic tasks and physical interpretations into instruction. The COSLA task was developed as part of my larger study, in line with these recommendations. I have also created a GeoGebra Applet (**https://www.geogebra.org/classic/vz2mcxqr**) designed to support students' experiences with vectors and coordinate systems, helping move instruction beyond purely abstract and computational approaches.

Lastly, although I was fascinated by Wilson's reasoning, in which he envisioned reaching the Treasure from the initial location as a kind of journey using linear combination, I came across a study reporting that students often employ similar "journey" imagery when adding vectors (Watson et al., 2003). For example, students may justify the equality in $\overrightarrow{AB}+\overrightarrow{BC}=\overrightarrow{AC}$ by reasoning that it represents moving from A to B and then from B to C. But this imagery can become problematic when interpreting the commutative property for addition such as $\overrightarrow{AB}+\overrightarrow{BC}=\overrightarrow{BC}+\overrightarrow{AB}$ since the latter expression does not give a satisfying meaning to them with the journey reasoning.

The Persistence of Motion Graph Reasoning Amid Quantitative Conceptions of Coordinate Systems: The Case of Ava

Robert Knurek
University of Southern Indiana

Teo Paoletti
University of Delaware

Heather Lynn Johnson
University of Colorado Denver

We report on a qualitative case study of a college algebra student, Ava, who participated in a series of online task-based interviews involving graphs of different dynamic situations. Our analysis focused on the nature of Ava's graph reasoning and coordinate system conceptions within and across these tasks. During Ava's interviews, she primarily demonstrated Variation and Covariation graph reasoning while conceiving of the coordinate system quantitatively. Yet, she also had an expectation that her graphs would represent the motion of the objects in the dynamic situations or the motion of the traces in the graphs themselves. Ava's Motion graph reasoning amid her quantitative conceptions of coordinate systems demonstrates overlap between quantitative and physical conceptions. Her case speaks to the richness of students' conceptions of graphs; even when they conceive of quantitative coordinate systems, they can also expect a graph trace to resemble the motion of an object.

Keywords: undergraduate education, technology, quantitative reasoning, graphing conceptions

Having students engage in tasks where they represent attributes of objects in dynamic situations graphically can be a productive way to foster students' quantitative and covariational reasoning (Carlson et al., 2002; Thompson & Carlson, 2017). However, even when the task is designed in a way that supports their graphical representations of quantitative relationships, students may or may not actually conceive of their graphs in this way. Instead, they may conceptualize them as literal pictures of physical objects (Clement, 1989; Lai et al., 2016; Leinhardt et al., 1990), depictions of motion (Kerslake, 1977), or chronological records of events (Janvier, 1998). Furthermore, students may or may not conceive of a given representational space, such as a Cartesian plane, as a coordinate system that can be used to represent quantitative relationships. Thus, whether or not a particular graphing task is effective depends, in part, on students' graph reasoning (Johnson et al., 2020) and underlying conceptions of coordinate systems (Lee et al., 2020).

Design considerations for digital graphing tasks revealed relationships between students' graph reasoning and their conceptions of coordinate systems (Johnson et al., 2024). We report on a case study combining two theoretical frameworks related to graph reasoning (Johnson et al., 2020) and coordinate system conceptions (Lee et al., 2020) to explain aspects of students' graphing activity that may seem counterintuitive or contradictory. We ask the following research question: What is the nature of students' conceptions of coordinate systems and graph reasoning within and across digital graphing tasks involving different dynamic situations?

Background

Graph Reasoning

Johnson et al. (2020) developed a graph reasoning framework to characterize students' conceptions of graphs, identifying four broad types: Covariation, Variation, Motion, and Iconic. *Covariation* and *Variation* graph reasoning involve students thinking about quantities and their relationships. For example, suppose a student is shown a dynamic situation in which a "Cannon Man" is shot vertically out of a cannon and descends with a parachute (Figure 1) and is tasked

with sketching a graph relating his height from the ground and his total distance traveled. A student demonstrating Covariation graph reasoning may sketch a graph and describe how it shows Cannon Man's height increasing and decreasing while simultaneously showing how his total distance traveled continues increasing. If the student exclusively describes their graph in terms of one of these changing attributes, they would be demonstrating Variation graph reasoning (e.g., only describing Cannon Man's height increasing and decreasing).

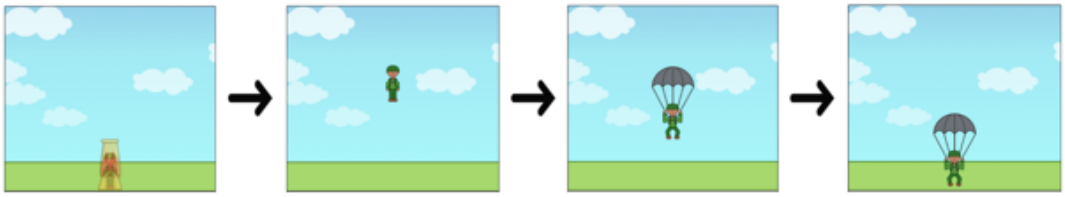

Figure 1. Cannon Man Dynamic Situation

Motion graph reasoning refers to students' reasoning about the physical movement within a dynamic situation. For example, a student demonstrating Motion graph reasoning may consider the Cannon Man dynamic situation (Figure 1) and describe their graph as representing Cannon Man's changing speed. *Iconic* graph reasoning, on the other hand, involves reasoning about physical features of the situation itself; a student demonstrating Iconic graph reasoning may describe their graph as representing Cannon Man's literal path. Johnson et al.'s (2020) framework highlights the diverse ways students may reason about and represent dynamic situations graphically.

Conceptions of Coordinate Systems

Lee et al. (2020) identified two types of coordinate systems students may conceive of when graphically representing dynamic situations: spatial and quantitative. A coordinate system is considered to be *spatial* when it is "mentally overlaid onto the space being represented" (p. 32). When students conceive of spatial coordinate systems, they determine relative locations of objects in the dynamic situations within that space. For example, given the Cannon Man dynamic situation (Figure 1), a student may conceive of a spatial coordinate system and plot points on a graph to represent the literal positions of Cannon Man in the air. Alternatively, students conceive of *quantitative* coordinate systems when they conceive of attributes in a situation as quantities and "project them onto some new space, which is different from the space in which the quantities were originally conceived" (p. 34). For example, in the Cannon Man situation (Figure 1), a student may conceive of a quantitative coordinate system and plot points on a graph to represent the relationship between Cannon Man's height from the ground and his total distance traveled. Notably, even when students are given an implied quantitative coordinate system, they may or may not conceive of the coordinate system quantitatively (e.g., using a coordinate system to represent physical locations even if neither axis entails a distance). Hence a student's meanings for the coordinate system can shape their graphing activity.

Methods

We report on a qualitative case study (Stake, 2005) of a college algebra student who participated in a series of four task-based clinical interviews (Clement, 2000; Goldin, 2000). This case stems from the first author's dissertation (Knurek, 2025a). In a preliminary report, we explored connections between a student's graph reasoning and conceptions of coordinate systems (Knurek et al., 2025b). Ava's case advances the prior work by demonstrating how

Motion graph reasoning can persist amidst a student's quantitative conceptions of coordinate systems. Ava completed interviews online via video conference, during which she interacted with a sequence of dynamic graphing tasks housed in the Desmos classroom (www.desmos.com) known as techtivities (Olson & Johnson, 2022).

During a techtivity, students are shown an animation of a dynamic situation and are asked to consider two specified attributes. Next, students are to explore changes in these attributes by dragging sliders (i.e., "Axis Sliders") along the axes of a Cartesian plane and interacting with a dynamic graph illustrating their slider movements. Then, students are to sketch a graph representing the relationship between attributes. Figure 1 (Cannon Man) and Figure 2 (Dynamic Tent, Toy Car, and 3D Printer) illustrate the four dynamic situations used for the interviews. In the Dynamic Tent techtivity (Figure 2a), students are asked to consider the height and width of a tent. In the Toy Car techtivity (Figure 2b), students are asked to consider a toy car's total distance traveled and distance from a cone. In the 3D Printer techtivity (Figure 2c), students are asked to consider the total amount printed and the height of the printed object.

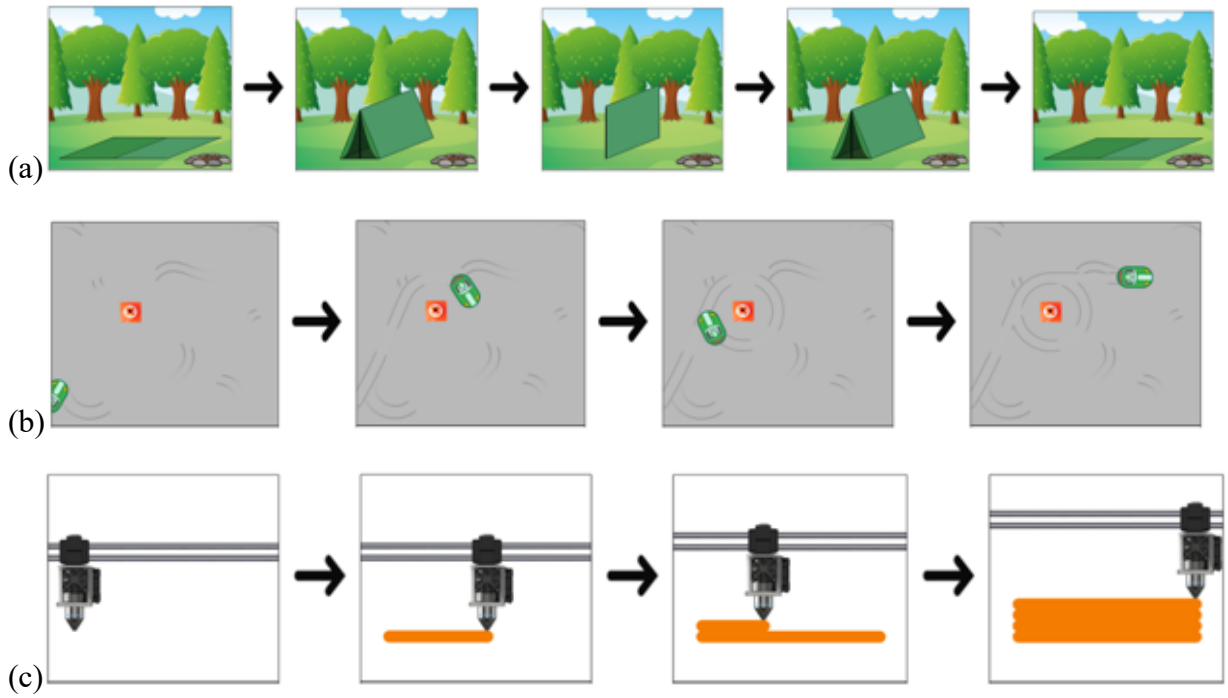

Figure 2. Dynamic Tent, Toy Car, and 3D Printer Dynamic Situations

Data Collection and Analysis

To collect data, the researcher conducted task-based clinical interviews (Clement, 2000; Goldin, 2000) to elicit students' current ways of reasoning by using interview protocols that support flexible and responsive questioning. As such, the four clinical interviews were akin to exploratory teaching (Steffe & Thompson, 2000), which is part of teaching experiment methodology.

Ava's interviews lasted approximately 20-30 minutes and were video-recorded. During the interviews, Ava shared her screen and completed techtivities while the researcher asked questions from the interview protocols, which were designed and refined during an earlier pilot study. The researcher took jot notes (Erickson, 1986) immediately after each interview to document reflections and takeaways to inform minor adjustments to interview questions for

subsequent interviews, making the approach iterative and responsive to Ava's emerging reasoning.

To systematically analyze the data, we used Wolcott's (1994) three-part framework: description, analysis, and interpretation. The first part, description, entailed reviewing both the transcripts and screen recordings of Ava's interviews and generating a detailed account of all her words, gestures, and cursor movements. For the second part, analysis, we engaged in conceptual analysis (Steffe & Thompson, 2000) to make inferences about how Ava conceived of quantities, coordinate systems, and graphs based on the descriptions. For the final part, interpretation, we drew on established theories and frameworks to make sense of Ava's thinking and answer the research question. This allowed us to take a step back and consider the broader meaning of our findings, building on the descriptions and analyses we had already conducted to make claims about Ava's reasoning and conceptions within and across techtivities.

Results

Our analysis of Ava's interviews revealed the persistence of her Motion graph reasoning (Johnson et al., 2020) amid her quantitative conceptions of the coordinate system (Lee et al., 2020). Across three interviews (i.e., Cannon Man, Dynamic Tent, and 3D Printer), Ava consistently conceived of the coordinate system quantitatively while demonstrating Variation and Covariation graph reasoning. Yet, she also conceived of some aspects of her graph as representing motion. During her other interview (i.e., Toy Car), Ava conceived of parts of the coordinate system spatially while demonstrating Motion graph reasoning.

In the following sections, we describe Ava's reasoning about each individual attribute while interacting with the Axis Sliders. Then, we present Ava's graph sketches and annotations while highlighting evidence of her graph reasoning and conceptions of coordinate systems.

Variation in a Quantitative Coordinate System

While interacting with the Axis Sliders, Ava consistently conceived of attributes in the dynamic situations as quantities and represented her conceptions of change for each attribute in a new space (i.e., the axes of the given Cartesian plane). For example, during the Dynamic Tent techtivity, Ava dragged the horizontal slider (Width) to the left as the tent's width decreased, then dragged the slider to the right as the width increased. She said, "So it starts at the widest it gets to in this video, and then it slowly like decreases until it gets to zero, and then it comes right back to its initial point." Next, Ava dragged the vertical slider (Height) up as the tent's height increased, then dragged the slider back down as the height decreased. She said, "The height starts at zero and it gradually increases and then like goes back to being zero again." Similarly, during the other three techtivities, Ava used the sliders along the axes to represent her conceptions of change for each attribute. Across all her interviews, Ava demonstrated Variation graph reasoning while conceiving of each axis in the coordinate system quantitatively.

A Coordinate System Involving Spatial and Quantitative Elements

During her Toy Car interview, Ava sketched a graph representing the toy car's proximity to the cone, rather than the relationship between the specified attributes (i.e., the toy car's total distance traveled and the toy car's distance from the cone). She started her graph by plotting a single point on the horizontal axis to represent the maximum distance the toy car traveled (Figure 3). Then, she plotted three points along the vertical axis, labeled "0ft," "5ft," and "10ft." Next, she labeled one of the points on the vertical axis as "cone" and said, "This is where the cone is at. So the cone is five feet from where [the car] started." Finally, Ava plotted points diagonally from

left to right in the plane while describing the toy car's proximity to the cone. We numbered each point in Figure 3 to indicate the order in which she plotted these points. Ava described the motion of the toy car while plotting the points:

> When it's further from its journey, it's closer to the cone [plots points labeled 1-4 from left to right on a diagonal line, Figure 3] and then further in its journey, approaching the cone, blah, blah, blah. And then we'll eventually get to the cone at some point in its journey [plots point labeled "5," Figure 3]. And then as it goes down, or as it continues its journey, it's getting further away from the cone [plots points labeled 6-10, Figure 3].

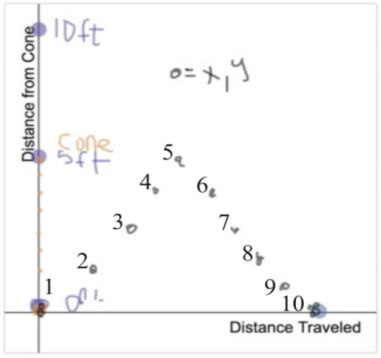

Figure 3. Ava's Graph Sketch during the Toy Car Techtivity

Ava sketched a graph to represent the toy car going to and from the cone. She labeled "cone" on the vertical axis to show the vertical location of the cone in the animation, then plotted points to show how the toy car approached the cone and continued away from the cone. We infer that Ava plotted the points from left to right either because the toy car traveled across the screen from left to right, or because she was focused on the temporal progression of the motion, accounting for experiential time (Thompson & Carlson, 2017). Ava's sketch and response suggests that she conceived of a coordinate plane involving spatial and quantitative elements, and provides evidence of Motion graph reasoning.

Covariation in a Quantitative Coordinate System

During her other three interviews (i.e., Cannon Man, Dynamic Tent, and 3D Printer), Ava sketched graphs representing the relationships between attributes in the dynamic situations. Figure 4 shows Ava's graph sketches for the Cannon Man, Dynamic Tent, and 3D Printer techtivities, respectively. Ava started each graph sketch by plotting points along the axes and in the region bounded by the axes. Then, she connected her points with line segments while describing the relationship between attributes. For example, during the Dynamic Tent techtivity (Figure 4b), Ava said, "When the height is lower at four, we see the width gradually become higher, gets to six, and when the height is even lower, the width is even higher." Ava described the relationships between attributes similarly during the Cannon Man and 3D Printer techtivities. In all three interviews, Ava demonstrated Covariation graph reasoning while conceiving of the coordinate system quantitatively.

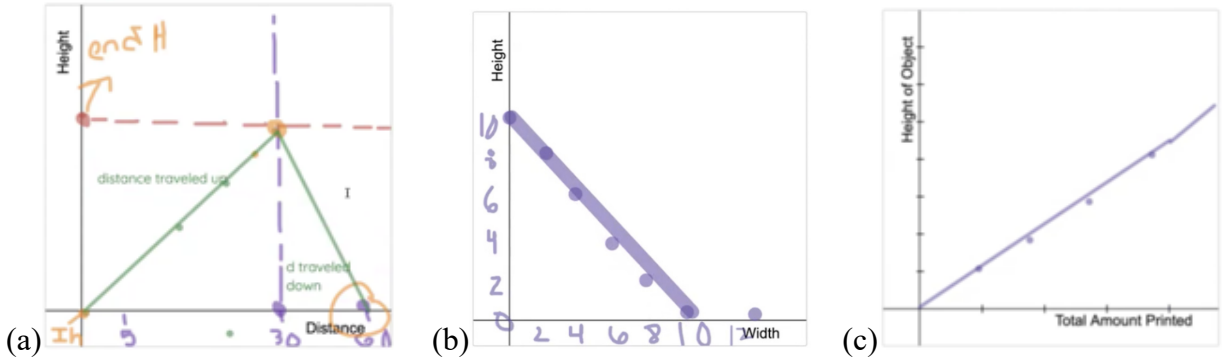

Figure 4. Ava's Initial Graph Sketches

Motion in a Quantitative Coordinate System

After Ava sketched each graph, her subsequent annotations and responses suggested that she conceived of her graphs not only as representing the relationship between attributes, but also as representing visible motion. For example, during the Cannon Man techtivity, the researcher asked Ava, "If Cannon Man just went up at a constant speed and down at a constant speed, would that change anything?" Ava responded, "Yes, because instead of my graph looking like this, it would look more symmetrical like this." She drew a picture in the top-right section of the plane that resembled an upside-down V with a vertical line through it (Figure 5a). She said, "The differences in the slopes would tell you like how fast it's going." Ava described the asymmetrical look of her graph sketch as representing Cannon Man's changing speed, with the different slopes representing different speeds (i.e., how fast it's going). During the Dynamic Tent, after finishing her graph sketch, Ava drew an arrow pointing downwards above her line segment (Figure 5b) and said, "The line goes this way." Then she drew an arrow pointing upwards below the diagonal line, crossed it out, and said, "It doesn't go this way." Similarly, during the 3D Printer techtivity, Ava drew an arrow along her line segment (Figure 5c) and said, "I think it goes in this direction." She proceeded to talk about how her graph showed the motion of the object getting "higher." Although Ava conceived of her graphs in terms of quantities and their relationships across all three interviews, her responses provide evidence that she also had expectations of her graphs representing motion; this included either the motion of the object in the dynamic situation or the motion of the trace in the graph itself. Thus, even though Ava was still conceiving of a quantitative coordinate system and evidencing Variation and Covariation graph reasoning for the majority of her interviews, her Motion graph reasoning persisted. To Ava, a graph should represent more than just the relationship between attributes; it should also incorporate some kind of motion that is reflected in the situation itself.

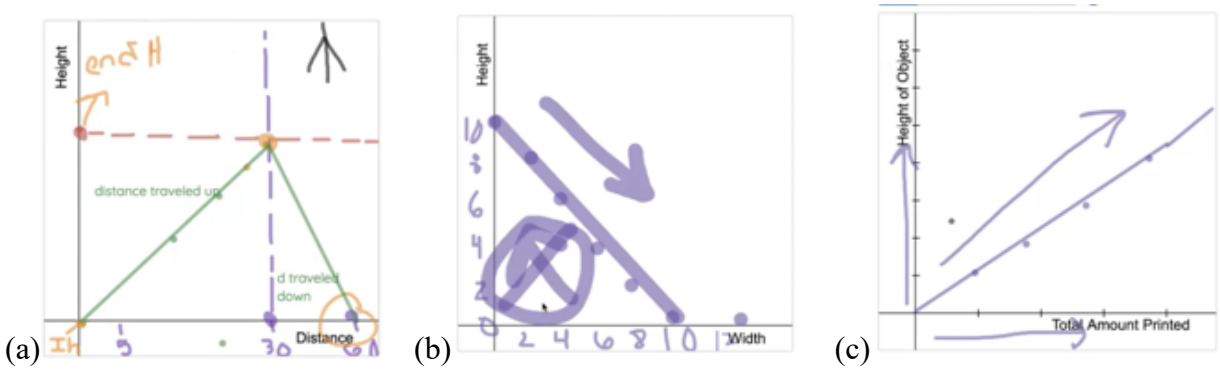

Figure 5. Ava's Graph Sketches with Subsequent Annotations

Discussion and Conclusion

This study provides empirical evidence demonstrating interrelationships between students' graph reasoning (Johnson et al., 2020) and their conceptions of coordinate systems (Lee et al., 2020). Ava's graph reasoning often aligned with her conceptions of coordinate systems in ways to be expected. Across interviews, Ava's Covariation and Variation graph reasoning emerged when she conceived of the coordinate system quantitatively. In conjunction, her Motion graph reasoning persisted amid her quantitative conceptions of coordinate systems. Ava's case shows how seemingly contradictory elements can hold together for students when they have multiple goals for graphing. Ava expected her graphs to represent both the relationships between attributes and the physical motion in the dynamic situations. This speaks to her conception of what a graph *should* represent (Johnson et al., 2020); to Ava, a graph should incorporate both quantitative and physical aspects of whatever situation she is representing.

Our findings have implications for researchers investigating students' graphing activity through tasks involving dynamic situations. Ava's case suggests that even when students incorporate the physical motion of objects into their graphical representations, they also can hold quantitative conceptions of coordinate systems. Thus, there is not a simple one-to-one correspondence between how students reason about graphs and how they conceive of coordinate systems. Researchers can use Johnson et al.'s (2020) and Lee et al.'s (2020) frameworks in tandem in future studies to gain deeper insights into students' graphing activity.

Lastly, we drew on two theoretical frameworks (Johnson et al., 2020; Lee et al., 2020) related to students' conceptions of graphs and coordinate systems, respectively. We acknowledge that other theoretical lenses, such as Moore & Thompson's (2015) constructs of static and emergent graphical shape thinking, could provide additional insight into some of Ava's sketches and responses (e.g., her use of arrows to describe the motion of a graph). However, we intentionally focused our examination of students' graphing activity to Johnson et al.'s (2020) and Lee et al.'s (2020) frameworks to investigate the interconnections of graph reasoning and coordinate system conceptions. In doing so, we were able to uncover some of the nuances involved in these constructs. Future research can continue to investigate students' graph reasoning alongside their conceptions of coordinate systems to gain deeper insights that may support the refinement of these frameworks to better reflect the complexity of students' conceptions and reasoning processes. Studies with larger and more diverse student populations could help validate and extend these findings, providing a clearer picture of how these constructs manifest across different mathematical contexts.

A Narrative Inquiry Into Students' Proof Journeys and Mathematical Master Narratives

Brittney Ellis, Texas State University
Tenchita Alzaga Elizondo, University of Texas Rio Grande Valley
Lino Guajardo, Central Michigan University

This study uses narrative inquiry to explore undergraduate students' experiences learning mathematical proof and engaging with proof culture. Drawing on interviews and journey plots from five students at Hispanic-serving institutions, we constructed interpretive narratives to examine how their stories reinforced or resisted mathematical master narratives, such as mathematics being done in isolation or requiring innate ability. Students' journeys revealed moments of joy and triumph, as well as loneliness and frustration. While elements of their stories reinforced master narratives—such as feeling isolated—others emphasized the effort required to develop proof skills, countering the narrative that mathematical ability is innate. Our findings highlight how learning environments and instructional practices influence students' engagement with proof and their perceptions of who belongs in mathematics. By analyzing how students navigate proof culture, this work contributes to efforts to make mathematics more inclusive and to better understand the cultural narratives that impact students' mathematical development.

Keywords: Proof Culture, Narrative Inquiry, Student Experiences, Master Narratives

Students' experiences learning mathematical proof—both inside and outside the classroom—offer valuable insights for the mathematics education community, yet remain underexplored in undergraduate research. Existing studies have examined what students in proof-based courses take away from lectures (Krupnick et al., 2018; Lew et al., 2016) and their beliefs about various aspects of proof, including the reading, writing, and understanding of proof (Guajardo & Lew, 2024; Lew & Mejia-Ramos, 2019; Weber & Mejia-Ramos, 2014). While these studies shed light on students' perceptions and learning outcomes related to proof, further research is needed to explore how students' experiences evolve over time as they navigate proof-based courses and engage with proof culture. Their experiences with this culture shape not only their beliefs about proof itself but also their identity and sense of belonging within the proof community.

Recent studies have begun to explore students' experiences through their own mathematical journeys (Melhuish et al., 2024; Wrightsman, 2025). Melhuish et al. (2024), analyzing student reflections on mathematicians' autobiographies, found that students often challenged dominant narratives within the mathematics community—such as the belief that mathematical ability is innate—especially when reflecting on their own paths, including the idea that one can struggle with math and still pursue a mathematics major. Similarly, Wrightsman (2025) used narrative inquiry to examine how students' perceptions of and engagement with norms in inquiry-oriented introduction to proof courses shaped their participation and mathematical identities. She found that while some students adapted to the change in expectations (i.e., collaboration, public reasoning), others struggled as their prior identities related to being "good at math" were unsettled. These studies highlight the importance of understanding how students' beliefs and identities related to mathematical proof and proof culture are shaped by the content, courses, and broader cultural narratives they encounter.

Building on the need to understand students' mathematical journeys, we adopted a narrative inquiry approach to explore students' evolving experiences with learning proof and engaging with proof culture. Broadly, we view proof culture as the commonly shared values, goals, norms and practices within the mathematics community related to proof and proving (e.g., Dawkins &

Weber, 2017). Students' stories about their experiences learning proof over time and engaging with proof culture are powerful because they have the potential to open a window into elements of master narratives that are being reinforced or challenged (e.g., Melhuish et al., 2024). When students' identities and stories diverge from the master narratives, they may feel excluded from the broader mathematical culture (Melhuish et al., 2024). Therefore, identifying how master narratives are reproduced or resisted in students' personal narratives is a necessary step toward making proof culture more inclusive. Without this understanding, we cannot determine which aspects of the master narratives need to change. To address this, our study investigated the following research question: How did students' retelling of their journey through proof-based courses and experiences with proof culture reinforce or counter master narratives in mathematics?

Theoretical Framing

The stories that people tell (and retell) about themselves in relation to the world around them are inextricably linked with their identities (Sfard & Prusak, 2005). Students' stories about their journeys learning proof are powerful because these personal narratives have the potential to challenge existing master narratives within mathematics and proof culture (McLean & Seyd, 2015; Melhuish et al., 2024). Master narratives are common cultural stories that influence how people behave and view themselves within a culture, and shape perceptions of who is considered 'good' at being part of the culture (McLean & Seyd, 2015). Unlike personal narratives—stories of individuals' lives—master narratives are "culture-specific stories" that individuals may "internalize or resist, consciously or unconsciously" (p. 323). Master narratives become particularly important in mathematics and proof culture as they often link 'doing mathematics' with 'doing masculinity' (Jaremus et al., 2020; Leyva et al., 2017; Mendick, 2006), while also perpetuating the dominance of whiteness (Battey & Leyva, 2016; Martin, 2019) and Eurocentric viewpoints (Rowlands & Carson, 2002). Notably, Melhuish et al. (2024) identified several mathematical master narratives: Mathematics is done by privileged white men; Mathematics is done by those who are brilliant, but socially inept; Mathematics is done in isolation; Mathematics is dry and not fun; Mathematics ability is innate, and easy for those with high ability; and Mathematics is individualistic and a meritocracy.

Following McLean and Seyd (2015), we adopted a narrative approach to theorize the relationship between individual identity and societal structures. Given their shared adaptability and subjectivity, narratives offer a fitting lens for examining the complex interplay between identity and culture. McLean and Seyd's model connects individuals' personal narratives with master narratives and potential alternative narratives. When individuals conform to master narratives, the dominant social structures are reinforced, whereas resisting them constructs an alternative narrative. Interestingly, McLean and Seyd argued that master narratives can be strengthened in both cases—"directly through unconscious internalization and indirectly through conscious opposition and negotiation" (p. 325). Although internalization is usually an unconscious process, master narratives can be evident in individuals' personal narratives.

Within a narrative inquiry framework, stories are used not to uncover objective truths, but to understand the meanings embedded in lived experiences and how those meanings connect (Coulter & Smith, 2009; McAlpine, 2016; Polkinghorne, 1995). Rather than aiming to "describe the world as it is," narrative inquiry seeks to retell events retrospectively, acknowledging that within constructivist or postmodern paradigms, a singular reality does not exist (Coulter & Smith, 2009, p. 578). Narratives are structured through a temporal and sequential ordering of events (McLean & Seyd, 2015) and typically include elements such as "social context,

complicating events, and an evaluative conclusion" (McAlpine, 2016, p. 33). Narrative inquiry typically takes two forms: *analysis of narratives*, which involves collecting participants' stories through interviews or written reflections (e.g., journaling) and identifying patterns or themes (Coulter & Smith, 2009; McAlpine, 2016) and *narrative analysis*, which begins with data that may not be in storied form and constructs narratives through analytic interpretation (Coulter & Smith, 2009; Polkinghorne, 1995). We leveraged both forms of narrative inquiry to examine students' accounts of learning proof and engaging with proof culture.

Methods

Data Sources and Participants

Data for this study was collected at two southern Hispanic serving research universities in the U.S. We conducted interviews with students who completed a survey and responded "yes" to the interview invitation. All interviews were conducted over Zoom. Students were asked to reflect on their journey through proof-based courses and their experiences with proof culture. We asked them to create a journey plot (McAlpine, 2016) by graphing their experiences using time as the horizontal axis unit and any unit they wanted for the vertical axis (see Figure 1). While we provided some possible units (e.g., level of confidence in writing/reading proofs, sense of belonging in the proof community), we emphasized that they could use *any* unit they wanted to visually represent their experiences with proof culture. Participants used the annotation feature in Zoom to draw their graphs. Two participants created multiple graphs on the same coordinate plane, meaning they chose several different vertical units to describe their varied experiences. We prompted them to walk us through their thought processes while creating their graphs, asking follow-up questions to elicit any specific experiences or memories they had related to pivotal moments. Table 1 contains self-identified background information about the five study participants and the vertical unit(s) they chose to represent with their graphs.

Table 1. Demographics and Background of Interview Participants

Name	Race/Ethnicity	Gender	Proof Courses	Vertical Unit(s)
Aiden	White Hispanic	Man	Intro to Proof, Modern Geometry	Support from professors, outside support, relationship with professors, "proofing ability"
Arthur	Hispanic	Man	Discrete Math, Algorithms (at elite university); Intro to Proof, Modern Algebra, Real Analysis	Understanding of proof, difficulty with proof
Ethan	Hispanic	Man (Cisgender)	Intro to Proof, Topology, Real Analysis, Modern Algebra I	Confidence reading/writing proof, understanding of proof, sense of belonging
Liam	White	Non-binary	Intro to Proof, Real Analysis I and II, Modern Algebra	Comfortability in reading and writing proof

Rollin	White Hispanic	Man	Intro to Proof, Modern Geometry, Modern Algebra, Real Analysis Boundary Value Problems	Understanding of what a proof is and how to read/write proofs

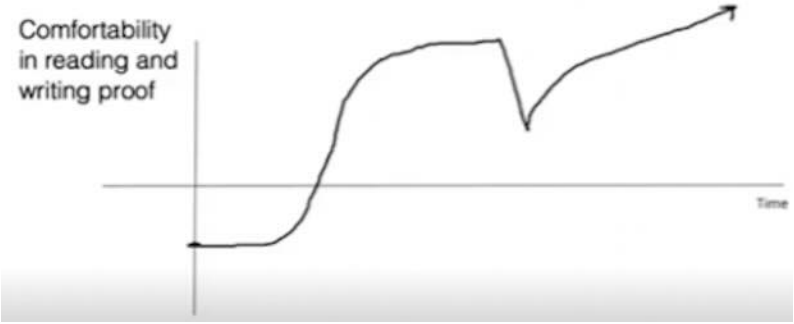

Figure 1. Liam's Journey Plot with vertical unit "Comfortability in reading and writing proof."

Data Analysis

We followed McCormack's (2000a, 2000b) guidance for transforming interview data into interpretive narrative accounts. First, we watched each interview and recorded active listening notes to re-engage with the storyteller after time had passed (McCormack, 2000a). As part of the note-taking process, we reflected on our positions as researchers in relation to the participants. Due to the subjective nature of this work, it was important for us to think about how our own subjectivity and positioning might influence the analysis process. For each interview, two authors independently drafted initial narratives. Although participants created journey plots with respect to time, their descriptions of the events within the plot were not always linear. Since narratives unfold over time and have a sequential structure, we focused on piecing together the participants' stories based on temporal aspects and sequences of events as we drafted initial narratives. Then, we synthesized the two narratives for each participant, paying attention to features one narrative captured that the other didn't, as well as the tone, flow, tense and structure. On average, each synthesized narrative was about four paragraphs long.

To strengthen credibility, we sent the synthesized narratives to each participant, asking if our interpretation was accurate and whether they would add or change anything. Two of the five participants responded affirmatively without suggesting changes. We then compared and contrasted the syntheses to identify shared or stand-alone experiences. For example, comparing Arthur and Liam's stories revealed a common experience of having an "aha" moment while independently studying proofs after hitting a low point with feeling comfortable understanding proof. Then, we used the master narratives identified by Melhuish et al. (2024) to indicate elements of the participants' stories that countered or endorsed the master narratives.

Results

The participants' stories reflected different challenges, involving individual reflection, reorientation towards proof, and striving to find community and support. Several journeys were marked by extreme highs and lows (Liam, Arthur) while others showcased a positive upward trend over time (Rollin, Ethan). We first present summarized versions of each participant's narrative, then highlight how certain aspects of their stories either reinforced or countered the following master narratives: *mathematics is done in isolation*, *mathematics is individualistic and*

a meritocracy, *mathematics ability is innate and easy for those with high ability*, and *mathematics is dry and not fun.*

Students' Summarized Personal Narratives

Aiden's Story: "It's us and the professor. If the professor can't help us, no one can." Aiden's journey into proof-based math courses was represented by an experience of loneliness and yearning for support. He was "surprised and very joyful" to discover the rigor in proof classes, expecting his "niche little hobbies" would help him succeed. But when asked to "translate Hilbert's axioms into symbols," he struggled to find help—tutors and other professors couldn't assist, leaving only the course instructor. The intro to proof class consisted mostly of lectures, and students "struggled" equally, offering little peer support. He realized proof is a "very lonely subject compared to other math subjects," and over time, support "dropped" due to its rigor. Still, he appreciated engaging with the professor's "hobby." Despite the loneliness, his love for math and proof reached a high point, and he believes his ability to engage with proof has improved.

Arthur's Story: "Cleared the fog a bit, wiped the mirror...it [was] a moment of clarity." Arthur's journey was marked by a battle between understanding and difficulty, and it was a readjustment of understanding what proof was that ultimately supported a positive outcome. Before college, he felt fairly confident with proof, but at a prestigious university, instructors expected him to know the basics without support, making him feel like a "single cog" and "the weakest link." After transferring to a local university, he struggled to balance life, work, and school, using math and proof as an escape. Working independently—sometimes at 3:00am—he had a "real moment of clarity," recalibrating his view of proofs to focus on how they relate to other exercises. The fog lifted, like he had "finally taken off his glasses to clean them." His experience shows that learning proof isn't nurtured by prestige, but by support, clarity, and connection, and through readjusting his perspective, he rebuilt his relationship with proof by finding the right environment to feel supported.

Ethan's Story: "I'm learning…getting there, I just don't believe I'm quite at that level yet." Ethan's journey through proof-based courses was one of growth and self-awareness as he strived to find his place within the proof community. Initially unsure of his skills in reading and writing proof, his confidence grew through courses like Modern Geometry and especially Topology, whose abstract nature "really forces you to hone your skills." Abstract Algebra further improved his understanding, though he still felt like he hadn't written proofs "nearly long enough" to take himself seriously among experts. Until he could answer questions on Math Stack Exchange, he couldn't confidently see himself as part of the proof community. He was "learning and getting there," even if not quite at that level yet. In contrast, his classroom community felt more supportive—he and his classmates were "in the same boat," helping each other through topics. Ethan's journey shows that mastering proof is not just about skill but about finding belonging, and while being part of the broader proof community still feels distant, he's found support and connection among peers.

Liam's Story: "Proof can be whatever it needs to be." Liam's story is one of turbulence, related to their experiences with "comfortability reading and writing proof." Starting college math in Calculus 3, they felt "thrown in" to advanced concepts like limits and epsilons, making proof feel like a "big beast" to conquer. An introduction to proof course with a norm-breaking instructor changed everything—accessible proofs increased their comfortability, and they began to love proofs, unlike their friend in a more "rigid" program. However, independently studying category theory challenged them again with its rigor and conciseness, forcing them to reckon

with their understanding. Things shifted when they eventually realized that each subfield has its own proof conventions. After a year of analysis, they needed to "get [themselves] out of this little box" and reframed proof as "whatever it needs to be…it's just a way to explain our reasoning for why this thing is true." This turning point allowed them to flourish, raising their comfortability with proof as they continued their studies in mathematics.

Rollin's Story: It is one thing to "read a recipe" and another to create a delicious cookie. Over the course of his education, Rollin encountered proof in various forms and contexts, gradually developing his proof knowledge and writing skills. In high school, he learned that a proof was a series of logical steps leading to "a correct answer," but this basic understanding couldn't handle the advanced proofs in research papers. At university, he learned to "make" proofs—logical steps and axioms—but realized that "writing" proofs required creativity and deeper knowledge, like the difference between "reading a recipe" and creating a delicious cookie. His skills grew through coursework and an opportunity he had to participate in a Research Experience for Undergraduates (REU), where he authored a proof of an optimal solution to Conway's game. Though he viewed the proof as "simple," it marked a turning point, showing he could "comfortably make them for research," even if he's "not quite there yet." Rollin's journey evolved from rigid steps to crafting original arguments, with research as the "ultimate goal" of proof writing.

Elements that Reinforced or Countered Master Narratives

Mathematics is done in isolation. Parts of Aiden's story both reinforced and countered the mathematics is done in isolation master narrative. On one hand, his experiences with math before proof classes countered this narrative because he actively sought help, not wanting to do math in isolation. On the other hand, when he started taking proof classes, his realization that only the professor can help reinforced this narrative because the situation forced him to learn proof mostly alone (only with the professor's help). Ultimately, his experiences in proof courses reinforced this narrative's strength. Arthur's experience in proof courses at the elite university—feeling like a "single cog" and "the weakest link"—also reinforced this narrative. Ethan's experience, however, countered this narrative because he felt like he and his classmates were all in "the same boat" and they helped each other when they could.

Mathematics is individualistic and a meritocracy. Aspects of the student stories reinforced and countered the master narrative mathematics is individualistic and a meritocracy. Liam's and Arthur's experiences reinforced it because they both arrived at a "moment of clarity" through individual reflection and effort, and felt personal satisfaction making it through a low point with continued persistence and hard work. Contrastingly, Ethan's experiences reflected valuing peer support and how people in the broader community helped each other on Math Stack Exchange, countering the narrative that one works for one's own personal gain (individualism).

Mathematics ability is innate, and mathematics is easy for those with high ability. The language Ethan and Rollin used throughout their stories reflected building proof knowledge and skills along the way, implying mathematics ability is not innate—countering this master narrative. For example, Rollin recognized that he was "not quite there yet" and Ethan was "learning and getting there," both articulating that even though they had learned a lot and their confidence with proof had grown, there was still more to learn. In comparison, Arthur and Liam both experienced struggling with proof at the beginning of their journeys because of the classroom environments they were in. While they did not directly endorse this narrative, the commonalities between their experiences—feeling like they were expected to have prior knowledge and grasp new concepts quickly—reinforced the master narrative to some extent.

Mathematics is dry and not fun. None of the participants' stories directly reinforced the master narrative mathematics is dry and not fun. Aiden's experience of entering proof courses and noticing how his "niche little hobbies" (which were logic related) were connected to proofs made him feel "surprised and very joyful," countering this master narrative. Even though he eventually found learning proof to be a lonely experience, he continued to enjoy proofs through the experience of interacting with his professors' hobbies (which were presumably exciting and fun to them). Logan similarly experienced joy and love for math when they took the intro to proof course with the professor who made proofs more accessible, and their enjoyment continued even after they hit a low point when studying category theory.

Discussion

In this paper, we shared five students' journeys through proof-based mathematics, each offering a distinct perspective shaped by personal experiences with proof culture. These narratives included moments of joy and accomplishment, as well as periods of isolation and struggle. While each story was unique, common elements emerged that connected students' experiences to mathematical master narratives previously identified in the literature (i.e., Melhuish et al., 2024). As discussed earlier, mathematical master narratives are stories tied to mathematical culture that shape perceptions of who belongs in mathematics and what it means to do mathematics. By examining how these narratives surfaced in students' accounts, we gained insight into how proof culture is experienced on a personal level. While elements of students' stories reinforced master narratives—such as Aiden's experience of isolation—others, like Ethan and Rollin, emphasized the sustained effort required to develop proof skills, which countered the master narrative that mathematical ability is innate.

A key takeaway from our results is the influence that learning environments have in shaping students' experiences with proof and their sense of support. Both Arthur's and Liam's stories contrast welcoming environments with isolating experiences at more "prestigious" universities. Arthur began his journey at an elite university where he felt unsupported and like the "weakest link" due to a lack of prior knowledge. After transferring, he found an environment that allowed him to take time for himself and succeed in proof. Similarly, Liam described a "norm-breaking" instructor who made proofs accessible and brought joy to learning proof—an experience that stood in stark contrast to their friend's more "traditional" and rigid program, which led to a strong dislike of proofs. Their redemption stories also revealed the "good side" of meritocracy (Weber & Melhuish, 2020), in which striving for improvement was motivating without being rooted in competition or comparison (i.e., the "bad side").

Taken together, these student narratives offer a meaningful lens into how proof culture is experienced and interpreted by students. Understanding which master narratives are endorsed or resisted in students' personal accounts of learning proof and engaging with proof culture provides a starting point for shifting these narratives. While master narratives are deeply embedded and unlikely to disappear entirely, elements within them can evolve to become more inclusive—especially when we recognize which narratives are most salient and how students are already challenging them through their lived experiences.

Acknowledgments

We would like to thank our research participants for their time sharing their stories with us and responding to follow up requests to confirm or challenge our interpretations.

Resources, Orientations, and Goals Informing Calculus Instructors' Enactment of Equitable Active Learning Teaching Practices Learned Through Approximations of Practice

Kaitlyn Stephens Serbin
University of Texas Rio Grande Valley

Karina Uhing
University of Nebraska at Omaha

We implemented a semester-long professional development workshop series, training Calculus I and II instructors to implement active learning and equitable teaching practices. The workshops actively engaged instructors in approximations of practice (Grossman et al., 2009) in which they learned to enact various teaching practices like designing tasks; eliciting, noticing, and responding to evidence of student thinking; orchestrating class discussions; fostering inclusive social norms; and equitably managing student participation. After they participated in the workshops, we interviewed the instructors about their decisions to implement the teaching practices from the approximations of practice in their teaching. We analyzed the instructors' resources, orientations, and goals that informed their decision to enact those practices.

Keywords: Approximations of Practice, Professional Development, Calculus, Active Learning, Equitable Teaching Practices

Despite the benefits of active learning and equitable teaching practices (Bartell et al., 2017; Freeman et al, 2014; Theobald et al., 2020; Thiry et al., 2019), university faculty have been slow to adopt them (Rasmussen et al., 2019; Stains et al., 2018). There is a need for more professional development (PD) on these teaching practices. At the K-12 level, PD and teacher preparation programs use Approximations of Practice (AoPs; Grossman et al., 2009) to give instructors opportunities to develop and enact specific teaching practices. *AoPs* are activities with a hypothetical teaching scenario in which instructors can simulate a teaching practice without the complexity of being in a real-time classroom. AoPs have been shown to be effective in helping K-12 mathematics teachers develop active learning practices (e.g., Amador et al., 2021; Howell & Mikeska, 2021; Krause et al., 2020; Lai et al., 2021; Roberts & Olarte, 2023; Schack et al., 2013). Their use in PD programs for university faculty has not been commonly documented, however. We propose that such implementation of AoPs in PDs holds promise for the training and professionalization of university mathematics instructors.

In this paper, we investigate how engaging in AoPs can support university instructors in implementing active learning and equitable teaching practices. We report on a study where Calculus I and II instructors participated in a PD program focused on equitable teaching practices and active learning through using AoPs. The instructors' decisions to implement the teaching practices from the AoPs could be informed by their resources, orientations, and goals (Schoenfeld, 2010), so we address the research question: *What are the resources, orientations, and goals that inform instructors' implementation of the teaching practices from the AoPs?*

Literature Review

Active learning is a large umbrella term that captures various pedagogies (e.g., group work, student presentations, class discussions) related to engaging students in class activities beyond passively listening to lectures or taking notes. Although there are numerous benefits associated with active learning in STEM courses (e.g., Freeman et al., 2014; Kogan & Laursen, 2014; Theobald et al., 2020), active learning is not necessarily equitable for students (White et al., 2025; Brown, 2018; Johnson et al., 2020; Reinholz et al., 2022). Thus, it is essential for

instructors who use active learning to attend to equity and inclusion in their courses. There are several teaching practices instructors can use to equitably implement active learning that have been suggested by researchers (e.g., Bartell et al., 2017; Freeman et al., 2014; Gutiérrez, 2010; Kuster et al., 2018; Laursen & Rasmussen, 2019; Reinholz, 2023) and professional organizations (e.g., Mathematical Association of America, MAA, 2018; National Council of Teachers of Mathematics, NCTM, 2014). Serbin et al. (2025) suggested that these practices of varied grain size align with these broader teaching practices: "(i) use meaningful engaging math tasks, (ii) facilitate student collaboration, (iii) elicit, notice, and use evidence of students' mathematical thinking, (iv) orchestrate class discussion on students' mathematical ideas, (v) attend to participatory equity and access in the classroom, (vi) foster an inclusive class community, and (vii) equitably assess student work" (p. 1568). Given the success of active learning and equitable teaching practices in calculus courses (Bressoud & Rasmussen, 2015; Hagman, 2021), mathematics departments in the US have made strides toward institutionally changing their mode of instruction in calculus to active learning (Smith & Rasmussen, 2025; Williams et al., 2022).

It is difficult for instructors to change their instruction, so there is a need for PD on active learning. PD programs for mathematics instructors can be implemented in a variety of formats, like pre-semester workshop days, workshop series, faculty professional learning communities (Stoll et al., 2006), and lesson study (Fernandez & Yoshida, 2012). PD programs can also be informed by various design principles. Soto and Marzocchi (2021) suggested such programs should emphasize building community among faculty participants, create opportunities for faculty to collaborate, encourage faculty reflection and persistence in improving their practices, build faculty's confidence and motivation, and provide a variety of PD formats. These and other researchers have emphasized the importance of actively engaging participants in PD programs to model active learning approaches (e.g., Akin et al., 2023). One such way to actively engage instructors in teaching practices during PDs is to provide opportunities to participate in AoPs, which we describe as follows.

Theoretical Framework

Theoretical Perspective Informing the PD Design

AoPs are productive activities for teachers to engage in during teacher education and PD programs (e.g., González, 2017; Kavanagh et al., 2020; Sapkota & Max, 2024). AoPs are "opportunities to engage in practices that are more or less proximal to the practices of a profession" (Grossman et al., 2009, p. 2056). These activities simulate a teaching scenario or practice, which provides an opportunity for teachers to rehearse and develop teaching practices without the complexity of a real-time class setting or risk of affecting students (Howell & Mikeska, 2021). AoPs can simulate various teaching practices, such as noticing students' mathematical thinking (Jacobs et al., 2010; van Es & Sherin, 2021) or responding to students' ideas in class discussions (Campbell & Elliott, 2015; Howell & Mikeska, 2021; Jackson et al., 2024; Kaka et al., 2021). The design of AoPs can vary by the type of teaching practice approximated, the medium of the scenario (e.g., classroom videos or written artifacts of student work), the degree of authenticity of the approximated teaching practice, and the scenario content.

Theoretical Perspective Informing the Data Analysis

To analyze our data, we drew on Schoenfeld's (2010) decision-making framework, which suggests a teacher's decision-making can be explained by their resources, orientations, and goals.

Resources. In Schoenfeld's (2010) framework, *resources* encompass an instructor's

knowledge inventory (including content and pedagogical knowledge), as well as the material resources available to teachers (e.g., technology, physical classroom spaces). These resources determine what is possible in a classroom at any moment. Resources also include interpersonal skills and practical knowledge that teachers bring into the classroom (Schoenfeld, 2011). What an instructor knows and has access to influences the decisions they make in real-time teaching.

Orientations. *Orientations* refer to a teacher's beliefs, values, preferences, and tastes (Schoenfeld, 2010). These orientations influence how teachers perceive and engage with classroom situations and what goals they consider to be important. Orientations are often implicit and develop over time with experience. They significantly shape teachers' real-time decisions.

Goals. *Goals* are the objectives, either explicit or implicit, that guide a teacher's decisions and actions (Schoenfeld, 2010). They can range in granularity, from broad aims, such as helping students to foster conceptual understanding of a subject, to more specific aims, like maintaining the class pace. Schoenfeld (2011) posited "goals recruit resources" (p. 459); teachers activate and apply their resources in service of the goals they prioritize. Instructors constantly re-evaluate their goals based on evolving classroom dynamics and shift their actions accordingly.

Methods

The 11 participants included part-time lecturers, full-time lecturers, and tenured professors, who taught Calculus I or II. Eight were faculty at a large public university, and three were faculty at a nearby community college in the southern US. Most faculty primarily lectured in their courses but were interested in implementing active learning.

The first author led a PD workshop series on using active learning while attending to equity and inclusion. The program consisted of two full-day sessions before the spring semester, with six two-hour sessions during the semester. The PDs drew on K-12 and undergraduate math education literature and focused on the following evidence-based teaching strategies: fostering inclusive classroom social norms; designing group-worthy mathematical tasks (Lotan, 2003) that require high levels of cognitive demand (Stein & Smith, 1998); eliciting, noticing, and responding to evidence of student thinking (NCTM, 2014); orchestrating class discussions using the 5 practices: anticipating, monitoring, selecting, sequencing, and connecting (Smith & Stein, 2018); and fostering equitable student participation (MAA, 2018). Instructors practiced these strategies through 15 AoPs that used videos of student thinking, scripts of classroom discussions, student quotes, and hypothetical student work to simulate classroom scenarios.

We conducted hour-long semi-structured interviews with each instructor after the PD series. Questions focused on participants' enactment of the teaching practices from the AoPs in their calculus classes. We provided participants a list of topics covered in the PDs and asked them to identify practices they tried implementing and the result. We asked about their experiences in the workshops and what they found helpful about the AoPs. Interviews were conducted over Zoom by the second author and an outside research team member who were not involved in facilitating the AoP workshops. Interviews were transcribed through Zoom and cleaned for analysis.

Our data analysis began by extracting excerpts where participants discussed their experience or decision to enact active learning pedagogies that were highlighted in the PDs. We deductively coded (Miles et al., 2013) these excerpts using the codes, resources, orientations, and goals, while considering Schoenfeld's (2010) descriptions of those. We characterized the types of resources, orientations, and goals discussed via inductive coding (Miles et al., 2013). For each participant, we compared excerpts and created a summary of how their resources, orientations, and goals seemed to influence their decision to enact teaching practices they learned in the AoPs.

Results

For this paper, we present case studies for two participants and describe the resources, orientations, and goals that informed their implementation of the teaching practices from the PD.

Case 1: Sumaya

Overview and What Practices She Implemented from the AoPs. Sumaya had taught university mathematics for 17 years. She primarily taught Calculus I, and during the semester that she participated in the PD, she taught Calculus II. During her interview, Sumaya claimed she implemented these teaching practices from the AoPs: fostering inclusive social norms, designing group-worthy mathematical tasks, eliciting evidence of student thinking, orchestrating class discussions, and fostering equitable student participation. When asked about which of the AoPs impacted her teaching the most, Sumaya brought up the steps of orchestrating class discussions. She remarked, "I wasn't aware that some of the practices that I had would fall into this definition of anticipating, monitoring, selecting, sequencing, and connecting." She went on to say, "After I attended the workshop…I learned that these are actually a sequence of different things that we can do for the class discussions, and so I became more mindful of doing them." Sumaya talked about how, before the workshop, she would anticipate student responses and monitor students during class, but because of "time constraints," she would often just take "the first answer that I would get. I would just say either yes or no and continue with that." But after attending the workshop, Sumaya "was more patient" and would "wait for more responses and then build upon those responses." Sumaya discussed how her participation in the AoPs helped her reflect on her teaching and find areas to improve upon. She said,

> I participated in this program because I wanted to better myself. But then some of the things, for example, the anticipation and selecting and sequencing, when I heard it, my first reaction was, "Oh, yeah, I'm doing this." But then when…we talked about it, and then when I went to the class, and I reflected on it, I realized that there is a lot of improvement that I can make...I became more mindful of everything.

Participating in the AoP helped Sumaya become more aware of the steps in orchestrating class discussions, which led her to be more intentional about selecting, sequencing, and connecting student responses. Below, we discuss our claim that Sumaya's resources, orientations, and goals informed her implementation of the teaching practices from the AoPs.

Goals and Orientations. A central focus of Sumaya's interview was her goals to *grow as an educator* and *engage students in their learning*. These goals were closely linked to Sumaya's orientation that *active learning is important*. Sumaya discussed how she had been committed to using active learning teaching strategies even before participating in the AoPs. She explained that at the beginning of her teaching career, she was very "lecture-based" because that is how she had been taught. However, over time, she "became interested in the teaching practices that best involve students and engage students in their own learning," attending conferences and workshops to learn more about active learning. Sumaya discussed the value of PD, saying they help with "becoming very mindful of our practices, reflecting on what we're doing, so that we can make adjustments." She went on to say that "if the focus goes into learning and what we can do for the students to engage them through active learning, how to be a truly equitable educator, then we can reach more students and help them with learning." These goals and orientation seemed to support Sumaya's decision to use active teaching practices from the AoPs in her class.

Another one of Sumaya's goals was to *provide students with appropriate scaffolding* so that they could engage with material and continue to work in small groups without needing constant assistance. Sumaya linked this to the teaching practice of designing group-worthy mathematical

tasks, which had been the primary focus of one of AoPs. She discussed how facilitating group work in a large class of 56 students in an auditorium classroom without the help of a TA was challenging. However, by carefully scaffolding group activities, Sumaya felt that the students "had some guidance to go through it [the worksheet]" and that providing "questions that would guide them to go to the next step, not necessarily making it too easy...would be one of the better ways to manage the large classroom." This goal seemed to influence Sumaya's decision to implement group-worthy tasks in her class, despite the challenges hindering her implementation.

Sumaya also exhibited the orientation of the *importance of valuing student contributions* and discussed her goal to *have students feel comfortable sharing their ideas* in class. She talked about how Calculus II "has difficult topics, so not all students are comfortable sharing their answers." Sumaya went on to say, "It's really important for them to engage without putting them in a position that would embarrass them. So, that was something that I tried to give value to all answers that I was receiving from the students." She concluded by saying, "I would always try to bring positive remarks to all sorts of answers, so that they feel more comfortable. Building trust with 56 students wasn't easy...But I think I was successful in that." Helping students feel comfortable directly connects to the teaching practices of fostering an inclusive classroom social norms and equitable participation from the AoPs. Sumaya commented that her participation in the AoPs "validated...how I want to approach my students, making sure everyone is included, making sure everyone's opinion does matter, that they have ownership over their learning, that I give credit for their effort, and not necessarily correctness of their answers." Her orientation and goal here supported her enactment of productively responding to student thinking and fostering an inclusive classroom social norms and equitable participation, which she practiced in the AoPs.

Resources. In terms of resources, Sumaya discussed how her *awareness of student backgrounds* and *knowledge of common student struggles* informed the way she structured class and designed tasks. Sumaya discussed the steps in orchestrating her class discussions, saying,

> Anticipating students' answers, that's always been in my mind the way that I make the worksheets or the way that I create those review sessions at the beginning of each class...So that I knew that, okay, this part seems a little bit difficult,...students are going to get caught...[or] make a mistake in this part.

She also described the challenge of supporting students with various mathematical backgrounds and trying to "balance" meeting the needs of different students. Sumaya remarked how she had "math majors in the class who are ready to learn more, and they want to go more in depth with the proofs," while also teaching "students who are really struggling with derivative, anti-derivative, very basic rules. So, how to balance that and be still equitable and inclusive. That was a challenge." Sumaya's resources here seemed to influence her implementation of equitable and inclusive teaching practices, which were addressed in the AoPs.

When discussing how she had implemented the practices of fostering equitable participation and inclusive social norms in her class, Sumaya brought up the cultural context of the institution. She talked about how during group work time, she would "make sure that everything is clear to the students, especially because we are a Hispanic Serving Institution, and some of the students, English is their second language." She went on: "I was very mindful of that...if the language is clear for the students...I let the students know that as I'm walking around, if something is unclear, make sure that you ask me, so I can clarify for you." By drawing on the resource of her *knowledge of students' backgrounds*, Sumaya could attend to equity and inclusion in her class.

Case 2: Richard

Overview and What Practices He Implemented from the AoPs. Richard taught university mathematics for 35 years. He taught a variety of courses, primarily Calculus II, which he taught during his participation in the PD. Richard claimed he implemented the practices of: eliciting evidence of student thinking during class, noticing and responding to evidence of student thinking, fostering inclusive social norms, and some of the five practices for orchestrating class discussions. Richard discussed how the AoP on responding to student thinking "made me more aware of how I need to be interacting with the students in certain areas." The AoP prompted participants to discuss what an instructor should have done differently. Richard recalled the scenario where a student asked about a computation, "From an instructor point of view, it was trivial, but the student was not understanding… the instructor had simply replied, 'You're supposed to already know that.' Of course, that puts the students down." He remarked,

> That scenario reinforced how, when a student asks a question, it's important to take it seriously…Not get frustrated that they didn't understand something trivial…That's important in teaching and interacting with students…to answer them as if they're serious mathematical questions and dig in to see where their misunderstanding was coming from.

Richard exemplified how he implemented the approximated practice while simplifying the expression x^{n+1}/x^n: "The first time that an expression comes up, I usually do it in slow motion and say, from now on, we'll just go to this." When a student asked about the simplification,

> Instead of saying, 'we talked about this earlier'…I tried to explain it in a different way... That's when that connection with the scenario in the PD came in…Just be patient, treat the question as a serious question, and let's see if we can figure out where the misunderstanding is and how to get him over that."

The AoP helped Richard intentionally respond to students in non-dismissive ways and elicit further evidence about their thinking. We posit that Richard's goals, orientations, and resources informed his implementation of these teaching practices that he learned in the AoP.

Goals and Orientations. Richard provided evidence of the goal of *helping students feel comfortable sharing answers and asking questions* and the related orientation that *it is important for students to feel comfortable and confident in class*. Richard described an instance of a student asking a question in class and being "more interested in just learning why, rather than is somebody gonna think I'm dumb." Richard claimed the student "felt comfortable in asking, and so to me, that meant that I maybe was partially successful in having an environment where they could ask questions like that…I found students were very open in offering up their mistakes." Richard perceived value in having a positive class environment where students felt comfortable and confident sharing answers, making mistakes, and asking questions during class. This goal and orientation seemed to support Richard's decision to enact teaching practices of fostering inclusion and productively responding to student thinking, which he learned about in the AoPs.

Another goal and orientation salient in Richard's interview were to *respond to students in productive, non-disparaging ways* and *it is important to value student contributions*. Richard claimed to "try to create a classroom environment where questions are taken seriously and with enthusiasm, and…that the failures are celebrated. So that we can learn a lot more by making mistakes and learning how to fix something than just by getting something right the first time." He valued students' questions, answering them with enthusiasm, and responded to students' mistakes in positive ways. This goal and orientation seemed to support Richard's implementation of responding to evidence of student thinking because he was intentional in responding to students' questions and contributions in ways that did not disparage the students. He described trying to productively respond to students in class by celebrating their mistakes, eliciting further

evidence of their thinking, and providing more explanations without embarrassing the student.

Resources. Richard's knowledge and experiences served as resources that seemed to influence his decision to enact the teaching practices from the AoP, like responding to student thinking in productive ways. He discussed how the AoPs contributed to his *knowledge and awareness of student interactions*, a resource that helped him consider different ways to respond to students. He stated, "That activity stuck with me. There were some discussions that made me more aware of how I need to be interacting with students." This *experience engaging in the AoP* and *learning about specific teaching practices regarding student interactions* served as resources he could draw on while responding to student thinking. His prior *knowledge of how to respond to students* was also a resource informing his decision to implement the teaching practices from the AoPs. He referred to an AoP scenario where an instructor "put a student down," explaining, "I think I'm pretty good about not responding to students that way. That particular scenario... reinforced how when a student asks a question, it's important to take it seriously." Richard had prior knowledge of how to interact with students based on his years of experience teaching, and the AoP helped reinforce that knowledge to use as a resource in his teaching.

Discussion and Conclusion

Given the calls to implement active learning and equitable teaching practices in calculus courses, we led PDs, training Calculus I and II instructors to use these pedagogies. The PDs were designed to actively engage instructors in AoPs to enact various active learning and equitable teaching practices. After participating in the PD, we interviewed instructors about their implementation of the teaching practices they learned in the AoPs. We focused on two case studies, Sumaya and Richard, for this investigation. Both instructors were able to describe how their experience engaging with the AoPs informed their implementation of the approximated teaching practices in their own classrooms. We investigated how their resources, orientations, and goals informed their decision-making while enacting teaching practices from AoPs.

Both instructors had goals and orientations related to engaging students, helping students feel comfortable in class, and valuing student contributions. We posit that having these goals and orientations influenced the instructors' decisions to enact active learning and equitable teaching practices like eliciting and responding to evidence of student thinking, fostering inclusive social norms, and fostering equitable student participation. Furthermore, an instructor's resources (e.g., knowledge, experiences) influence the decisions they make in their teaching (Schoenfeld, 2010), particularly whether to enact the practices they learned in the PD. For Richard, the AoPs served as a resource, reinforcing his goals and prior knowledge of how to respond to students, which seemed to influence how he responded to student thinking in class. For Sumaya, her knowledge and awareness of student backgrounds informed how she implemented practices from the AoPs, such as fostering inclusive social norms and equitable participation. Overall, our case studies exhibit how instructors' resources, orientations, and goals could influence the instructors' decisions to enact the teaching practices learned in the AoPs.

Our findings contribute to the literature on PD for university mathematics faculty and provide implications for PD designers. The AoPs in our PD served as a resource that supported instructors in deciding to implement active learning and equitable teaching practices. AoPs have great potential to train university instructors to implement active learning. They provide a low-stakes environment for instructors to develop new teaching practices. Our case studies showed how engaging in AoPs allowed instructors to reflect on their teaching practice, be more mindful of how they interact with students, and reinforce their pedagogical knowledge. Thus, we suggest that designers of PD programs for university faculty actively engage their participants in AoPs.

Can Self-Regulated Learning Practices Shift Without Intervention? An Exploratory Study of Calculus I and II Students

Meaghan Allen
University of New Hampshire, SNHU

Orly Buchbinder
University of New Hampshire

This study examines changes in self-regulated learning (SRL) skills among undergraduate Calculus I and II students, without explicit interventions. Using pre- and post-surveys aligned with Zimmerman's SRL model, we identified both improvement and decline across items assessing various SRL practices. Calculus II students showed significant improvements in planning, self-control, and information management, which appear to be supported by student maturity, conceptual course content, and collaborative instruction. In contrast, Calculus I students exhibited a decline in performance-phase strategies, reflecting challenges from large lectures, formulaic content, and first-year adjustment. The researchers' hypotheses on potential reasons for the observed results were corroborated by the course instructor and teaching assistants. However, more research is needed to understand these patterns and their underlying causes. Our findings suggest that while some SRL skills may develop naturally in more advanced contexts, first-year students may require targeted support to become more effective learners.

Keywords: Calculus, Self-Regulated Learning (SRL), Study Skills

Calculus courses play a critical role in university education, particularly for STEM majors, as they often serve as gateway or gatekeeper courses. Success in these courses can significantly influence students' trajectories in STEM fields, while difficulties can create barriers to persistence. Due to their central role, improving student learning and success in Calculus has been a priority for both instructors and education researchers. Understanding not only what is taught but also how students approach learning is essential for designing effective instructional reforms. In particular, it is important to understand students' use of self-regulated learning (SRL) skills, which encompass cognitive, metacognitive, behavioral, motivational, and affective aspects of learning (Panadero, 2017).

This study was conducted within the context of a larger initiative aimed at improving teaching and learning in the Calculus sequence at a large public university in the northeast of the USA. The larger reform effort at this university encompassed Precalculus, Calculus I, and Calculus II. While all courses use a lecture–recitation format, the primary focus of the reform was on recitations. In these sessions, students engaged in conceptually rich activities and collaborative group work, supported by Learning Assistants (LAs) alongside Graduate Teaching Assistants (GTAs). After several years of applying these reforms, students often continued to use unproductive study methods despite instructional changes. Motivated by this, we sought to investigate the learning strategies of students in Calculus I and II and examine how these strategies "naturally" change over the semester without any particular intervention. To this end, we administered a 64-item Likert survey at both the beginning and the end of the semester.

In this paper, we report on survey items that showed statistically significant changes, whether positive (improvement) or negative (decline), in specific SRL skills. We focus on items where the direction of change differed between Calculus I and Calculus II students. To explore possible explanations for the observed changes, we enlisted interpretations from the course instructors, TAs, and LAs, and included them in this report. Our research question is: *How do undergraduate*

Calculus students' SRL skills change over a semester without formal intervention, and how do these changes compare between Calculus I and Calculus II students?

Literature Review and Theoretical Background

Calculus Reform

Undergraduate calculus courses function as critical gateways, affecting students' success and persistence in STEM. National data show that while many students enter calculus with prior high-school exposure, fewer than 60% earn an A or B, and confidence and enjoyment often decline (Bressoud, 2015). Across institutions, about 11–20% of STEM-intending students do not continue, with women's attrition roughly 1.5 times that of men, even controlling for prior achievement (Ellis et al., 2016; Rasmussen & Ellis, 2013).

To address these issues, many institutions reform introductory courses by integrating active learning and student-centered pedagogies to reduce attrition and promote deeper learning. Courses emphasizing collaborative problem solving, conceptual tasks, and real-world applications yield higher concept-inventory gains, improved exams, and reduced equity gaps (Kramer et al., 2023; Rasmussen & Ellis, 2013). Scaling these practices remains challenging: only 23% of Precalculus–Calculus II courses use active-learning strategies, with usage declining in higher-level courses (Rasmussen et al., 2019).

Metacognitive and study-skill development is another critical factor for student success or lack thereof. Structured study routines, including problem sets, review tasks, and guided reflection, improve performance and engagement (Boelkins & Pfaff, 1998; Khan, 2020). These practices support consistent study habits, conceptual understanding, and monitoring of learning – core self-regulated learning (SRL) skills. Despite their importance, SRL practices are rarely made explicit in traditional courses, leaving students to develop them independently.

Self-Regulated Learning (SRL)

Self-regulated learning (SRL) includes cognitive, metacognitive, behavioral, motivational, and affective aspects of learning (Panadero, 2017). Students with strong SRL skills set goals and actively select, monitor, and adjust strategies to achieve them. They also demonstrate more expert-like thinking individually and in groups (Stanton et al., 2021; Van De Bogart et al., 2017), which correlates with higher achievement, motivation, and lifelong learning (de Boer et al., 2018; Donker et al., 2014; Richardson et al., 2012; Rosário et al., 2019; Theobald, 2021).

Metacognition, a core SRL component, refers to awareness and control of one's thinking and learning (Stanton et al., 2021). Students with strong metacognitive skills assess understanding, identify gaps, select strategies, and evaluate outcomes. In mathematics, metacognition supports problem-solving and abstraction (Desoete & De Craene, 2019; Pólya, 1945/2014; Schoenfeld, 1992). Research shows SRL skills can be taught through explicit interventions (de Boer et al., 2018; Donker et al., 2014; Richardson et al., 2012). Yet, college instructors often prioritize content over SRL scaffolding (Moos & Ringdal, 2012), and secondary-level opportunities are often implicit (Dignath & Büttner, 2008). As a result, undergraduates enter with limited metacognitive knowledge and SRL skills (Pintrich, 2002). This gap is especially consequential in mathematics, where first-year calculus requires shifts in thinking, strategies, and time management. Research on SRL at the undergraduate math level remains sparse, even though its discipline-specific nature underscores its relevance for early STEM courses (Panadero, 2017).

Cyclical Phases SRL Model

This project uses Zimmerman's (2000) Cyclical Phases Model of SRL, involving three phases: forethought, performance, and self-reflection. In forethought, students analyze tasks, set goals, and plan strategies guided by motivation. In performance, they execute tasks and monitor progress. In self-reflection, they evaluate outcomes and attributes, shaping future learning. Zimmerman's model, grounded in social-cognitive theory, is widely used in STEM SRL research (Panadero, 2017; Gamby & Bauer, 2022; Jin et al., 2023; Layco, 2020; Marchis, 2012).

SRL is closely linked to motivation influencing learning performance (Zimmerman & Schunk, 2011). Expectancy-Value Theory frames motivation as learners' expectations for success and task value (Wigfield & Eccles, 2000). Within the SRL model, motivational beliefs affect goal setting, strategy selection, and engagement during forethought, while reflection shapes future expectations. Effective SRL enhances control, mastery, autonomy, and confidence, supporting intrinsic motivation (McCombs, 2013; Reeve et al., 2012). Framing this project with Zimmerman's SRL model allows analysis of how calculus students plan, enact, and reflect on their learning. The framework was used to both develop the survey and to interpret survey data on strategy use, motivation, and metacognitive engagement.

Methods

Setting and Participants

This study is part of a broader NSF-funded initiative to transform STEM gateway courses, focusing on the calculus sequence at a large public university in the northeastern United States. Calculus recitations were redesigned with conceptually rich activities and active learning, including collaborative problem-solving in small groups (CBMS, 2016). Calculus courses follow a lecture-recitation format: large lectures (~ 120 students) led by a faculty instructor three times a week, and recitation sections (~ 20 students), led by GTAs supported by LAs twice a week.

Data came from Spring 2025 students in Calculus I and II, who are predominantly STEM majors (89% and 99%, respectively), and share similar demographics, reflecting the university's predominantly white population. In Spring 2025, the same experienced instructor taught both Calculus I and II courses. There are minor but meaningful distinctions in the prior preparation of the two groups. Spring Calculus I students had not reached the mathematics proficiency threshold and were placed in Precalculus in the Fall. Spring Calculus II students usually completed Calculus I in the Fall, indicating their initial stronger mathematical preparation. Additionally, the instructor of both courses in Spring 2025 had taught Calculus I in the Fall. Thus, students in Calculus II experienced continuity of instructional style, whereas Spring Calculus I students had a different instructor for their prerequisite Precalculus course.

Instrument and Data Collection

Students' SRL skills were assessed with a 64-item survey. Items are measured on a 4-point Likert scale ranging from "1 (disagree)" to " 4 (agree)." The survey is theoretically grounded with items aligned with Zimmerman's (2000) SRL phases – forethought, performance, and self-reflection – and capture a range of skills (e.g., planning in forethought, task analysis in performance, and evaluation in self-reflection). Due to space constraints, examples of survey items will appear in the results section. Many items were drawn from well-established SRL instruments, such as Schraw and Dennison's (1994) Metacognitive Awareness Inventory, and Marchis' (2012) SRL inventory, and modified to the context of college-level calculus. The initial survey was piloted in Fall 2024 with 299 calculus students and revised following statistical and

qualitative analyses. The revised instrument used in Spring 2025 had good to excellent reliability (Cronbach's Alpha values ranging from 0.87 to 0.94) of the three SRL subscales.

The same survey was administered at the beginning and at the end of the semester. Students completed the survey online via Qualtrics, which took approximately 15 minutes. Only data from consenting students were included in the analysis. The final sample comprised of 74 (out of 181) students in the Calculus I course and 78 (out of 193) students in the Calculus II course, who completed both pre- and post-surveys.

Data Analysis

Quantitative analysis involved descriptive statistics for all survey items and assessing internal consistency using Cronbach's alpha. Although Likert-scale survey data are ordinal, parametric methods, such as paired *t*-tests, are widely accepted in educational research when sample sizes are adequate and data approximate normality (Norman, 2010; Chen & Liu, 2020). Given the size of the current study and alignment with these established practices, paired two-tailed *t*-tests were conducted on pre–post differences within each course, and effect sizes were calculated. The survey was not anonymous, allowing for matching pre- and post-responses. Although we initially did not intend to compare across the courses, course-specific analyses revealed notable differences between the Calculus I and Calculus II cohorts, which were further explored.

To contextualize the quantitative results, particularly the statistically significant changes observed on certain SRL items, we reached out to the course instructional staff, shared with them the statistical analysis, and asked them to comment on these findings and suggest possible explanations based on their classroom experiences. Responses were received from one instructor, two GTAs, and three LAs. We incorporated the background information and the insights they provided into possible interpretations and explanations for the observed findings.

Results

Across all three SRL phases, the average student response was "somewhat agree," showing moderate use of SRL strategies in both Calculus I and II. This suggests that students in both courses engage in SRL strategies frequently, though not consistently at the highest level. Considering pre–post course changes, on average, Calculus I students' SRL scores decreased from 3.034 (SD = 0.688) to 2.935 (SD = 0.782), which is statistically significant ($t = -2.141$, $p < .036$, Cohen's $d = -0.315$). Calculus II students' scores increased slightly from 2.948 (SD = 0.741) to 2.990 (SD = 0.778). Furthermore, when examining pre-to-post semester shifts in overall SRL scores, a distinct pattern emerged: Calculus I students' responses declined on most SRL items, whereas Calculus II students' responses increased on most items (Table 1).

Table 1: Counts of Items by Average Change in Calculus I and II

	Declined	No Change	Improved
Calculus I	47	1	16
Calculus II	18	2	44

At the item level, 20 survey items showed a statistically significant change over the semester. Of these, several items reflected significant declines in Calculus I students' responses, while many indicated significant gains for Calculus II students. These differences between Calculus I and II students warranted further examination of how their SRL habits change.

Items with Statistically Significant Changes in Both Calculus I and Calculus II

Three survey items, seen in Table 2, demonstrated statistically significant change for both Calculus I and II. Importantly, these items followed opposite trends: Calculus I students reported declines, whereas Calculus II students reported improvements.

Table 2: Items with Statistically Significant Changes for Calculus I and II

Item	Class	Pre-Mean	Post-Mean	p-value	Effect Size
18: I try to understand the reasons behind mathematical formulas and concepts.	Calc I	2.946	2.703	0.0407*	-0.405
	Calc II	2.782	2.974	0.0348*	0.323
31: I ask questions during lectures or recitation sessions when I don't understand something.	Calc I	2.919	2.649	0.0101*	-0.401
	Calc II	2.641	3.026	0.0010**	0.611
57: When I need to solve a mathematical problem, I think of several ways to solve it and choose one that makes the most sense for me.	Calc I	3.054	2.824	0.0428*	-0.38
	Calc II	2.756	3.000	0.0109*	0.403

Item 18: "I try to understand the reasons behind mathematical formulas and concepts." Table 2 shows that Item 18 was statistically significant for both Calculus I and II, but in opposite directions. Calculus I students showed a significant decrease in this SRL skill, with mean scores declining from 2.946 on the pre- to 2.703 on the post-survey ($p < .0407$). Conversely, Calculus II students showed a significant increase, with mean scores rising from 2.782 to 2.974 ($p < .0348$). This item falls within the Performance Phase of Zimmerman's (2000) SRL model and is categorized under Information Management Strategies. One possible explanation for the difference in the direction of change in responses between Calculus I and II is the course content. Calculus I emphasizes limits and derivatives, often in procedural, formula-driven ways, potentially discouraging deep engagement with mathematical reasoning. By contrast, Calculus II introduces integrals, sequences, and series, which are conceptually complex and allow multiple solution strategies, fostering motivation to understand the reasons behind computational strategies. Reflections from the instructor, GTAs, and LAs provide additional perspective. The instructor noted many Calculus I students were "pretty focused on just getting through," contributing to reliance on procedural strategies. In Calculus II, instructional staff emphasized the "why" behind concepts, theory, applications, and deeper understanding, discouraging "plug and chug" approaches. Taken together, these results suggest both course content and instructional practices shape students' development of information management strategies.

Item 31: "I ask questions during lectures or recitation sessions when I don't understand something." As seen in Table 2, Item 31 revealed notable differences in help-seeking approaches between Calculus I and Calculus II. In Calculus I, mean scores significantly declined from 2.919 on the pre- to 2.649 on the post-survey ($p < .0101$). In contrast, Calculus II students reported significant growth in this area, with mean scores rising from 2.641 to 3.026 ($p < .0010$). This item is in the Performance Phase of Zimmerman's (2000) SRL model and is categorized under Help-Seeking. The contrasting outcomes between Calculus I and II may be partially explained by the differences in classroom climate and familiarity with instructional staff. The course instructor for both Calculus I and II noted that "Calc I was a huge lecture," which may have discouraged students from asking questions. On the other hand, many of the Calculus II students had the same instructor throughout the year in both courses, which may have fostered a stronger rapport and comfort. A Calculus II GTA and LA in different recitations described

deliberate efforts to encourage questions and create a supportive environment. One GTA reflected, "I was very happy with the learning environment my LA and I created along with all of our students." Collectively, these perspectives suggest that differences in classroom climate, continuity of instructional practices, and explicit encouragement of questioning likely contributed to the increase in those practices among Calculus II students.

Item 57: "When I need to solve a mathematical problem, I think of several ways to solve it and choose one that makes the most sense for me." Comparisons of planning skills in Calculus I and II, measured by Item 57, revealed opposite trends in student development over the course of the semester. As shown in Table 2, Item 57 was statistically significant for both Calculus I and Calculus II. Calculus I students' mean scores significantly decreased from 3.054 on the pre- to 2.824 on the post-survey ($p < .0428$), whereas Calculus II students' scores significantly increased from 2.756 to 3.000 ($p < .0109$). Within Zimmerman's (2000) SRL model, Item 57 belongs to the Forethought Phase and is categorized under Planning. Similar types of differences in course content and instructional practices, as described for Item 18, likely influenced students' planning skills. Calculus II's focus on integration techniques, and sequences and series, where there are multiple solution strategies, may be more conducive to seeking various solution paths, compared to Calculus I, which focused more on procedures for finding limits and derivatives. The instructor noted that planning skills may have improved in Calculus II because students must evaluate "all the paths we can go down to solve" a problem, whereas Calculus I problems follow a straightforward path. A GTA emphasized recitations highlighting multiple solution strategies, and an LA noted that peer collaboration exposed students to alternative approaches. Together, these factors support the development of planning skills in Calculus II, while the more linear nature of Calculus I may limit growth.

Course Specific Significant Changes

In addition to the items discussed above, several other survey items showed statistically significant changes for either Calculus I or Calculus II, though not both. Due to space constraints, we summarize the results here and focus on a select few items.

Calculus I students demonstrated significant improvement in two areas of self-regulated learning: Item 42, reflecting careful reading of instructions before starting a task (Forethought Phase/Planning Category), and Item 52, highlighting self-control in exam preparation (Performance Phase/Self-Control Category). These gains suggest that students were increasingly attentive and deliberate in their problem-solving approaches and exam strategies. Eleven other items showed decline, including Item 49 (Performance Phase/Help-Seeking Category), which measures help-seeking from instructors or GTAs. This decrease aligns with findings for Item 31, suggesting that Calculus I students were generally less comfortable seeking support from the instructional team. These results reflect areas for growth and provide valuable insight into where additional encouragement or support could further strengthen students' SRL skills.

For Calculus II, four items showed statistically significant changes. Students improved on two items, which reflected enhanced skills across all three SRL phases, but declined on Item 8: "I can motivate myself to learn mathematics when I need to" (Forethought Phase/Conditional Knowledge). Interestingly, this item had a slight, non-significant increase for Calculus I, but a significant decrease for Calculus II students ($p < .019$), making it the only item with a reversed direction of change between the two courses. The instructional team was unsure why motivation decreased for Calculus II students, indicating a need for further research to better understand the factors contributing to this decline.

These results indicate that both courses can foster growth in students' SRL skills. Calculus I students showed improvements in self-control, while Calculus II students generally improved across several categories. These patterns highlight the potential for targeted instructional strategies to support continued development of self-regulated learning in both courses.

Discussion and Scientific Significance of the Study

This study examined changes in self-regulated learning (SRL) skills among Calculus I and II students that occurred without SRL interventions. The analysis revealed contrasting patterns across the two courses, despite their similar pedagogical approach and being taught by the same instructor, which we found surprising and tried to explore further. Calculus II students showed measurable gains in SRL skills, including planning, self-control, and information management, whereas Calculus I students exhibited declines across most SRL skills. Prior research on SRL demonstrated that students often struggle to develop self-regulatory skills independently and that explicit scaffolding or intervention is typically required for meaningful growth (Panadero, 2017; de Boer et al., 2018; Dignath & Büttner, 2008). Our findings regarding Calculus I students align with these previously observed results, but not for Calculus II students.

Calculus II students showed notable increases in many of their SRL skills. Several factors may explain this pattern. Improved instructional practices through a larger reform effort fostered opportunities for students to practice SRL skills. One GTA noted that her students "were very active participants in recitation and also seemed to develop good relations amongst each other," illustrating how a supportive, interactive environment can encourage self-regulated behaviors. Student maturity and prior experience with college-level mathematics also likely contributed to increased capacity for planning, monitoring, and reflecting on learning. Finally, course content that offered multiple solution strategies and encouraged deeper engagement may have supported intrinsic motivation and skill development.

In contrast, Calculus I students showed declines in several SRL skills, consistent with both SRL research and literature on challenges in introductory calculus. Students were less likely to seek help and engaged less in performance-phase strategies, reflecting the difficulties of large, formula-focused lectures and the cognitive and emotional demands of first-year calculus (Bressoud, 2015; Ellis et al., 2016). Instructional team members noted that many students were still adjusting to college-level study habits and heavier course loads, suggesting that SRL skills may not develop automatically (cf. de Boer et al., 2018). These findings underscore the importance of supporting SRL skill development, particularly in university STEM gateway courses where students may lack experience and confidence.

The results have several implications for calculus instruction and undergraduate mathematics education. They highlight the potential for instructional practices and course design to promote SRL even without formal interventions, while reinforcing the need to target first-year students with explicit scaffolding. SRL remains under-researched in undergraduate mathematics despite its role in promoting persistence, motivation, and conceptual understanding (Panadero, 2017). There is a clear need for research-based interventions, and we are currently designing one tailored for calculus students. Overall, supporting SRL must complement curriculum reform, as improving teaching alone cannot equip students with the skills to regulate their own learning.

Proportional reasoning is a central concept for students to learn, yet they often struggle when solving proportionality-type problems. While prior work has examined students' solution strategies, little attention has been given to the meanings of equivalence that support proportional and multiplicative reasoning. This study investigates how students reason about equivalence in measurement contexts with tasks adapted from Cook et al. (2021). Using task-based clinical interviews with four preservice secondary teachers, we analyzed responses to tasks involving relationships such as "1 lunar cycle = 28 days." Focusing on one participant, we identified the use of two ways of reasoning about equivalence which proved productive for her. Findings highlight the critical role of descriptive reasoning for connecting quantities and magnitudes in proportional situations. We argue for expanding research on equivalence in measurement-based proportional contexts.

Keywords: proportional reasoning, multiplicative reasoning, equivalence, measurement problems

Introduction & Literature Review

Studies using the students-and-professors problem (S&P problem), as well as others like it, highlight the nuance and complexity that can be involved when using proportional reasoning to successfully reason about quantities involved in such problems (Christianson et al., 2012; Clement et al., 1981; Cohen & Kanim, 2005; Fisher, 1988; Van Dooren et al., 2009). Proportional (and multiplicative) reasoning has been well-studied (e.g. Clark et al., 2003; Lesh et al., 1988; Modestou & Gagatis, 2010; Vergnaud, 1983, 1988) and for good reason- such reasoning has been referred to as a critical connector between elementary-level math and higher-level math (Lesh et al, 1988). Despite the importance of proportional reasoning in the mathematics curriculum, students' experiences have not been sufficient in supporting them in developing such reasoning (Tjoe & de la Torre, 2014); this highlights the need for research continuing to explore students' proportional reasoning.

Although much scholarship has been done on students' solution processes in S&P-type problems, little attention has been paid to the meanings of equality and equivalence that support students in reasoning productively about these scenarios. More broadly, we observe that, while interpretations of the equals sign have received a large amount of attention (Jones, 2008; Jones & Pratt, 2006; Kieran, 1981), very few studies have examined the interpretations that support productive reasoning about equivalence in proportional, quantitative scenarios. Additionally, while much of the research into the S&P problem (and those like it) has focused on producing the correct algebraic equation (e.g., $S = 6P$), very little attention has been paid to how students might reason about the magnitudes involved in such problems. This leads us to pose the following research question: In what ways might students productively reason with equivalence as they engage in tasks involving proportional quantities?

Theoretical Perspective

Equivalence

For a context in which to discuss students' ways of reasoning about equivalence in proportional contexts, consider the following tasks originally described by Cook et al. (2021):

> Task A: In Glenn Junior High school, there are 28 students for every 1 teacher. Determine the number of students if there are 37 teachers. Then write an equation that generally relates the number of teachers, *T*, to the number of students, *S*, in Glenn Junior High.
>
> Task B: There are 28 days in a lunar cycle. Determine the number of days that pass in 37 lunar cycles. Then write an equation that generally relates a number of lunar cycles, *L*, and the number of days that pass during those lunar cycles, *D*. (p. 36)

Both tasks are variations of the S&P problem described by Clement et al. (1981). In the spirit of inquiring about solutions to these tasks, Cook et al. (2021) developed a conceptual analysis to answer questions a student might ask when approaching Task A and Task B. The solutions to and interpretation of both tasks require flexible use of equivalence. The authors hypothesized three ways of reasoning that could support students' productive engagement with these measurement/proportionality tasks: *numerical*, *transformational*, and *descriptive*.

A *numerical* way of reasoning identifies two expressions as "equivalent when they have the same numerical value" (Cook et al., 2021, p. 36). In the context of expressions such as $2(x + 1) = 2x + 2$, a numerical way of reasoning is a natural default because, for all values of the variable x, the left-hand and right-hand sides evaluate to the same number. However, numerical ways of reasoning can fail when referring to a statement such as '28 days = 1 lunar cycle' (as 28 is not equal to 1). These kinds of measurement equations require a different kind of reasoning. To that end, Cook et al. (2021) identified two other ways of reasoning about equivalence, a *transformational* way of reasoning and a *descriptive* way of reasoning. The transformational way of reasoning involves some manner of algebraically appropriate modification of the expression or equation (e.g., distributing the 2 in $2(x +1)$ to obtain $2x +2$). A descriptive way of reasoning, adapted from the work of Prediger & Zwetzschler (2013), "treats two objects as equivalent if they describe, represent, or model the same quantity or situation" (Cook et al., 2021, p. 37). For example, a student might engage in descriptive reasoning when referring to a clock to grapple with modular arithmetic or referring to area under a curve to justify why two integral expressions might be the same. Descriptive ways of reasoning are particularly important for proportionality tasks, as attention to measurement and magnitude can help students reason through the task.

Quantities and Magnitudes

Undergirding the solution to proportionality problems is attention to the quantities involved. Thompson (1994) defined *quantity* as a scheme consisting of three components: quality of object, unit or dimension, and the ability to quantify the object. An individual, for Thompson, engages in quantitative reasoning when working with all three components of the scheme. Thompson et al. (2014) establish that *magnitude* can be thought of as a scheme at several levels. Of relevance to this report, one of Thompson's levels refers to Wildi's (1991) definition of magnitude of a quantity *Q* as "the measure of *Q* with respect to a unit *u*, times the magnitude of *u*" (Thompson et al., 2014, p. 5). The invariance of magnitude with respect to change in measure is highlighted by using this definition; this creates a powerful mental image for magnitude which can be used by the student in proportionality contexts. In the context of Task B, 28 days and 1 lunar cycle are equal because 28 and 1 both describe measurement of the same duration of time, albeit in different units (the length of one day, |day|, and the length of one lunar cycle, |lunar

cycle|, respectively). In the language of Thompson and Wildi, 28*|day| = 1*|lunar cycle|; this setup helps lead to the algebraic solution to the task, *28L = D*. The solution equation treats the variables *L* and *D* as measurements, while |lunar cycle| and |day| are units of measure. We associate this approach with a descriptive way of reasoning. We hypothesize that attending to these features can be productive for reasoning about proportional quantities; it is unclear, however, whether and how these ideas might emerge when working with students.

Methods

We conducted task-based clinical interviews (Clement, 2000) with four students at a large public research university in the United States. All four participants were pre-service secondary teachers, completing the third year of their coursework in the Spring semester of 2025. Individual interviews (one participant per interview) centering on Tasks A and B from the previous section were completed in Spring 2025 and were approximately 40 minutes in length. We recorded student words and utterances, as well as their written work, via iPad and the ExplainEverything app. We presented participants first with Task A before presenting Task B. As the participants worked on both tasks, the interviewer (third author) asked them to explain their reasoning via clarifying follow-up questions, focusing on key proportional and quantitative relationships in the two tasks (e.g., does 28 students = 1 teacher, and why? Does 28 days = 1 lunar cycle, and why?). We also asked participants to describe similarities or differences between the two tasks to elicit more details from their line of reasoning. Our analysis in this proposal focuses primarily on one participant's responses to Task B. We selected Emily (pseudonym) because her responses were particularly vivid and illustrative of the types of reasoning conjectured by Cook et al. (2021).

Transcripts were produced for each interview session. The first three authors analyzed the transcripts and video recordings of the participants' work, employing Clement's (2000) cycles of interpretive analysis with the ways of reasoning hypothesized by Cook et al. (2021) serving as initial codes. Our goal was to develop models of the student's reasoning that provided a rational description of her language and actions; models were discussed and negotiated until all three researchers were in agreement. The transcripts were coded for instances of each way of reasoning about equivalence in Cook et al. (2021)— numeric, transformational, and descriptive—and screen captures of relevant portions of the video recording were used to augment the transcripts.

Results

For Task A, Emily began by finding the answer and using numbers to work backward in an attempt to find the relationship that made sense ("if there's one teacher, then there's 28 students, there's two teachers, then there's 56 students"), leading her to the correct algebraic solution of *S = 28T*. Further, she justified her choice by using a numerical way of reasoning to eliminate the reversal error as a possible answer ("If you did it the other way…you have five students, you do not have 140 teachers"). Emily used this line of reasoning for Task B as well:

> *Emily*: So we have 37 cycles that have 28 days in each of them [*writes 37*28*]... So that would be [1036] days that pass in 37…days. Um, then write an equation that generally relates the number of lunar cycles, L, the number of days that passed during those lunar cycles. Um, so if we have one lunar cycle, it's gonna be the same way that it was before [referring to her work in Task A]. If we have, I think it's gonna be 28 L equals D [*writes 28L = D*]. 'cause if you had it the other way, if you had 28 D, would still be like after 28 days it should equal one lunar cycle [*writes 28D = L*]. But if you have, if you put in 28

for D, you get 28 squared, which is 784 [*writes 784 L*]. And that is not one lunar cycle…So I think that this would have to be the general equation for L and D [*boxes 28L = D*].

We infer Emily relied on numerical ways of reasoning to justify her equation by arguing that the rule written the other way would provide an incorrect numeric relationship between the number of days and lunar cycles.

The interviewer continued by asking how Emily might respond to an assertion that one does not equal 28, so therefore one lunar cycle cannot equal 28 days. Her response pivoted to using a descriptive way of reasoning about equivalence:

Emily: Well, I would ask them if one foot equals 12 inches [*writes 1 ft = 12 in*]. So I think that's a pretty common…conversion… so one and 12 are not equal, but our units are different [*underlines 'ft' on the left and 'in' on the right*]...your units are different, but these two things [*referring to 1 ft and 12 inches*] are equal. But just because the units are different does not mean that in this case [*scrolls up to her work on Task A, which has 1 teacher ≠ 28 student*] I can say one teacher [*underlines 'teacher'*] equals 28 students [*underlines 'student'*]. Yeah, our units are different, but the value of those units is not the same.

The interviewer then asked her to elaborate about what she meant by the displayed equation, 1 LC = 28 days. Emily responded by drawing the number lines in Figure 1 and partitioning it into pieces which she claimed represented the 28 days ("28 is the number of subsections contained inside of one lunar cycle"). She articulated:

Emily: We can't cut one teacher up into 28 even pieces and say that those are the students… each of these [tick marks] is not equal to one student…one teacher's not made up of 28 students, but one lunar cycle is made up of 28 days.

Emily argued that one lunar cycle is composed of 28 days (28*|day| = |lunar cycle|). Hence, she leveraged a meaning for magnitude consistent with Thompson et al.'s (2014) description of a Wildi magnitude to justify the former equation; Emily stated that the same magnitude of time could be measured in terms of 28 times the magnitude of a day or 1 times the magnitude of one lunar cycle. Further, Emily contended it cannot be said that 28*|student| = |teacher| as they did not represent the same magnitude.

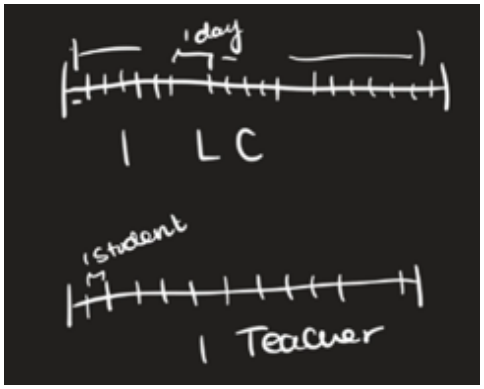

Figure 1. Emily's number lines comparing a partition of one lunar cycle and one teacher.

We infer that here Emily attended specifically to the idea that there is a measurement comparison that can be made between days and lunar cycles, while the same cannot be said for students and teachers; as a result, the latter magnitudes are incommensurate.

She continued to focus on the measure, consistent with understanding that 28*|day| = |lunar cycle| when asked to identify what is true for Task B which is not true for Task A:

Emily: So here we're saying the amount of time that has passed is the same. So if you're talking about, um, the length of one day multiplied by 28 [*writes length (day) * 28 = 1 LC*]...that will give you one lunar cycle. And you can say the same thing the other way…you can divide a lunar cycle up into 1/28 of a lunar cycle, and that's one day [*writes 1/28 LC = 1 day*]. But if we come down here and we say, "Okay, well one student times 28, does that equal one teacher? How many teachers does 28 students make up?"... 1/28 of a teacher that does not pop out one student. Like I can very confidently say that that is not one student.

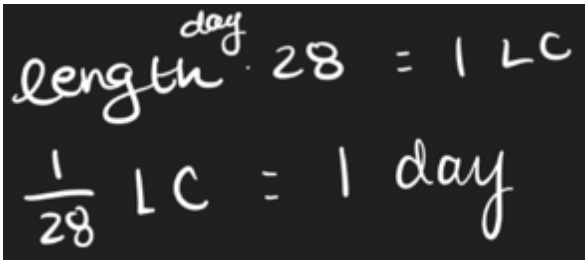

Figure 2. Emily's comparison of units for Task B.

In this excerpt, Emily explicitly sets off a distinction between days and length of days, indicating an attention to the magnitudes at play. Importantly, she identifies that (1/28)*|lunar cycle| = 1*|day|, which is a feature distinguishing the Wildi magnitude scheme from less sophisticated magnitude schemes (Thompson et al., 2014).

The interviewer continued by later asking Emily to respond to a student who wrote both $D = 28L$ and $28D = L$. First, Emily says "so I guess that's the difference. I'm talking about length here [*refers to L in 28D = L*], but here I'm talking, if we're talking number of days [*refers to D in 28D = L*], which is what the problem states and the number of days that pass…". Here, she clearly distinguishes the measurement of the number of days and lunar cycles ("if we're talking number of days") versus the magnitude of each unit ("I'm talking about length here"); this is again consistent with the descriptive way of reasoning of the equation as proffered by Cook et al. (2021) (i.e.., "they describe, represent, or model the same quantity or situation" (p. 37)).

As she continued to reason why $D = 28L$ and $L = 28D$ could not both be true, she paralleled the initial reasoning she gave for why $D = 28L$ was the correct answer; Emily used numbers to justify why four days would not equal 112 lunar cycles, as illustrated in Figure 3 below.

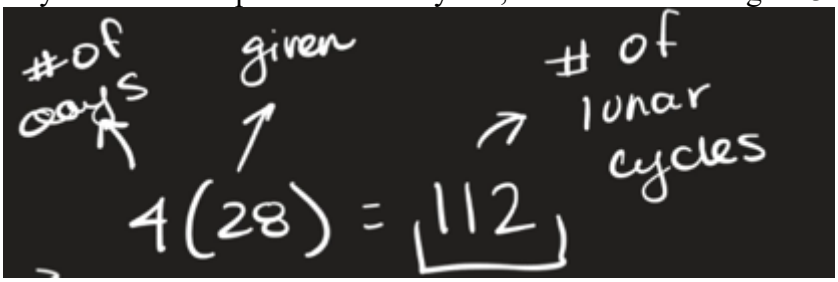

Figure 3.Emily's use of numerical ways of reasoning justifying why D = 28L.

She immediately referred to her initial line of reasoning ("the way I reasoned with it to begin with was with 37 times 28 gives me [1036] days…so then either that [*referring to her original reasoning*] would be wrong or this reasoning [*referring to the claim that 28D = L*] would be wrong"). Immediately after reestablishing the falsehood of the equation $28D = L$, Emily used both numerical and descriptive ways of reasoning by saying "if we're gonna think about it in

practical terms, [one] lunar cycle, we can say that's a month…we have four days. That's not 112 months". We infer that Emily used a descriptive way of reasoning to support the numerical way of reasoning she had established earlier.

The distinction between measurement and units of measure became more evident as the interview continued:

Emily: This [*referring to D = 28L*] would be the number of lunar cycles . But here [*referring to her work in Figure 2b*], this is the number of days and this is the number of lunar cycles that have passed, which is not equivalent. These two things are not equivalent. Length of a lunar cycle and number of lunar cycles that have passed.

Int: Okay. And so those are, those are, those are different things, but clearly they're related in some way. [*Emily agrees.*] Um, so how…are they related?

Emily: Mm. Well, if you have three lunar cycles that have passed, right? So we're talking about the length of three lunar cycles… that is the length of those three lunar cycles. Each one of these is a lunar cycle. [*draws the number line in Figure 4a*] The length is not three…or I guess, um, 'cause if we're talking about like, each of these have 28 days [*produces Figure 4b*]...So I would say yellow is the length of one lunar cycle, and then blue is saying that three lunar cycles have passed [*produces Figure 4c*]….Because this is three lunar cycles, this is one, the length of one lunar cycle. Within here you have 28 [*produces Figure 4d*].

Int: So are you thinking about, about the, say the space between the blue brackets?...Is that the number of, are you thinking about that as the number of lunar cycles or the length of three lunar cycles? Or both, or neither?

Emily: Well, I guess the length, this is, this would be saying three lunar cycles have passed….We have three lunar cy- three full lunar, lunar cycles that have gone by, but the length of each one is the length of a day, times 28. So that's like each of these have 28 little, little markings in them [*produces Figure 4e*].

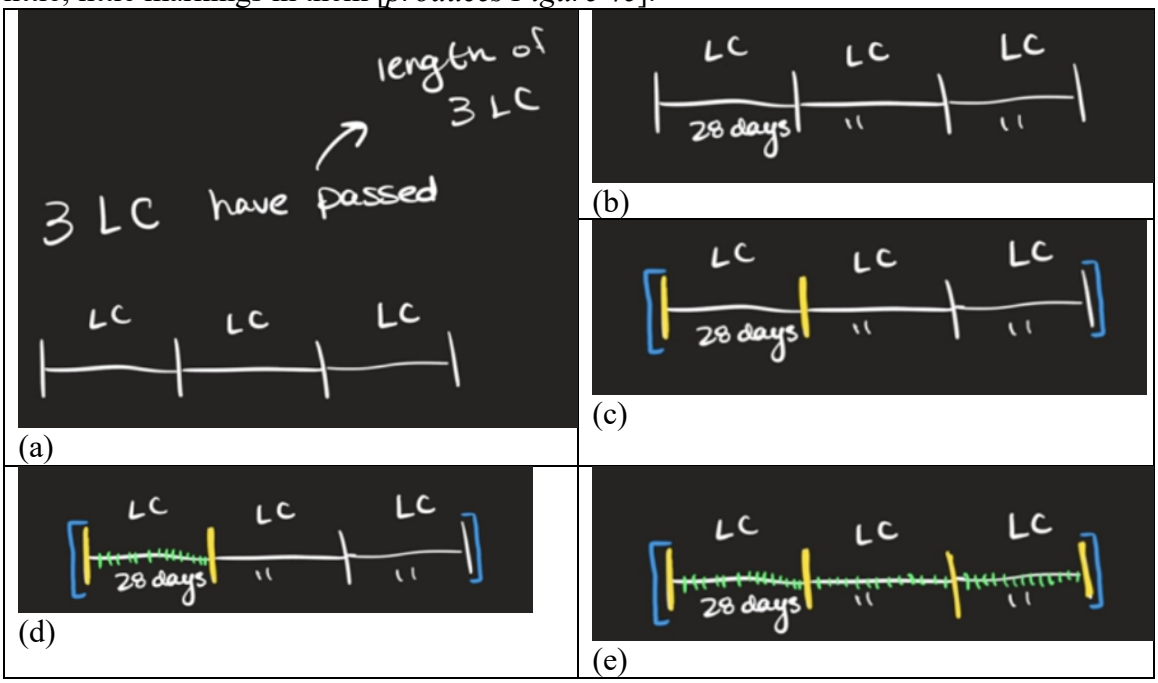

Figure 4. The evolution of Emily's number line diagram for 3 lunar cycles.

From this interaction, we infer that Emily argued 3*28*|day| = 3*|lunar cycle|; we particularly highlight Emily's careful attention to the distinction between the length of a lunar cycle (in yellow) and the accumulated duration of three lunar cycles (in blue). She then described how each lunar cycle consists of 28 days to draw a final representation. The final argument is an extension of her prior use of the Wildi magnitude accompanied by a clear representation of her reasoning. Namely, a single duration of time, as represented by the total line segment in Figure 4a, could be measured using two different units. With lunar cycles as her unit, the duration comprised 3*|lunar cycle|. With days as her unit, the duration comprised 3(28*|day|), which was an extension of her earlier reasoning with Wildi magnitudes. Combining these two arguments Emily concluded 3*28*|day| = 3*|lunar cycle|.

Discussion

Emily successfully used both numerical and descriptive ways of reasoning about equivalence when solving Tasks A and B. We claim that both the numerical and descriptive ways of reasoning about equality were essential to her productive approaches to these tasks. Whether she used one or the other, we observe, depended on the nature of the objects she was equating. When attempting to derive and verify the correct algebraic equation to Task B (relating, for example, D and L via $D = 28L$), Emily relied on numerical way of reasoning. On the other hand, when equating magnitudes of time (e.g., 1 lunar cycle and 28 days), Emily relied primarily on descriptive ways of reasoning. Put another way, Emily demonstrated numerical ways of reasoning to relate the *measurements*, and a descriptive way of reasoning to relate *magnitudes* (durations of time). Moreover, we note that equating durations of time (such as 1 lunar cycle and 28 days) do not lend themselves to a numerical way of reasoning because, indeed, the numerical values (measurements) are different. Taken together, these insights underscore that a descriptive way of reasoning can not only be useful but *critical* for students' reasoning about proportionality and measurement, especially considering that a numerical way of reasoning is predominant when working with most other types of algebraic expressions.

This paper contributes to the field by establishing that a descriptive way of reasoning about equivalence can be critical to students' thinking and provide a detailed example. We highlight that her work provides a clear and explicit empirical example of a student reasoning with Wildi magnitudes as described by Thompson et al. (2014). Specifically, by viewing the equality of 28 days and one lunar cycle in terms of being different measurements of the same magnitude, Emily was able to productively reason through the apparent contradictions of the solution process and extend the equality to larger periods of time than the one initially proposed by the problem. We note that while the students-and-professors problem has been studied extensively, we are unaware of research examining measurement conversion proportional situations such as Task B. We call for additional research exploring such scenarios and how students may rely on different ways of reasoning about equivalence (and magnitudes) when reasoning about such situations.

Choice and Circumstance: Sources of Faculty Momentum Toward Active Teaching Practices

To study what shapes instructors' use of student-centered active teaching methods, we examined multiple influences across the faculty career span, using survey data from over 600 mathematics faculty. We present a path model that incorporates factors from graduate teaching experience and job choice to professional development, departmental norms, and involvement in student-oriented scholarly and professional activities. We adapt Adelman's concept of momentum to interpret results and highlight the role of early decision-making and professional environments that reinforce teaching-focused choices in shaping faculty teaching practices.

Keywords: active learning, student-centered teaching, professional development, institutions

Improving instruction has been called the "best bet" for strengthening undergraduate STEM education (Singer, 2013, p. 768). Yet many students do not experience research-based instruction in STEM classes, where 60%-90% of instructors rely on lecturing (Hurtado et al., 2012; Larsen, Glover & Melhuish, 2015; Rasmussen et al., 2016). While minority, first-generation and poor students benefit most from these high-impact practices, these groups least often encounter them (Kuh, 2008). As Fairweather (2008) asserted, "The key… lies in getting the majority of STEM faculty members to use more effective pedagogical techniques than is now the norm" (p. 13).

High-quality, teaching-focused professional development (TPD) can be powerful in shaping instructors' teaching practices (Lattuca, Bergom & Knight, 2014; Laursen et al., 2019). For example, Archie et al. (2022) showed that TPD on inquiry-based learning (IBL) fostered gains in mathematics' instructors knowledge, skills and availing beliefs, that were in turn positively associated with later classroom uptake of IBL. Most future faculty have had little prior learning about teaching (Austin et al., 2009; Golde & Dore, 2001); thus, early career may be an optimal time to offer TPD, when faculty are learning to balance teaching with other duties (Turner & Boice, 1987) and before they settle into habits that serve students less well. Many STEM disciplines have thus offered professional development to early-career faculty (CSSP, 2012), focused on teaching and how to navigate research, service, and collegial relationships. However, the evidence is slim about the impact of this early-career positioning (Connolly & Millar, 2006).

We set out to understand whether and how TPD targeting early-career mathematics instructors influenced their teaching practices. In this paper, we focus on findings about alumni who had previously completed the program. We wanted to learn how alumni are teaching now, and what influenced their teaching—including early-career TPD, other professional learning, and their work environments. As part of a holistic take on the influences on teaching, we also sought to understand alumni careers more fully, considering their other roles such as scholars, leaders and participants in professional societies, and we compared alumni with a matched comparison group to learn whether and how the groups differ. Our research questions and hypotheses are:

RQ1. What are the overall differences in the teaching, scholarly and leadership activities, and institutional environments of alumni and comparison group faculty?
Hypothesis: Alumni program status (vs. Comparison) will predict more active

teaching when other independent variables in the model are held constant.

RQ2. What social, professional, and institutional factors predict differences in the use of active learning strategies for teaching? *Hypotheses: Departmental expectations and instructor beliefs that support active teaching are associated with more active teaching in practice. Instructors who engage in career activities related to active teaching, equity and outreach also will teach more actively.*

RQ3. How do early career experiences around teaching influence the role and nature of teaching in instructors' later careers? *Hypothesis: Indicators of early-career interest in and pursuit of teaching-oriented jobs will predict the emphasis on teaching in instructors' careers, as expressed by the number of courses they teach.*

Prior Work and Conceptual Frameworks

Many studies have examined barriers and supports to instructors' uptake of active teaching approaches (e.g., Dancy & Henderson, 2010; Henderson & Dancy, 2007, 2011; Lund & Stains, 2015; Walczyk, Ramsay & Zha, 2007; Yik et al., 2022). Psychological and personal factors, such as beliefs about learning and teaching and prior experience with active teaching, are often highlighted in these studies, as are classroom factors such as the layout of classroom space, class scheduling, and the nature of the course and students. The institutional context where faculty work also has a sizable influence on their ability and motivation to change their teaching, including teaching loads, course coordination, and institutional reward systems (Austin, 2011).

Removing such barriers can therefore serve as leverage to improve teaching. Professional development can increase knowledge and skills and foster facilitating beliefs. Other strategies operate on parts of an institutional system, such as structures that increase accountability for teaching quality, and cultures that support teaching change (Borrego & Henderson, 2014). Manduca (2017) centers the individual learner in an even broader landscape, "as an active agent who learns over time and is responsible for making changes" (p. 416). In addition to formal professional development and institutional context, she highlights "the community of learners that surrounds and supports an individual as they learn and change" (p. 418). Peer communities may support teaching change both during TPD and through disciplinary or departmental groups. Together these ideas cast growth in teaching as a complex, incremental and long-term process, not a simple result of one-off professional development or binary decisions to change.

Moreover, teaching is only one part of a faculty career, so a full picture of faculty teaching must attend to academic careers and how they develop. Calling out insights from the sociology of science, Hermanowicz (2012) noted that the concept of a career is inherently sociological, with its dependence on "advisors, mentors, college origins, doctoral programs, social class backgrounds, colleagues, collaborative networks, postdoctoral appointments, employing departments, employing universities, disciplines, fields, professions, and reward systems… that make careers possible and which differentiate them" (p. 210). This view leads us to attend to educational history and career activities in our study, and to the norms of the overlapping social communities in which faculty careers develop (Ebert-May et al., 2025).

As theoretical framing, we use Adelman's notion of "momentum" (1999), developed in his study of bachelor's degree attainment and racial inequities in this outcome. Dissatisfied with standard accounts of academic achievement, he explored how early elements of students' academic paths, such as the level of their high school mathematics courses, had shaped their college outcomes many years later. This approach highlights that many factors influence individuals' paths and may play out over decades, and draws attention to influences that are not pre-set but can be changed by institutions and individuals themselves. Wang (2017) uses the

concept of momentum to clarify antecedents of community college student success, highlighting learning experiences and motivation as well as academic factors that may combine to overcome inevitable friction and help students toward their academic goals. While we focus on a different sphere, our study likewise addresses multiple factors—preparation, motivation, environment, choice—that help to move people toward or away from specific outcomes over long times.

As a metaphor, the term "momentum" highlights forward impetus or motion toward an outcome, what a person needs to build and maintain in order to progress. Momentum may vary in pace or direction over time, depending on diverse individual and environmental factors that may boost momentum or break it by adding friction. It recognizes individuals as "active, responsible participants" in their trajectories, neither laying blame on them for disruptions in momentum nor treating them as "passive creatures whose fate is wholly molded" by institutions (Adelman, 2006, p. xxiv). In this project, we are interested in sources of momentum that impel faculty toward use of active approaches to teaching. The notion entails a developmental perspective on faculty careers (Baldwin & Blackburn, 1981) and is well suited to our retrospective, multi-factor study that considers instructor change as a trajectory, rather than an event, and to our use of path analysis as an approach to modeling a complex data set.

Context for the Study

Particular challenges face studies of TPD that focus on outcomes that are important but take time to develop, such as use of research-based teaching practices. The program must be large, long-lived, and stable over time in design, so that multiple cohorts can be combined to develop a sample with sufficient statistical power. Our study gathered data from MAA Project NExT (PN), which had several features favored by research (e.g., Giersch & McMartin, 2014; Manduca, 2017), related to duration and frequency, mentoring, content, format and facilitation. The year-long TPD program includes three multi-day gatherings and online interactions. Participants interact with peers and seasoned faculty, face-to-face and online, using a variety of mechanisms to foster interaction. Program topics focus on the needs, concerns and interests of new faculty, e.g. teaching methods, curriculum choices, inclusive teaching and advising, outreach, undergraduate research, time management, and balancing multiple faculty duties. The format of the first summer workshop typically includes 1-2 hour interactive blocks for plenary talks, table discussion, mini-workshops, a networking fair, and group meals. Later meetings emphasize participant-planned sessions, plenaries, and social time. Finally, the program is overseen by a committed leadership team with expertise in professional development, bolstered by a diverse set of session leaders, speakers and mentors who model diverse careers, lives, and specialties.

Study Methods

Study Participants

Current analyses of the survey dataset used 634 responses from 492 instructors who participated in Project NExT ("alumni") and 142 from a comparison group constructed by matching alumni survey respondents to non-alumni peers. We surveyed all program participants from 1994-2018. We used the Mathematics Genealogy Project (Jackson, 2007) to match alumni to non-alumni peers by graduate institution, year of Ph.D., and advisor. The peer group is broadly matched in general experience of doctoral education, mathematical subfield, and prestige of doctoral degree, and faced comparable job markets as new PhDs. The final sample reflected a 50% survey response rate. All responses contained complete information about instructors'

teaching and described in-person classes. The IRB-approved survey was administered in winter-spring 2022.

Survey Instrument

The survey contained 47 items (some with long lists of choices) asking about topics related to careers as math instructors. These included: 1) the benefits of Project NExT or an alternate professional development project, 2) academic career activities, 3) participation in professional development, 4) participation in professional societies, 5) involvement in research and grants, and 6) their department's expectations in evaluating their work, with a parallel section asking about activities that brought respondents personal career fulfillment. To assess the teaching component, we used items similar to the TAMI-IS survey (Hayward et al., 2018). It asked instructors to choose a course they had taught recently and estimate the amount of class time spent in a range of teaching activities (e.g., Lecture or Group Work). We also probed basic demographics, years of experience teaching at the college level, and institutional characteristics.

Data Analysis

Based on our hypotheses, we tested a three-part model with the outcome variables of Active Teaching, Amount of Teaching and Program Status. We used the statistical software AMOS to examine model fit and regression weights of the independent variables entered into the model using a predetermined set of variables. Of the original set of 28 variables, 16 were significant predictors. To save space, only significant predictors are presented in Table 1 and Figure 1.

We followed best practices in confirmatory path modeling by checking assumptions, reporting multiple model fit statistics and specifying the model *a priori* to analysis. The model was calculated using Maximum Likelihood Estimation and model fit was evaluated using two indices: the Comparative Fit Index (CFI) and the Root Mean Square Error of Approximation (RMSEA). CFI values range from 0 to 1, with values < 0.95, and RMSEA values ≤ 0.09 interpreted as evidence of good fit (Rigdon, 1996).

The path model had three parts, all using items from the alumni survey. Hypothesized relationships between independent variables and *Active Teaching* asked if departmental and personal expectations and career activities for active learning instruction translated to practice. We also wanted to know the predictive association between early career activities and the amount of teaching instructors reported. The third part of the model examined selection into Project NExT, seeking to hold possible confounding variables constant to gauge the relationship between attending PN and later active teaching.

Results

Table 1 describes the variables used in the path analysis, showing where they appear in the path model (denoted by →), and the value of the path coefficient. Figure 1 shows the variables in the model and their path coefficients. We report variables with significant standardized regression coefficients, where * denotes probability $p<0.05$, and ** denotes $p<0.01$. Model fit was "good" with a Chi-Square/Df = 5.8 ($p < 0.001$), CFI = 0.94 and RMSEA = 0.088 (Hu & Bentler, 1999). Correlations (not shown in Figure 1) between independent variables in the model were lower than r=0.2, with no collinearity of predictors. While 16 predictors are shown, another 12 were used in the model but were not significant predictors and are not included in Table 1 or Figure 1.

The model describes three interlocking regression analyses. As hypothesized, departmental expectations and personal beliefs were strong predictors of Active Teaching, our primary

outcome measure (Outcome Model, Fig. 1 right side). The R-squared value for this model component was 0.27. Departmental expectations to use methods other than lecture had the strongest independent association with Active Teaching (b=0.28), and the personal importance of active teaching also predicted the outcome variable (b=0.19). The factor variable TDO, an aggregate of six items, gauged participation in career activities around teaching, equity and educational outreach. TDO was positively associated with teaching actively (b=0.21). Instructors who taught a greater number of courses in the past two years also incorporated methods of active learning (b=0.14).

Table 1. Variables in Path Analysis, Description, Path Model Association and Path Coefficient

Variable	Description	Path & coefficient
Active Teaching	Factor variable derived from survey questions asking for estimates of class time spent in teaching activities such as Lecture, Group Work, Discussion, Presentation and Short Explanations. (Higher Score is more active, -3 to +3)	Main outcome variable
Expectation_Variety	How does YOUR ACADEMIC DEPARTMENT rate the importance of the following for evaluating your career progress? - Use a variety of teaching methods (1-4)	→ Active Teaching -0.12**
Expectation_Not Lecture	(as above) -Departmental expectation to use methods other than lecture (1-4)	→ Active Teaching 0.28**
TDO	Factor variable asking about teaching, diversity and outreach career activities derived from checklist of survey items.	→ Active Teaching 0.21**
Important_Active	How do YOU rate the importance of the following in terms of what fulfills you personally?- Teaching in more active and engaging ways (1–4)	→ Active Teaching 0.19**
Important_Equity	(as above) - Promoting equity and diversity in your department and institution (1-4)	→ Active Teaching 0.09*
Teach_Freq	How many course sections have you taught in the last two academic years? Integer)	→ Active Teaching 0.14**
Program	Has participated in Project NExT or comparison (0 = Comparison, 1 = NExT)	→ Active Teaching 0.13**
Female	Gender Female (1= Female, 0= Male) (Other was listed as option but no one chose)	→ Program 0.07*
Years_Taught	Number of years taught (Integer)	→ Program -0.11**
PD_Inst	Factor variable of checklist items asking about participation in professional development at institution, higher score indicates more participation (-3 to +3)	→ Program 0.12**
Belongs_AMS	Belongs to American Mathematical Society (0, 1 = belongs)	→ Program -0.08*
Sought_Teaching	Please agree or disagree with the following statements about your early teaching career. - When I started my career I sought out a faculty position that emphasized teaching (1-4)	→ Program 0.20** → Teach_Freq 0.12**
Highest_Degree	Highest mathematics degree offered at institution (1-4, Associates to Ph.D.)	→ Program -0.14** → Teach_Freq -0.23**
Early Teach	Which of the following was (or is) true about yourself during your early career? (1-4 years after you received your Ph.D). - I taught more than one class each semester	→ Teach_Freq 0.10*
Early_Active	Which of the following was (or is) true about yourself during your early career? (1-4 years after you received your Ph.D). - I taught using active or inquiry-based methods	→ Teach_Freq 0.08*
Tenure_Elig	Is your position tenure eligible? (0, 1 = Yes)	→ Teach_Freq 0.14**
EarlyTeachwanted	Which of the following was (or is) true about yourself during your early career? (1-4 years after you received your Ph.D) - I designed my own courses	→Teach_Freq -0.11**

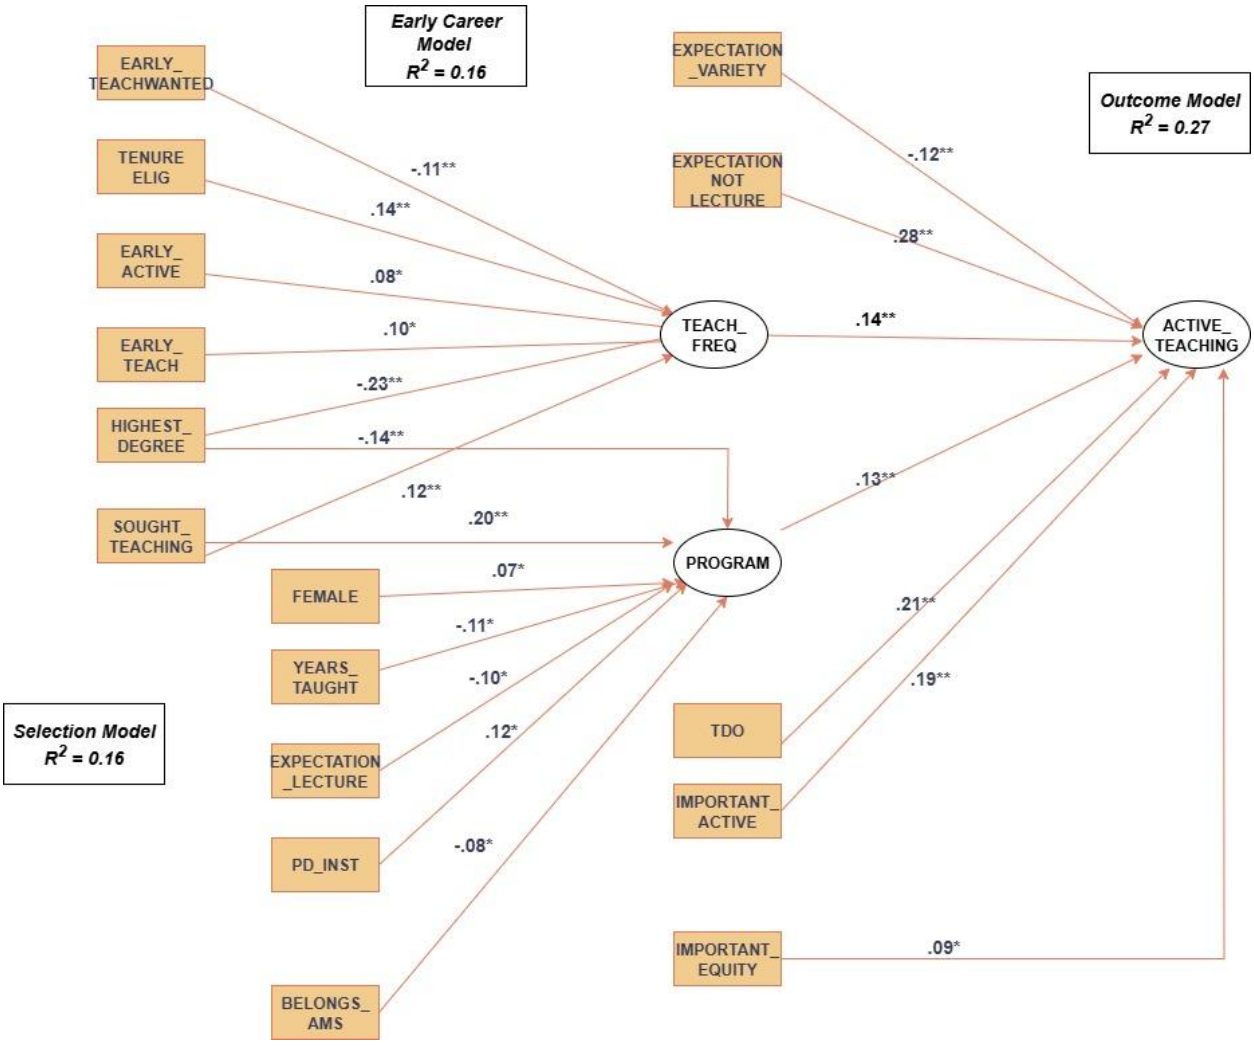

Figure 1. Three-Part Path Model of Relationships between Active Learning, Program Status & Teaching Frequency

Early career practices and decisions were associated with the amount instructors taught (Early Career Model predicting Teach_Freq variable, Fig. 1 upper left). This component of the model had an R-squared value of 0.16. Teaching at institutions offering Masters or Bachelors as the highest degree was highly associated with the amount instructors taught in the past two years (b=-0.23), as was having a tenure-eligible position (b=0.14). Initial career choice, reflected by the statement, "When I started my career I sought out a faculty position that emphasized teaching," was associated with more teaching later in a career (b=0.12). Moreover, those who taught greater numbers of courses in their earlier career were more likely to teach a greater number of classes later (b=0.10), and those who taught actively continued to do so, albeit this effect was relatively weak (b=0.08). Overall, these results showed the impact of early decisions on later career practices.

The third part of the model described and adjusted for differences between Project NExT alumni and the matched comparison group (Selection Model, Fig. 1 lower left predicting Program variable). In general, PN alumni were more likely to be less experienced teachers (b= -0.11) and women (b=0.07) and took part more in professional development at their institutions

(b=0.12). They were also more likely to work in departments with less expectation to lecture (b=-0.10). This component of the model is useful at showing differences between groups that persist after matching and holds these differences constant when assessing the Program variable.

Finally, the program effect for Project NExT was statistically significant, indicating that PN alumni were more likely to teach in an active manner. The raw effect size comparing PN to the comparison group was δ=0.63, considered a large effect (Bakker et al., 2019). Using Program in a regression model holds all other variables constant and determines if any remaining variance in active teaching can be explained by group membership. Here, PN group membership persisted in its association with active teaching with a standardized regression coefficient of b=0.13.

Discussion and Conclusions

We highlight a few key findings. First, the results demonstrate that faculty adoption of student-centered active approaches to teaching is not the product of any single influence or decision (Austin, 2011; Henderson & Dancy, 2007). Future faculty make choices that launch them toward a career in an institution that centers teaching (Austin et al., 2009). New faculty may be encouraged to use active teaching methods by social norms and departmental evaluation criteria that value teaching (Ebert-May et al., 2025). They may pursue professional development on teaching, early in their career and later, in the discipline and at their institution. When these activities are rewarding and supported by peer behaviors and norms, people feel fulfilled and more likely to continue to pursue them. Using a momentum lens, these factors are mutually reinforcing and all build faculty momentum toward use of active teaching methods.

Our finding about the association of the TDO construct with active teaching is new to the literature: faculty who take up active teaching are also more likely to take up other scholarly and professional activities that are likewise centered on student experiences and inclusion, such as outreach, diversity and equity work, and engagement with teaching change initiatives. We suggest that active teaching and TDO activities may reinforce one another and may gain further momentum in institutional settings where they are valued and rewarded.

Also salient is the role of early-career experiences and choices in influencing outcomes up to 25 years later in our sample. Pursuing and securing academic work that emphasizes teaching exemplifies the role of choice, while graduate school experiences of teaching may involve a mix of choice, constraint, and chance: all of these are positively associated with active teaching in the model. Moreover, past participation in Project NExT has a measurable and positive association with use of active learning that persists even when other factors are held constant. In text comments that we separately analyzed, PN alumni indicated that both their initial learning experiences and ongoing interaction with a disciplinary peer cohort were influential in shaping their current teaching. Ongoing analyses will elucidate all these associations and link them to additional data sets from this study and to prior research, seeking to build a full picture of how momentum toward use of active teaching practices waxes or wanes among mathematics faculty.

This study examines how institutions navigate praxeological uncertainty when implementing Modeling Life, a mathematical modeling curriculum for life sciences students. Using the Anthropological Theory of the Didactic, we analyzed implementation across five institutions where didactic transposition processes remain under active negotiation. We identify four interconnected patterns: positioning uncertainty, epistemological conflicts, human resource demands, and systematic adaptations. These findings illustrate how novel mathematical organizations whose requirements exceed existing institutional conditions both generate and are shaped by institutional adaptation processes during ongoing curricular development.

Keywords: mathematical modeling, ATD, biology majors, institutional perspective

The growing importance of mathematical modeling to the research methodologies and conceptual frameworks of the life sciences has prompted numerous calls for reforming the mathematical experiences of life science majors (Brewer & Smith, 2011; Steen, 2005). However, research has documented persistent barriers to implementing modeling-focused approaches in undergraduate mathematics education (Barquero et al., 2015; Bennoun, 2022). Studies identify institutional constraints including faculty's epistemological commitments to *applicationism* and *monumentalism* (Barquero et al., 2015), rigid corpora of mathematical knowledge at university level (Bosch, 2014), and institutional conditions that favor traditional calculus approaches over modeling-centered curricula (National Research Council, 2013). With highly standardized topics like calculus or linear algebra, "the scholarly mathematical *praxeologies* that are selected as knowledge to be taught and the *praxeologies* that are actually taught in the classroom constitute a very stable corpus of knowledge" (Bosch, 2014, p. 115). This stability is not present with bodies of knowledge that are new to mathematical programs at institutions, creating opportunity to study transposition processes during active development. The UCLA *Modeling Life* curriculum represents a modeling-centered approach that has been adopted by multiple institutions. Previous work documenting challenges to implementing novel curricula indicate that the Anthropological Theory of the Didactic (ATD) would allow for examination of the institutional dynamics that underly curricular transformation processes. Adopting this lens, we analyze *Modeling Life* implementations across five institutions to examine these dynamics.

Theoretical Perspective

ATD explains how mathematical knowledge transforms as it shifts between institutions, such as scholarly communities that use knowledge and scholastic communities that teach it. ATD concerns itself with how institutional conditions affect mathematical teaching and learning by coordinating analysis of didactic transpositions, praxeologies, levels of codetermination, and operating epistemologies (Bosch, 2014; Chevallard 2002). These tools aid in understanding why curriculum innovation often encounters systemic, institutional resistance and how

implementation challenges arise from mismatches between innovative praxeological requirements and existing institutional conditions.

Knowledge also undergoes systematic transformation as it moves between institutions; this *didactic transposition* reconstitutes scholarly knowledge as knowledge-to-be-taught. The transformation is not so simple as articulating a list of topics and techniques. It emerges from activity within the noosphere, the institutional sphere where curriculum designers, policymakers, textbook authors, and educational experts select, organize, and adapt mathematical content for institutional contexts. External didactic transposition refers to processes within noospheric activity while internal didactic transposition subsequently transforms this prescribed knowledge into "knowledge actually taught" and ultimately "knowledge learned" through classroom interactions between teachers, students, and mathematical content (Bosch & Winsløw, 2020). Both the process and the mathematical knowledge are shaped by the institutional conditions.

ATD's primary object of analysis is *praxeology*. These are organized blocks of knowledge and practice that describe how mathematical work is accomplished within institutions. A praxeology comprises two interconnected components: (i) a praxis block consisting of types of tasks (T) that individuals encounter and techniques (τ) used to solve them and (ii) a logos block containing the technology (θ) that describes, explains, and justifies the techniques, supported by theory (Θ) that provides broader theoretical foundation (BarbÉ et al., 2005). Mathematical organizations (MOs) are structured collections of praxeologies that make up the mathematical knowledge, and they operate within specific institutional contexts. An important undertaking for ATD is to elaborate the ecological conditions that enable praxeological development, maintenance, and evolution, as well as which institutional factors support or hinder the construction and survival of MOs (Bosch & Gascon, 2006). Chevallard's (2002) levels of didactic codetermination show how each level influences lower levels, explaining why curriculum implementation challenges stem from inter-level conflicts that require coordinated institutional responses rather than isolated pedagogical changes.

ATD has also examined the epistemologies underlying mathematical instruction that influence how MOs develop and function within institutions. For example, the "visiting monuments" paradigm treats mathematics as established works to be consumed and appreciated. This creates praxeologies where tasks are phrased in terms of procedures and techniques focused on algorithmic implementation of those procedures. In contrast, a "questioning the world" paradigm treats mathematics as tools for addressing genuine problems, creating praxeologies where tasks emerge from authentic inquiry and techniques developed in response to problem-solving needs (Bosch & Winsløw, 2020). Similarly, "applicationism" views mathematical modeling as mere application of pre-established mathematical knowledge to external domains (Barquero & Bosch, 2015). This leads to modeling appearing as end-of-chapter exercises following content presentation, creating a weak logos block where the technology and theory present modeling as supplementary to mathematical development rather than as mathematically generative. In contrast, an epistemology that positions modeling as integral to mathematics itself enables praxeologies with strong logos blocks where the technology and theory establish modeling processes as fundamental to mathematical understanding and concept formation.

Whereas in previous studies, external and internal transposition occur simultaneously (Bergsten et al., 2010; Bosch et al., 2021; Bosch & Winsløw, 2020; Strømskag & Chevallard2024; Winsløw et al., 2014), we use didactic transposition and praxeology to describe situations where external transposition (noospheric selection and prescription) has not settled into a reference MO by the time instructors begin internal transposition. We refer to this situation

as *transposition instability*. Under this condition, institutions attempt to position, implement, and legitimate courses in the absence of reference MOs, even though instructional practice is already underway. As a result, stakeholders face *praxeological uncertainty*, understood here as indeterminacy regarding which praxeologies should be taught, how they relate to existing curricular pathways, and on what grounds they can be justified within the institution. In this study, we examine how praxeological uncertainty emerges when institutions attempt to adopt novel MOs under conditions of transposition instability.

Mathematical Organizations of Modeling Life

The MOs of *Modeling Life* are constructed around dynamical systems and biological modeling. The praxis block centers on task types that require students to formulate, simulate, interpret, and revise mathematical models for phenomena like disease transmission, population dynamics, and gene regulation, in order to predict system behavior. The tasks demand techniques that combine analytic methods (linear stability analysis and equilibrium classification), numerical approaches (Euler's method, simulations), and computational tools (Python, SageMath). Freshman life science students construct meaning for differential equations by identifying feedback relationships in biological systems, entailing interdisciplinary reasoning about biological processes and their mathematical representations simultaneously. The logos block comprises technology that emphasizes concepts directly relevant to life sciences: state space representations, vector fields, bifurcation theory, and covariational reasoning. This technological discourse positions derivatives as linear approximations of vector fields rather than rules or slopes, and integration as accumulated change rather than antiderivatives. The underlying theory proposes an epistemological shift because the tasks emerge from biological questions (e.g., what is a genetic switch?) and the justifications for the mathematical techniques follow. Two characteristics distinguish these MOs from calculus praxeologies. First, the primacy of modeling over mastery of procedures entails the creation of a logos block that explicitly bridges disciplinary boundaries. The technological discourse brings to the fore both mathematical concepts and biological processes, and the theoretical framework positions mathematical validity as dependent upon biological plausibility. Second, the computational praxis block assumes simulation, visualization, and manipulation of parameters as standard mathematical practices, which enable tasks about sensitivity analysis, for example. The presence of these praxeologies create specific institutional demands: faculty must possess or develop interdisciplinary expertise, computational infrastructure becomes important, and assessment practices must evaluate conceptual synthesis rather than procedural execution. The MOs themselves thus create the conditions for transposition instability, as their requirements often exceed existing institutional capacities while their epistemological foundations challenge established mathematical teaching cultures.

Methods

We visited all five sites implementing *Modeling Life* materials, which represent variation in departmental context, institution size, and implementation maturity. We focused exclusively on adopting institutions since non-adopting cases provide limited insight into implementation processes (Ragin, 2006). At each site, we conducted semi-structured interviews with stakeholders including *Modeling Life* instructors, faculty teaching related courses, administrators, teaching assistants, and support staff (site characteristics in Table 1). Interviews elicited

stakeholders' salient experiences pertaining to developing, implementing, and sustaining the course (Leech, 2002). We treat absence of a reference MO as an observable condition when stakeholders report contested or changing learning goals or prerequisite expectations. We interpreted stakeholders' reports of adaptations and adjustments to curriculum, contested positioning of the course, or shifting academic oversight as evidence of transposition instability.

Table 1. Site characteristics

Institution	Years Operating	Department	Approx. Enrollment	# Interviews
UCLA	10+	Life Sciences Core	2400	12
UC Santa Cruz	1	Mathematics	160	7
U. Arizona	6	Mathematics	120	7
Utah State	1	Mathematics	60	10
Harvard	1	Mathematics	30	10

Results

We present short vignettes of each site, organized to show evidence of the state of external transposition (e.g., noospheric activity) and institutional responses that instantiate praxeological uncertainty (e.g., positioning moves, epistemological tensions, resources adaptation). We obscure interviewees' identities and attribute conditions they mention to their institution.

At Utah State, praxeological uncertainty emerged through transposition instability operating under conditions of perceived external disruption. At the time of our site visit, a state legislative mandate for general education, including Quantitative Literacy (QL), was interpreted by stakeholders as consistent with the university's land-grant mission to prepare citizen scholars for workforce needs. Participants anticipated a potential reconfiguration of curricular priorities towards critical thinking, data science, and meaningful quantitative work. Although the concrete implications of the mandate for the mathematics department were not yet fully specified, the transfer of curricular authority from home disciplines to a general education center was understood by some as an opportunity for reform, while others perceived it as a destabilizing force for established content and pathways. As one administrator noted, the legislation would break established curricular structures, disrupting what what Diaz-Eaton (under review) identified as "forces that hold the 'canon' sacred." These legislative changes, including significant budget reallocations, functioned as concrete, enacted constraints and new powers, shaping anticipatory positioning around curricular innovations. In this context, the *Modeling Life* approach was viewed by stakeholders as aligning with the direction signaled by the mandate. However, departmental leadership was hesitant to commit sustained resources amid budget pressure and unresolved questions about course evaluation and students' revised pathways. Within this environmental uncertainty, instructors endeavored to predict the eventual audience for the course and align the MOs with their anticipated needs, including retaining, excluding, modifying, or emphasizing MOs from the traditional and modeling focused versions of the course. Overall, *Modeling Life* occupied an ambiguous institutional position: it was sufficiently aligned with emerging priorities to proceed, but its long-term stabilization and the securing of additional, dedicated resources for its full development remained a concern.

At Harvard, a different kind of positioning uncertainty emerges through consideration of students' pathways through mathematical programs. There, *Modeling Life* was conceived as an

alternative to the precalculus/calculus requirement, but not as calculus preparation, since the praxis blocks contrast starkly. This reflects institutional uncertainty about how MOs with fundamentally different praxeological structures should relate within mathematical programs. However, the introduction of *Modeling Life* creates system-level effects throughout the mathematical program that can impact other students, as it draws life science students away from traditional courses and subsequently relieves pressure on the precalculus courses regarding what praxeologies are now suitable. Additionally, students' hesitancy to take a course that hadn't been offered before indicates their perception of instability due to the institution's inability to provide clear positioning information about MOs still undergoing noospheric negotiation. These uncertainties both emerge from, and contribute to, broader system-level effects throughout mathematical programs.

Stakeholders across multiple sites evidenced epistemological conflicts between the praxis and logos blocks of *Modeling Life* and institutional commitments to traditional mathematical praxeologies. At UCLA, the initial response from the mathematics department was fierce and vigorous opposition to the new course viewing it as "not real math" or "not rigorous enough." Faculty resistance surged from both the logos blocks of *Modeling Life* positioning mathematics as emergent from biological inquiry, and the praxis blocks using geometric and numerical methods. Chevallard (2015) noted that teaching systems establish an "authorized" version of knowledge and, Diaz-Eaton (under review) argued the language of rigor is often wielded to justify deviations from that authorized knowledge. It is beyond the scope of this paper to argue the mathematical rigor of *Modeling Life*, however we note that its technology integrating feedback mechanisms, state space representations, dynamical systems, and covariational reasoning are all rigorously articulated areas of mathematical practice. Indeed, multiple stakeholders explained that taking a pure mathematics approach as being "not in the right frame of mind" since teaching *Modeling Life* requires "letting go" of the usual mathematical practices. Thus, it seems that productive integrations of this course into the ecology of mathematics departments might further entail an epistemological reorientation towards the course's theoretical underpinnings, namely, positioning mathematics as emergent from biological inquiry rather than as monuments to visit (Chevallard, 2012). Instructors willing to engage in this shift may yet feel "nervous" or "surprised" by the textbook's approach, as did an instructor at Utah State.

These epistemological conditions create institutional pressure on the survival of *Modeling Life*'s praxeologies by demanding faculty orientations that mathematics departments may find difficult to supply, forcing institutions to either modify their implementation approach or develop new human resource strategies to support MOs whose requirements exceed traditional faculty preparation. At our sites, we observed plural strategies to address faculty knowledge and epistemological gaps, with a commitment to maintaining praxeological integrity. At UCLA dedicated teaching lines were authorized to support course development and maintenance. U. Arizona dedicated resources to a co-teaching model in order to induct new instructors to the implementation cycles. This positions co-teaching as a mechanism for developing faculty capacity to implement MOs whose praxeological requirements exceed traditional preparation. Although it is expensive, administrative stakeholders there recognize that courses like *Modeling Life* cannot be sustained with a "rotating cast of characters," and that co-teaching, particularly when paired with a dedicated lead instructor, provides for continuity, recruitment, and is essential for the long-term viability of the course. Additionally, administrative and instructional stakeholders asserted that co-teaching facilitates a collaborative environment which becomes engaging for students. UCLA and Harvard rely heavily on undergraduate learning assistants, but

how those resources are used differ. At UCLA, learning assistants have successfully completed the course and can help students who have GTA's that are not as familiar with the interdisciplinary MOs. At Harvard, the learning assistants have not completed the course, but they are drawn from a pool of students with advanced applied mathematics knowledge. Investment of resources in undergraduate learning assistants created a low student-to-teacher ratio, creating opportunities for the instructor to focus on generating pedagogical notes that would make the course "teachable by others."

The positioning of *Modeling Life* within degree plans and mathematical programs also places demands that create incoherence, where praxis blocks diverge from the philosophy enacted through the logos blocks. For example, at Harvard, concern for students' success in later physics courses necessitated inclusion of some tasks from traditional calculus praxeologies, such as trigonometric functions, with companion differentiation and integration techniques. The instructor reflected that these changes were "not very closely tied to anything else we're doing," suggesting that the praxis block was not aligned with *Modeling Life*. Similar adjustments were made to *Modeling Life* at Utah State to satisfy constraints attributable to downstream statistics courses. An instructor at U. Arizona observed that these kinds of modifications "weakened the course a little bit." Interpreting their comments in terms of the ATD, the ecologies in these institutions created a divergence where the logos block supporting the traditional calculus tasks was largely absent (see BarbÉ et al., 2005) and, when obliged, in conflict with the praxeologies of *Modeling Life*. These adaptations preserve prerequisite functions while introducing praxeological tensions between modeling-centered and traditional procedural approaches.

Resource constraints systematically modified the computational praxeologies of the MOs. At Utah State, stakeholders explained that time limitations inhibited integrating coding into the course work because there were only three (credit) hours a week allocated to the course. The full realization of the computational praxis block would require a 4 or 5 credit-hour course, however an existing mathematics course was repurposed to realize *Modeling Life* there. Thus, to suit the institutional conditions, the computational praxeology was removed entirely. Yet, the instructor excluded treatment of limits, despite protestations from colleagues, to avoid "just teaching typical calculus." They opposed specific praxis blocks to preserve logos blocks they perceived as fundamental to the course's philosophy. Student population characteristics also drove systematic adaptations to praxis blocks as institutional conditions forced modifications to task types and techniques. Institutions expanded praxis blocks to include foundational quantitative reasoning tasks (proportions, percents) or adjusted the pace of technique development to accommodate local student preparation, demonstrating how demographic constraints shape praxeological boundaries during external transposition. At UCLA, programming components were "softened" with labs becoming "much easier on the coding" because they could be "brutal" for students with no prior coding experience. Here, the expectation shifted from students writing Python code to modifying provided code to run simulations. This transformation altered both the task types (T) from code generation to code interpretation and modification, and the associated techniques (τ) from syntax mastery to parameter manipulation. The logos block adapted correspondingly, with the technology (θ) repositioning computational work from teaching coding to using simulations to emphasize important ideas from the course. Harvard adopted Chat GPT for coding to bypass syntax learning constraints. These modifications preserve the logos block's emphasis on the value of simulation while adapting the techniques to institutional realities.

UCLA differed from the other sites in that sustained noospheric activity located *Modeling Life* within the Life Sciences (LS) Core, a separate academic unit. There, faculty possessed

epistemological commitments to the praxeologies underlying *Modeling Life*, such as praxis blocks centered on biological questions giving rise to logos blocks positioning mathematics as a tool. Within the unit, resources were allocated towards course releases for material development, funding for ongoing evaluation, and strategic hiring of quantitative biologists dedicated to course maintenance. This permitted both the iterative refinement of MOs as specific praxeologies were adopted and discarded, and the production of concrete instructional materials to unify multiple course sections. These artifacts then served as a reference MO (BarbÉ et al., 2005), at least provisionally as new instructors were inducted to the course and the faculty of the LS Core sought to secure ongoing resource allocation. As a result, many of the tensions observed at other sites were attenuated. The pre-med and life science majors' willingness to satisfy degree requirements with *Modeling Life* further legitimized it. A secondary consequence was that downstream courses could build upon the praxeological foundation of *Modeling Life*, reinforcing the institutional integration of its MOs.

Implications & Future Directions

Our analysis identifies four interconnected patterns of praxeological uncertainty when institutions adopted *Modeling Life*'s MOs. Institutions experience positioning uncertainty as they struggle to locate *Modeling Life* within existing academic structures. Epistemological conflicts emerge between faculty commitments to traditional mathematical praxeologies and modeling-centered approaches. Novel MOs create human resource demands that exceed faculty's preparation. Finally, institutional constraints drive systematic adaptations to MOs as they strive for ecological fit within the local conditions. These findings demonstrate transposition instability creating praxeological uncertainty about *what* is being adopted, *how* it should function institutionally, and *for whom* it was offered. The literature identifies broad challenges to to innovative mathematical education such as "monument" paradigms (Barquero et al., 2015), institutional inertia (Bosch et al., 2020), and faculty preparation gaps (Díaz Eaton, 2017), but provides limited analysis of underlying mechanisms. Our findings reveal specific processes through which these barriers operate. *Modeling Life*'s interdisciplinary MOs create institutional tensions operating across multiple codetermination levels. Unlike content-focused innovations that accommodate existing structures, integrating dynamical systems with biological reasoning requires coordinated changes spanning disciplinary, pedagogical, and institutional levels. UCLA's LS Core created dedicated institutional space where hybrid MOs could develop without competing against traditional departmental expectations, addressing what Winsløw et al. (2014) identified as constraints from mathematical domain isolation. Yet, at each of the sites, pressures to adapt *Modeling Life* arose from the noosphere. ATD permitted insights into how and why challenges to innovative MOs operate through specific praxeological mechanisms, rather than general resistance patterns (e.g., Shadle et al., 2017). We acknowledge that some praxeological uncertainty emerged from the interdisciplinary characteristics of *Modeling Life*'s logos blocks rather than its shift in mathematical content. This presents challenges to potential instructors trained in analytic and symbolic techniques, at the pedagogical level of codeterminacy, that could be addressed through collaboration with life science colleagues (Bennoun, 2022). It is yet unclear what features of collaboration could support a bridge between disciplinary domains.

Students' Perspectives of Proof Community Values and Goals

Tenchita Alzaga Elizondo, University of Texas Rio Grande Valley
Lino Guajardo, Central Michigan University
Brittney Ellis, Texas State University

Undergraduate students' views on proof provide insight into how they engage with mathematical practices, yet little is known about the values and goals they associate with proof. We surveyed 32 students at two Hispanic-Serving Institutions and identified themes related to values and goals of the proof community across three domains: the proof itself, the utility of proof, and the prover. Students' perspectives often echoed mathematicians' values such as rigor and explanatory power, but also emphasized less-documented dimensions, including creativity, problem solving, and educational aims. By highlighting both alignment and extension of disciplinary norms, these findings suggest ways to better support students' participation in proof-based mathematics.

Keywords: Proof, values and goals, norms, proof community

Undergraduate students' experiences with mathematical proof offer important insights for the mathematics education community, yet this area remains relatively underexplored. Prior research has examined what students retain from proof-based instruction (Krupnick et al., 2018; Lew et al., 2016) and their beliefs about various dimensions of proof, such as reading, writing, and comprehension (Guajardo et al., 2025; Lew & Mejia-Ramos, 2019; Weber & Mejia-Ramos, 2014). These studies illuminate students' perceptions and learning outcomes, but further work is needed to understand how students engage with the norms and practices of proof-based mathematics throughout their coursework.

Several aspects of mathematical proof present challenges for students, including abstraction (Rowland, 2001; Weber, 2004) and unfamiliar writing norms and conventions (Dawkins & Weber, 2017; Lew & Mejia-Ramos, 2019; Melhuish et al., 2025). For example, prior research has documented that students may struggle with making implicit arguments explicit (Samkoff & Weber, 2015; Selden & Selden, 2003). These difficulties can impact students' self-efficacy and their sense of identity within the mathematical community (Wrightsman, 2025). Additionally, a common narrative in mathematics is that ability is innate and success comes easily for those with high aptitude (Melhuish et al., 2024). Together, these challenges and perceptions can contribute to an exclusionary and elitist culture in mathematics.

Community values and goals serve as foundational elements for the norms that shape how individuals see themselves, and are seen by others, within the mathematical community. The values and goals students perceive as important to the proof community influence which norms become salient in their experiences in proof-based courses. While existing literature has identified values that professional mathematicians associate with proof (e.g., Dawkins & Weber, 2017), we know less about how students perceive these values and goals. This is especially relevant as instruction in proof-based courses increasingly emphasizes student-student interaction, creating more opportunities for societal narratives about mathematical ability and participation to influence classroom dynamics (Battey & McMichael, 2021). To address this, we investigated the following research question: What values and goals do students perceive as important to the proof community?

Theoretical Perspective

For this study, we leverage Lauden's (1984) work on scientific communities' norms, values, and goals. A scientific community has various accepted results that it produces, these are referred to as theories of the community. A value can then be defined as the "good" attributes of these theories (Laudan, 1984). For instance, for the mathematics community, proofs are considered part of their theory and as such, a *value* would be for a proof to be rigorous and follow deductive logic (e.g., Dawkins & Weber, 2017). Additionally, a community has certain goals that they aim to achieve which then guide the rules and methods of the community (i.e., norms, Laudan, 1984). These norms are upheld by the shared values and goals that a community aims to achieve (Dawkins & Weber, 2017). Goals and values are inextricably linked, in that, goals are specific aims that a community or individual hopes to achieve and values are the underlying motivations and rationale for wanting to reach those goals (Laudan, 1984). Within the math education community, specific mathematicians' values and norms have been identified, however we are interested in understanding students' perspectives of the proof community's goals and values.

In proof classrooms, students are expected to embrace mathematicians' proof norms, yet they may not be aware of the mathematicians' value and goals underlying those norms (Dawkins & Weber, 2017). For example, the norm that "justification in proof should be deductive and not admit rebuttals" (p. 129) reflects the shared value that mathematical knowledge is a priori. Although students are often expected to write proofs in this way (Dawkins & Weber, 2017), they may perceive this practice as forced upon them without understanding the rationale (i.e., value) behind it. Without a shared understanding of the values and goals tied to these norms, students may find them arbitrary or meaningless (Dawkins & Weber, 2017). Further, Dawkins and Weber, citing Solomon (2006), noted that "asking students to adapt norms without corresponding values can leave students feeling passive and marginalized with respect to their learning of proof" (p. 133). Understanding the values and goals students associate with the proof community can help make these norms feel more meaningful and less arbitrary or imposed.

When goals and values of proof and proving are not explicitly discussed, students are left to infer them on their own. For example, while *a priori truth* is a valued aspect of mathematical proof (Dawkins & Weber, 2017), conciseness is also valued—unnecessary justifications are often omitted in published proofs (Selden & Selden, 2013). Students may not recognize this norm, as Weber and Mejia-Ramos (2014) found that students often believe every step should be included in a proof and that readers should not be expected to fill in gaps. Students may, in fact, prioritize clarity over conciseness. Another commonly held value is the exclusion of references to the author of the proof (Dawkins & Weber, 2017; Melhuish et al., 2025), as proofs are intended to be "autonomous objects," independent of their authors. Additionally, de Villiers' (1990) roles of proof—verification, explanation, systematization, discovery, and communication—highlight goals (and values) focused on the proof itself, such as its structure and presentation. However, these goals provide limited insight into values and goals related to other aspects of proof, such as the role of the prover or the proving process. Exploring the values and goals students identify can further efforts to make these aspects more explicit.

Methods

Data collection

We designed a survey that asked students to identify values and goals that they associate with the proof community. The survey included a short introduction to our study and described what we meant by a community's perceived values and goals. We then asked them: 1) *In your*

experience, what are some things that are valued about proof within the mathematics community? and 2) *In your experience, what are some goals related to proof that people work toward within the mathematics community?* Following each question, we asked students to describe a situation from their experience as math students that reflected their identified values and goals. Responses to this question gave us insight and context into the students' personal experience with these values and goals. The survey was distributed to students across two institutions in the southwestern United States, both of which are Hispanic-Serving Institutions with one school having over 90% Hispanic student population. Students were asked to complete the survey if they had taken at least one proof-based course. We received a total of 32 responses from students, see Table 1 for description on the students' proof experience (students selected 1-2 or 3+ courses), gender, and race/ethnicity (both self-reported). All 32 respondents answered the question on values and 28 of the 32 respondents answered the question on goals.

Table 1. Student demographic information (number of students indicated in parentheses)

Proof Course Experience	Gender	Race/Ethnicity*
1-2 courses (14)	*Female (10)*	*African American (1)*
3+ courses (16)	*Woman (2)*	*American Indian (1)*
	Male (16)	*Asian American (1)*
	Non-binary (2)	*German (1)*
	N/A (2)	*Hispanic (19)*
		Latinx (3)
		Mexican/Mexican American (2)
		White (8)
		White Hispanic (3)

**Some students self-identified as multiple race/ethnicities*

Analysis

To analyze our data, we used an open coding approach to identify themes related to proof community values and goals. We started by collaboratively coding the values: the authorship team reviewed each survey response and assigned tags summarizing the student-identified value(s). Students' personal stories of their experiences were used to help contextualize their identified values and resolve disagreements among the team. Since students often reported multiple values, we applied as many tags as needed to capture their full response. Disagreements were addressed in real time during the group coding process. After completing the value coding, each author individually open coded the goals. We then met to compare tags, discuss discrepancies, and reach consensus on the final coding.

After tagging all responses for values and/or goals, the first author synthesized the codes into overarching themes. During the initial coding, the team noticed that students' responses often referenced different aspects of proof—such as the proof itself versus the person constructing it. With this in mind, the first author categorized each theme according to the aspect of proof it described. For example, when students noted that the proof community valued *the structure and strength of a proof,* this was classified as a theme related to the proof itself. Once the themes were developed and grouped, the full authorship reviewed them, resolving any disagreements through discussion until agreement was reached among the full team. These finalized themes are presented in the next section.

Results

We found that the students identified values and goals of the proof community referenced three aspects of proof: (a) the proof itself, (b) the utility of a proof, and (c) the prover behind the proof. Within each category, we identified themes pertaining to both values and goals. The results are organized accordingly, with themes related to values presented first, followed by those related to goals. Table 2 summarizes these themes.

Table 2. Values and Goals Identified by Students

Aspect of proof	Value Themes	Goal Themes
The Proof Itself	*Truth and Objectivity of a proof* *Structure and Strength of a proof* *Clear Communication & Language of a proof*	*For proofs to be accessible and approachable* *For proofs to be clear and rigorous* *For proofs to be logically sound*
The Utility of the Proof	*Proofs' explanatory power* *Proofs' power to justify the validity of a claim* *Proofs' General Applicability*	*Use proofs to prove general statements* *Use proofs to understand why mathematical concepts work*
The Prover	*Problem Solving Skills* *Creativity and Ingenuity* *Knowledge and Expertise*	*To have a mathematics research career* *To improve proof skills* *To educate others*

The Proof Itself

Values and goals that fell into this category reference attributes about the proof itself. In other words, these are values and goals that students identified that related to the aesthetics of a proof or features that a proof should have.

Values. We found three themes related to attributes that are valued in a proof. The first value was related to the *truth and objectivity of a proof*. Students highlighted the axiomatic basis of proofs and the objectivity of deductive logic. One noted that the proof community valued "that the steps to get to the proof are logical [...] proof is a logical based construction that follows order and does not require opinions," while another emphasized that a proof "establishes certainty through logical rigor, ensuring that conclusions follow inevitably from accepted assumptions." Students also identified values related to the *structure and strength of a proof*. Students saw value in rigor, resilience, and adherence to precise structural rules. Some pointed to the value on "how organized [proofs] can be," with one recalling a professor describing an entire course on proof organization. Others emphasized rigor, such as a student reflecting on epsilon–delta proofs: "Being almost right wasn't enough. Every inequality and bound had to be airtight." Lastly, students identified values related to *clear communication and language of a proof*. Students saw value in clarity, conciseness, and precise mathematical language. One recalled an instructor's reminder "that while proofs do require logically sound steps, they are still meant to be read," while another noted losing points on "proofs that are correct in every way, except they are 'too long/complicated'". Precision with notation also mattered; as one student explained, "I

mistakenly switched up delta and epsilon [...] it was not 'wrong,' but my instructor noted it's best to stick to traditional convention."

Goals. Similar to the values, we found three themes related to goals that students identified that the proof community has for a proof. The first was a goal for proofs *to be accessible and approachable*. Students saw this as the goal of making proofs intuitive and understandable, with one student explaining that they "try to make my proofs easy enough to understand so that everyone can be able to be involved within a proof whether they're a contributor or simply learning from it," while another emphasized the importance of this goal as they felt "discouraged by terms like 'obviously' or 'clearly'" when intermediate steps were omitted. Students also noted there is a goal for proofs *to be clear and rigorous*. That is, students saw it as a goal to construct rigorous proofs that cleanly use mathematical symbols and notions. One student noted that proofs should "establish rigorous truths," another noted that "it's only through rigorous definitions and components that proofs are constructed," while another described relying on notation "to make things better and clearer for the reader." Lastly, students identified a goal for proofs *to be logically sound*. This goal primarily referred to constructing proofs by building on axioms and deductive reasoning to establish truths, as one explained, this involves "a showcasing how certain truths can be used to further demonstrate assumed truths (or contradictions) logically," a goal they connected to their practice of structuring proofs through lemmas and theorems.

The Utility of the Proof

Values and goals that fell into this category reference attributes about the utility of a proof. In other words, these are values and goals that students identified that related to the purposes and uses of proofs.

Values. We found three themes related to attributes that are valued in the utility of a proof. First, students valued *proofs' explanatory power,* noting how proofs can deepen understanding of mathematical concepts. For instance, one student noted "proofs give us a window into WHY math works the way it does, allowing in-depth understanding of mathematical concepts." They explained how they have seen this in action as they have "been able to apply concepts I learned from proofs presented to me in a Complex Variables course to solve proofs in other classes." Second, students saw value in *proofs' power to justify the validity of a claim,* highlighting their function in establishing the truth (or falsity) of a claim. As one student noted "a proof ensures that a statement that can be taken as fact is actually factual" and then notes the power this has in their own schoolwork: "theorems and lemmas are what power my work. It ensures that what I'm 'stating' is actually meaningful and correct." Lastly, students valued *proofs' general applicability*. This refers to a proofs' power to establish general results that extend across contexts. For instance, one student stated that proofs are valued "for their ability to provide general statements to solve a certain type of problem," and that their ability to "provide a statement that solves a multitude of problems is essential for math to function."

Goals. Students identified two goals related to the utility of a proof. First, they noted that a goal for the proof community is that proof should be used to *prove general statements,* highlighting how proofs can be particularly useful the more general the statement is that they prove. For instance, one student mentioned that by proving general statements they can "actually put proofs to use, using them to solve problems and such." Second, many students identified that a primary goal of proof is to *use proofs to understand why mathematical concepts work.* This goal refers to how proofs can provide insight to the prover about how the proofs work and the mathematical concepts they can be applied to. One student noted how proofs can provide insight

into different algorithms they use in their math courses, stating that these algorithms are "based on a strong understanding of mathematical structures, which are founded by theorems that are justified by proofs." Another student recalled how one of their math professors researched algebraic partitions and how proofs helped them "better understand how they worked inherently." Lastly, one student reflected on how "proofs have helped me [understand mathematics] such that I feel it adds meaning to mathematics."

The Prover

Values and goals that fell into this category referenced attributes about the prover. In other words, these are values and goals that students identified that related to the person who creates the proofs.

Values. We found three themes related to attributes that are valued about the prover. First, students valued provers' *problem-solving skills*. This value addressed skills like critical thinking, deductive reasoning, and the ability to approach a proof in different ways. One student commented how "being critical in questioning proofs is of high value" explaining how their professor encouraged them to question "our inherent trust in the proofs and challenged us to think deeply about why it worked." A different student highlighted the value of approaching a proof in multiple and unique ways recalling a class where they "would all provide our own version of the proof. This made us think about how to go about problems and different ways we could look at these things." Second, students identified *creativity and ingenuity* as valued traits in a prover, referring to how provers who have original ideas and can generate novel proofs are valued. For instance, one student stated that "original thoughts and ideas are greatly valued within proofs" while another reflected that in advanced mathematics, value lies in "being able to create not only an accurate proof, but also an elegant one, which, if possible, is a novel way of solving the problem." Lastly, students captured the notion that *knowledge and expertise* are valued in a prover. In other words, deep content knowledge and mastery of the proving process is of great value. As one student mentioned, "[w]hat matters is the steps that are taken to get there, the knowledge that the mathematician has to make the proof clean and beautiful," while another recalled a professor's remark that "the great graduate students and researchers always take the extra step and review proofs and extra problems in the textbook to receive those skills" underscoring the effort required to develop expertise.

Goals. We found three themes related to goals students identified for a prover. The first goal for a prover is *to have a mathematics research career*. This goal encompasses many aspects of being a research mathematician like advancing the field, making new discoveries, and proving new results. One student reflected that their professors "are also excited to discuss proofs of new or recent results, emphasizing that this is the ultimate goal" while another noted how their professor often shared their "post-doctoral experience and opportunities to receive jobs and how to achieve these goals." The second goal focused on *improving proof skill*. Here, students often reflected on their own educational journey and noted that the goal was to continuously improve. For example, one student described a personal milestone: "Be able to read and understand a proof independently," recalling a time when they were reading a proof on infinitely countable sets, saying "I read along this proof understanding the argument, and when I asked the professor if my interpretation was correct he said yes. I was so joyous and proud of myself and being able to understand the proof." Lastly, students recognized that there was a goal *to educate others*. This goal referred to both the classroom and peer support. As one student put it, the goal was to "train others to think critically" recalling class discussions where students were asked to critique sample proofs and propose improvements. Another, reflecting on tutoring and helping out their

peers, commented that a goal would be to clearly explain "details of a proof for student understanding."

Discussion

In this study, we investigated the values and goals that students perceived as important to the proof community. Their perspectives were both varied and nuanced, reflecting attributes of the proof itself, the utility of proofs, and attributes of the prover (see Table 2). The themes we identified connect with and extend findings from existing literature. For instance, the value themes *Truth and Objectivity of a proof* and *Structure and Strength of a proof*—highlighting the value of axiomatic foundations, deductive logic, and rigor in proofs— align with the mathematician value that "mathematical truth is a priori" (Dawkins & Weber, 2017, p. 128). Similarly, the value theme *Proofs' Explanatory Power* directly corresponds with the value that "proofs should increase mathematical understanding" (p. 130). Finally, the theme *Clear Communication and Language in a proof*, including consistent use of notation, resonates with the value "mathematicians desire a consistent set of norms and practices" (p. 131). These parallels suggest that many student perspectives are well already aligned with the broader mathematical community.

At the same time, our findings introduce dimensions not previously documented in the literature. While much prior work has focused on values related to the proof itself (e.g., Dawkins & Weber, 2017; Melhuish et al., 2025; Selden & Selden, 2013), our participants also identified values connected to the utility of the proof and attributes of the prover. Notably, their attention to the prover reflects an awareness of the proving process, recognition of the human element in proof production, and appreciation of skills such as problem solving, creativity, and expertise. These responses challenge the tendency to treat proofs as "autonomous objects" divorced from their authors (Dawkins & Weber, 2017, p. 130). Although not often explicitly captured in prior literature, we believe these values are ones many mathematicians would likely endorse. Additionally, our study extends the field by documenting student perspectives on the goals of proof—an area often left implicit. Closely tied to values, goals illuminate the purposes behind proof values and provide insight into how students make sense of the proof community.

An important observation from our findings is that the themes related to the values and goals students identified often aligned with their respective groupings—namely, aspects of the proof, its utility, and the prover. For instance, the value themes *Proofs' explanatory power* and *Proofs' power to justify the validity of a claim* correspond with the goal theme to *Use proofs to understand why mathematical concepts work.* Similarly, the value theme *Problem-Solving Skills, Creativity and Ingenuity, and Knowledge and Expertise* aligned with the goal theme *To have a mathematics research career*, as these attributes are central to advancing the field. While these connections are unsurprising given the intrinsic relationship between values and goals (Laudan, 1984), it is notable that this alignment emerged clearly in the students' responses. This suggests that although students may sometimes view mathematical norms as arbitrary or meaningless (Dawkins & Weber, 2017), they are attuned to many of the values and goals upheld by the proof community. Moving forward, the challenge is to help students make these connections more explicit as they deepen their engagement with the community.

Mathematics graduate teaching assistants (MGTAs) are central to undergraduate instruction, yet their professional development (PD) is often limited. The Engaged Learning & Intentional Teaching Experiences PD program is a multi-institutional effort to strengthen MGTA PD around active learning, equity, and inclusion. To examine how such initiatives can be enacted and sustained, we studied departmental culture at two participating universities (Beta and Gamma) using Bolman and Deal's (2017) Four Frames model, focusing on the structural and symbolic dimensions. Interviews with nine departmental leaders revealed five cross-cutting categories shaping MGTA involvement. Findings highlight how sustainable change requires alignment between structures (e.g., coordination, PD requirements) and symbols (e.g., values for equity and active learning). At Beta University, mathematics coordination structures reinforced symbolic commitments, embedding MGTAs in active learning reforms. At Gamma University, symbolic commitments appeared stronger but lacked structural reinforcement.

Keywords: graduate teaching assistants, institutional change, active learning, department culture

Mathematics graduate teaching assistants (MGTAs) are often a primary point of contact for undergraduate students in introductory mathematics courses. Serving in roles such as instructor of record or recitation instructor, these graduate students are responsible for delivering course content to thousands of undergraduate students each year (Selinski & Milbourne, 2015). MGTAs impact the learning experiences of a large population of undergraduate students making their professional development (PD) for teaching critical. How MGTA PD is enacted within a department varies across institutions, but literature suggests the need for sustained PD beyond a pre-term orientation (Beisiegel et al., 2019; Defranco & McGivney-Burelle, 2001; Miller, 2018). However, establishing such a program requires a supportive department culture and structures in place to sustain these efforts.

The authors of this paper are part of a team of researchers that designed and implemented a PD program for MGTAs. The Engaged Learning & Intentional Teaching Experiences (ELITE) PD program is a large-scale, multi-institution project supported by a collaborative National Science Foundation grant. Key components of the work involve examining the graduate PD culture at participating institutions and introducing the ELITE PD program. Each ELITE PD MGTA participant, regardless of institution, attends a minimum of one year of PD. This work aims to prepare MGTAs to teach using active learning and enhance equitable and inclusive teaching practices. Understanding the impact of these changes requires an initial baseline understanding of the culture at the different institutions.

This paper uses Bolman and Deal's (2017) Four Frames of Leadership: Structures, People, Power, and Symbols, which has been used to understand change in STEM education (e.g., Couch et al., 2024; Reinholz et al., 2019). For this manuscript, we focus on the structures and symbols that are evidenced through interviews with department leaders and analysis of the institutions. In particular, we aim to investigate the following:

1. What structural and symbolic features of departmental contexts shape the development and involvement of MGTAs?
2. How are symbolic commitments and structural realities aligned (or not)?

Literature Review

MGTA Development in Mathematics Departments

MGTAs play an essential role in many mathematics departments. Formal responsibilities often include grading student work, staffing tutoring centers, teaching recitation sections that accompany courses led by an instructor of record, and, in some institutions, serving as instructors of record themselves (McLeod et al., 2025). Informal responsibilities can involve gathering insights on student mathematical thinking, conceptions, and misconceptions to share with instructors of record, as well as serving as role models who help bridge the gap between faculty and undergraduate students.

The support, training, and challenges MGTAs experience can vary widely between institutions; in some, the training might be as little as a short few days before the term starts, while in other departments, MGTAs may receive multi-year professional development with weekly sessions (Cho et al., 2011; Ghalichi et al., 2023). Additional support can include having a course coordinator meet with them regularly, separate from formal PD. However, despite the support MGTAs receive, they also face a number of challenges that can impact their ability to, in turn, support their students. These challenges can include navigating power dynamics with faculty and students, managing financial stress since most graduate programs provide modest funding that may be insufficient to meet living expenses, and meeting unclear or even competing expectations in how they work with students and perform their role, especially when departmental or institutional culture and values are not aligned between faculty or administration (Cramer, 2019). Additionally, MGTAs have responsibilities as students themselves with their coursework, theses, or dissertations.

The ELITE PD program is designed to support MGTAs through such challenges as they take on teaching roles, providing at least one year of sustained PD. However, implementing pedagogical practices – even those supported by research, such as active learning and equitable and inclusive teaching – is well established to be difficult, with "[e]nacting and sustaining educational change requir[ing] a systemic approach, focused on culture" (Reinholz & Apkarian, 2018, p. 2). To this end, we focus on understanding departmental culture, particularly regarding the role of MGTAs and their work within departments, to understand how the ELITE PD program may be enacted and sustained within local contexts.

The Four Frames Model

For this study, we utilized the Four Frames Model as a theoretical framework. The Four Frames, developed by Bolman and Deal (2017), is a theoretical framework that has been used in STEM education to understand departmental culture, particularly to support departmental change initiatives (Couch et al., 2024; Reinholz et al., 2019), such as the ELITE PD program.

The four frames provide lenses for understanding an organization's culture: structural, people, power, and symbolic. The structural frame focuses on formal roles, expectations, and policies. The people frame emphasizes individual needs, relationships, and employee development in support of organizational goals. The power frame highlights dynamics such as competition for resources, authority, and influence. The symbolic frame captures culture, shared meaning and values, and identity, making it especially relevant to how initiatives are carried out.

Structural changes are most effective when paired with symbolic shifts that reinforce their meaning (Reinholz & Apkarian, 2018), highlighting both the relationship between these frames and the importance of symbols. For example, if different sections of Calculus 1 provide varied student experiences and content, a structural adaptation could be creating a course coordinator role or requiring a common syllabus. However, without shared value for horizontal integration among faculty and MGTAs, structural changes are less likely to be impactful.

Symbols Shared beliefs, values, and priorities guiding MGTA work	**Structures** Formal division of labor, role definitions, and responsibilities for MGTA work	**People** Promotion, tenure, training, mentoring, work plans	**Power** Expertise, authority, agenda-setting

Figure 1. Framework: Four frames (MGTA Context). Adapted from Reinholz & Apkarian (2018)

Methodology

As part of the broader ELITE PD program focused on MGTA professional development in active learning, equity, and inclusion, we conducted interviews with departmental leaders at two participating institutions: Beta University and Gamma University. Both of these institutions are large public universities that offer graduate programs (i.e., master's and PhD) in mathematics or closely related fields and employ graduate students in teaching roles within the mathematics department, with roles ranging from recitation leaders to instructors of record. Additionally, at the time of data collection, Beta was designated as a Minority-Serving Institution.

Between Beta and Gamma, a total of 9 departmental leaders were interviewed. These individuals were selected based on their roles in shaping MGTA teaching and professional development. For example, department chairs and associate chairs often oversaw TA contracts and assignments, while course coordinators and PD providers regularly worked with MGTAs, often serving as their first point of contact for teaching support. At Gamma, this included the department chair, associate chair, graduate program chair, and the PD provider; while at Beta this included the department chair, PhD director, two course coordinators, and the PD provider, who was also involved in course coordination.

The nine interviews were semi-structured, 60-minute interviews and conducted virtually via Zoom during the 2021-2022 academic year. The interview protocol included questions about MGTAs' roles, teaching practices, and support structures. Participants were also asked to reflect on their beliefs about active learning and equitable teaching, departmental values related to these approaches, and any specific indicators or metrics of their institution's or department's commitment to diversity, equity, and inclusion.

These interview transcripts were analyzed using Bolman and Deal's (2017) four-frame model as an interpretive lens. We initially coded each transcript using Bolman and Deal's (2017) four frames as discrete categories but found this approach limiting because the frames often overlapped (e.g., PD could simultaneously appear as a structural requirement and as a human resource aimed at supporting people). We therefore shifted to an inductive analysis (Miles & Huberman, 1994) that identified five categories that reflect cross-cutting areas that shape departmental culture: (1) agenda setting and authority, (2) autonomy and constraints, (3)

expertise and resources, (4) collaboration and alliances, and (5) institutional and departmental initiatives.

We used the five categories from the broader study's analysis to organize and interpret patterns in how departments understood and engaged with MGTAs, applying Bolman and Deal's (2017) four frames as an analytical lens. To ensure consistency, we developed a structured codebook that was co-constructed and negotiated between the two coders to define how each frame could be expressed within each category. Table 1 shows examples from the data illustrating the *autonomy and constraints* category. For example, when examined through the *symbolic* frame, an interviewee expressing desire to allow MGTAs to choose if they wanted to implement active learning in their classroom was interpreted as giving *autonomy* to MGTAs. In contrast, MGTAs roles as *structured* in a department may be *constrained* in ways that impact their pedagogical choices.

Table 1. Interpreting the Autonomy and Constraints Category in Terms of Symbols and Structures

Frame	Codebook Definition	Example
Structural	Formal policies and role definitions that set limits on individual decision-making authority.	"MTGAs usually aren't involved much above the 100 level… almost everything they're doing is with our 100 level....In those courses… there's usually a coordinator, it's pretty structured. We're usually writing every exam…sometimes even common worksheets." [constraint]
Symbolic	Cultural values and expectations that shape perceptions of autonomy and conformity.	"So, is it active learning? Is it lecturing? That is really up to the instructor or the TA. So if a TA is teaching their own section of a course, they can lecture if they want to. They can do active learning if they want to." [autonomy]

For this manuscript, we focus on the structural and symbolic frames, which Reinholz and Apkarian (2018) highlight as central to sustainable instructional change. This focus allowed us to examine how formal systems and values shaped MGTA roles, expectations, and support across Beta and Gamma.

Results

Our results highlight how Beta and Gamma's departmental contexts shape the development and involvement of MGTAs, revealing both alignments and misalignments between structures and symbols that can respectively support or constrain change associated with MGTA PD.

Agenda-Setting and Authority

This category captures how departmental agendas are established, prioritized, and enacted. At Beta, agenda-setting is most visible in the structure of College Algebra and Precalculus

courses. Both of these courses, which are frequently taught by MGTAs, were coordinated. These courses are coordinated by designated faculty pairs who oversee grading, office hours, and course implementation, reflecting a structural–symbolic alignment aimed at improving DFW rates in introductory mathematics. The Ph.D. Director described the coordinators as administrators, with the coordinated courses being "very coordinated" with exam, course content, and schedules determined by the coordinators. Notably, the College Algebra course at Beta seemed prioritized by the department with College Algebra described as having active learning directly embedded in the course structure using worksheets, unlike Precalculus.

At Gamma, fewer such structures exist. Course structure and MGTA responsibilities – such as facilitating recitations – are largely determined by individual instructors of record. Some coordination does occur, with College Algebra and Calculus described as the "most tightly coordinated." As one department leader explained: "the instructors… together with the undergrad committee… sit down and say, 'Okay, this is the text …and these are the topics we're gonna cover.'" This informal coordination was also enforced via course assignments: "the active learning occurs in classes that are coordinated, so if the person is not going to be participating in that coordination, then you'd say, 'Well, you're not going to teach this class.'"

Across both institutions, MGTAs are excluded from formal agenda setting. As one departmental leader put it: "TAs… tend to be… roped into… very late in the game." However, Beta provides more structured oversight and embeds its value for active learning into the formal design of College Algebra, a course MGTAs often teach as instructors of record.

Autonomy and Constraints

This category addresses how individual autonomy is shaped and limited by departmental policies and expectations. At Beta, MGTA autonomy varies by course and supervising instructor. Active learning is encouraged and embedded into introductory courses such as College Algebra, though no specific teaching methods are formally mandated. MGTAs teaching College Algebra are required to attend regular meetings to discuss their instruction. Symbolically, instructor-of-record autonomy is valued, as reflected in the lack of formal active learning requirements, yet coordination structures exist to facilitate active learning. As the course coordinator stated: "So there's been a push at the 100 and the 200 level…to do active learning...College Algebra is the one that does the most [activities]."

At Gamma, MGTA autonomy depends on experience and the preferences of the instructor of record. First-year MGTAs are required to attend an orientation and teaching seminar. Some lead their own sections, while others follow prescribed recitation plans. Symbolically, autonomy is framed as a professional right, which can translate into freedom without clear guidance. Active learning is valued in principle but interpreted broadly, resulting in no shared vision for teaching. As one leader stated: "what active learning should do is it should activate and engage a learner… And I include a great mesmerizing lecture."; whereas other leaders described active learning as activities that engaged learners like exit tickets and in-class problem-solving. Overall, Beta offers clearer expectations and more structural support for active learning, while Gamma provides fewer formal guidelines and lacks a cohesive symbolic vision for active learning.

Expertise and Resources

Expertise and Resources highlight how individual expertise is recognized, developed, and leveraged within a department. At Beta, MGTAs sometimes receive feedback or are observed based on content and student engagement, though course structures vary by course and instructor. For instance, coordinated courses offer more support, with MGTAs teaching College

Algebra attending weekly coordination meetings to discuss upcoming content and address teaching challenges. Coordinators also run workshops for faculty and MGTAs who teach College Algebra. However, recent changes to coordination roles have created uncertainty about who is responsible for MGTA support. Symbolically, course structures emphasize introductory courses and reflect valuing MGTA growth through workshops, meetings, and observations, though equity is not a focus: "equity, diversity and inclusion doesn't show up on the observation protocol anymore. It's mostly focused on the content, the teacher, there's a little bit about student engagement."

In contrast, Gamma offers structured teaching support through a weekly seminar and teaching workshops emphasizing inclusivity, equity, and professional skills, though these are required only for first-year MGTAs. Symbolically, MGTAs are positioned as professionals-in-training, with development tied to both classroom competence and long-term career preparation: "I'd like them, when they graduate, to feel that they have… been given the opportunity… to grow professionally in ways… meaningful… in terms of their career." While Gamma's teaching support is more formalized and integrates instructional development, its influence beyond the teaching seminar is unclear due to inconsistent symbolic support for active learning and the absence of stronger coordination structures. Beta's support, by contrast, is more localized and tied to coordination structures.

Collaboration and Alliances

Collaboration and Alliances identifies formal and informal partnerships that support shared goals, shaped by collaborative structures and community-building practices. At Beta, MGTAs–particularly those teaching College Algebra–participate in weekly coordination meetings for formal support and share office spaces which allows for additional opportunities for informal exchange. Leaders described the weekly meetings as vital for discussing teaching and fostering interaction between MGTAs and faculty: "they're allowed and encouraged to interact with the teaching faculty… that interaction is encouraged."

At Gamma, collaboration occurs through PD activities, shared spaces, and faculty-led groups. Participation is largely voluntary and not structurally supported yet was reported as functioning well: "I would say my estimation would be that TAs talk to each other about 85 to 90% of the time, and that they reach out to people outside of their TA friendships." Overall, Beta offers more consistent collaboration opportunities within coordinated courses but limited structural support outside them, while Gamma's informal community appears strong despite fewer structural supports, especially beyond the first year.

Institutional and Departmental Initiatives

This category encompasses reforms that reflect and advance broader priorities through structural change and symbolic commitments, particularly around diversity, equity, and inclusion (DEI) and active learning in mathematics. At Beta, DEI and teaching-related initiatives (e.g., workshops, surveys, infrastructure investments) are largely faculty-focused, with MGTAs inconsistently included. Symbolic gestures–such as MGTA teaching awards–exist, but DEI in particular has been absent from MGTA teaching support and classroom observations (e.g., equity is missing from feedback forms), reflecting symbolic tensions in the department: "our chair actually pushed back on [our DEI committee]... his belief is that it is everybody's responsibility to attend to those things… not just a single committee." Departmental discussions are underway regarding DEI-focused PD for MGTAs and more inquiry-based approaches to teaching precalculus.

At Gamma, many ongoing DEI initiatives were described, including workshops, DEI committees, and related communications. Some leaders reported encouraging MGTAs to participate: "But I see the leaders, you know, above me. I see [them encourage MGTAs], definitely." Hence, Gamma integrates graduate students into some DEI initiatives both symbolically and structurally more than Beta. However, the extent to which these initiatives influence everyday MGTA instructional practice was unclear.

Discussion

Across the five categories we identified, Beta demonstrated stronger structural-symbolic alignment in its introductory courses, with MGTAs playing a central role in advancing active learning and equity goals aimed at reducing DFW rates. Structures such as coordination meetings, embedded activities in College Algebra, and PD through observations, workshops, and teaching awards position the department to build on emerging initiatives like inquiry-based precalculus and the ELITE PD program. The teaching support that Gamma provides reflects stronger symbolic commitments to DEI and active learning, yet these values are not consistently reinforced through departmental structures. This is evidenced by Gamma's coordination structures, which were often described as informal or unofficial, and a lack of a shared vision for active learning within the department. Without that alignment, Gamma's ability to sustain MGTA-focused initiatives may be less stable than Beta's. However, importantly, this study provides only a snapshot of these two institutions, which continue to evolve through interventions, faculty turnover, funding, and policy shifts. Future work will revisit these sites after ELITE PD's implementation and extend analysis to include the other two frames (power, people) frames.

Even within this snapshot, however, these cases suggest that departments like Beta may be more likely to sustain initiatives when their formal structures (coordination, PD, incentives) reinforce their symbolic commitments (e.g., equity, active learning). This resonates with the findings from Reinholz et al. (2019) where "insufficient changes to culture" (p. 1140), such as the lack of structures, can impact sustainability. Departments with concrete structures may be better positioned to institutionalize new practices like the ELITE PD program. Symbolic commitments alone (e.g., valuing DEI, active learning) will likely not be enough for long-term persistence of initiatives without accompanying structural supports. Where structures are absent or fragmented, even strong symbolic endorsements risk remaining rhetorical, leaving initiatives perhaps less likely to be sustained or fully realized. Finally, MGTAs can play a critical role advancing departmental goals around active learning, equity, and inclusivity, but their influence may depend on whether both structures and symbols support their PD and the enactment of those values. Department leaders are well-positioned to make a positive impact on teaching culture and support MGTAs by making decisions and setting policies that bring structures and values into alignment (Couch et al., 2024).

Lastly, this study also contributes methodologically by highlighting the value of examining departmental culture through each of the four frames rather than using the frames as discrete codes, which facilitated our understanding of how individual aspects of the departments contributed to the culture around MGTA development at Beta and Gamma University through these different lenses.

"You Can't Unring the Bell:" Examining Relationships Between Objects, Tools, and Outcomes From a NIC Working Toward Critical Transformation in Undergraduate Mathematics

Amy Been Bennett
University of Nebraska-Lincoln

Rachel Funk
University of Nebraska-Lincoln

Kadian M. Callahan

University of Nebraska-Lincoln

Developing reflective practitioners can lead to and sustain new practices in undergraduate mathematics. In this study, we used Cultural Historical Activity Theory (CHAT) to examine relationships between objects, tools, and outcomes from a Networked Improvement Community (NIC) seeking to critically transform introductory mathematics. By examining interviews and observer field notes, we found three pathways that connected NIC members' individual and collective goals (objects), NIC activities and resources (tools), and NIC members' perspectives on teaching and students (outcomes). We found that sometimes objects, mediated by tools, led to outcomes, but not always. Although the transformation that NIC members envisioned was not realized, the experience shaped their thinking about teaching and students in impactful ways such that "You can't unring the bell."

Keywords: Institutional change, reflective practitioners, Cultural Historical Activity Theory, introductory mathematics

Despite evidence that traditional teaching practices do not serve a diversity of students, practices in undergraduate mathematics remain largely unchanged (Seymour, et al., 2019, Stains et al., 2018) and disproportionately impact the academic success and persistence of students belonging to historically underrepresented groups (e.g., racial/ethnic minorities, women, first generation students) (e.g., Olson & Riordan, 2012; Theobald et al., 2020, Totonchi, et al., 2023). Research shows that one way to effectively cultivate change is through engaging mathematics faculty in experiences that develop them as reflective practitioners. This grass-roots change strategy encourages and supports faculty in trying new instructional practices and sustains their commitment to change (Borrego & Henderson, 2014). Communities of faculty, administrators, and students can be particularly effective in prompting such changes. One structure for forming such teams is a Networked Improvement Community (NICs; Penuel et al., 2020). NICs engage in multiple cycles of inquiry and improvement (e.g., observe-plan-act-reflect cycles) to collect and analyze data and make data-informed decisions (Martin et al., 2020).

The project described herein involved members of a NIC at one institution working together toward critically transforming introductory mathematics. The purpose of this qualitative study was to understand how the original objectives (objects) of the NIC compared to its outcomes as mediated by activities and resources (tools). This NIC was part of the ACT UP Math grant, a research practice partnership that engaged institution-based NICs comprised of mathematics personnel (e.g., faculty, instructors, administrators, and students) to explore data on student performance and experiences in introductory-level mathematics courses in order to make critical transformations within their mathematics departments. The goal of ACT UP Math was to help mathematics departments achieve critical transformations in their undergraduate programs, specifically by increasing members' awareness of how historically marginalized students experience the dominant culture of mathematics.

Theoretical Framework

Drawing primarily from participant reflections and researcher field notes, we use Cultural Historical Activity Theory (CHAT; Engeström, 1987; Vygotsky, 1978) to examine relationships between the objects, tools, and outcomes of the NIC. CHAT is an anthropological framework used to explain the object-oriented activity of an individual or group of individuals (Engeström, 1987; Vygotsky, 1978). The CHAT framework has multiple iterations, for the purpose of this study we focus on the second generation CHAT framework (Engeström, 1987) as it highlights the importance of collective activity, including the social, cultural, and historical components that shape said activity. In this iteration of the CHAT framework, an activity system is conceptualized as involving seven components: subject, tools, object, outcomes, rules, community, and division of labor. A subject (i.e., an individual) uses tools to make progress toward an object (i.e., a goal). Through the successful use of mediating tools, objects are turned into outcomes of the activity system (Engeström & Sannino, 2017), but an individual's actions are shaped by the broader community in which they're situated, and the rules (or norms), and division of labor within that community which collectively govern how that community operates.

The CHAT framework has been applied to study how activity systems operate as they work toward transformative action. Reinholz et al., (2017) examined the efforts of departmental action teams (DAT) within university STEM departments and compared their objects, tools, and outcomes to a faculty learning community via an activity theory lens. Hancock and Miller (2018) focused on an activity system of K-12 teacher candidates within the Department of Special Education. The object of their activity system was learning to teach with inclusive practices, and alongside the governing rules, surrounding community, and division of labor, the tools collectively mediated the outcome of preparing teacher candidates for inclusive education.

In this study, the community of the activity system consists of the Tau NIC, the subjects are the NIC members, the objects are the members' collective and individual goals for their work, the tools are the resources, activities, and opportunities throughout the experience, the rules are the explicit and implicit norms determining how NIC members interact with one another, and the outcomes are the results of the NIC's efforts. We address the research question: *What is the relationship between the objects, tools, and outcomes of a two-year networked improvement community that sought to critically transform undergraduate mathematics?*

Methodology

Tau University is a public, research-oriented university in the Southeast United States. The NIC included 11 mathematics department members, nine instructors and three (not mutually exclusive) administrators. In the following paragraphs, we provide more context about the Tau NIC and describe how Subjects (Tau NIC members) made progress toward an Object (their collective and individual goals for the NIC) through the use of tools (resources, activities, and opportunities within the NIC).

Our study methodology is critical ethnography (Palmer & Caldas, 2015). Within this research-practice partnership (Coburn et al., 2021), we were embedded within the NIC community as ethnographic researchers and as members who regularly attended NIC meetings (e.g., Hagman et al., 2024). The primary source of data for this study is individual interviews conducted with NIC members during Jan-Feb 2025, which occurred at the conclusion of their (formal) work as a NIC within the ACT UP Math project. We triangulated quotes from NIC members with a secondary data source, observation field notes that two researchers completed during each monthly NIC meeting. Since the NIC operated as an activity system, the observation

notes allowed us to look up specific tools and events that NIC members mentioned in interviews and create a cohesive story of the NIC's journey. All names are pseudonyms; most NIC members opted for the research team to select a pseudonym for them.

We operationalized the second generation of CHAT as an analytical framework (Engeström & Sannino, 2017) to describe the work of the Tau NIC as an activity system. Our data analysis consisted of several iterations of analyses for each data source (e.g., interviews, observation field notes), similar to narrative coding (Saldaña, 2016). In previous work, we described the community of the Tau NIC and focused on their early efforts during the first year, as described by the NIC's three co-leaders (Bennett et al., 2025). Our prior analysis focused on the implicit rules that existed in the NIC (e.g., collegial, honest discussions during meetings), which led to the leaders establishing an explicit rule that deficit-oriented discourse about students, such as student lack of preparedness, was "off the table" for NIC meetings. The co-leaders shared that dwelling on topics about which they did not have agency hindered their progress as a NIC, thus, creating a rule that limited unproductive conversations helped the NIC focus on achieving their goals. The analysis of this study continues through the end of the project and captures NIC members' reflections on their overall experience.

Engeström & Sannino (2010) elaborated on how to describe the object of an activity system, emphasizing that "one needs to distinguish between the generalized object of the historically evolving activity system and the specific object as it appears to a particular subject, at a given moment, in a given action" (p. 6). Similarly, in our analysis of individual member interviews within the collective NIC experience: we found that individual-level objects did not always match the collective NIC goals, similar to the idea that "the generalized object is connected to societal meaning, [while] the specific object is connected to personal sense" (p. 6). Thus, we analyzed parallel planes within the NIC activity system (Grimalt-Álvaro, & Ametller, 2021).

Grimalt-Álvaro and Ametller (2021) describe how each element of the second generation of CHAT can be viewed through different planes, or grains of focus. For instance, the Tau NIC is an activity system situated within a mathematics department; thus, the subject could be defined as an individual member or the entire NIC (or perhaps, the entire department, if the department was working toward similar goals). Selecting a particular plane of focus determines other components of the system, that is, selecting the individual plane dictated that objects correspond to individual NIC members' goals. However, as Grimalt-Álvaro and Ametller (2021) note, the planes cannot be held fully separate, as they are still part of the entire activity system. Thus, we analyzed the NIC activity system along the individual-level plane, but recognized that NIC members were situated within the NIC community and had some shared objects, tools, and outcomes. The relationship between these components are described in our findings.

Findings

In this section, we share characteristics of the Tau NIC as an activity system. We focused on the individual plane of analysis to identify Objects (goals), Tools, and Outcomes of NIC members and then organized them into salient themes they expressed in common. Then, we explore the relationship between these components by providing rich examples of the connections between them.

Objects

When the Tau NIC formed, their stated, collective goal (object) was to achieve critical transformations in their undergraduate mathematics program. In reality, "critical transformations" were interpreted and operationalized in various ways; namely, each NIC

member held a different idea about the goal of the NIC. NIC members operationalized "critical transformations" as a "massive, structural change" that was "truly innovative" and gained "buy-in from the whole department." Beyond this notion of grandiosity and overall improvement, there was not a tangible object. In this way, the specific object varied as it related to a specific subject (each NIC member) at a given time. Here, we share individual-level objects that at least three NIC members held in common.

1. Change course content and policies and develop shared resources for teaching,
2. Help students learn and develop metacognitive skills,
3. Challenge perspectives about students and "change hearts and minds"
4. Learn how to collect and analyze student data, and
5. Develop relationships and collaborations with colleagues.

In a later section, we describe in more detail the challenges, barriers, and frustrations that NIC members faced as they worked toward critical transformations.

Tools

Faculty described several tools that influenced them or their experiences in the NIC. We organized these tools into four primary themes:

1. opportunities to reconsider traditional approaches to undergraduate mathematics teaching and learning and the impact on students overall and on historically marginalized populations in particular,
2. reflection exercises to surface attention to cultural biases and their own teaching practices,
3. qualitative and quantitative data collected from their students, and
4. resources to support student learning.

The NIC read and discussed articles on traditional approaches to mathematics and the impact on students' sense of belonging, motivation, and academic outcomes. They took cultural bias assessments and viewed recordings of themselves teaching class with attention to their interactions with students and how different students were engaging in the learning experience. Qualitative data about students' experiences in NIC faculty's courses and suggested improvements were collected from students through interviews, focus groups, small-group discussions, and end-of-course surveys. NIC faculty also collected qualitative and quantitative data by surveying their students at midterm and toward the end of the semester about their experiences during class (e.g., opportunities to ask questions) and outside of class (e.g., working, care-giving), and their academic engagement, self-efficacy, and sense of belonging. These data were compared to students' grade predictions and performance on assessments at mid-term and at the end of the course. The NIC discussed patterns and trends in the data and reflected on what they expected and what the data revealed. Then, NIC faculty discussed ways to address challenges that students were having in mathematics courses and shared ideas related to cultivating a growth mindset and teaching students how to learn. Through the use and discussion of these tools, faculty were regularly reflecting on their own beliefs and practices and students' learning experiences, identifying instructional changes they could make to better support their students, and then supporting each other as they planned, implemented, and revised their practices.

Outcomes

Individual NIC members reflected upon their journey within the NIC, and in so doing shared multiple outcomes from their experience. The majority of outcomes related to an individual or

personal outcome rather than a collective outcome; for instance some members felt that their own awareness of student perspectives increased. However, many of these individual outcomes were shared in common by (at least three) members of the NIC. Here, we share the outcomes which were most salient:

1. an increased knowledge and appreciation of student perspectives based on data,
2. a shifting perspective on one's relationship with students,
3. increased critical consciousness,
4. closer relationships with colleagues, and
5. an increased willingness to experiment and adapt instructional practices in their own classroom.

For example, some NIC members described having a greater understanding of the factors impacting their personal relationships with their students. One NIC member, Ethan shared how being involved in the NIC increased his awareness that "different people have different needs," and also emphasized that this knowledge made interactions with students more complicated, or a "mixed bag".

Relationship between Objects, Tools, and Outcomes

Recall in the CHAT framework, tools are intended to mediate from the activity system's object to the outcome. In our analysis of NIC members' objects, tools, and outcomes along the individual plane, we found the common themes listed above for each CHAT component. To explore the connections and relationship between the Tau NIC's objects, tools, and outcomes as an activity system, we now look across components and focus on specific examples from NIC members. We observed that the three CHAT components were evident in different combinations. Sometimes, tools clearly mediated the path from an object to an outcome. However, there were also times when specific tools led to an outcome, but an initial object was not explicitly stated, or other times, objects were realized as different outcomes due to a lack of mediating tools. We organized the examples of the relationship below to illustrate these relationships as reflected in the data. Figure 1 illustrates three different pathways we observed that connect CHAT components within the Tau NIC activity system. Each pathway is indicated by a different color.

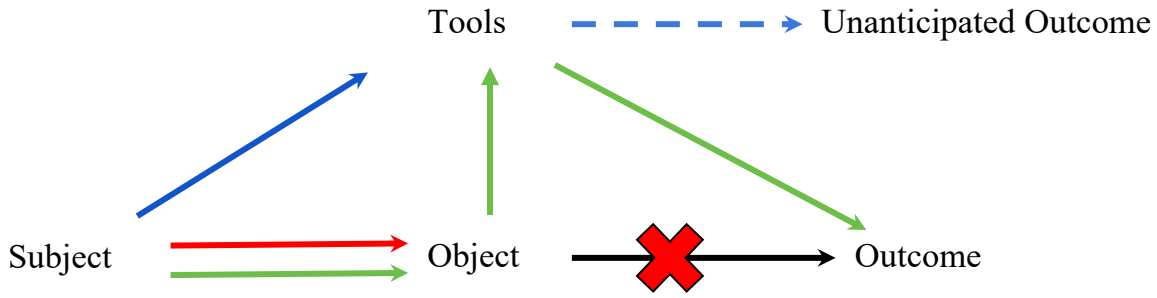

Figure 1. Pathways of connections between CHAT components within the Tau NIC activity system

Objects, mediated by tools, led to outcomes. For some members, all CHAT components aligned in the ideal relationship that the framework emphasizes. Kayla's experience illustrates this connection: her goal of supporting students' metacognitive development (Object #2) shaped how she approached student data (Tool #3). She explained that she would need to have a goal in mind before looking at the data, so that she could better focus her analysis. By organizing and interpreting student data through the lens of fostering students' metacognitive skills, she identified concrete strategies for course development (Outcomes #1 & #5), later noting, "I have

opportunities to do instructor meetings with my college algebra instructors [and metacognitive skills] will be the focus of the meetings, because the data said, this is what our students need. So to me, that's the biggest takeaway." Kayla identified a goal and reached her desired outcome through the mediation of proper tools provided by the NIC. This relationship between subject, object, tools, and outcome is indicated by the green pathway in Figure 1.

Specific tools led to a [new] outcome. In other cases, tools were the most salient link between the NIC experience and outcomes, but there was no explicitly stated object at the outset. Jordan, for instance, described how metacognitive discussion prompts (Tool #4) and student surveys (Tool #3) provided through the NIC informed his classroom practices (Outcome #5): "This allowed me to think about ways in which I can foster better cognition in my classroom." Similarly, Adele emphasized how the collection of student data (Tool #3) prompted a shift in her instructional priorities (Outcomes #1 & 5) to focus on teaching students how to learn: "After seeing the numbers… it made me shift my attention in other directions instead to work more on how to help students with their study skills and their learning skills and all that." This relationship seemingly excluded the object component of CHAT, which led to an unanticipated or secondary outcome. We indicated this relationship between subject, tools, and outcome (2) by the blue pathway in Figure 1.

Lack of [the right] tools led to a disconnect between object and outcome. Ethan joined the Tau NIC with a goal of collecting and analyzing student data (Object #4) to better understand the relationship between student identity and learning, specifically, how a student's identity might impact their learning of mathematics. However, the NIC struggled to find the relevant tools to address this goal; they collected survey data about student identity (e.g., demographics, learning disabilities; related to Tool #3) but were unable to come to any conclusions about their analysis that were clearly connected to Object #4. Ultimately, Ethan reflected that the outcome of his experience in the NIC was a personal change in himself (Outcome #3):

> You ring a bell, and you can't unring the bell. And so I think [the NIC] has changed the way that I think about things. […] I think that the way that an individual's identity impacts them and everything, including their learning in a math class is– it's very complicated, and it's delicate. [...] Different people have different needs.

Ethan noticed that he became "overly aware" of his students in a more holistic way and that his increased critical consciousness would continue to influence how he interacted with students in his classes; he "can't unring the bell."

Other NIC members experienced a disconnect between their goals and outcomes. Abel shared, "when I joined the project, I thought we were going to, you know, create something that we could use in the course. And I saw that that wasn't happening right away, and there wasn't any sign of a concrete deliverable that we could get." Abel first states his goal of creating materials to use in his course (Object #1), then expresses his realization that the object would not come to fruition as an outcome. Similarly, Garrett hoped for the NIC to accomplish a "massive structural change," like new departmental policies on "using calculators and notecards" or "content changes to courses to make them more accessible to students (Object #1). He drew on initial tools, such as reading articles about other institutions enacting similar departmental changes (Tool #1) and then attempted (unsuccessfully) to get buy-in from Tau administrators. Ultimately, his object was not realized as an outcome but did lead to unexpected outcomes: "I didn't really necessarily pull off a big, huge structural change. But I think I made a significant impact to some students in my classes" (Outcome #2). The relationship between CHAT components described by Ethan's, Abel's, and Garrett's experiences is indicated by the red

pathway in Figure 1. We note that there was an attempt to use tools in these cases, but they were not used successfully to mediate a desired outcome.

Discussion

We addressed the research question: *What is the relationship between the objects, tools, and outcomes of a two-year networked improvement community that sought to critically transform undergraduate mathematics?* We investigated this relationship by first conducting analysis on the individual plane (Grimalt-Álvaro, & Ametller, 2021) to identify objects, tools, and outcomes that were meaningful to each NIC member, as well as relationships between these three components. This analysis aided us in describing how each of these three components were connected (or not) within the work of the NIC. Our analysis of pathways between components (see Figure 1) revealed three distinct relationship types: (a) a clear connection between object, tools, and outcome, (b) tools leading to an outcome (without an explicit object), and (c) a disconnect between objects and outcomes (due to a lack of the right tool mediating this relationship). To describe the third relationship, we shared examples of how objects fail to be realized as outcomes when the appropriate tools are not present. For a community aimed at achieving critical, institutional transformation, it may be imperative that the activities, resources, and opportunities available to individual members are aligned with explicitly stated objects.

We note that several of the tools used were chosen by the Tau NIC leaders or implemented due to recommendations from the larger ACT UP Math team. Additionally, Objects #3 and #4 were emphasized by the ACT UP Math project. These objects were realized as outcomes for a subset of individual NIC members, but as externally driven goals, they were not taken up by the NIC as a whole. Research on departmental action teams (DAT) to transform undergraduate STEM programs emphasize that departments are key locations for initiating sustainable change within the complex university system, but it is crucial that the "DAT's focal issue is not externally defined" (Reinholz et al., 2019, p. 66). Reinholz and colleagues argued that DATs should focus on the collaborative process of their work, suggesting that "the DAT begins with a series of activities to develop a shared vision, consensus on the focal issue, and a set of goals" (p. 66). In our past work (Hagman et al., 2024; Tremaine, 2024), we acknowledged the challenge of aligning individual goals to the collective efforts of the NIC and highlighted tensions that arose when there was a disconnect between the vision of the NIC and that of the project leadership team. In this study, we again observed this tension between competing goals. As others have recognized (e.g., Reinholz et al., 2017), there are advantageous and disadvantageous ways of including external influence on a community working toward change (e.g., via facilitators), which could be explored further in future studies.

In spite of challenges, the experience of participating in the Tau NIC helped to develop reflective practitioners. We found that through the NIC, faculty reflected on their own beliefs and practices and on students' learning experiences and outcomes, which in combination with their objects and tools, influenced outcomes impacting their perspectives on teaching and approaches to supporting students (e.g., Borrego & Henderson, 2014). For instance, Ethan's critical consciousness development, while not his initial intention, significantly impacts how he interacts with students and views them as whole, complex individuals. By first understanding the personal and intrinsically motivated goals of faculty, we can purposefully select the tools and objects of collective transformation efforts. This intentionality and alignment may result in sustainable changes and have long-lasting impacts on faculty members' teaching and views of students. We encourage those who work with mathematics department faculty toward institutional change to consider the alignment of goals, tools, and objects as they develop reflective practitioners.

Teacher Professional Development as a Mechanism for Cultivating Competence and Professional Identity in Graduate Student Instructors' Transition to Faculty Roles

The University of Memphis

In the past decade, teacher professional development has gained popularity as a tool for preparing graduate student instructors. Research demonstrates the immediate positive impacts of this training for both the undergraduate students the graduate students teach and the graduate students' own professional teacher identity development. However, much less is known about its long-term impact. For this study, we interviewed eleven former graduate student instructors who participated in such a training program and now have a position in higher education with teaching responsibilities. We leverage Lankveld et al.'s (2016) framework of psychological processes and contextual factors for teacher identity development to explore their sense of competence as mathematics educators as they transition into their new higher education contexts. Findings suggest that a sense of connectedness to new peers and past training experiences supports productive comparison and reflective practice that promotes identity growth in new academic environments.

Keywords: Teacher identity, graduate student instructor, teacher professional development

Introduction

Teacher professional development for graduate student instructors (GSIs) has been an important research priority for the Mathematical Association of America (MAA)'s Special Interest Group Research in Undergraduate Mathematics Education; these efforts are codified in evidence-backed resources published by the MAA (e.g. the 2018 Instructional Practices Guide or the 2020 College Mathematics Instructor Development Source) (Yee et al., 2023). The duration of these efforts provides us with a unique and vital opportunity to conduct longitudinal research on the impact teacher professional development has on GSI's as they transition into faculty roles.

We are particularly interested in this transition phase because professional development for novice instructors positions them as future change agents (Hauk & Speer, 2023) within their new institutions. Additionally, GSIs, in particular, are receptive to learning and implementing student-centered strategies (Ellis et al., 2016). As GSIs transition to new institutions, they must acclimate to a new departmental culture and navigate changes in their teacher identity.

Theoretical Perspective

Developing a professional identity is an essential process for novice mathematics educators as they become members of the professoriate. Professional identity – which shapes an individual's beliefs, values, and motives as they navigate membership of their community – is constituted and reconstituted by their experiences in the profession (Beisiegel & Simmt, 2012). This process is accelerated with the transition from graduate school to faculty roles (Colbeck, 2008). Lankveld et al.'s (2016) systematic review of teacher identity literature identified four contextual factors (interaction with students, staff development activities, direct work environment, and the wider context of higher education) and five psychological processes (a

sense of appreciation for teaching, a sense of connectedness to other educators, a sense of competence as an educator, a sense of commitment to educate the next generation, and the ability to imagine their future teaching career trajectory) that impact the development and maintenance of teacher identity in higher education. For this report, we will focus on a sense of competence and how it is related to the other strengthening and constraining factors.

In Lankveld et al.'s framework, competence represents an educator's feeling of being well prepared/equipped to teach courses assigned, as well as their feeling of being a valued contributor, collaborator, or resource to the instructional mission of their department. Competence also includes feelings of preparedness for instructional leadership roles, such as directing a tutoring center or volunteering for a textbook adoption taskforce. Competence captures a teacher's overall sense of confidence in what they "bring to the table" as an educator.

Within our study, staff development activities are drawn from the teacher professional development program, *Promoting Success in Undergraduate Mathematics through Graduate Teaching Assistant Training (PSUM-GTT)*, which was implemented at three large, public universities in the United States between 2015 and 2022. Each location adapted the five program components to fit the constraints of their local context. The development program spanned three to four years and incorporated a pedagogical seminar, a Critical Issues in Undergraduate STEM Education workshop series hosted by visiting researchers, active learning support from a teaching assistant coach, regular one-on-one peer mentoring (Manzanares et al., 2023; Lanius et al. 2025), and regular opportunities for written and oral reflection (Lanius et al., 2024).

Research Question

Our overarching research question is: In what ways does this multifaceted teacher professional development experience shape the teacher identity of GSIs transitioning into faculty roles? However, in this report, we narrowly focus on the question: In what ways are new faculty's sense of competence within their new institution impacted by past participation in a teacher professional development experience?

Methods

Data Collection

A graduate student on the research team conducted interviews with 11 former program participants utilizing an interview protocol designed by the training program's research team. The protocol aimed at soliciting participants' historical perspectives on the components of the professional development program (i.e., mentorship, teaching, program didactics), their insight into their experiences of their current position, and the ways that previously engaging with the program impacted their recent experiences. The interview protocol underwent one round of revision after the first interview to edit questions for clarity and interview length. Each interview took approximately 1.5 hours. Interviews were first transcribed with Otter.ai, with the graduate student and two research team members editing the transcripts for accuracy and anonymization.

Participants

The eleven interview participants had transitioned into a career with a teaching component after participating in the teacher training program while earning their graduate degree from one of the three universities. Four participants had undergraduate teaching experience when the teacher training program began, and therefore served only as mentors. Six participants began the training program as mentees and later became mentors. One participant was a mentee, a mentor

and a teaching assistant coach. One participant was employed where they earned their graduate degree, one was employed at the institution where they earned their undergraduate degree, and the remaining were employed at four-year institutions they had not attended. Two participants had been in a faculty position with teaching responsibilities for over two years, three were in their second year as faculty, five had completed one semester as faculty at their new institution, and one was a post-doctoral researcher with a one-course per semester teaching load.

Analysis

As the interviews were quite extensive, for the purposes of this report, the research team narrowed the corpus to portions of the interview transcripts that were specifically addressing the faculty members experiences at their new institution. The research team used a priori coding (Saldaña, 2013) with a codebook we developed from Lankveld et al.'s framework. In addition to marking codes where they applied in the text, each coder took analytic memos to capture how these constructs uniquely manifested and how the codes related to one another. For example, a passage of text might be marked "staff development activities → competence". As the purpose of this project is exploratory and does not aim to make any frequency claims, we did not conduct interrater reliability statistical analyses. Instead, we had open discussions for consensus building where coders could share their independent findings and receive feedback.

Results

Because the constructs within the teacher identity framework interact in unique ways for each junior faculty member, we discuss results at the individual level before generalizing.

Alex

Alex reflected that as a novice GSI they only lectured, which mirrored the lecture-heavy learning experiences they had as an undergraduate. With support of the training program, they developed comfort with utilizing engagement techniques like group work and think-pair-share, and came to appreciate the value of active learning strategies. In their new faculty role, they conveyed a continued sense of competence in their teaching practices and expressed a curiosity to learn more teaching strategies (sparked in particular by an exposure to alternative grading in their new department). Although they are confident in their instructional practices and enjoy discussing teaching with others, they are careful not to present their approach as "*my way is the best*". A sense of connectedness, to both the GSI training program and to their new colleagues, is key to their growing sense of competence because it allows them to reflect on their teaching and gain insight by observing their peers. In the language of the teacher identity framework, Alex's professional identity and competence is heavily influenced by the skills they developed in the training program and a sense of connectedness derived from participating in the program's community of practice and engaging in teaching discourse with new department members.

Bojing

For Bojing, the sense of connectedness they developed while a GSI in the training program supported their sense of competence, particularly through the process of observing a peer teach and also being observed by a peer. They reflect that their teaching experiences as a GSI have helped them to thrive in their new faculty position and to be less stressed in comparison to others at their institution. Bojing is in an interesting position, now serving as a faculty member in the department where they earned their undergraduate degree. They report struggling to be seen as a

colleague with teaching knowledge by some people in their department and instead are seen as a former student. This tension is reflected in how they engage in teaching-related discourse with new department members: "*We talk about teaching usually. We're pretty open about it. I'm at more of a teaching university. I don't know if I'd say I'm a resource per se, but sometimes I give out ideas or suggestions.*" In the language of the teacher identity framework, Bojing's professional identity and competence is positively influenced by a sense of connectedness to others, which allows productive comparison, and is negatively mediated by the direct work environment which introduces a struggle to be perceived in a new way by department members.

Carmen

For Carmen, the self-reflection practices they developed while a GSI in the training program have directly influenced their sense of competence as a teacher. While a GSI, this reflection was facilitated by observing another GSI teach. As a faculty member, their connection to students in a large lecture setting has inspired further reflection on how to improve their teaching through an equity lens. Carmen shares that they have a strong teacher identity, explaining "*I think I'm a better teacher than researcher.*" Their sense of connectedness to other educators in their department has changed since they were a GSI. As a novice GSI, when they felt like they didn't know something, they were reluctant to find support. The training program was integral in developing their competence as an effective educator and they recognize they will always be learning. As a faculty member, they don't mind being the new person, and "*feeling dumb*". They are comfortable connecting with people in their new context and addressing problems early. They reflect, "*…you're supposed to have all the answers, quote, unquote, because you're now the doctor, faculty member.…But if you've been in the situation, you know, you're never above it. And there's always going to be something within every situation, you could do better.*"

Domingo

For Domingo, participating in the training program gave them the confidence to be an instructor. They speak of coming into their new context as a faculty member with a "*collaborative mindset*", which reflects a readiness to connect with other educators. Comparing their training to other new faculty further enhanced their sense of competence, particularly among colleagues who had no prior experience as an instructor. In their new context, they shared experiences of refining existing department resources to share and incorporating inclusive teaching practices and active learning strategies and reporting that it worked well.

Edric

For Edric, being given teaching responsibilities as a graduate student was intimidating because they felt a duty to try their best to do well. Their current feelings of competence are derived from those early teaching experiences, especially as they compare their training and experiences to those of graduate students at their current institution. As a faculty member, they do not see themself as a resource within their department, but do frequently talk to others about teaching. In terms of their teacher identity, they describe themself as a "*new teacher*", as they are struggling with classroom time management and teaching large lectures. They report a drive to try new approaches for their new context, like incorporating iClickers for large lectures.

Fadi

As a GSI, Fadi quickly employed the things that they learned in the training program and talked to others about them. This participant's sense of competence directly feeds into their sense of connectedness and drive to engage with others around teaching. The converse was also true, with them sharing an experience where they felt less connected and consequently felt less competent as an educator. Fadi felt like a "*spokesperson*" for the goals of the training program and has brought this forward into the future, still trying to advocate for the use of active learning strategies in the classroom. Fadi has a strong sense of self as an instructor, explaining "*I was confident that I could be a good teacher, I had a lot of supporting evidence, right?*" Despite being the newest hire in their department, they further share "*I definitely feel confident that I have something to contribute to these spaces, even though… I'm the newest hire in the department. I still feel like I have a space and some skill set that I can share with others*".

Gerard

Before participating in the GSI training program, Gerard had a couple of years of teaching experience and recognized that they weren't growing as an educator. Through the connections they made with the community that grew around the training program, they started trying active learning techniques: "*I mean I was told by many [program] mentors how important active learning is, and I really started implementing them. And it turns out that they are. They're super important and super engaging for students.*" At their new institution, they report that teaching is very different than at a big university and that they're doing much more active learning in the classroom and are exploring developing new skills, like implementing inquiry-based learning into the classroom. Fostering a sense of connectedness remains important for Gerard. For example, when teaching statistics for the first time, they found a colleague who was willing to share their materials and talk to them frequently about teaching the course. Additionally, in comparing themself to other new faculty, they feel more prepared and thus competent as an instructor, but also explain, "*I'm growing, and I'm learning always.*"

Harley

As a faculty member, Harley feels a strong sense of competence in effectively implementing group work and other activities that they learned while participating in the GSI training program. A sense of connectedness from participating in the professional development program also contributed to their growing sense of competence in the classroom. Their reflection on the training highlights the role of connectedness in developing competence:

> *"When there were seminars, that was good… I appreciate those things. And also the time that we got to share with each other because when you're teaching, it's a local thing. It's changed to university, university, university. So it's really important to share tools, strategies, and get to know about classes. So having that kind of conversation is really good. So I enjoyed that. And I got to know some ideas."*

In their new departmental context, they view themself as a resource for others, for example substitute teaching for other faculty.

Ivon

Participating in the GSI training program helped Ivon to feel knowledgeable and like they were a better teacher. The sense of connectedness they developed within the program community directly contributed to this confidence, with them reflecting "*I participated in many meetings,*

where we were sharing each other's opinion about active learning…It gave me various ideas…it comes with experience, and it comes with meeting your mentor, or attending those critical issues seminar meetings. So, I was feeling pretty confident as a teacher". In their new context they have mixed feelings about their competence as a teacher. They shared two issues that have preoccupied them: (1) communicating with students because some students have left feedback in course evaluations about their accent, and (2) making class more engaging. Engagement is of particular concern for them in the large lecture format, where they are teaching a large course for the first time and feel less prepared than their colleagues. On the other hand, they do feel like a useful resource to the teaching assistants helping with the course. Ivon continues to seek connection with others, reflecting "*there is no unique way of teaching. So it really is interesting to see how my friends are teaching. I sometimes wish to go to another person's class to see how. Although I'm teaching pretty well, sometimes students are not super excited because it's math.*"

Jasper

Jasper candidly shared that they did not want to participate in the GSI training program. However, now as a faculty member, they see how much they have learned. This appreciation is further deepened by comparing their experiences as a GSI to the teaching experience of others on the job market: "*I was way more aware of a lot of the education research and how to deliver materials and issues like that, compared to a lot of the people who I was working with…I was like, 'holy cow, like I got a great foundation from this seminar', because other people were just like, 'Oh, I've never heard of that before.'*" Although Jasper has a strong sense of competence, their new context gave them new challenges to navigate, such as multiple course preps, time management, and balancing teaching and research. In terms of connecting with new colleagues and engaging in discourse around teaching, they shared "*I feel like right now, I'm just like taking a lot of stuff in, but I feel like I will be able to participate more in the future.*"

Kyla

For Kyla, participating in the training program supported their sense of competence as an educator and gave them the language to express what they were doing in the classroom with others. As a GSI, they felt competent to generate new tactile activities and to try new teaching or grading approaches. In comparing themself to other faculty at their new college, they feel "*worlds ahead*", with particular confidence in their ability to effectively take on a large teaching load. They are currently working with others on writing an open access book. In summarizing their perspective on being a teacher, they shared "*I tend to be very modern in my thinking. I tend to be very, 'oh, let's just try this. That didn't work. Okay, let's try something else.'*"

Discussion

As GSIs, program participants were members of a community of practice that fostered a sense of connectedness. Participants frequently cited the relationships they cultivated through the program, specifically mentoring interactions and peer discussions in seminars, as central to their growth. These training experiences provided a foundation for reflective practice and normalized teaching-related dialogue within their academic communities. Many participants report continuing these practices within their new context. For a majority of our interviewees, productive comparison with new colleagues – on prior training and teaching experiences – supported self-reflection, which bolstered their sense of competence as a new faculty member and inspired them to grow their teaching practices. This process of social comparison enabled

them to locate themselves within the broader institutional teaching culture and engage more meaningfully in pedagogical discourse. For many, it was through navigating a new professional environment, making these comparisons, and engaging in reflective dialogue that participants further developed their confidence and competence in their teacher professional identity.

Reflecting on their experiences as GSIs, many participants noted the value of constructive feedback through peer teaching observations. Participants noted this feedback directly contributed to their instructional improvement, and when it was absent in the new environment, they expressed disappointment. Jasper shared, *"And so I've gotten a few helpful insights from faculty mentoring but I felt like I got a lot more from the peer mentoring."* This may indicate that new faculty mentors and department chairs should implement an observation protocol designed to provide constructive feedback, such as the red-yellow-green feedback system (Yee et al., 2022) or teaching TRIOs (Bleiler-Baxter et al. 2020).

For two participants, mathematics research was their only career goal when they entered graduate school, and participation in the teacher training inspired a shift in their career goals. All participants acknowledged that the GSI training program substantially supported their job search process because it enabled them to effectively articulate their teaching philosophies and to effectively discuss pedagogy with faculty search committees.

Conclusion

The PSUM-GTT training program functioned as a formative site for teacher identity construction, where GSIs developed not only a sense of competence but also a sense of belonging to a professional teaching community. For many participants, their strong teacher identity inspired them to pursue teaching-focused careers.

As participants transitioned into faculty roles, their prior participation in the PSUM-GTT training program continued to have a lasting and transformative impact on how participants perceived themselves as educators. The program instilled instructional confidence, fostered pedagogical curiosity, and provided language and frameworks for articulating and refining teaching practices. Further, we saw that a sense of competence as a teacher can be deepened by the experience of transitioning itself, when GSIs-turned-faculty are given a new context to situate themselves within and to compare themselves to. Many participants described entering their new departments with a stronger foundation of teaching skills and a clearer understanding of how to reflect on and improve their teaching practices compared to peers. On the other hand, comparing themselves to faculty with a much broader range of teaching experience also provided new opportunities for reflecting on where they currently are and for identifying opportunities for growth.

In conclusion, we found that a sense of competence is not a static psychological process, but rather a dynamic, socially constructed aspect of teacher identity, deeply influenced by prior training experiences, interpersonal connections, and institutional context.

Statement on Generative AI Use

Our first draft of this manuscript was over the page limit. ChatGPT-5 and Claude.ai were asked to suggest ways to condense. All suggestions were thoroughly discussed as we have an ethical responsibility to accurately represent the participants appearing in our report.

Acknowledgments

The Role of Syllabi in Measuring Teaching: Comparing Planned and Enacted Behavior

Tim Archie

Syllabi contain information about an instructor's teaching and have been used as a measure of change in response to professional development. Syllabus scores have been linked to more widely used and resource intensive measures of change, including observations and surveys. We used the theory of planned behavior to examine the relationship between syllabus scores and self reported teaching practices and tested for changes in these measures in response to professional development. We found syllabi scores can approximate instructor teaching intentions, which seemed to manifest in their use of teaching practices. Instructors' teaching intentions changed in response to PD, but their teaching practices did not. These findings are consistent with the theory of planned behavior, indicating that intentions change before behaviors, which supports the use of syllabi as a measure of change that can be economically deployed and detect nascent changes in teaching practices.

Keywords: syllabus, teaching, professional development, theory of planned behavior

Non-didactic, student-centered teaching practices are well documented as effective for enhancing student learning and achievement in undergraduate STEM education (Freeman et al., 2014). Evidence also indicates that student-centered teaching practices contribute to reducing achievement gaps among students historically underrepresented in STEM (Ernst & Colthorpe, 2007; Haak et al., 2011; Eddy & Hogan, 2014; Freeman et al., 2014). Despite these benefits, widespread adoption remains limited; estimates suggest that only about 20% of STEM instructors consistently implement student-centered teaching practices in their teaching (Stains et al., 2018; Eagan, 2016). Consequently, many students have little exposure to student-centered teaching practices and miss out on their potential advantages.

Professional development (PD) has been identified as an influential strategy in increasing instructors' use of student-centered teaching practices in undergraduate STEM education (Khatri et al., 2013; Laursen et al., 2019). However, relatively few studies have examined the relationship between teaching-focused PD and the instructional practices of STEM faculty across disciplines such as math, chemistry, physics, and biology (Archie et al., 2022; Benabentos et al., 2020; Borda et al., 2020; Chasteen & Chattergoon, 2020; Manduca et al., 2017; Bathgate et al., 2019). Research in this area may be limited, at least in part, by the research methods commonly utilized in this research, including classroom observations, surveys, and interviews. These research methods are time-consuming and labor-intensive and thus make this type of research expensive to conduct. More economical research methods have the potential to encourage new research, especially given the current funding constraints in STEM education research.

Syllabi are a rich data source that can be collected easily and analyzed quickly using syllabus scoring tools such as the Measuring the Promise (MtP), a syllabus rubric that been shown to detect changes in teaching practices (Mumpower et al., 2024), including changes in response to professional development (CTE, 2017; Favre et al. 2021; Schmid et al., 2021). While the MtP authors emphasize that the "syllabus is only a proxy to actual classroom practices and student

learning and is in itself neither a measure of teaching effectiveness nor necessarily an accurate reflection of an instructor's values," it can be argued that the syllabus can reflect an instructor's intentions for teaching: it is created before an instructor performs any teaching and describes the intent of the course and what student will learn (Palmer et al, 2014a). Research has shown that syllabi and classroom observations are positively associated (Laursen & Archie, 2018), suggesting that instructor intent indeed translates to their teaching.

The temporal relationship between syllabi and teaching practices is well aligned with the Theory of Planned Behavior (TPB) in which behavioral intentions are the primary determinants of actual behavior (Ajzen, 1991). Intentions, in turn, are shaped by three key constructs: attitude, subjective norms, and perceived behavioral control. Attitude refers to an individual's overall positive or negative evaluation of a given behavior. Subjective norms represent an individual's perception of social pressure to carry out or avoid the behavior. Perceived behavioral control reflects the extent to which an individual believes they can perform the behavior and exercise control over it. Importantly, for intentions to translate into action, individuals must possess the requisite ability to perform the behavior. Consequently, perceived behavioral control is hypothesized to exert a direct influence on actual behavior, in addition to its effect on intentions.

The TPB has been employed to examine shifts in teaching and learning within STEM education (Reinholz & Andrews, 2020). Specifically, it has been used to explain mathematics and physics instructors' adoption of research-based instructional strategies after participating in professional development programs (Archie et al., 2022; Chasteen & Chattergoon, 2020). In this study, the TPB is used to explore the relationship between the syllabus and instructors' teaching practice, using the MtP syllabus rubric as an indicator of change in practice. In this study, we answered two research questions:

1. What is the relationship between instructors' behavioral intent (syllabi scores) and their behavior (use of student-centered teaching scores)?
2. Do instructors' behavioral intentions and behavior change after participating in professional development?

Methods

The study design was approved by the university's IRB and all instructors gave informed consent.

Study Population and Survey Sample

Study participants were early-career undergraduate mathematics instructors who participated in MAA Project NExT), New Experiences in Teaching, professional development program. Briefly, this full-year program provides strategies and advice for teaching and navigating the academic environment, with an emphasis on a variety of inclusive and student-centered approaches to teaching (MAA, n.d.; Higgins, 2012). Because this analysis focuses on syllabi as a measure of change, rather than on outcomes of the PD, we do not describe the program in detail.

Participants completed a pre-survey at the end of the academic term preceding participation in the PD program, a mid point survey 1 year into the PD program, and a final survey at the end of the PD program. The survey asks respondents to report on a specific course they taught and to upload the syllabus for their selected course. A total of 171 instructors completed the pre survey and provided a syllabus, 110 completed the midpoint survey and provided a syllabus, and 72 completed a final survey and provided a syllabus. To maximize statistical power, we computed a "post" syllabi score from the final time point (n = 72) or the mid time point for survey

participants who provided a syllabus at the mid time point, but not at the final time point (n = 70), for a total of 142 respondents.

Of the 171 unique respondents, 168 provided some demographic information. 48% identified as men, 46% identified as women, 5% identified as other than man or woman. 72% identified as white, 15% identified as Asian, 8% identified as Hispanic, and 3% identified as Black. 61% were assistant professors and 34% were non-tenure-track instructors or visiting professors. 41% taught at a PhD granting institution, 44% at a 4-year institution, and 15% at a Master's granting institution. 16% taught at a minority-serving institution, and the remaining 84% did not or did not know if they taught at a minority-serving institution.

Survey measures. In this study, the TPB construct of "behavior" was operationalized using self-reported teaching practices. Respondents were asked to report the percentage of time they used 11 teaching practices in a specific course over the course of the term, totaling to 100%. We then computed "behavior": as the proportion of time using three student-centered teaching practices (student group work + student presentation + class discussion). Syllabi scores were used as a measure of the TPB construct "behavioral intent", and the scoring procedure is described in the following section. Departmental expectations to use non-lecture based teaching strategies represented the "subjective norm" construct. The item was worded as "How much do colleagues in your department have formal or informal expectations for instructors' teaching? - Expectation to use a variety of techniques" and was coded on a five-point scale (1=not at all, 5=a great deal).

The TPB construct, "perceived behavioral control", was operationalized by one item, "How much effort have you made to implement active learning strategies in your teaching?" and was coded on a five-point scale (1=no effort, 5= a great deal of effort).

Instructors were asked three growth mindset questions (Dweck, 2006) that have been shown to be related to the use of student-centered teaching practices (Aragón et al., 2018). These items were reverse coded on a five-point scale (1 = strongly agree, 5 = strongly disagree).

Syllabus scoring. Prior to coding, syllabi were deidentified with respect to instructor name(s) and contact info, higher education institution, and other wording that might identify the course. Calendar year dates were removed to mask whether the syllabus was part of the pre-program or follow-up sample.

Two of the authors (SL, SW) followed an iterative process to test and modify the Making the Promise (MtP) rubric. They first applied the MtP rubric to four annotated reference syllabi from the rubric authors (CTE, 2017) and discussed findings. They then applied the MtP rubric to 15 college-level course syllabi collected in prior mathematics education studies. The authors scored several syllabi individually, then discussed their scoring rationales until they came to consensus. They revised the rubric to specify the levels of evidence for each item, to clarify rubric language, and to distinguish items so they were non-overlapping, and repeated this process several times across the set of 15 syllabi. This yielded a detailed modified rubric outlining three scoring levels (low, medium, and high) for each of 15 items. An overview of the modified MtP rubric items and scoring is provided in Figure 1.

Like the original MtP rubric, our modified rubric contained five subsections: learning goals, assessment, schedule, classroom environment, and class activities. Added language specifies the kinds of evidence that support scoring and allows the rater to reliably assess whether the strength of evidence for each item is low, medium, or high. These descriptions also support the rater in making decisions around evidence that can be inferred from the syllabus text. Such evidence can be used to support scoring an item as medium, but cannot be used to support a high score.

Following this iterative process, the two authors individually rated a new set of ten mathematics syllabi, five collected for this study. Author TW calculated interrater reliability statistics on the results, finding an interrater agreement of 65%, an intraclass correlation (ICC) of 0.73, and a Kappa of 0.67. These statistics are in acceptable ranges for interrater reliability; a Kappa of 0.618-0.8 is considered "substantial" (Cohen et al., 2000). One rater subsequently applied the rubric to the entire dataset of mathematics syllabi (n = 380). Eight syllabi were excluded due to substantial missing information (e.g., grading scheme) that made the syllabus impossible to score, or a lack of alignment with inclusion criteria (e.g., not an undergraduate course). A total of 353 syllabi were scored on each of 15 individual items. Low, medium, and high item scores were converted to 0, 1, or 2 points, respectively, then multiplied by the item weight (Figure 1) to arrive at a numerical score. We adjusted the weighting of items #9 and #14, as described in Figure 1. The total maximum score for each syllabus was 54.

Any rubric is potentially influenced by bias, and bias can be magnified by differential weighting of items. We reduced item weighting where our syllabus set tended to lack information important to evaluating the item, but did not alter the weighting of the original authors' judgments of the relative importance of different items. Overall, the original MtP rubric puts significant weight on learning goals, learning objectives, and the alignment of those goals with assessments and classroom activities, and less heavily weights the quality of classroom activities and the classroom environment. A differently weighted rubric could generate score patterns and analyses with slightly different implications.

Item	Short definition	Modifications made	Item weight	Max item score
1	Big picture learning goals and measurable smaller learning objectives are articulated or implied. Together, goals and objectives address all of Fink's six dimensions of learning (Fink, 2013).	Focused on breadth of learning goals, operationalized as number of Fink's dimensions included in the set of learning goals and objectives (rather than mere presence of learning goals).	3	6
2	Learning goals and learning objectives are separately defined and clearly articulated. Learning goals be may written broadly, but learning objectives are measurable and use specific action verbs.	Reduced overlap with item #1 with a focus on the degree to which learning goals are clearly and measurably articulated (rather than the presence of learning objectives).	3	6
3	Learning objectives are appropriately pitched to the course level, class size, position of the course within the curriculum, and characteristics of students taking the class.	Not assessed for this study, due to a lack of needed contextual information.	0	0
4	Assessments are aligned with learning goals and objectives.	Focused on alignment only; removed considerations of grade weighting.	3	6
5	Major assessments are well defined, rationalized, and involve "authentic tasks".	No changes.	2	4
6	There is frequent formative assessment and scaffolding of learning that encourages students to attend to past learning and iterate their efforts.	Added wording about scaffolding and iteration of effort.	1	2
7	Assessments are adequately paced, spreading out the student workload and giving students information in a timely manner to make decisions about enrollment.	Focuses on how well pacing information aids students in making enrollment decisions. Removed wording about scaffolding, reducing overlap with #6.	1	2
8	The grading scheme is weighted appropriately for the assessment design.	Focus is placed on grade weighting. Removed wording about goals alignment. Both changes reduce overlap with #4. Removed wording about where the grading scheme is placed in the syllabus.	1	2
9	Schedule is fully articulated and provides evidence for a logical progression of learning.	Reduced weighting from 3 to 2 because schedule information was often provided in a course LMS, not accessible to this study	2	4
10	Invites the learner and indicates a positive and collaborative class environment.	Removed wording about "big questions" addressed by course content.	2	4

11	Supports connected and lifelong learning. Answers the question: Why should you learn this for your life?	Removed considerations about grading schemes to reduce overlap with #8.	2	4
12	Signposts that the work will be challenging, and students will be supported to enable their success.	Focused on methods for supporting students through challenging work. Removed wording about rigor and expectations to reduce overlap with #1, 2, 4, and 8.	1	2
13	An organized, learning-supportive, interactive document.	No changes.	1	2
14	Classroom activities are aligned with assessments.	Removed wording about alignment with learning objectives, to reduce overlap with #4. Reduced score weighting from 3 to 2 because information needed to score this item was rarely provided.	2	4
15	Learning activities are derived from evidence-based practices.	No changes.	2	4
16	Class activities engage students in a variety of ways.	No changes.	1	2

Figure 1. Rubric items, definitions, and modifications to the original Making the Promise rubric and scoring.

Data Analysis

A structural equation model was used to answer RQ1. (AMOS 31, SPSS Inc., Chicago, IL, USA). This analysis was limited to 99 survey responses with complete data and only included one response from any individual respondent across time points. The model was calculated using maximum likelihood estimation and model fit was evaluated using two indices: the Comparative Fit Index (CFI) and the Root Mean Square Error of Approximation (RMSEA). CFI values range from 0 to 1, with values ≥ 0.95 indicating good fit (Hu & Bentler, 1999). RMSEA values ≤ 0.05 are interpreted as evidence of close fit (Browne, 1993).

RQ2 was answered using independent samples t-tests to test for differences in pre and post syllabus scores and average use of student-centered teaching practices.

Results

A path model was used to answer RQ1. The model fit indices were within acceptable ranges (CMIN = (df) 3.830 (2) $p = 0.147$, CFI = 0.99, RMSEA =0.035). As shown in Figure 2, we found positive, statistically significant standardized direct effects in all but one of the specified paths in the structural model. Among the four variables hypothesized to influence behavioral intention (syllabi scores), both perceived behavioral control (effort in implementing student-centered practices) and attitude (growth mindset items) showed comparable moderate effects, while subjective norm (departmental expectations for teaching) showed a minimal and non-significant direct effect. Behavioral intention and perceived behavioral control were both expected to directly influence behavior (use of student-centered teaching practices), with each showing a moderate positive association with behavior. The model explained moderate amounts of variability in both behavioral intention ($R^2 = 0.23$) and behavior ($R^2 = 0.31$).

T-tests used to answer RQ2 revealed statistically significant positive change (Table 1) in overall syllabi scores and in two of the five syllabus categories: learning goals and assessments. All other categories showed positive minimal effects that were not statistically significant. Instructor use of student-centered teaching practices shifted from 32% to 35% from pre to post, a minimal and not statistically significant difference.

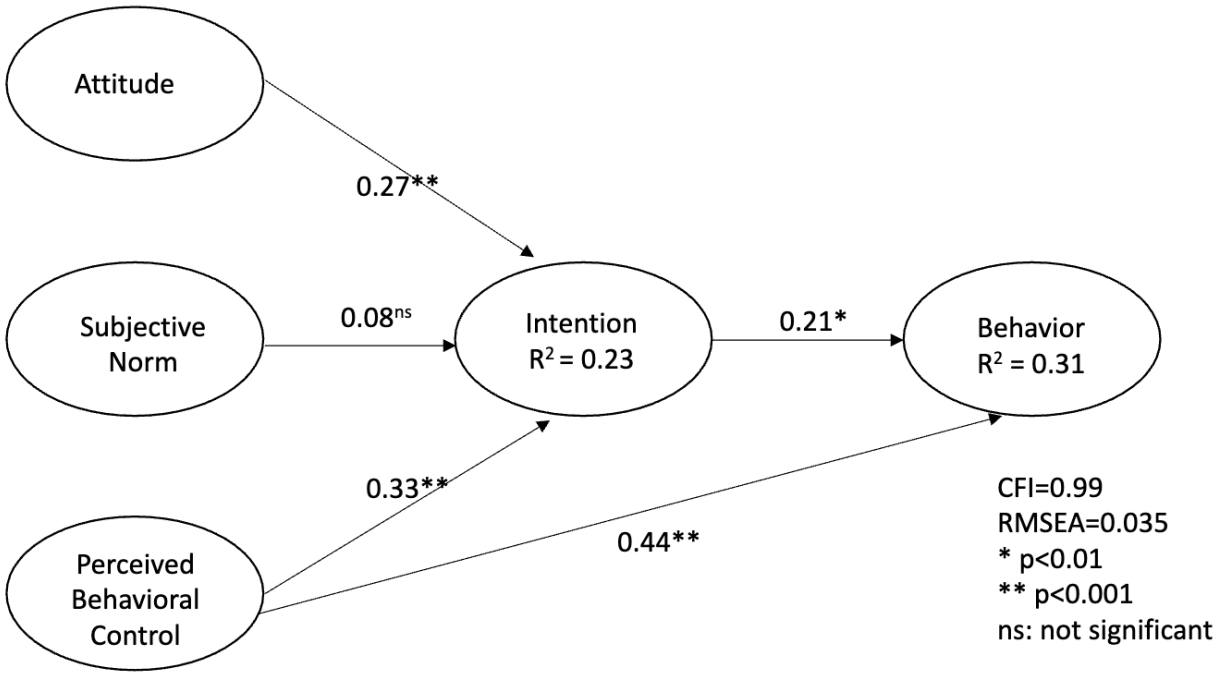

Figure 2. Structural equation model of the theory of planned behavior with standardized direct effects.

Table 1. Pre/post comparison of syllabus scores, subscores, and average percent course time using student-centered teaching practices: T-test results

Category	Pre	Post	*t*	*df*	*p*	*d*
Overall score	24.3	26.7	2.724	324	0.007	0.31
Learning goals	5.98	7.12	3.300	324	0.001	0.37
Assessments	8.73	9.58	3.100	324	0.002	0.35

Discussion

RQ1 results showed that syllabi scores are positively associated with instructors' use of student-centered teaching practices and are consistent with the TPB and prior research. These findings indicate that instructors' teaching is aligned with their teaching intentions as communicated in their syllabi and is consistent with prior TPB research, which has found behavioral intent to be a strong predictor of behavior (Armitage & Connor, 2001). Also consistent with prior research, we observed that behavioral intent and behavior were moderately influenced by perceived behavioral control. We found that the greater the effort of instructors to use active learning teaching practices, the more likely their syllabus and teaching were student-centered. Attitudes about students also showed a positive relationship with syllabus scores, indicating that an instructor's attitude influenced their intentions for the course and, subsequently, their teaching practices. Lastly, we found no significant association between subjective norm and behavioral intention, indicating that perceived departmental expectations for using a variety of teaching practices did not relate to instructors' syllabus scores. While this finding is unexpected and inconsistent with some prior research (McConnell et al., 2020,

Bathgate et al., 2019), it is consistent with prior applications of the TPB that have also found no meaningful association between subjective norms and behavioral intent (Armitage & Conner, 2001; Archie et al, 2022).

For RQ2, the results showed statistically significant positive change in overall syllabi scores and in two of the five syllabus categories: learning goals and assessments. All other categories showed positive but minimal effects that were not statistically significant. These results suggest that the overall shift in the syllabi scores was driven primarily by these two categories. It is plausible that some PD content was directly or indirectly related to articulating their learning goals in their course materials. The lack of meaningful change from pre to post average use of student-centered teaching practices was unexpected. However, because much of the data used in this study was collected during the pandemic, these findings are not likely to be fully reflective of their teaching constrained by the challenge of adapting student-centered teaching practices to remote teaching formats.

The findings from this study are encouraging as it provides evidence that syllabi can be a useful measure of an instructor's teaching practice. While the syllabus may not reflect enacted teaching practices, our findings indicate that a syllabus scored with the MtP rubric can approximate the type of teaching practices used by a given instructor. A syllabus can be a more accessible and cost-effective means of characterizing teaching and measuring differences across time points in response to teaching-focused interventions such as professional development.

While the findings from RQ1 indicate the intention that instructors infuse into their syllabi manifests in their teaching behaviors (and use of student-centered teaching practices), the findings from RQ2 showed a positive shift in intention, but no significant change in teaching practices. These findings suggest that while instructors intend to change their teaching practices, they may need more time to gain skills and knowledge to use the teaching practices they aspire to use. Thus, the syllabi and corresponding MtP score may be a more useful and realistic measure of short-term PD outcomes than more resource-intensive methods such as observations or surveys.

An Analysis of Connections Between Epistemological Obstacles Experienced Within the Quantification Unit of a Transition-to-Proof Course

Sean Clark
Virginia Tech

Rachel Arnold
Virginia Tech

Anderson Norton
Virginia Tech

Students' conceptions play a large role in how they learn math. When students experience challenges, or epistemological obstacles, they may struggle to adapt their ideas that previously served them well. Little research has been done regarding interactions between co-occurring epistemological obstacles. This report utilizes a proposed adjacency matrix methodology for analyzing the co-occurrence of epistemological obstacles. Our results show that students' difficulty noticing hidden quantification had strong thematic connections to two other challenges: quantifying the negation and transforming logical implications into related forms.

Keywords: Epistemological Obstacles, Quantification, Proof and Proving, Logical Implication

Prior research has documented students' persistent challenges when reasoning about logical statements in transition-to-proof courses (TTP; e.g. Dawkins & Roh, 2020; Epp, 2003; Norton et al., 2025). Many of these challenges persist even in response to research-based instruction, and researchers characterize such challenges as necessary in students' development of logical structures, such as logical implication (LI; Norton et al, 2025; Steffe, 1992).

Antonides et al. (2025) observed that existing mathematics education research usually studies students' learning challenges independently, even though students might experience multiple challenges in tandem. Norton et al. (2025) found that students' ways of reasoning impact the profile of challenges that they experience. To support researchers, Antonides et al. (2025) proposed a methodology for mapping connections between co-occurring learning challenges.

This paper aims to add to the literature by investigating challenges experienced concurrently by students during research-based instruction on quantification. Quantifiers, such as "for all," play an essential role in mathematical study as they, when taken together with predicates, allow for reasoning about mathematical objects, their properties, and relationships between objects. Moreover, there is a wealth of literature documenting students' persistent challenges with quantification in logical statements (e.g. Dawkins & Roh, 2020; Epp, 2003; Shipman, 2016).

We asked the following research questions: (a) During research-based instructional interactions on quantification, what challenges do students experience concurrently? and, (b) What ways of reasoning do students demonstrate when challenges are experienced concurrently within the same interaction? In response, we analyzed video of the first six classes of the quantification unit in an undergraduate TTP course. This paper reports on the study's results and shares themes in student reasoning within the two pairs of EOs that co-occurred most frequently.

Theoretical Framework

Following Brousseau (2002), we characterize learning challenges that persist in response to research-based instruction as *epistemological obstacles (EOs)*. They are "the effect of a previous piece of knowledge which was interesting and successful, but which now is revealed as false or simply unadapted" (p. 82). Students may experience an EO when they become aware of a conflict or perturbation in their thinking, but teachers may notice this tension first.

We situate our investigation of concurrent EOs within Antonides et al.'s (2025) proposed methodology for mapping co-occurrences of EOs experienced within instructional interactions.

This six-step process begins with a literature review of EOs and it culminates in the generation of an adjacency matrix whose rows and columns are these EOs and whose entries indicate the number of times pairs of EOs co-occur in a single instructional interaction. The resulting adjacency matrix can then be visualized as a weighted graph, allowing "researchers to visualize connections between EOs and the strength of each connection" (p. 1321). We elaborate on this six-step process within our Methodology section below.

Methodology

To collect data about EOs, we used the 6-step methodology outlined by Antonides (2025).

Step 1: Literature Review

An extensive literature review was conducted within a larger study, "The Proofs Project" (e.g., Norton et al., 2025). We summarize here the EOs pertinent to our study.

Students consistently struggle with implicit, or "hidden," quantification (coded Qh; Shipman, 2016; Durand-Guerrier, 2003; Epp, 2003). For example, "If $x > 2$, then $x^2 > 4$" implicitly refers to *all x*. When quantification is unhidden, students struggle to quantify a statement's negation (coded Qneg; Dawkins & Roh, 2020). Multiple quantifiers introduce additional struggles (coded Qmult; e.g., Adiredja, 2020; Dawkins & Roh, 2020; Dubinsky & Yiparaki, 2000).

Students also experience difficulties when proving quantified statements. For example, they may question why the *Principle of Universal Generalization* (see Copi, 1954) proves a "for all" statement (coded PUG; Dawkins et al., 2022; Norton et al., 2023). Students may also conflate the value of a variable (e.g. $\varepsilon = 1$) with its role (e.g. the distance between two points; coded Qrv; Dawkins & Roh, 2022).

Challenges related to LIs of the form $p \rightarrow q$ have also been documented. Students might treat LI as biconditional (coded LIff; Epp, 1999, 2003; Rumain et al., 1983; Wagner-Egger, 2007) or struggle to transform an LI into, for example, its converse or negation (coded LIt; e.g., Antonini, 2004; Hawthorne & Rasmussen, 2015; Hub & Dawkins, 2018). Furthermore, students may conflate the negation of $p \rightarrow q$ with its opposite statement, $p \rightarrow \sim q$ (coded NO; Epp, 2003; Arnold et al., 2024), and they may experience difficulties drawing distinctions between the negation and a disproof of a statement (coded NF; Norton et. al., 2025).

Step 2-4: Data Collection and Analysis

Data consist of a subset of six video-recorded 50-minute classes within the quantification unit of an inquiry-oriented undergraduate TTP course taught by the second author. Table 1 outlines the topics discussed during the classes analyzed within this study (Class 15 was a review day and was not analyzed). Students sat at tables in groups of approximately five students, engaging in group discussion captured on iPads via audio- and screen-recording. We refer to the five groups as the Hexagons, Rectangles, Circles, Squares, and Triangles. We analyzed the recorded videos,

Table 1. The classes analyzed for this report and the respective subjects covered.

Class	Discussion
13	Introduction to the existential quantifier
14	Writing existential proofs, writing nonconstructive existence proofs
16	Comparing constructive vs. nonconstructive existence proofs
17	Introduction to the universal quantifier
18-19	Writing "for all" proofs, constructive vs. non-constructive for all proofs

Table 2. A table with descriptions of EOs that occurred.

EO Code	Description
Qh	Overlooking hidden quantifiers
Qneg	Demonstrating uncertainty about the quantification of the negation
NO	Treating the negation $p \rightarrow q$ as its opposite statement $p \rightarrow \sim q$
PUG	Questioning or neglecting the *principle of universal generalization*
LIt	Difficulty transforming LIs into related forms (converse, negation, etc.)
Qrv	Conflating the role of a variable with its value
NF	Struggling to articulate the difference between negation and disproof
LIff	Interpreting LIs as biconditional (e.g. assuming $p \rightarrow q$ means $q \rightarrow p$)
Qmult	Struggling to make meaning of statements with two or more quantifiers

noting timestamps where EOs were elicited. We marked EOs based on a codebook (see Table 2) developed from our literature review. When students were perturbed, we coded the interaction with an EO that most closely captured their experience. After coding, we demarcated our data into chunks by instructional task. Video from the task launch, group discussions about the task, and subsequent whole-class discussion comprised a single chunk.

Step 5-6: Generating and Interpreting Results

We counted co-occurrences within each chunk as follows. If no EOs were coded, our matrix A remained unchanged. Otherwise, for each distinct pair of EOs (i,j) within a chunk, we updated our matrix A, increasing by 1 the entries in row i column j (A_{ij}) and row j column i (A_{ji}). For example, when Qh, Qneg, and PUG co-occurred within a chunk, regardless of the number of each code's occurrence, a 1 was added to $A_{Qh,Qneg}$, $A_{Qneg,Qh}$, $A_{Qh,PUG}$, $A_{PUG,Qh}$, $A_{Qneg,PUG}$, and $A_{PUG,Qneg}$. All distinct codes experienced by any group were counted as co-occurrences. Using this adjacency matrix, we generated a graph in which each vertex was an EO and weighted edges between EOs represented the pair's number of co-occurrences. Then, we analyzed the strongest connections visible in the graph for themes across chunks in which those connections appeared.

Results

The adjacency matrix and weighted graph, shown in Figure 1, identify which EOs (see Table 2) students experienced concurrently (RQa). We omitted from our graph those EOs not elicited or with no connections. 8 chunks had concurrent EOs, 5 chunks had a single EO, and 2 chunks had zero EOs. Several EOs co-occurred at least once, with Qh and Qneg exhibiting the most connections with other EOs (17 and 11, respectively). The graph highlights two prominent

	Qh	Qneg	NO	PUG	LIt	Qrv	NF	LIff	Qmult
Qh	–	3	2	2	3	2	2	1	1
Qneg	3	–	2	1	1	2	2	0	0
NO	2	2	–	1	1	1	1	0	0
PUG	2	1	1	–	1	2	0	0	0
LIt	3	1	1	1	–	0	1	1	0
Qrv	2	2	1	2	0	–	0	0	0
NF	2	2	1	0	1	0	–	0	0
LIff	1	0	0	0	1	0	0	–	0
Qmult	1	0	0	0	0	0	0	0	–

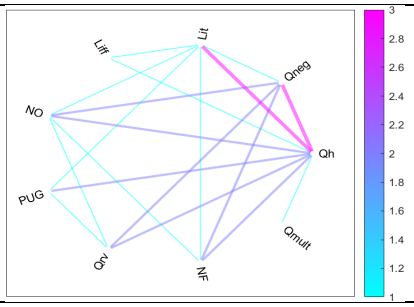

Figure 1. Our study's resulting adjacency matrix (left) and weighted graph of EO connections (right).

Table 3. All chunks where Qh, Qneg, or LIt co-occur. Gray rows indicate tasks reported on in this paper.

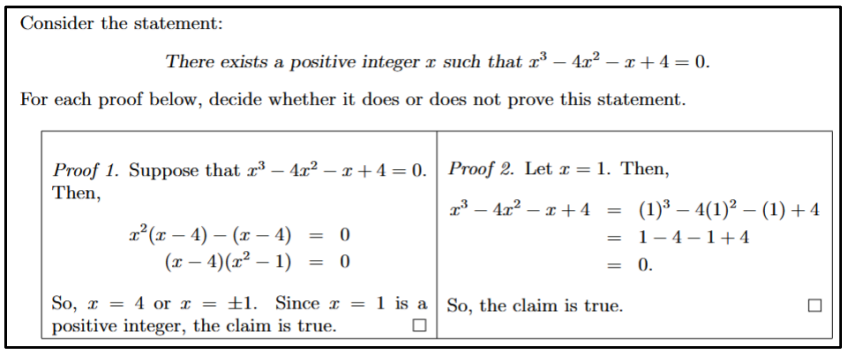
Class, Chunk	Task Name	Co-Occurring EOs
13, 3	Proof Comparison Task (PCT)	Qh, LIt, Liff
14, 4	Vector Multiplicity Task (VMT)	Qh, Qneg, NO, PUG, Qrv
16, 1	Types of Existence Proofs	Qh, Qneg, NF
16, 2	Proof Evaluation Task (PET)	Qh, Qneg, LIt, NF, NO
17, 1	Proving vs. Assuming Existence Task	Qh, LIt, PUG

connections that appeared within three chunks each: (a) hidden quantification and quantifying the negation (Qh-Qneg), and (b) hidden quantification and transforming an LI (Qh-LIt). The chunks and associated tasks in which Qh, Qneg, or LIt co-occurred are outlined in Table 3. We elaborate on results from the Proof Comparison Task (PCT), Vector Multiplicity Task (VMT), and the Proof Evaluation Task (PET) because they exemplify each prominent connection twice.

Proof Comparison Task (PCT)

In PCT (Figure 2), students considered whether two proofs did or did not prove the given existence statement. *Proof 2* is valid, but *Proof 1* assumes the existence of x: "Suppose that $x^3 - 4x^2 - x + 4 = 0$" implicitly means "Suppose *there exists an x such that* $x^3 - 4x^2 - x + 4 = 0$."

Every group's discussion about PCT was coded as Qh because students experienced difficulty unhiding the quantification of x in *Proof 1*. In the Triangle group, a student said, "If this was in the way of if-then, then *Proof 1* might not be correct because it started with the conclusion. Since it's a 'there exists,' it's fine. You just need to prove the existence." Because *Proof 1* began with the equation, she compared this to beginning a proof of an LI by assuming the conclusion. Whereas she understood this was a flawed approach to proving an LI, she believed it was acceptable when proving an existence statement. Another student said, "Yeah, I think they both work. Just, one of them gives you a single answer and the other gives you three answers." She distinguished the two proofs only in terms of how many "answers" were provided. Following group work, the instructor explained why the first proof assumed the existence of x. This prompted one student from the Rectangle group to ask, "Would it be possible to, like, reword it into, like, 'there exists an x such that if the equation equals 0… x =1 or something? [...] If you were to transform [PCT existence statement] into an implication, then, like how would *Proof 1*…would it still hold?" When the instructor observed that *Proof 1* would be a proof of the converse of the proposed LI, the student was surprised–prompting us to code the interaction as LIff. We also coded LIt because the student experienced difficulty attempting to transform the given statement into an equivalent LI.



Consider the statement:

There exists a positive integer x such that $x^3 - 4x^2 - x + 4 = 0$.

For each proof below, decide whether it does or does not prove this statement.

Proof 1. Suppose that $x^3 - 4x^2 - x + 4 = 0$. Then,

$$x^2(x-4) - (x-4) = 0$$
$$(x-4)(x^2-1) = 0$$

So, $x = 4$ or $x = \pm 1$. Since $x = 1$ is a positive integer, the claim is true. □

Proof 2. Let $x = 1$. Then,

$$x^3 - 4x^2 - x + 4 = (1)^3 - 4(1)^2 - (1) + 4$$
$$= 1 - 4 - 1 + 4$$
$$= 0.$$

So, the claim is true. □

Figure 2. The PCT from Class 13, chunk 3.

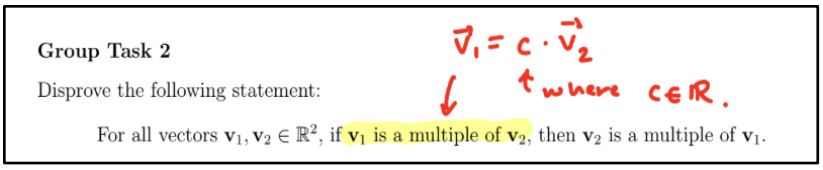


Figure 3. The Vector Multiplication Task (VMT), given during Class 13, Chunk 4.

Vector Multiplicity Task (VMT)

VMT is shown in Figure 3. Before students began work on this task, the instructor provided the definition of "v_1 is a multiple of v_2." Note that both the hypothesis and conclusion hide the quantification of a scalar c within their definitions. Moreover, c need not be the same value in each statement. Four groups arrived at the equation $v_2 = 1/c\ v_1$ and then spent significant time attending to this scalar; the Triangle group focused on recalling linear algebra concepts and never derived the equation. Of the four groups, two groups did not discuss c's quantification (coded Qh) or attempt to write a proof and two groups experienced difficulty attending to quantification of c in the conclusion (coded Qneg) while writing a proof.

The Circle group determined that a disproof entailed providing a counterexample.

Student 1: So since it says for all vectors v_1 and v_2, could we just find a counterexample? [...]

Student 2: Or you can do it specifically. v_1 equals like 〈1,1〉 and you multiply it by 2 …

Student 1: Yeah, or I guess you could say, like, so $v_1 = cv_2$, then that means $v_2 = 1/c\ v_1$ and since 1/c is not a real number… I mean it's a real number… but it's not like an integer.

Student 2: I think it's supposed to be that c is an integer, otherwise it would be true.

While discussing, the group's scribe wrote the statement and its negation symbolically (Figure 4). After solving $v_1 = cv_2$ for $v_2 = 1/c\ v_1$, they questioned whether $1/c$ was a valid multiple. There was no mention of c's quantification in either definition. Their inclusion of "where $c \in \mathbb{Z}$" for both the original statement and their negation (Figure 4) further corroborates that: (a) they overlooked the shift in quantification of c in "v_1 is a multiple of v_2," and (b) c's quantification remained unchanged in the negation. We also hypothesize that their writing, "where $c \in \mathbb{Z}$," seemed only to mimic that of the instructor's (Figure 3), and we conclude that the existential quantification of c remained implicit in the word "where" (coded Qh).

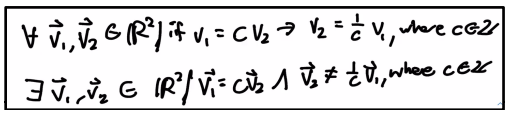

Figure 4. The Circle group's understanding of the VMT's original statement and its negation.

In contrast, the Rectangle group discussed the quantification of the scalar, which they called k. After identifying a counterexample wherein v_1 should be the zero vector, they noted $v_1 = kv_2$ when $k = 0$. However, they struggled with how to show precisely that v_2 was not a multiple of v_1.

Student 1: ...prove that v_2 times $1/k$ does not equal v_1 because… 1 over zero can't exist.

Student 2: Honestly, it doesn't have to be k.

Student 1: Well, it can be any letter.

Student 2: Well, the k has to be different. […]

Student 1: It'd just be $1/k$. Like you'd write, so you'd, like, let $kv_2 = v_1$ and then, like, you show that is $1/k\ v_2$ and let $k = 0$ and you prove that that doesn't exist. If k is 0, $1/k$ can't exist. You don't have to use two separate…

Student 2: But, I'm saying like it doesn't have to be $1/k$. It could be anything. […]

Student 1: Yeah, yeah, but I'm saying, like, the general case.

The group seemed to agree that they must show no scalar existed, but their understandings of "there does not exist" seemed to influence their reasoning differently; Student 2 understood it as "for all," whereas Student 1 seemingly did not. Instead, he viewed $1/k$ as addressing "the general case," perhaps because k was a variable. However, his focus on algebraic manipulation overshadowed his ability to operationalize the meaning of "there does not exist." We characterize this as Qneg, as Student 1's quantification of k in "v_2 is not a multiple of v_1" prevented his noticing that $1/k$ introduced a dependency that removed arbitrariness of the scalar.

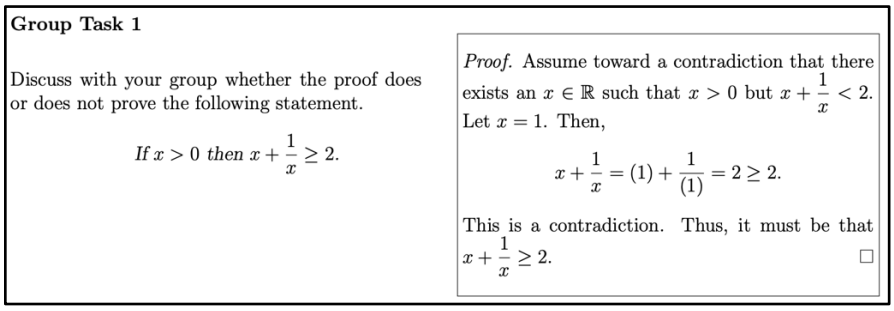

Figure 5. The Proof Evaluation Task, given during Day 16, chunk 2.

Proof Evaluation Task (PET)

PET (Figure 5), adapted from Shipman (2016), invites students to analyze a flawed proof by contradiction. The task is designed to perturb students' thinking regarding whether they can or cannot choose the value of a variable x when it is assumed to exist. When one assumes an x exists, its value is fixed, yet unknown. This stands in contrast to the logic of proving existence, wherein we may choose a specific x-value. Students experienced a variety of EOs when working on PET, but most notably our strongest connections, Qh-Qneg and Qh-LIt, co-occurred within this task. We note that only one group's discussion was coded as Qh with all others coded Qneg.

A student in the Square group began discussing saying, "'If P, then Q'… negation is, what, P and not Q?" The group agreed it was, and one student explained, "Yeah, so it's assuming the negation, then showing the negation is false, so the original statement must be true." In attending to the predicate of the negation (P and not Q), the group overlooked the quantification of x (coded Qh). With quantification hidden, they concluded the proof was valid.

In the Rectangle group, one student observed, "I feel like if you're assuming toward a contradiction that there exists an x-value then you can't give a constructive example…because there's nothing guaranteeing that the example you give is the assumed existing value." Another student questioned, "Are you allowed to use just one example or do you have to prove for all x-values?" expressing uncertainty about quantification (coded Qneg). Discussion then shifted to what statement the proof *did* prove. One student asserted it was a valid proof of the converse which prompted one student to disagree, and another to say, "That's the negation." They experienced difficulty transforming the LI to fit the logic of the proof (coded LIt).

Discussion

Our results revealed, via number of connections, the centrality of Qh and Qneg in the challenges students experience within instructional interactions on quantification. While we might expect Qh and Qneg to have a strong connection (as negating quantification requires unhiding it first), the equally strong connection between Qh and LIt was surprising. In the discussion that follows, we characterize students' ways of reasoning when the connections Qh-Qneg and Qh-LIt occurred (RQb).

For students to experience the challenge of quantifying the negation, they must first unhide the quantification. Therefore, because challenges are EOs only when they *persist*, students cannot experience both Qh and Qneg simultaneously. So, when Qh and Qneg appeared together, it indicated that, for some groups, quantification remained hidden, and for others, attending to quantification was challenging.

PCT was the only task discussed above in which Qh appeared without Qneg. Because all five groups experienced Qh, we conjecture that students' existing ways of operating on algebraic equations (solving for x), prevented them from noticing implicit quantification. In VMT, only those groups who attempted to write a proof experienced Qneg. Without reaching this stage, quantification of the scalar remained hidden. In PET, only the Squares experienced Qh, as they were focused instead on the logical structure of an LI and its negation. This finding echoes Norton et al.'s (2025) claims that one must conceptualize LI as a single object before they can attend to its quantification. All other groups were perturbed (coded Qneg) by the proof's use of a single example x=1.

Our Qh-Qneg analysis validates existing literature (e.g. Dawkins & Roh, 2020) that students still experience difficulties with quantification after unhiding it. Students' existing ways of reasoning also seem to impact students' abilities to unhide quantification, but the act of proof writing appears to assist students in attending to quantification.

The two tasks, PCT and PET, in which this connection appeared engaged students in determining whether a given (flawed) proof was valid. Each proof contained implicit quantification that perturbed students and, when hidden, resulted in their conclusion that the proof was valid. In the case of PET, those groups that successfully unhid quantification determined the proof was logically flawed. LIt was coded, during whole-class discussion in PCT and group discussion in PET, when students tried to determine a statement that the proof *did* prove.

Our analysis of the Qh-LIt connection suggests tasks that engage students in proof evaluation are effective in eliciting experience of Qh. And, when a proof is invalid, students have opportunities to analyze the logical structure of the proof to determine what, if anything, the proof does prove. This echoes a study by Hub & Dawkins (2018) who used proof evaluation tasks to elicit student reasoning in clinical interviews.

Conclusion

Our implementation of Antonides et al.'s (2025) methodology for mapping connections between EOs supported our identification of key themes in student reasoning. Hidden quantification was highly connected to all challenges experienced by students, and most strongly connected to Qneg and LIt. Analysis of these two connections revealed three key findings. First, students' existing ways of reasoning (e.g. algebraic reasoning and treatment of LI) influenced their ability to unhide quantification. Second, engaging students in proof writing assisted students in noticing quantification. Lastly, proof evaluation tasks in which quantification is implicit are effective in eliciting students' experience of Qh and in offering students opportunities to transform statements to determine the logical structure of a proof.

Studying co-occurring EOs highlighted nuances in students' reasoning and offers perspective on the challenges related to quantification documented in prior literature. Our study showed students' experience of hidden quantification was essential for them to have opportunities to experience other necessary challenges (e.g., Qneg and LIt). This finding suggests the importance of instructors' abilities to notice, elicit, and address head-on EOs during instruction.

Is Equivalence Just "Same Number"? College Students' Numerical vs Non-Numerical Conceptions of Equivalence

Claire Wladis
City University of New York

Alison Mirin
City University of New York

Benjamin Sencindiver
University Texas, San Antonio

As coursework extends beyond arithmetic, students encounter forms of equivalence beyond numerical equality. This study examines how college students characterize equivalence in mathematics generally, and specifically for equations and expressions. Responses from 198 students were analyzed and coded as numerical or non-numerical. Across questions, most responses appealed to numerical criteria, treating equivalence as equality to a single number, with higher prevalence of non-numerical criteria correlating with higher-level courses. We observed multiple variants of both numerical and non-numerical criteria, including converting algebraic expressions to numbers to justify equivalence. Findings highlight the need for educators to support students in distinguishing types of equivalence and their associated criteria.

Keywords: equivalence, equality, algebra, expressions, equations, solution set

Equivalence has been identified as a "big idea" in mathematics and is formalized via the notion of an equivalence relation (Charles, 2005; Cook et al., 2022; Siemon, 2022; Tay, 2019; Toh & Yeo, 2019). Student understanding of equivalence is crucial for their *inferential knowledge*–their understanding of the validity of mathematical procedures (Mirin et al., 2025). As students progress from arithmetic to algebra, and then to more advanced mathematics, they move beyond numerical equality and regularly encounter equivalence in many contexts, involving different types of objects and equivalence criteria. For example, equivalence criteria for algebraic expressions and equations go beyond determining whether two numbers are equal.

Here we consider students' characterizations of equivalence, both generally and in the context of expressions and equations—attending to the extent their equivalence criteria link to numerical equality or non-numerical equivalence. This provides insight into how students' criteria for the familiar notion of numerical equality intersect with their equivalence criteria in other contexts. Better understanding how college students conceptualize equivalence is critical to improving instruction that supports understanding of equivalence across mathematical contexts.

Equality and Equivalence in Mathematics

The terms "equality" and "equivalence" have been used in many ways in research and instruction (Asghari, 2019). To clarify the focus of this research, we define our use of this terminology (while recognizing that others might use terms differently). Here, we define *numerical equality* as a relationship where two objects are equivalent if (and only if) they are each equal to the same numerical quantity. Numerical equality is one type of equivalence relation where every equivalence class could be represented by a canonical element that is a single numerical value. Equivalence of numerical expressions (e.g., $6(2)$ and $9 + 3$) is one type of numerical equality. For example, one way to determine equivalence is to conclude that both $6(2)$ and $9 + 3$ can be represented by the canonical element, 12, of the equivalence class.

When equivalence involves something other than numerical equality—i.e., when it compares

objects that cannot be represented by single numerical values—we call this *non-numerical equivalence*. In algebra, students encounter non-numerical equivalence in the context of equivalent algebraic expressions and equations. Two *algebraic expressions are equivalent* if they are equal to the same numerical output for every domain input (i.e., for every possible combination of substitution of numerical values in for the variables; *insertion equivalence* [Zwetzschler & Prediger, 2013])[1]. For example, $3x - 2x$ and x are equivalent because they are equal for all x-values; however, neither $3x - 2x$ nor x are always equal to a single numerical value. Relatedly, two *algebraic equations are equivalent* if they have the same solution set; i.e., they have the same truth values for every possible domain input. For example, $|3x - 2x| - 2 = 12$ and $|x| = 14$ are equivalent because they are true for the same values of x (only $x = \pm 14$).

Before algebra, numerical equality is often the most prevalent type of equivalence.[2] As a result, many K-12 studies have investigated whether students conceptualize the equals sign from an *operational* (as announcing the answer to a calculation) vs. a *relational* (as describing an equivalence relationship) view (e.g., Kieran, 1981; Knuth et al., 2008; McNeil et al., 2006; Stephens et al., 2013; Stylianou et al., 2024); studies with college students show they may also hold operational views of the equal sign (Fyfe et al., 2020; Weinberg, 2010). However, much less research has explored how students conceptualize non-numerical equivalence criteria.

Some studies (e.g., Cook et al., 2022; Jones et al., 2012; Mirin, 2019; Tondorf & Prediger, 2022; Wladis et al., 2022; Zwetzschler & Prediger, 2013) have considered how students relate *transformational* activity (i.e., equivalent symbolic representations can be transformed into one another) or *substitutive* activity (i.e., equivalent symbolic representations can be substituted for one another) to other equivalence criteria that justify this activity (e.g., *descriptive* criteria: representations describe the same situation; *insertion* criteria for algebraic expressions). The literature on students' work with algebraic expressions and equations suggests that they tend to focus on transformation without attending to underlying descriptive, insertional, or other criteria that are a *reason* for the validity of transformation (e.g., Cook et al., 2022; Sfard & Linchevski, 1994). It is thus unsurprising that for many students view an equation's "solution" as the result of transformation rather than a property of the equation (e.g., Frost, 2015; Tsamir & Tirosh, 2023).

While there is substantial research on students' thinking on numerical equality, there is much less on non-numerical equivalence. What literature does exist has thus far tended to focus on describing types of equivalence that students attend to or invoke in specific contexts, such as while solving equations or transforming expressions (e.g., Cook et al., 2022; Tondorf & Prediger, 2022). Our work complements this by describing what students think "equivalence" means, how they characterize "equivalent expressions" and "equivalent equations", and by explicitly considering how this relates to numerical vs. non-numerical equivalence criteria.

Method

Open-ended items on equivalence were administered to 198 students at a U.S. community college in 18 different courses, ranging from developmental elementary to linear algebra. Courses also included statistics, discrete mathematics, mathematics for elementary teachers, intermediate algebra, precalculus, and Calculus I-III. We operationalized course level based on algebra prerequisites: "low" = no algebra prerequisite: "mid" = elementary algebra prerequisite; "high" = intermediate algebra prerequisite. Items were administered during class. Some students

[1] We note that, with *n* variables, the "inputs" involves *n*-tuples.

2 We note that non-numerical equivalence relations do exist in earlier grades (e.g., shape similarity or congruence).

were given all three questions (40), some only 1 and 2 (77), and some only 1 and 3 (81).

Q1. What do you think equivalence means in mathematics?
Please give an example or two to show what you mean.
Can mathematical equivalence mean anything else?
Circle one: *Yes* *No* *I'm not sure*
Please explain how you know.
Please give an example or two to show what you mean.

Q2. How could you check whether two mathematical **expressions** are equivalent?
(An expression is a mathematical phrase that does **not** contain an equals or inequality sign.)
Please give an example or two to show what you mean:
Are there any other approaches you could take to check whether two mathematical expressions are equivalent?
Circle one: *Yes* *No* *I'm not sure*
Please give an example or two to show what you mean:

Q3. How could you check whether two mathematical **equations** are equivalent?
(An equation is a mathematical phrase that **contains an equals sign**.)
Please give an example or two to show what you mean:
Are there any other approaches you could take to check whether two mathematical equations are equivalent?
Circle one: *Yes* *No* *I'm not sure*
Please give an example or two to show what you mean:

Six researchers collaboratively employed *reflexive thematic analysis* (Braun & Clarke, 2006). This led to the emergence of several themes, one of which was "equivalence as numerical equality vs. non-numerical equivalence relationship" (details of other themes are discussed in other work, e.g., Wladis et al., 2022c, 2022b). After themes were developed, they were used as the basis for generating a codebook for formal coding, including codes indicating whether students cited numerical equality (i.e., examples or explanations describing numerical equality criteria) and/or non-numerical equivalence (i.e., examples or explanations appeared to illustrate non-numerical equivalence criteria). Not all student work merited one code or the other (e.g., because of ambiguity). Some students showed evidence of both; thus, codes were not mutually exclusive.

Results

First, we consider frequencies indicating whether students, when asked to describe and give examples of what equivalence means in mathematics (Q1), provided examples of numerical equality and/or of non-numerical equivalence relationships (Table 1).

Table 1. General Equivalence Item (Q1) Results (subset of students given Q1 and Q3).

	course level				*p*-value		
Numerical equality vs. non-numerical equivalence	low	mid	high	total	mid vs. low	high vs. mid	high vs. low/mid
cited numerical equality	91%	87%	91%	89%	0.2491	0.6862	
cited non-numerical equivalence	0%	0%	14%	2%		0.0015**	0.0001***
n	37	62	22	121	$^{**}p \leq 0.01$; $^{***}p \leq 0.001$		

Roughly 9 of 10 students cited numerical equality in Q1, while only 2% referred to non-numerical equivalence (those that did were all enrolled in higher-level courses). Just because students did not volunteer non-numerical equivalence examples does not mean they can't provide them; however, these patterns do suggest that college students' primary equivalence associations may be numerical.

Conceptualizing equivalence as numerical equality was also common in response to Q2 (equivalent expressions) and Q3 (equivalent equations); coding frequencies are given in Table 2. We then proceed to characterize students' examples in more detail. Due to space constraints, we

illustrate just a few subcategories with a few brief examples of student work.

Table 2. Type of Equivalence Criteria Applied to Q2/Q3 (Some students provided more than one type.)

Numerical equality vs non-numerical equivalence criteria	Q2: expression item				Q3: equation item			
	low	mid	high	total	low	mid	high	total
numerical equality, arithmetic calculation	56%	41%	33%	44%	65%	34%	21%	40%
numerical equality, transform to numeric	44%	19%	56%	32%	20%	40%	50%	37%
other type of numerical equality	0%	22%	0%	12%	0%	9%	7%	6%
any kind of numerical equality	**94%**	**78%**	**89%**	**84%**	**80%**	**81%**	**79%**	**80%**
same solution set					0%	0%	7%	1%
transformation equivalence	6%	16%	22%	14%	5%	11%	0%	7%
other possible non-numerical equivalence	0%	3%	11%	4%	0%	4%	7%	4%
total possible non-numerical equivalence	**6%**	**19%**	**33%**	**18%**	**5%**	**15%**	**14%**	**12%**
"same solution" but ambiguous whether numerical/non-numerical					15%	2%	7%	6%
n (provided examples to compare)	16	32	9	57	20	47	14	81

Numerical Equality Criteria

Students attended to numerical equality criteria in different ways. In some cases students provided entirely numerical examples. Iota, a Calculus I student, stated for Q1 that equivalence means "when a answer is equal to each other", for Q2 wrote "we can substitute or solve the math expression and see if it is similar" and for Q3 wrote "solve the problem on both sides and if *they equal to each other* [emphasis added] they are equivalent". Figure 1 shows examples they gave.

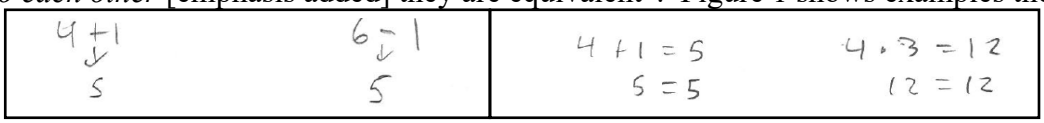

Figure 1. Examples given by Iota for Q2 (left) and Q3 (right)

In Q2, Iota gave numerical expressions with arrows to show numerical equality (Figure 1, left); whereas in Q3 they wrote $4 + 1 = 5$ and $4 \cdot 3 = 12$ and on the next line showed that the left and right side of each equation are equal. They write their work differently in Q3 vs. Q2, suggesting that they might view expressions and equations as different. Although it's somewhat ambiguous which objects Iota is comparing in Q3, their criteria for equivalence involves *comparing individual numbers*, suggesting a focus on numerical equality.

In some cases, students provided algebraic rather than numerical expressions or equations but then *converted* them to numerical values. Lambda, a student in elementary algebra, answered Q2 by writing "plug in numbers in the expressions" and then gave the examples shown in Figure 2.

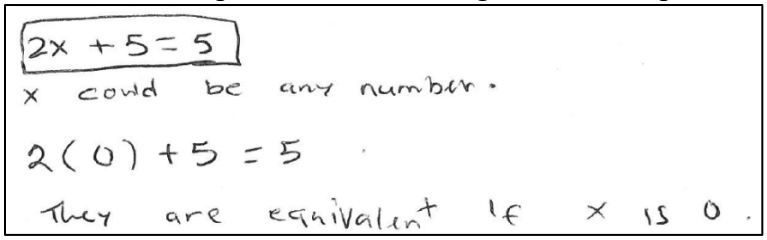

Figure 2. Examples given by Lambda for Q2

Lambda appears to have substituted a single value for x into an algebraic expression $2x + 5$ and, performed numerical calculation to demonstrate that $2x + 5$ is equal to 5 if x is 0. Although Lambda provided an algebraic expression, their demonstrated *criterion* for equivalence is

consistent with numerical equality because it involves comparing single numerical values. This example, though numerical, incorporates some aspects of insertional equivalence; they assess equivalence by checking that expressions are equal for a *particular* value of x. The extent to which Lambda might conceptualize the more generalized notion of insertion equivalence of algebraic expressions can't be determined from this answer alone. However, their focus on a single numerical value (vs. considering all values in the domain) does suggest that they may be more comfortable using numerical equality criteria over non-numerical equivalence criteria.

Some students seemed to impose numerical equality on algebraic expressions differently—by setting them equal to a fixed value (e.g., Mu, linear algebra student, Figure 3). In Q1, Mu stated "Two things are equal to each other. Whatever is on the left side is equal to the right side."

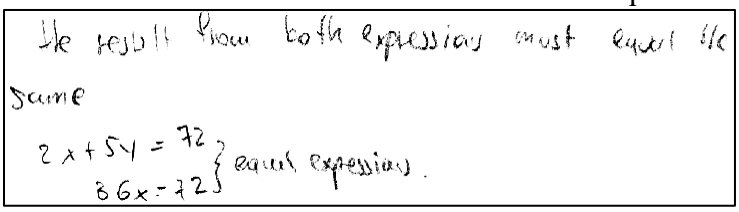

Figure 3. Example given by Mu for Q2

In Q2, Mu describes that the "result from both expressions must equal the same", and then they set two algebraic expressions equal to 72, calling them "equal". Like Lambda, Mu has taken two algebraic expressions and made them numerically equal, rather than considering how algebraic expressions represent larger sets of values and therefore are related by non-numerical equivalence criteria. As with prior students, Mu may be able to produce examples of non-numerical equivalence criteria in other contexts; however, their focus on setting algebraic expressions equal to a single number to illustrate equivalence suggests that they may be more comfortable with numerical equality criteria than non-numerical equivalence criteria.

When students answered Q3, they often talked about "solving" equations to determine equivalence, but it was also often ambiguous exactly which objects they were comparing. For example, one student in a combination intermediate algebra/precalculus course wrote for Q3, "You can check by solving the equations and see if they are equal to each other"; in this case, it is unclear what is "equal" (equations? x-values? solution sets?) and thus this response was coded as ambiguous. In other cases, there was evidence that students appeared to conceptualize equations as representing a single numerical value, suggesting an orientation around numerical equality criteria. Xi, a Calculus I student, wrote for Q3 "If they both add up to the same number" and then wrote the work in Figure 4.

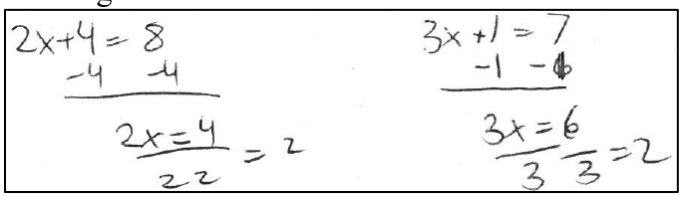

Figure 4. Example given by Xi for Q3

Xi solves two algebraic equations correctly, but their framing of equations "add[ing] up to the *same number* [emphasis added]", and their use of equals signs suggest a possible operational view of the equals sign, or even perhaps that the equations themselves are conceptualized as equal to the number 2 (it is ambiguous from their writing whether this is the case—taken together, this suggests a likely orientation towards numerical equality rather than non-numerical equivalence when considering the equivalence relationships between these algebraic equations.

Non-numerical Equivalence Criteria

While it was not always completely clear when students were using non-numerical equivalence criteria, we did observe various responses that suggested students may be attending to these criteria. For example, one student (Rho, in Calculus III) explicitly referred to equivalent equations having the "same solution set" in Q3 and provided the work given in Figure 5.

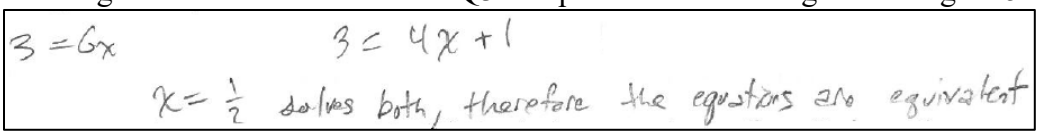

Figure 5. Example given by Rho for Q3

Rho uses the term "solution set" and provides the "solution" in equation form rather than representing it as only a single numerical value (e.g., like Xi in Figure 4). This suggests that Rho is using non-numerical equivalence criteria when considering the equivalence of equations, even though they, like other students, focus on a solving process that generates a single solution.

As expected, some students described *transformation* of algebraic expressions/equations as a type of non-numerical equivalence criteria. For example, Sigma, a student in a combined introductory algebra/statistics course, wrote in response to Q2 "find the value of each expression and see if they are the same value", giving examples in Figure 6.

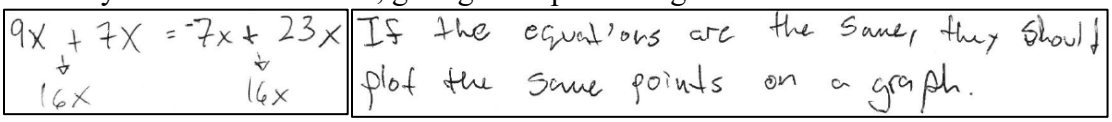

Figure 6. Sigma's Examples in Q2

Unlike students who converted algebraic expressions to numerical examples (e.g. Lambda, Mu), Sigma did not convert expressions to single numerical values; instead, for them, getting the "same value" appears to mean transforming expressions algebraically into the same algebraic expression representing a generic value (e.g., achieving the same "simplest form", $16x$, through transformation). While Sigma does not explicitly describe how these expressions have the same outputs for all the same inputs (i.e., non-numerical insertion equivalence for algebraic equations), they also provide a second example (Figure 6, right), describing "equations" as "plot[ting] the same points on a graph", which may be referring to insertion equivalence in the sense that $y = 9x + 7x$ and $y = -7x + 23x$ represent the same line (i.e., have the same solution set; i.e., $9x + 7x$ and $-7x + 23x$ have the same outputs for all the same inputs).

Some students illustrated another potential type of non-numerical equivalence criteria by describing equations as equivalent when they represent the same relationship, perhaps appealing to a type of descriptive equivalence (Figure 7).

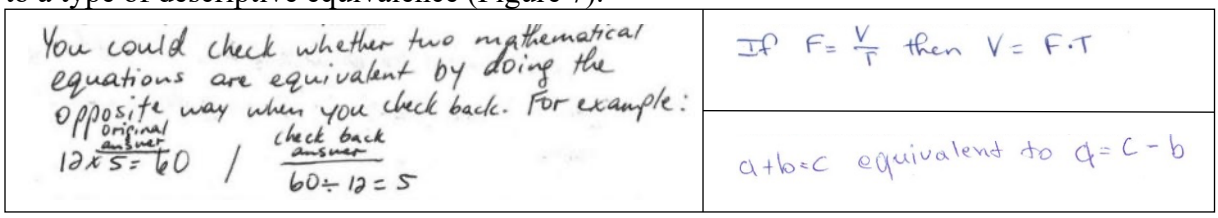

Figure 7. Examples of "Same Relationship". Upsilon (Q3, left), Phi (Q3, upper right), Chi (Q1, lower right)

Upsilon, an elementary algebra/statistics student, Phi, an elementary algebra/math for elementary education student, and Chi, an intermediate algebra and precalculus student, all provided examples of equations that appeared to represent the same "relationship" between the numbers/letters. While Upsilon provides arithmetic equations, we note that if they are comparing

the two equations ($12 \times 5 = 60$ and $60 \div 12 = 5$), their equivalence criteria (whether the numbers in the equation represent the same multiplicative relationship) are not about comparing individual numerical values. (As with other students, it is not completely clear which objects Upsilon is comparing—they may be comparing the numerical equality of the expressions 12×5 and 60 by performing division; however, their use of the term "equation" and similar patterns in examples given by Phi and Chi suggest that some students may be using this type of "same relationship" non-numerical equivalence criteria to determine the equivalence of equations, even if it is not completely clear whether Upsilon is personally making this comparison in this excerpt). Both Phi and Chi appear to be comparing equivalent algebraic equations where the equations represent the same multiplicative or additive "relationship" between the same variables. This type of criteria is not typically called "equivalence" in the curriculum, but it does represent an important non-numerical equivalence relation that could be productively leveraged during equation transformations. The work of these students may illustrate an opportunity for the mathematics community to consider alternate ways of characterizing certain types of equivalent equations using non-numerical equivalence criteria that some students may already be noticing. This could be a potentially productive route to explore for improving instruction.

Discussion

Across our sample, students predominantly described numerical equality criteria. The frequency of non-numerical equivalence criteria increased with course level; however, even in higher-level courses, numerical equality criteria still dominate. This occurred even in contexts where students were explicitly asked if equivalence could have other meanings, when they were asked specifically about equations and expressions, and when they themselves provided examples of algebraic expressions/equations. This is somewhat surprising, given the centrality of non-numerical equivalence (e.g., of expressions and equations) in algebra and beyond. On the other hand, the broad use of a single term, "equivalence", to describe different types of objects and criteria across the curriculum could lead to ambiguity in these distinctions for students. In particular, if existing instruction does not address the ways that the term "equivalence" is used to describe *different* equivalence criteria in different contexts, this may predispose students to try to make sense of all equivalence criteria under the lens of numerical equality (the one type of criteria that may be the most overtly addressed in existing curriculum and instruction).

One limitation of this study is that it asked students about their meanings for the term "equivalence". Although students encounter many examples of equivalence relations in the K–16 curriculum, the term "equivalence" may not always be used, and therefore, even when students recognize non-numerical equivalence relationships, they may not associate them with the term "equivalence". A helpful area for future research could be to investigate how students enact equivalence criteria in comparison to what they themselves call "equivalence".

This research demonstrates a critical need to explore more carefully how instruction shapes the development of student conceptions of non-numerical equivalence criteria, especially those for equivalent algebraic expressions and equations. In particular, it is important to better understand which kinds of instructional approaches support students in understanding the context-dependent nature of equivalence criteria, including distinctions among numerical expressions, algebraic expressions, and algebraic equations.

Verbalized Transformational Reasoning in Small Group Discourse

David Brown
Portland State University

Transformational reasoning is a powerful form of reasoning that can be leveraged during collaborative mathematical activity. However, little research has been done to investigate how transformational reasoning supports collaboration, if at all. Using Brown's (2025) framework for identifying verbalized transformational reasoning and Staats' (2021) poetic structure methodology, the present study sought to investigate how transformational reasoning supported students to collaborate. The results demonstrate that students spent the bulk of their time collaborating on a collective solution by warranting the operation(s) they envisioned transforming the objects.

Keywords: Transformational reasoning, poetic structures, discourse analysis

Inquiry classrooms provide many opportunities for students to engage in collaboration, which has been shown to improve student success. Verbalizing one's reasoning and building on others' reasoning is what drives collaboration. Researchers studying collaborative mathematical activity are interested in understanding how the individual's reasoning, once verbalized, contributes to the collective solution of the mathematical activity. Hence, analytical tools that allow the researcher to track the developing collaborative activity while remaining focused on the students' shared reasoning are needed. Staats (2021) makes the case that common discourse analysis methods "discourse away" the mathematical reasoning of the students (p. 1). To address this concern, she introduced a method of discourse analysis that focuses on student reasoning, called *poetic structures* analysis.

The term poetic structure comes from the work of the linguistic anthropologist Roman Jakobson (1960). Staats comments that in Jakobson's conception, "any time a repetition causes listeners to attend to the form of the statement, or to use the form of a statement to construct meanings, the poetic function of language is in play" (2008, p. 29). A poetic structure is a verbal repetition that involves "similar syntax and at least one word in common" between two phrases (Staats, 2021, p. 5). This definition provides other scholars with a means for identifying meaningful repetition that share mathematical ideas.

Staats (2008; 2021) argued that students communicating their reasoning is the foundation of understanding. Furthermore, "…if communication is a central process for mathematical learning, we must account for the linguistic processes that allow students to construct mathematical ideas" (Staats, 2008, p. 26). Repetition with similar syntax "allows a speaker to recognize an existing idea and modify it in a way that is concise and easy to understand" (Staats, 2008, p. 29). Hence, the use of poetic structures supports the researcher in tracking the ways in which various warrants evolve through conversation between individuals as a collective product is developed (Staats, 2021).

For this study I adopt a socio-cultural perspective of learning. A socio-cultural perspective of learning takes into account that classrooms are socially and culturally situated environments that are not removed from one's prior experience and not separate from one's peers. Coordinating the notions that communication is the foundation of understanding (Staats, 2021), and learning is actively participating in a community of practice (see Lave & Wenger [1991]), communication supports individuals to engage in authentic activity of the community in which they are seeking

membership. Furthermore, mathematics classrooms are micro-communities that approximate the mathematics community at large; students learn by becoming active *doers* of mathematics. This suggests that there are two intertwined processes that take place in the individual, a cognitive and a social component of their learning.

I conducted a multiple-case study to understand how transformational reasoning (Simon, 1996) supported students to develop a collective product. I coordinated Brown's (2025) framework for identifying and describing verbalized transformational reasoning with Staats' (2021) poetic structure analysis to understand how verbalized transformational reasoning was used by the students as they developed a collective solution. In this report, I will emphasize the cognitive component of transformational reasoning and demonstrate that the students' verbalized reasoning supported collaboration. As was evident in the ways in which various phrases were repeated and evolved into the collective solution that was produced.

Theoretical Perspective and Relevant Literature

Transformational Reasoning

Simon (1996) coined the term transformational reasoning to describe a type of mathematical reasoning that he noticed students were spontaneously engaging in, that resulted in the students coming away with a sense of how a model worked. Simon defines transformational reasoning in the following way:

> Transformational reasoning is the mental or physical enactment of an operation or set of operations on an object or set of objects that allows one to envision the transformations that these objects undergo and the set of results of these operations. (1996, p. 201)

This definition includes (a) an object (or objects) that is (are) being transformed, (b) the operation(s) that affect the object (or objects), and (c) results of the operation(s) on the object(s). The process of transformational reasoning involves identifying (a) and (b), which allows one to *envision* the transformation taking place, and once (c) is attained one can examine them together to draw conclusions about the entire process to understand why it works. Envisioning the operation(s) on the object(s) is what constitutes transformational reasoning, but the components serve as signals of it.

Scholars have studied transformational reasoning in a variety of math contexts. This scholarship demonstrates that transformational reasoning can support students to: (1) learn about rates of change (Carlson et al., 2002; Johnson, 2012), (2) identify the invariant algebraic properties in related rates problems (Engelke Infante, 2021), (3) ascertain evidence in both proving and proof-related activity (Brown, 2025; Harel, 2001; Harel & Sowder, 1998), (4) continually refine and generalize their arguments (Ellis, 2007), and (5) identify key ideas (Raman, 2003; 2004) for a proof (Zandieh et al., 2008). All of the research here supports the claim that transformational reasoning can foster the development of a deep conceptual understanding.

I studied five pairs of students engaged in different implementations of an inquiry-oriented mathematics task and sought to understand how transformational reasoning contributed to the collective math activity. Specifically, I investigated the following research question: *how does the use of verbalized transformational reasoning facilitate the evolution of the collective product of the students' mathematical activity?*

Methods

Context and Background

The data analyzed in this report come from the NSF-funded project, *ASPIRE in Math* (DUE# 1916490). The *ASPIRE in Math* project sought to support students in their transition to advanced math while also supporting instructors to shift to inquiry-oriented instruction. Among the project deliverables is a curriculum for the guided reinvention of fundamental concepts in real analysis. The curriculum development efforts were guided by the design theory of realistic mathematics education (Gravemeijer, 1994). The curriculum tasks take students step by step through developing a conjecture equivalent to the Intermediate Value Theorem (IVT), developing an approximation method to find roots of continuous functions, and then leveraging the approximation method to introduce concepts like sequences and convergence, among others (Larsen et al., 2022).

All of the data comes from two different public institutions in the Pacific Northwest; these included a research-focused public university and a community college. All of the participants were math majors or minors, and the names in this report are all pseudonyms. The data analyzed consists of videos of each of the pairs of students as they worked on a task, transcripts of the video, and Google Docs of the students' work.

For this report, I analyzed student work on the *fifth-degree polynomial task*, which states: true or false, every fifth-degree polynomial has at least one real root. Students were paired up and asked to justify their answer. The goal of the task is to generate a conjecture that is logically equivalent to the IVT. Often students will observe that the claim is true and justify it using algebra or calculus knowledge. First, the students may recall that odd degree polynomials have end behavior that tends to infinity in one direction and negative infinity in the other, so it must pass through the x-axis. Alternatively, students may use an algebraic approach that leverages factoring to identify potential complex roots in pairs. While both solutions are valid, the class proceeds with the end behavior argument since the goal is to reinvent the fundamentals of analysis.

Once the arguments have been generated, the teacher then works with the students to scrutinize the main components of the argument to tease out the IVT conjecture assumptions. After these activities, the teacher asks the students to write a claim in the form: If [blank], then f has at least one real root. One example of this claim is "if a function f is continuous with both a positive and negative output, then f has at least one real root".

The Cases

The overarching methodology used in this study is a multiple-case study (Yin, 2018). A case consists of a pair of students working on the fifth-degree polynomial task. The case begins when the students share their initial reasoning and ends when the focus shifts to writing a conjecture. See table 1 below for an overview of the cases.

Table 1. Description of the cases

Case	Student Names	Context	Date
1	Chloe & Gabe	Teaching Experiment	Summer 2018
2	Will & Kevin	Whole Class Teaching Experiment	Spring 2020
3	Shay & Justin	Introduction to Proof Class	Winter 2021
4	Andrew & Jovan	Bridge to University Mathematics	Winter 2022
5	Harriett & Josue	Introduction to Proof Class	Fall 2022

Poetic Structures Analysis

Staats (2021) details her methodology for identifying and describing poetic structures in transcript data. A poetic structure is a phrase that "shares syntax and at least one word in common" (Staats, 2021, p. 5). Repeated syntax may take the form of Subject-Verb-Object, or something similar.

In alignment with Staats' (2021) approach, I went through the transcripts line-by-line. In a spreadsheet I recorded (a) the line number, (b) current speaker, (c) phrase that I determined was a repetition, (d) line number of original speaker, (e) original speaker, (f) source of the repeated phrase, and (g) whether or not the repeat was internal or across talk turns. A poetic structure was only recorded if it was on the same topic, so repeats like "3 minus 2" and "4 times 8" would not be considered poetic structures (Staats, 2021). Each poetic structure was the longest stretch of talk that captured the idea the student expressed; this improved the validity in the analysis since it allowed me to capture more of the students' verbalized reasoning (Staats, 2021, p. 6). Staats notes that the method cannot be relied upon to identify all of the poetic structures present in the data, rather the goal of the method is to "value consistency over completeness" (Staats, 2021, p. 8). Lastly, I identified each poetic structure according to Staats' (2021) framework, with the addition of Brown's (forthcoming dissertation) poetic structure of *elaboration* (see table 2).

Table 2. Types of Poetic Structures

Type	Definition
List	Saying a pattern
Echo	Revoicing a short phrase to confirm listening or validate an idea
Comparison	Saying two things are associated
Contrast	Posing two things as alternatives
Interposed List	Two lists are collated
Consolidation	Two or more previous poetic structures are combined
Expansion	A previous phrase has a novel clarifying phrase inserted
Reversal	Two phrases switch places syntactically
General	Repetition mobilizes a prior comment without a distinctive structure
Elaboration	A previous phrase that gets repeated with some words replaced in order to clarify an idea

Transformational Reasoning Analysis

Once the poetic structures analysis was complete, each transcript was coded according to components of Simon's (1996) definition of transformational reasoning. My previous work (Brown, 2025) demonstrated the utility of operationalizing Simon's definition of transformational reasoning. I identified objects, operations, and outcomes. Objects were mainly nouns or pronouns that named or referred to mathematical objects. Operations were adjectives or verb phrases that indicated that the student had modified a mathematical object. Outcomes were most commonly in the form of a claim that included a reference to the object. Each instance of transformational reasoning was recorded in a memo along with a description of my model of the students' envisioning activity. The combination of objects, operations, outcomes, and the description of what a student may be envisioning constitutes (at best) a second order model of student thinking.

Final Steps

Once the poetic structures and transformational reasoning analyses were completed, I overlaid them to analyze how verbalized transformational reasoning was communicated via a poetic structure, if at all. Finally, I conducted a cross-case analysis to extract meaningful patterns in the ways in which the transformational reasoning was used to advance the collective product of students' mathematical activity.

Results

In this section, I will discuss the ways in which students used poetic structures when verbalizing or refining verbalized transformational reasoning as they developed a collective product. I begin by showing how the various components of transformational reasoning were expressed using poetic structures.

Objects and Outcomes

Of the three components of transformational reasoning, objects and outcomes are the most obvious for the observer to witness. Students often make statements about objects and in the claims that they make, one can find the outcome of their transformational reasoning. Objects were not a major component that needed to be negotiated in the fifth-degree polynomial task since the students were largely working with the object as a fifth-degree polynomial as a graph or an equation.

Outcomes were often unchallenged by the students. However, within a students' own explanation the outcomes were commonly rephrased utilizing a poetic structure. For example, consider Shay's (they/them) initial justification for the fifth-degree polynomial claim.

> It'll always have… it will always have at least one real root, because the two… because it's an odd degree. One end will always approach negative infinity and the other will approach positive infinity. So, it'll have to approach… it will have to cross zero at one point on the negative side.

Underlined above is the poetic structure that Shay used to *elaborate* on the meaning of having one real root. The single underline represents a "direct" repeat, and then the double underline demonstrates what was changed from the first sentence to the last. Shay's transformational reasoning likely involved mentally comparing several generic odd-degree polynomial graphs, where they focused on the tails of each graph and observed that one tends to positive infinity and the other to negative infinity. Then it is likely that Shay envisioned tracing a point along the curve. Shay's new outcome "it will have to cross zero…" indicates a shift in their thinking from "always have at least one real root" which likely resulted from envisioning the curve passing through the x-axis.

Similarly, in Will and Kevin's group, Will provided his intuition for the IVT by using a poetic structure to verbalize his transformational reasoning. Will says, "[The IVT] just basically says, if it goes two different places then it has to go to the place in between those two places". In this quote, the double underlined portion is an *expansion* poetic structure. Will expressed his intuition for the IVT as an IF-THEN statement. The transformational reasoning that he verbalized indicates that Will was imagining two points separated on a coordinate-plane. Then the operation "to go" indicates he likely envisioned connecting the two points as one would by drawing a graph on paper. The expansion poetic structure served the purpose of connecting not only his hypothesis to his conclusion, but the objects and operation to the outcome he envisioned.

As was discussed in the two examples here, the operation that one envisions transforming the objects plays a major role in explaining one's reasoning. In what follows, I will discuss how the operation was warranted through poetic structures.

Warranting Operations

Many of the conversations during the fifth-degree polynomial task involved articulating operations that transform objects. Here I will discuss two examples of pairs of students warranting a claim by making the operation they envisioned transforming objects explicit.

Chloe and Gabe were tasked with determining whether or not $p(x) = x^5 - x - 5$ has a real root on $[0,2]$. The pair began by seeking to factor the polynomial. Once that attempt proved fruitless, they shifted gears to graphing the polynomial. The pair proceeded as expected by evaluating the polynomial at integer values zero and one, followed by $x = ½$ and one of the teacher-researchers observed that the pair appeared to be seeking a sign change.

Teacher-researcher: So, you're just trying to see if the output is positive or negative?

Gabe: Right, to see if it crosses the, uh, x-axis.

Teacher-researcher: So, how would that tell you that it crosses the x-axis?

Gabe: For this one it gives insight into seeing what areas, like, if we see that, if we saw that this was positive [pointing with left hand to the y-intercept $(0, -5)$ and with the right hand to a location above the x-axis where $x = ½$] we'd be like, somewhere between here and here [moves hand from the location of $x = 0$ to $x = ½$ on the x-axis], oh it definitely crossed for sure.

Teacher-researcher: Mm, why's that?

Gabe: Cuz it's a continuous function and it's not just going to skip a chunk of the y-axis. So, it would have to cross the x-axis at some point.

There are a number of poetic structures in this short transcript excerpt. The most salient poetic structure to pay attention to is Gabe's elaboration in line 4 above (double underlines). Gabe elaborated on his explanation in line 2, after the teacher-researcher sought to ascertain the goal of Chloe and Gabe's activity. In line 4, Gabe expanded on the operation he envisioned as transforming the objects, but still he glossed over the hidden assumption. In line 5, the teacher-researcher probed Gabe's thinking further. This prompted Gabe to make the operation explicit: he was using continuity. Gabe's statement about continuity is an *elaboration* (dotted underline) given that he replaced the warrant from line 4 but kept the same conclusion. Importantly, the explication of this warrant proved to be a critical point in the students' activity, and it later showed up as a major warrant in their written argument.

Andrew and Jovan. The bulk of Andrew and Jovan's activity involved trying out different operations on fifth-degree polynomials and determining whether or not that operation preserved the fifth-degree polynomial. Consider the following exchange that occurs between Andrew and Jovan.

Andrew: Um, ok so like, if it's a negative 5th degree polynomial, that still has one real root, it's just on the opposite side of the y-axis.

Jovan: Yeah, it would just be going. It would start going down.

Andrew: Mhmm. It would begin going down, do your bumps [as he is speaking, he moves his right hand from left to right, and wiggles his fingers to indicate the 'bumps'], and then continue going in the direction it started, right?

Jovan: Well since it's odd, it would just be, instead of going up from left to right, it would be going… right? [While Jovan is speaking, Andrew draws a curve in the air with his stylus]

Andrew: Right, like the whole function would be coming from the top, squiggly squiggly, and then continue downward through the x-axis [as Andrew is speaking, he sketches the function he is imagining, doing the squiggles as he says squiggles, and showing the overall trend of the curve]. Or if it already was, it would just be downward, but at some point, it will cross…[[Andrew goes on to compare odd and even degree polynomials]]

Jovan: Yeah.

Andrew: So, a negative wouldn't change that…

Throughout this entire exchange, Andrew and Jovan are negotiating Andrew's operation of "negative". Andrew's transformational reasoning likely involved a series of transformations on different objects. For starters, it is likely Andrew appended a negative to the leading coefficient of some polynomial equation he was working with in his mind. Then, given his routine use of DESMOS in class, he likely plotted the equation he had in mind. Once he and Jovan began discussing the claim, it is likely Andrew then shifted to thinking of the graph as emergent, given the way he sketched the graph in the air and described the shape of the graph.

Jovan began by trying to warrant Andrew's operation by describing what he envisioned happened to the graph after operating on it via "negative". Andrew *expands* on Jovan's verbalization in line 3 by describing what he envisioned in terms of the outcome of the transformation. Jovan is still seeking clarification, and he now compares the shapes of fifth-degree polynomials to negative fifth-degree polynomials. Andrew's final *expansion* in line 5 of the excerpt satisfied Jovan's uncertainty, as evidenced by Jovan's "yeah" in line 6. The negotiation of this operation revealed the key point for Andrew and Jovan: that a fifth-degree polynomial has a real root whether its graph emerges up from the left to the right, or down from the left to the right.

Discussion and Conclusion

The findings presented above suggest that the teacher can anticipate that conversations about transformations of objects are likely to be a key part of mathematically productive collaborations. In terms of components of transformational reasoning, these transformations are what I referred to above as the operations. As the students collaborated on the collective solution to the fifth-degree polynomial task, they sought to warrant their belief by verbalizing the operation with which they transformed the objects. Gabe warranted that the polynomial was continuous. This was a pivotal connection with which Gabe and Chloe argued that a root existed. For Andrew and Jovan, the operation that Andrew expanded on allowed the pair to warrant that the fifth-degree polynomial claim was plausible at all.

Additionally, the findings suggest that a signal of successful verbalized transformational reasoning is actively connecting the claim to the observation of the outcome of the transformation that was envisioned. For example, Shay began by stating confidently that a root always exists, but through use of the operation "to approach", they were able to connect the claim to the definition of a root by stating that "it must cross zero". Despite the encouraging findings from this study, more research is needed to ascertain productive ways to support students to engage in transformational reasoning actively.

Acknowledgments

This work is part of the *ASPIRE in Math* project (NSF DUE #1916490). The opinions expressed do not necessarily reflect the views of the NSF. A great many thanks to my advisor Sean Larsen for his support on this project.

Examining the Self-Regulation Strategies of Students in a Developmental Mathematics Course

Peter Sassman
Northern Illinois University

Self-regulated learning (SRL) skills have been linked to academic success, particularly in developmental mathematics courses. This study investigates student SRL strategies in a developmental College Algebra course, taught using Inquiry-Based Learning (IBL) and supplemented with ALEKS. While SRL strategies have been investigated in a variety of contexts, research is lacking in IBL courses with ALEKS support. Data were collected from seventy-four students using open-ended surveys, which were used to answer the research question: What SRL strategies do students use in an IBL with ALEKS course? This was answered in three learning contexts: in-class, ALEKS time, and outside studying. Findings indicate that seeking social assistance and seeking information, especially from ALEKS were the most reported strategies, followed by note-taking and practicing problems. However, very few students reported using SRL strategies related to goal-setting and planning. This suggests that students may need more support in developing SRL strategies, such as through interventions.

Keywords: self-regulated learning, inquiry-based learning, ALEKS, developmental mathematics

Over the last few decades, there have been concerns about the college-readiness of students entering colleges and universities, including discussions on how to prepare students for university level mathematics. One of the principle ways to approach this issue is by including developmental mathematics courses in their catalog, which often have large enrollment rates (Chen, 2016). However, there is often a high withdrawal rate for the students in developmental mathematics courses (Adelman, 2004).

One vital component of student success in mathematics classes is students' ability to self-regulate their learning. Self-regulated learning (SRL) is the ability of a student to take an active part in their learning process, by setting goals and motivating themselves, using different strategies to complete their learning task, and reflecting on their learning and strategy usage (Zimmerman, 2002). Students with more SRL strategies have often improved in their mathematics scores (Kramarski & Gutman, 2006; Mevarech & Fridkin, 2006; Throndsen, 2011), while students who do not possess these SRL strategies often struggle more in mathematics courses (Bol & Garner, 2011, Isaacson & Fujita, 2006; Ley & Young, 1998; Zimmerman, 2002).

SRL interventions have yielded positive results, helping both improve students' SRL skills, as well as their mathematics scores (Bol et al., 2016). Another possible approach to improving students' SRL skills is by creating more active learning-based classes (McDonough & Sullivan 2008; Zimmerman 2002). For example, classes using a problem-based learning model showed increases in SRL skills (Blumberg 2000; Sungur & Tekkaya, 2006). This also connects with the university efforts to create more active learning-based mathematics courses, as the benefits of active learning have been well documented (e.g. Freeman et al., 2014).

One specific type of active learning model is known as Inquiry-based learning (IBL), where students are given investigative tasks that allow them to be engaged in the creation of important mathematics (Laursen & Rasmussen, 2019). Generally, in IBL classes students are practicing mathematics as a mathematician would. For example, creating and testing conjectures, making generalizations, providing justifications, and reflecting on their conclusions (Mesa et al., 2020). IBL generally involves student collaboration, where students work together to build their

knowledge, while the instructor facilitates the learning rather than being the sole source of knowledge. IBL has generally seen positive effects on academic achievement in mathematics classrooms, as well as reducing learning gaps for underrepresented students (e.g. Kogan & Laursen, 2014; Laursen et al., 2014).

Another common change universities are making is by implementing technology like intelligent tutoring software. A specific type of software that does this is Assessment and Learning in Knowledge Spaces (ALEKS), which has been used more in the last decade in mathematics courses (Cosyn et al., 2021). ALEKS provides examples and tutorials to students while assessing their understanding. Research on ALEKS has been mixed, with some research finding ALEKS was at least as good as a traditional lecture course (Sun et al., 2021) but some research finding ALEKS did not affect the passing rates (Childers & Lu, 2017). However, in mathematics classes, ALEKS seemed to have a more positive effect when used as a supplement to an active-learning style classroom (Boyce & O'Halloran 2020; Sun et al., 2021).

Theoretical Perspective

One prominent model of SRL is Zimmerman's (2002) model, which has three phases: the forethought phase, the performance phase, and the self-reflection phase (Zimmerman, 2002). The forethought phase includes analyzing the task at hand and motivating oneself to perform the task. Analyzing the task includes setting goals and determining specific strategies to accomplish these goals. Motivation includes self-efficacy, which is a student's belief in how well they can complete a task. Self-efficacy is often affected by the student's perceived skill level, outside factors like feedback from instructors or peers, and observing peers performing the task (Bandura, 1977). Motivation also includes intrinsic motivation, or how much the student is interested in the task and what they hope to achieve by completing the task.

The performance phase occurs during the completion of the task. This phase involves how a student completes a task, such as how they focus, the time they spend on the task, and the different strategies they use. The performance phase includes self-observation, where the student monitors their progress, tries different strategies, and changes or adopts them depending on their perceived effectiveness. Examples of strategies may be working with peers or taking breaks.

Once the task is complete, the self-reflection phase begins. In this phase, the student evaluates themselves, for example by comparing their task completion to the task standards. This also includes a self-reaction, where the student may feel satisfied with the task and adapt the new learning strategies or become defensive and not change their strategies. This then leads into and affects the forethought phase of the next task, completing the cycle.

This study sought to explore the SRL strategies of students in developmental mathematics courses. My research questions are: What self-regulated learning strategies do students use in an IBL with ALEKS course?. Specifically, (1): What self-regulated learning strategies do students use during the IBL class-time? (2) What self-regulated learning strategies do students use during the ALEKS homework time? (3) What self-regulated learning strategies do students use during outside-class time, not including homework?

Methods

The course studied is a developmental but credit-bearing mathematics course, College Algebra with Review, taught at a mid-sized, PhD granting university in the Midwest. This course has the same content as the regular College Algebra course but has more credit hours and therefore more in-class time. This extra in-class time allows students to work through the same content at a slower pace and alleviates some concerns about active learning requiring more class

time. The content of this course is basic algebra, coordinate geometry, and functions. The course description on the syllabus includes "[the] course is taught using Inquiry-Based Learning with a focus on collaboration". Instructors of this course are given advice by the course coordinator and materials to use during the semester, but the day-to-day activities and teaching methods are up to the instructor, allowing variability in the IBL with ALEKS implementation by class section.

Five instructors and their students participated; one instructor taught two sections and the others each taught one section. Students from all sections were chosen using self-selection sampling, where the participants could participate in a Qualtrics survey. This survey was administered after the first exam. The number of students participating in each section were: Section 1 (both sections from one instructor): 23 (28%); Section 2: 16 (41%); Section 3: 9 (23%); Section 4: 12 (30%); and Section 5: 14 (35%), for a total of 74 participants.

Data was collected using student questionnaires containing open-ended questions to provide in-depth understanding of the students' SRL strategies. The questionnaire was designed to avoid providing examples of strategies to the students. The questionnaire was designed around Zimmerman & Pons' (1986) structured interview, which was developed to assess students' use of SRL strategies, and included questions about the following categories of learning strategies: self-evaluation, organizing, goal-setting and planning, seeking information, keeping records and monitoring, environmental structuring, self-consequences, rehearsing and memorizing, seeking social assistance, and reviewing records. For this project, I am interested in the dichotomy of the class setup, where students learn with IBL in the class but have ALEKS software guide them for homework. Therefore, I modified the categories to include both in-class and ALEKS contexts to illustrate and shed light on these contextual differences.

I initially coded the responses from questions 1-3 using the modified Zimmerman & Pons' (1986) codebook. These questions were phrased by giving a context and asking students to write out their methods. For example, question 1 was "[The math course] has in-class sessions that may involve listening to the instructor, working on problems individually, collaborating in groups, or having whole-class discussions. What particular methods, if any, do you use to help you learn and understand the mathematics content during class?" Each participant response could receive multiple codes, including the same code multiple times, in the case participants described two different strategies that fit with the same code. As the responses were coded, the categories were split into a few different subcategories or codes, based on the student responses, and some categories were added. After completing the codebook for questions 1-3, questions 4 and 5 were then coded with the same codebook. Questions 4 and 5 asked more broadly about their study habits. For example, "Think about your general process of preparing for and studying for [this math course]. How do you prepare for and study for this class?". Therefore, the responses were generally longer and more complex but still ranged between one and five sentences. When coding questions 4 and 5, two extra categories were added.

Results

What SRL Strategies do Students use During the IBL Class Time?

Table 1 lists the frequencies of codes in relation to each question. Seeking social assistance occurred most frequently with 58 participants using at least one of the strategies in this category. The prevalence of the strategies focused on social assistance is consistent with the class structure, which emphasized collaborative learning. 40 participants described learning with their peers, which were coded as Peer-Learning or Peer-Seeking. Peer-Learning was used when participants described working with groups generally and often had statements concerning

collaborative learning. For example, one participant described this as "finding an answer and comparing it with another person, if we get different answers, then I solve using their method and see if it would apply better." The code Peer-Seeking was used on statements describing asking group members for help if they were struggling, such as "ask my group if I don't understand". With this mixture of codes, the participants appeared to be using the group work sessions both to get help from their peers, as well as for collaborating with others, suggesting students may use group work differently. In addition, 18 participants were coded with Instructor-Seeking and Tutoring-Seeking, with 16 and 2 participants respectively. This is consistent with the class style, as the instructor walked around during group work, providing help for groups.

Table 1. Codes and Frequencies

Category	Code	Q1	Q2	Q3	Q4-5	Total
Seeking social assistance	Peer-Learning	29	1	9	6	36
	Peer-Seeking	11	6	2	15	23
	Instructor-Seeking	16	0	3	20	29
	Tutoring-Seeking	2	3	2	7	11
Seeking information	ALEKS-Seeking	8	2	5	16	29
	Explanations-Seeking	0	39	0	10	41
	Notes-Seeking	6	11	0	27	32
	Video-Seeking	2	6	5	13	22
	Internet-Seeking	2	9	4	8	19
Keeping records and monitoring in class	Taking-Notes	19	0	0	5	22
	ALEKS-Notes	0	16	0	5	17
	Problem-Notes	0	5	0	1	6
Organizing	Summarizing	2	0	0	1	2
Self-Evaluation	Self-Evaluation	3	8	5	3	15
Rehearsing and memorizing	Rehearsing-Flashcards	1	0	1	0	2
	Rehearsing-Formulas	1	1	1	5	6
	Rehearsing-Problems	13	3	7	0	22
	Rehearsing-Steps	0	1	0	0	1
	Rehearsing-Review	2	0	8	10	14
Environmental structuring	Music-Structuring	0	1	0	0	1
	Library-Structuring	0	2	1	2	5
Reviewing records	Reviewing-Quizzes	0	0	4	6	9
	Reviewing-Notes	0	0	10	0	10
Goal-Setting/Planning	Goal-Setting	0	0	0	7	7
Effort Regulation	Effort-Regulation	0	2	0	8	10
	Paying-Attention	0	0	0	2	2

The next most frequent categories were Keeping records and monitoring in class (19), Seeking information (17), and Rehearsing and memorizing (17). The only code that was utilized in Question 1 was Taking-Notes. The category Seeking information had 17 instances, spread across four codes: ALEKS-Seeking (8), Notes-Seeking (5), Video-Seeking (2), and Internet-

Seeking (2), while Explanations-Seeking had no instances. However, Question 1 asked about in-class strategies, so it is possible that the students interpreted the question as asking about the course generally, rather than only their in-class activity. Finally, six participants were coded with Note-Seeking, where they described using previously made notes to help with their understanding, such as "[Using] notes from previous work, either in class notes or ALEKS".

For the Rehearsing and memorizing (17) category, four different codes were used: Rehearsing-Problems (13), Rehearsing-Review (2), Rehearsing-Flashcards (1), and Rehearsing-Formulas (1), with no participant being coded with Rehearsing-Steps. 17 participants described using practice problems to help with their understanding, such as "writing the same question repetitively and troubleshooting until I find a method that applies to each question.". This was the most common code, with only a few other participants using the other strategies.

The categories Summarizing and Self-Evaluation were coded to two and three participants respectively. Summarizing most likely referred to outside of class activities, such as "write examples/notes to revise later if I need to remember how to do something". Self-evaluation was only described twice, such as "Finding an answer and comparing it with another person, if we get different answers, then I solve using their method and see if it would apply better.". The four categories Environmental structuring, Reviewing records, Goal-Setting and Planning, and Effort Regulation were not coded to any participants.

What SRL Strategies do Students use During the ALEKS Work Time?

The category Seeking information was the most frequently used category of codes, with a 67 participants. The most common code was Explanation-Seeking, with 39 participants. This referred to the ALEKS showing explanations. Notes-Seeking (11), Internet-Seeking (9), and Video-Seeking (6) showed that participants were also referring back to their classroom notes or worksheets to help study and using the internet and video websites as well. While ALEKS helps explain topics and has videos, some participants were still using outside resources. Finally, ALEKS-Seeking was used twice, where participants used ALEKS more often than required.

The next most frequent category is Keeping records and monitoring in class, with 21 participants. With 16 participants making statements about taking notes while working in ALEKS, note-taking appears to have a similar importance to students as note taking in class, which has 19 such codes. This strategy also shows more involvement with the software, as those students are not only trying to solve the problems and read the explanations but trying to record important information. The second code is Problem-Notes, as six participants considered writing down the problem in their notebook to solve, a strategy to help them learn.

The category Seeking social assistance was coded for 10 participants. Seven participants were coded with Peer-Seeking or Peer-Learning, implying that some students work together on their ALEKS work. Three participants were also coded with Tutoring-Seeking. Eight participants also used Self-Evaluation strategies during their ALEKS time. For example, one participant described evaluating their work as: "[I] try solving an example problem on my own before looking at the answer". This strategy shows more involvement with self-guided learning, where the student is working through the problem themselves, and evaluating the work afterwards.

Rehearsing and memorizing had five participants coded, with three participants describing using more practice problems in ALEKS to study. One participant described writing out the steps to help, while another participant described writing down equations. This may imply students are focusing on working through the problems in ALEKS as strategies.

Finally, three and two participants respectively were coded in the category Environmental structuring and Effort Regulation. These focused on working in the library. The two participants

coded in Effort-Regulation described taking regular breaks from ALEKS. No participant was coded with the categories Summarizing, Reviewing Records, or Goal-setting and planning. While Summarizing and Reviewing Records may not be as relevant to ALEKS work, it was surprising that there were no mentions of Goal-seeking and planning. With the course requirements of three hours of ALEKS a week and a certain number of modules completed, setting goals seems like it would be a common strategy to be utilized.

What SRL Strategies do Students use During Outside-class, Non-ALEKS Time?

The category Rehearsing and memorizing contained seventeen participants, with the majority of codes being Rehearsing-Problems and Rehearsing-Review. The students described practicing problems to help them review. For exam 1, which was administered prior to this survey, the students were all given study guides covering review problems. Eight participants specifically described using these to help review, such as "I do the optional review work and check my answers with the key". One participant also described reviewing using flash cards, and another by writing down all the formulas multiple times.

Sixteen participants were coded with Seeking social assistance, with 11 students seeking peer support specifically. These included statements about study groups, such as "helping and explaining to a friend". The category Seeking information had fourteen participants, with relatively equal amounts of codes for using ALEKS, the internet, and online videos to review.

Fourteen students were categorized in Reviewing records. Ten students were coded with Reviewing-Notes, using their past lecture or ALEKS notes for better review. For example, one participant described using their notes by: "looking through the notes taken during class and retrying problems that I got wrong and seeing if I could get them correct", where their in-class notes were helpful, using the important problems they recorded. In addition, four students were coded with Reviewing-Quizzes, where they used their past quizzes and feedback to review.

Finally, five students were classified using the code Self-Evaluation. For example, this participant describes working through problems they struggled with, then assessing their work: "[I] write a question on a worksheet I struggled with and try to answer it without looking back at the worksheet". One student was also coded Environmental structuring, having studied in the library. Summarizing, Goal-setting, and Effort-Regulation were not described in question 3.

What SRL Strategies do Students use in an IBL With ALEKS Course?

The purpose of questions 4 and 5 were to help students provide strategies regarding goal-setting and planning, as well as giving them a chance to list more learning strategies they may have forgotten. Seven participants described goal-setting across questions 4 and 5, such as: "I work with my group outside of class on the assignment given to us for the next class at the library". Here, they had a goal of preparing for class beforehand, and planned study sessions with their group members to help be prepared when class starts. The category Effort-Regulation was described by 10 participants. For example: "I get up frequently and walk away from my computer, either to go outside or grab food to give myself a break". Two participants were also coded with the code Paying-Attention. For example, one participant wrote "I prepare [for class] by getting as much sleep as I can", which may help the student stay focused during class.

The category Seeking information saw higher rates of ALEKS-Seeking, Notes-Seeking, and Video-Seeking in questions 4 and 5, compared to questions 1-3. This implies that there are still a variety of sources students look to when the material is difficult, with their notes being a more common source, but also ALEKS and videos online. The most frequent category of SRL strategies is Seeking information. Using ALEKS to help with studying contained the most

substantial codes. Video-Seeking and Internet-Seeking had frequencies of 22 and 19 respectively. A similar number of participants (33) described using the notes they took, either in-class or during ALEKS, to help them study. Seeking social assistance was the next most common category, focusing on their peers, with 23 Peer-Seeking codes and 36 Peer-Learning codes. 29 and 11 participants were coded with Instructor-Seeking and Tutoring-Seeking respectively; thus, some students did seek out their instructors if they needed additional support. However, most of the codes involving asking the instructor for help were in Question 1, so it is possible the Instructor-Seeking occurred mostly during class.

Keeping records and monitoring in class, as well as Rehearsing and memorizing were the next most frequent categories, which was also described in previous questions. Rehearsing and memorizing focused mostly on using and practicing with practice problems (22), which is consistent with mathematics courses. 14 participants also described using instructor created exam review sheets. Although other strategies for memorization were listed (such as using notecards), they were only described by a few participants. Self-Evaluation was mentioned by only 15 participants. Most of these instances revolved around using ALEKS. Reviewing quizzes (9), Effort-regulation (12), Goal-setting (7), Environmental structuring (6), and Summarizing (2) had less frequencies compared to the other codes and categories. It was expected that Goal-setting, Environmental structuring, and Effort-regulation would have more instances, as the course had relatively strict requirements with ALEKS. However, it is possible that the participants did not consider these strategies or thought they did not apply based on the questions in the survey.

Discussion

Overall, the SRL strategies used by the participants matched the categories originally given by Zimmerman and Pons (1986). The most common SRL strategies used were Seeking social assistance and Seeking information, focusing on ALEKS and online sources. The strategies of taking and reviewing notes from lecture and ALEKS were also commonly used strategies, as well as practicing problems to help with memorization. However, other memorization strategies, as well as the SRL strategies of Self-Evaluation, Organizing, Environmental structuring, Goal-Setting, and Effort-Regulation were not utilized by many participants. Instead, participants seemed to be focusing on strategies to learn the in-class material and using ALEKS for practice. This also connects to the issue that students did not describe many goal-setting strategies, even when prompted, which is an integral part of the SRL cycle. This may suggest that the course structure is beneficial for the Performance Phase of Zimmerman's (2002) cycle, but students are struggling with the Forethought Phase. However, this might be addressed by incorporating literature on goal setting, such as weekly goal-setting journals (Bol et al., 2016).

One limitation is that the survey was administered close to the start of the semester. This is the time students are still getting used to the course, have just completed their first exam. Therefore, after getting their exam scores, students may reflect on their study strategies and adapt as the semester goes on. As the in-term exams are the largest assessments students receive (outside of the final exam), students may not have been focusing much on the Self-Reflection phase. In this case, all of the students' feedback came from ALEKS and smaller weekly quizzes, so they may not have been evaluating their general study habits, and instead focused on smaller issues they were having with specific content. This could also explain some of the issues with goal setting described above; that is, it is possible students may have started adding more goals after evaluating themselves after the exam. It would be beneficial to do more research specifically on goal-setting in this style class, or to see if any of these SRL strategies change throughout the semester.

This paper explores findings from a quasi-experimental study, focusing on the implementation and impacts of an innovative corequisite mathematics intervention. Conducted in a large U.S. community college, the study is evaluating the impacts of the Statway Corequisite course on student outcomes compared to the business-as-usual statistics corequisite course. Preliminary analyses show positive student outcomes in courses using the curriculum. The paper investigates the extent to which key implementation fidelity components are associated with those outcomes. These components include the use of a contextualized curriculum designed to be relevant to students, incorporating student collaboration in online and in-person classes, and addressing the social-emotional and academic needs of students. Understanding the impact of these components on student outcomes has implications for the design of corequisite mathematics coursework.

Keywords: Corequisite, fidelity of implementation, mathematics curricula, social-emotional learning, pedagogy

This paper focuses on understanding the implementation and impact of an innovative corequisite mathematics intervention in a large-scale quasi-experimental study. Conducted in a large U.S. community college, the goal of the study is to evaluate the impacts of the Statway Corequisite course on student outcomes and to understand the implementation components that relate to those outcomes.

Background

Over the last two decades, evidence has shown that structural changes such as math pathway implementation and corequisite model adoption have helped more students advance to, and succeed in, college-level math than traditional models of developmental remediation (e.g., Jenkins et al, 2021). That evidence has led to many states, including Tennessee, Texas, Louisiana, and California, championing corequisites in their developmental education strategies and to many colleges incorporating multiple math pathways for students to earn college math credit (Education Commission of the States, n.d., Hodges et al., 2020).

Statway Corequisite is a statistical reasoning curricular offering developed by Carnegie Math Pathways (CMP) at WestEd. It is designed as a one-term college-level course with a corresponding corequisite support course that aims to accelerate students through a college-level statistics course in a single semester. The college component of Statway Corequisite covers the learning outcomes of standard introductory college statistics courses, supporting both in-person and online formats. The foundational concepts and skills needed for success in the college-level lessons are included in the corequisite component (e.g., percentages, simplifying expressions, probability, etc.). Statway Corequisite combines a contextualized curriculum grounded in real-

world application with an active, collaborative learning approach and student supports that help build learner mindsets and a sense of belonging.

Statway Corequisite instructional design is based on research on teaching for understanding and the development of mathematical practices (Bransford, Brown, & Cocking, 2000). The Statway Corequisite pedagogy emphasizes productive struggle with challenging problems (Schmidt & Bjork, 1992); making conceptual connections explicit (Hiebert & Grouws, 2007); deliberate as opposed to routine practice (Ericsson, 2008; Pashler, Rohrer, Cepeda, & Carpenter, 2007); opportunities for rich mathematical discourse (Moschkovich, 2007); and collaborative learning in promoting mathematical sense-making (Esmonde & Langer-Osuna, 2013; Webb, 2009).

Statway Corequisite Design Principles

The design principles for Statway Corequisite approach to curriculum, pedagogy, and student supports include the following:

Students feel that the course has value. Many students who have struggled with math often question the value of mathematics in their daily lives and long-term goals. Statway Corequisite is designed to help students see this value through a curriculum that includes relevant contexts that students see as personally engaging (Hulleman & Harackiewicz, 2009). Given the curriculum's emphasis on relevance and engagement, instructors are discouraged from introducing other, more traditional materials and approaches. In implementing the course, the focus is on depth into core ideas and skills rather than coverage of the full curriculum.

Instructors engage students in collaborative group work. Modeled after typical mathematics lessons in Japan (Shimizu, 1999), the instructional approach relies on small group, collaborative work within the four phases of a Problem Cycle: The Problem Launch to prepare students for productive struggle, Working the Problem in small groups, Discussing the Problem to make public students' thinking, and Conclusion to highlight the key concepts drawn from student thinking. The Problem Cycle provides a structure for instructors to facilitate group work by preparing students for collaboration and bringing ideas together that surface during the collaborations. Students collaborating in groups is key to this approach and is often an indicator of its use. The online version of the course requires students to meet synchronously to collaborate on the lessons' problem situations. Student interactions throughout the online lessons and debriefs are recorded and shared with the instructor, who then responds accordingly.

Students demonstrate Productive Persistence, or the combination of tenacity and good strategies. Research has shown that psychological aspects such as mindsets, "grit" or passion, and perseverance for long-term goals, self-control, and engagement are important predictors of academic achievement (Dweck, Walton, & Cohen, 2014). Statway Corequisite's approach supports these non-cognitive factors through a collection of Productive Persistence activities and routines, including a growth mindset writing activity, a contract activity to develop a sense of belonging, supports for forming groups to strengthen student ties, and instructor email routines that foster a sense of community.

Framing Fidelity of Implementation

Program fidelity is typically defined as "how well an intervention is implemented in comparison with the original program design" (O'Donnell, 2008, p. 22). The level at which a program is implemented with fidelity is often related to the results (Hill & Erickson, 2019). Various frameworks for fidelity exist in literature (e.g., O'Donnell, 2008; Century et al., 2010; Bos et. al, 2023), with most rooted in the five factors proposed by Dane and Schneider (1998):

Adherence to the intended program, exposure to the program, quality of delivery, program differentiation between conditions, and student responsiveness to the program.

For this project, we focused our definition of fidelity on the elements of the course related to its design principles, roughly aligning them with Dane and Schneider's framework elements of adherence, student responsiveness, and program differentiation, as summarized in Table 1. Assessing the quality of delivery was outside of the scope of the project. Elements of exposure, such as students engaging in Productive Persistence activities, overlapped with adherence and were not analyzed separately. In addition, since the focus of the curriculum is depth, not breadth, traditional indicators of exposure, such as the number of lessons completed, do not directly apply. For **adherence**, we focus on the teachers' implementation of the course design principles: (1) the primary curricular resource used is Statway Corequisite, designed to be relevant and valuable to the student population; (2) whether or not teachers use group work, and (3) whether or not teachers teach the Productive Persistence lessons that designers designated as essential. **Student responsiveness** focuses on whether students report the math class, as implemented, being relevant, and whether they show improvement in non-cognitive outcomes related to productive persistence. As well as being a fidelity indicator, improvement in non-cognitive outcomes is also a secondary outcome measure of the full study. Student responsiveness would also include whether students engaged in collaborative work, which is being measured in adherence. **Program Differentiation** looks at what is the same or different between the treatment and control conditions for the key elements of fidelity. We will look at similarities and differences in the curricula taught, rates at which teachers' use group work, differences in students' report of math class relevance, and differences in students' non-cognitive outcomes.

Table 1. Fidelity of implementation of the Statway Course.

Fidelity factor	Key components		
	Students feel that the course has value	Instructors engage students in collaborative work	Students demonstrate productive persistence
Adherence	Teacher uses Statway	Teacher uses group work	Teacher teaches required productive persistence activities
Student Responsiveness	Students report math class is relevant	[See Adherence]	Students' non-cognitive outcomes improve
Program Differentiation	Difference of curricular materials Difference in students' report of math class relevance	Difference in rates teachers implement group work	Difference in students' non-cognitive outcomes by condition

While student responsiveness and program differentiation are important, this paper focuses on describing the fidelity in terms of adherence, with the presentation also including treatment impact analyses using adherence fidelity as a moderator.

Methods

Study Context

This fidelity of implementation analysis is set within the context of a large-scale quasi-experimental study of the impact the Statway Corequisite course has on student outcomes, such as grades and persistence. The research team partnered with a large community college system in the Southwestern United States and spanned eight academic terms. The study team collected baseline data on students' prior math achievement and demographics, and course-taking outcomes (grades, credits). In addition, the team collected data outlined in the "Methods" section to assess fidelity of implementation, non-cognitive student outcomes, and to understand other contextual factors.

Results of the quasi-experimental design (QED) study, with a sample of over 1,800 students, indicate that students in the treatment course, in comparison to business-as-usual students, earned higher course grades (ES = 0.51, $p < 0.001$); were almost 50% less likely to earn a grade of D, F, incomplete or withdraw from the course (DFWI) compared to business-as-usual ($p < 0.001$); and, though non-significant, were about 20% more likely to complete the course. (Walters et al., in press). The current paper explores fidelity components that may have led to these promising results, with the presentation also examining whether the treatment impact varies by level of fidelity.

Study Design

The preliminary quasi-experimental analysis was conducted with 1,861 students (771 in Statway and 1,090 in business as usual) across multiple campuses of a large community college system. This paper focuses on adherence fidelity components directly under teacher control, which applies only to the treatment teachers in the main sample. The research questions are:

- To what extent is Statway Corequisite implemented with adherence fidelity?
- Does the treatment impact vary by the level of adherence fidelity?

Analysis related to the second question will be included in the presentation.

Teachers were chosen as a unit for analysis because we did not see meaningful variation from term to term with respect to the fidelity components. The sample for fidelity analysis included 17 treatment instructors, where 10 taught in person and seven taught both in person and online. Each instructor taught up to three sections each of the eight study terms. Class sections varied between three and 18 students, with a total of 49 in-person sections and 14 online sections.

Over the course of each study term, all teachers were asked to complete logs and then complete a post-term survey at the end of the term. Most, but not all, teachers of in-person sections were observed one time each term and interviewed soon after the observation. Teachers of online sections were interviewed in the second half of the term. At the end of the study, all treatment teachers were asked to complete a fidelity survey. In addition, treatment students' online platform usage records were collected for all but two terms.

Data Sources

The data sources are detailed below. Unless otherwise noted, treatment and control teachers completed both using the same protocol.

Instructor Fidelity Survey. This survey was administered to treatment teachers after the completion of other study activities. Teachers were asked the percentage of course materials used

that were Statway Corequisite, if group work was used, and which Productive Persistence activities (e.g., email routines and forming groups) they implemented in their classroom.

Post-Term Instructor Survey. The post-survey was administered at the end of each semester and included questions about teaching practices, such as the use of small groups.

Instructor Logs. Logs were administered six times in the fall and spring semesters and four times in the summer terms, approximately every two weeks. Log questions included how often students worked in small groups. Responses were averaged for each teacher and each term that they taught a study course.

Observations. Trained researchers observed classes during all semesters, excluding the short summer terms. They observed each teacher's in-person class at least once over the course of the study and often once within each term they taught. The team coded the observations using the Toolkit for Assessing Mathematics Instruction – Observation Protocol (TAMI-OP), a matrix covering a variety of teacher and student behaviors in the classroom divided into two-minute intervals (Hayward, Laursen, & Weston, 2021). The two main indicators of fidelity were the percentage of class time in which the variables "WG" (Working in groups on structured group work) and "OG" (Other group activity, such as a Think/Pair/Share) were coded.

Interviews. Most teachers participated in one interview a term. Interview topics included describing a typical lesson, differences between a typical lesson and the observed lesson, any modifications made to the curriculum, and any social-emotional lessons taught.

Course Usage Data. Usage data from the online homework platform included records of which students attempted college and corequisite exercises. The number of exercises attempted per student for the college and corequisite components was then averaged for each teacher and term.

Fidelity Measures

For each adherence fidelity component, teachers' implementation was rated as "Meeting Standards" or "Not Meeting Standards," as specified below. In rare instances, interview data were used to adjust ratings if there was strong evidence of meeting or not meeting the metrics. The metrics for meeting standards are:

Uses Statway. Reported on the Fidelity Survey, that 90% or more of the course materials were Statway course materials, and, on average, students completed 20 or more Statway exercises per term. If usage data are unavailable for all terms a teacher taught, the rating is based on the Fidelity Survey.

Uses Group Work. Meets three or more of the metrics in Table 2 below. Using multiple measures helps to account for missing or inconsistent data.

Table 2. "Uses Group Work" Fidelity Metrics

Fidelity Metric	
Online	In Person
Fidelity Survey: On a 3-point scale, teachers reported students working in groups "Occasionally" or "Regularly."	**Observations:** Group work codes WG and OG comprised 25% or more of the observation class time. **Logs:** On average across responses, teachers reported students spending 25% or more of class time working in groups.
Logs: On average across responses, teachers agreed or strongly agreed, on a 4-point scale, that "The majority of my students are consistently engaged [while] working in small groups."	
Post-Survey: On a 4-point scale, teachers reported students working on math problems together in small groups, "Most of my classes," or "Almost all of my classes."	

Teaches required Productive Persistence activities. Reported on the Fidelity Survey, teaching three of the four required Productive Persistence lessons.

Findings

All treatment teachers' implementation met metrics for at least one adherence fidelity component, with all but two teachers (92%) meeting metrics for two or more adherence fidelity components. However, roughly half of the treatment teachers' implementation met metrics for all three adherence fidelity components. Metrics indicate a higher percentage of in-person teachers implemented each fidelity component than online teachers, though the percentage difference is minimal (2% – 7%). There were also high rates of meeting fidelity metrics across all adherence fidelity components, with the total percent of teachers meeting metrics ranging from 75% to 88%. These results are summarized in Table 3.

As mentioned above, the main study's findings indicate students have stronger positive outcomes in the treatment course as compared to the control course, likely due to the implementation of these three adherence fidelity components: using the Statway curriculum, using group work in lessons, and teaching the required Productive Persistence lessons. Additional analyses incorporating these components into the analytic model will be included in the RUME presentation.

Table 3. Teachers meeting fidelity metrics across the sample

		Fidelity component			Number of fidelity components		
		Uses Statway	Uses Group Work	Teaches Required PP Lessons	One or more	Two or more	Three or More
Online	N Meeting	5	5	6	7	6	3
	% Meeting	71%	71%	86%	100%	86%	43%
In Person	N Meeting	15	13	15	17	16	10
	% Meeting	88%	76%	88%	100%	94%	59%
Total	N Meeting	20	18	21	24	22	13
	% Meeting	83%	75%	88%	100%	92%	54%

Implications

The positive QED findings, coupled with the high rates of fidelity of implementation, indicate the key components of the treatment course are likely related to positive student outcomes. Beyond the adoption of this particular course, this has implications for improving all corequisite mathematics courses. Use of curriculum with problem contexts designed to be relevant to students increases interest and engagement, while also helping students connect mathematics use to their lives, to their studies, and future goals. Incorporating collaborative learning strategies that foster mathematical discourse, give students' voice and agency, and provide opportunities to build habits of mathematical reasoning. Practices and routines that promote safe and supportive group learning nurture students' sense of belonging in the classroom, helping them to productively struggle and persist through the course. Addressing all are important for improving student outcomes (Huang, M., 2018).

More broadly, this study demonstrates the importance of measuring fidelity in large impact studies. Without such data, it is impossible to understand the factors that may contribute to an intervention's success and can be used to scale the intervention in other contexts.

Conclusion and Next Steps

This study demonstrated positive student outcomes associated with the Statway Corequisite course, likely due to the course design and use, incorporating student collaboration in online and in-person classes, and addressing the social-emotional and academic needs of students. Additional work will investigate fidelity components related to student responsiveness to confirm and uphold the results from adherence. Program differentiation will be analyzed to further confirm and illustrate any meaningful differences between the treatment and control implementation.

Artificial Intelligence and Cognitive Demand During a Domain and Range Mathematics Task

Victoria Delaney
San Diego State University

Lily Sawi
San Diego State University

Sunday Stein
San Diego State University

Ryan Aniceto
San Diego State University

This study examines students' cognition during high demand mathematics tasks when an AI tool is available. Using video recordings, we analyze 20 undergraduates' cognitive demand on a task involving a nonroutine roller coaster application of domain and range. Our findings show wide variability in how students approach the task, how and how often they elected to use ChatGPT (half chose to use it, half did not), and the levels of cognitive demand that students exhibit in their solutions and thinking. Students that solve the task with high demand tend to grapple with its nonroutine aspects and challenge AI output, while students that solve with low demand give decontextualized prompts, struggle to use AI output, and/or trust AI despite hallucinations. We discuss implications that undergraduate mathematics researchers and educators might consider to preserve opportunities for students to experience high demand problem solving.

Keywords: Domain and range, cognitive demand, AI in education

Artificial intelligence (AI) tools are becoming commonplace in higher education. Although the notion of using computers to support, transform, or even replace mathematical thinking is not new (Kaput, 1992; Pea, 1985), AI tools present a new frontier for teachers and students as they can mimic human reasoning at most stages of problem solving. Prior and recent works that have studied AI in mathematics education have reached varying conclusions. For instance, AI can serve as a helpful scaffold when used deliberately (Yoon et al., 2024) and in ways that preserve human demand for thinking. On the other hand, AI tools can stunt learning opportunities when students use them in ways that disable their ability to master mathematics on their own (Bastani et al., 2024). Regardless, findings from these works suggest that ignoring the impact of AI tools on students' thinking and learning opportunities will pose serious detriments to researchers and mathematics practitioners. It is our goal to draw attention to this phenomenon by studying the nature of students' mathematical thinking when AI tools are made available to them.

Examining how students think with AI tools matters because AI prompting is a cognitive activity. When querying an AI chatbot, a student must *envision* what it is they need to know and write a query that will likely generate the information that they need to reach resolution (Subramonyam et al., 2024). At present, we lack research that details the extent to which students (a) engage with mathematical envisioning as they create AI prompts, and (b) how the presence of AI impacts their own cognition as they reason mathematically on demanding tasks. This study addresses both of these gaps. Using video analysis and attending carefully to students' thinking during AI interactions (e.g., Stein & Delaney, 2025), we observed 20 undergraduate students solve high demand tasks when given access to ChatGPT. We ask, *what is the nature of the cognitive demand when students solve a nonroutine mathematics task with AI?*

Theoretical Framework

We examine the changes in cognitive demand during a mathematics task and the interactions between students and AI throughout its enactment. Stein and colleagues refer to a *mathematics*

task as "activity, the purpose of which is to focus students' attention on a particular mathematical idea" (*note:* we omit the "classroom" aspect of their definition as our study was conducted with individual students) (1996, pg. 460). Historically, mathematics tasks have been considered in the context of what students are expected to produce with a given set of resources (Doyle, 1983). AI tools may potentially change this conception, since they function as general-purpose cognitive resources that remove the need for focused student attention, depending on how they are used.

High demand tasks have functioned as a primary source from which students can learn (Shavelson et al., 1986). These tasks demand cognitive processes, such as identifying key information and activating prior knowledge that is useful for constructing solutions (Doyle, 1983). *High cognitive demand tasks* require students to make conceptual connections, generate nonalgorithmic solutions, and consider multiple solution strategies (Boston, 2012; Stein & Smith, 1998). Again historically, technologies have influenced mathematical activity and cognition, including the cognitive demand of tasks (Hollebrands, 2003; Sherman, 2014). However, technologies' potential to mediate student learning has been contingent on students' knowledge about how to use them productively toward the task's goals (Delaney & Kinsey, 2021). As students can use AI tools without sophisticated knowledge of how they work, it is not yet known if, for whom, and to what extent AI tools will influence students' cognitive demand as they solve rigorous math tasks.

Methods

Four researchers with expertise in undergraduate lower-division mathematics education and AI tool integration designed and collected data for this project in spring 2025. Our goal was to investigate the nature of students' mathematical thinking and reasoning when ChatGPT-4o was made available to solve a mixture of closed-form and non-routine questions. The questions were given to students in three separate 20-minute tasks. In this paper, we analyze 20 students' responses to one component of the algebra task (see Figure 1), and the ways in which students' uses of ChatGPT impacted the cognitive demand of the task as they solved it.

We recruited students via physical campus advertisements. To participate, students needed to have taken a mathematics course in the past 12 months to reduce the likelihood that they would be completely unfamiliar with the tasks' mathematics concepts. We also collected information about students' academic year, major, and undergraduate math courses. We recruited from a variety of majors, and 9 of the 20 participants were not explicitly STEM students, although some listed 4-5 math intensive courses on their screener survey. They studied biology, geography, liberal studies (2), marketing, business management, economics, food/nutrition, and psychology.

During a 10-minute pre-task interview, one researcher asked participants additional questions about their typical AI use on school assignments, beliefs about AI, and the extent to which their instructors demonstrated or encouraged AI use in their courses. A detailed account of students' AI beliefs and practices can be found in (Delaney et al., 2025). Following the pre-interview, each participant was instructed to "think aloud" as they solved the math tasks on an iPad screen that recorded their responses temporally. A lead interviewer reminded students to think aloud, asked open-ended questions (e.g., "what are you noticing right now?") during problem solving, and assured participants that we were primarily interested in studying their thinking and reasoning. A second researcher managed video and audio recordings, kept time during the sessions, and took field notes that captured instances where the student appeared to be grappling with the mathematics. We concluded with a post-task 10-minute debrief.

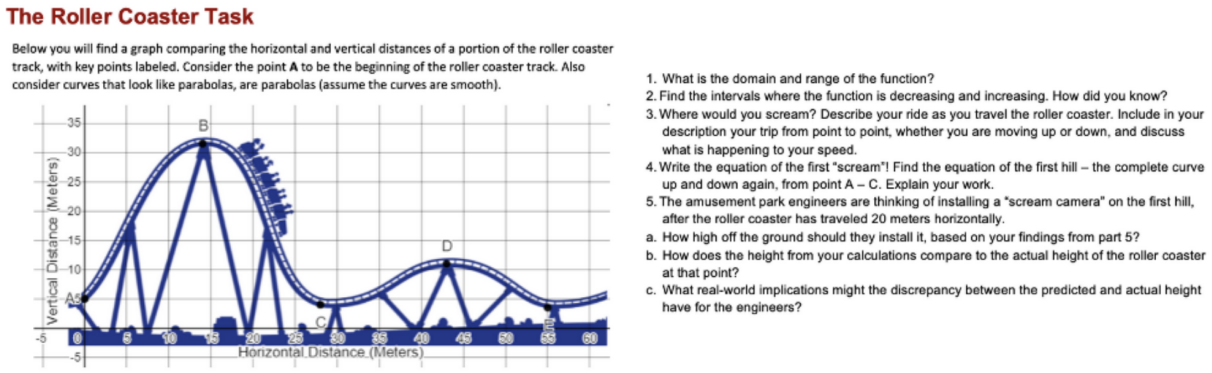

Figure 1. The roller coaster task, adapted from the Virginia Department of Education.

Data Analysis

We focus on the domain and range subcomponent of the Roller Coaster task because it is a routine question (*"What is the domain and range of the function?"*) with a nonroutine solution. We conjectured that if students maintained the cognitive demand of the task, they would attend to the ambiguous right-side of the graph (a high demand feature), which continues despite a fifth point labeled "E" at around (4, 55). We further hypothesized that students' *in situ* experiences with roller coasters would enable them to reason about its domain and range holistically, rather than anchoring on canonical domain/range representations and processes from math courses.

The first and second authors analyzed the Roller Coaster task video recordings (Derry et al., 2010) of each student using the Mathematics Task Framework (Boston, 2012; Stein & Smith, 1998). We contextualized the Mathematics Task Rubric to the Roller Coaster task, first solving it ourselves and mapping students' solutions to definitions from the original framework (see Table 1). We individually rated students' cognitive demand as they gave their solutions, noting that some students experienced higher levels of cognitive demand as they were thinking about domain and range compared to their demand as they wrote down their domain/range solution. After giving our initial ratings, we collectively compared ratings, discussed our interpretations with respect to the framework, and resolved disagreements. For example, we determined criteria for "complex, nonalgorithmic thinking" and reviewed the ratings we gave iteratively to ensure that we were interpreting them consistently. Once initial agreement was reached and ratings stabilized, the first author reviewed all ratings one final time to check for internal consistency.

Table 1. Cognitive demand rating of the roller coaster task, adapted from the Mathematics Task Rubric

Definition	Domain Definition and Example	Range Definition and Example
0 - Not applicable *Guessing, non-math thinking*	Guessing without procedures or mentioning previously learned domain facts, rules, definitions.	Guessing without procedures or mentioning previously learned range facts, rules, definitions.
1 - Memorization *Reproducing previously learned facts, rules, or definitions.*	Reproducing previously learned values for the domain. ***Example:*** "I would say negative to positive infinity…it was 100% on the AP Calc test."	Reproducing previously learned values for the range. ***Example:*** "I can remember from high school…range just keeps going, unless it ends at zero."

2 - Procedures without Connections *Focused on correct answers without connecting to underlying meaning.*	Finds values for the domain without connecting to underlying meaning or ambiguity of where the track ends. ***Example:*** "So the domain is like the x, so it goes from 0 to 60 meters."	Finds values for the range without connecting to underlying meaning or grappling with multiple local nonzero minima. ***Example:*** "The range is the y, so it goes from zero to…34? 32.5? This is the maximum, it's not quite 35."
3 - Procedures with Connections *Procedures for the purpose of developing deeper levels of understanding of mathematical concepts.*	Reasons about domain by connecting to ambiguity about where the track ends. ***Example:*** "...Assume it starts at zero, there's a closed endpoint …and it goes up until 60? 55? I'm going to say infinity, because it goes on with nothing else."	Reasons about both range values (starting and ending) in the context of the graph's min. and max. ***Example:*** "It looks like the lowest point is at 5 meters, and the highest is at the peak, point B, which looks like 32 meters. So yeah, 5 to 32."
4 - Doing Mathematics *Complex, nonalgorithmic thinking, use relevant knowledge and experiences.*	Reasons about the domain in the situated context of a roller coaster. ***Example:*** "It says consider point A to be the start. But the track has to connect with this, eventually, come around to point A."	Reasons about the range in the situated context of a roller coaster. ***Example:*** "B is the highest peak on the graph. There could be a higher peak beyond there, but at least on this graph, the peak is 33."

Findings

Students' strategies, ChatGPT uses, and cognitive demand varied drastically. Most students spent 0:30-4:00 minutes solving for domain and range, although some grappled with its meaning for 4-10 minutes and one aerospace engineering student spent all 20 minutes on it. Figure 2 shows students' cognitive demand, the time they spent, and whether or not they used AI. Table 2 shows students' written responses to the task, if they used AI, and how many prompts they used. Completely coincidentally, 10 students used ChatGPT and 10 did not.

*Table 2. Students' written solutions to the domain and range portions of the roller coaster task. Students who chose to use ChatGPT are listed in the left two columns with number of prompts given in parentheses. *Indicates STEM.*

Student (no AI)	Written Solution	Student (used AI)	Written Solution
Student_1	D: $(-\infty, \infty)$, R: [5, 30]	Student_4 (1)	D: n/a, R: $3 \leq y \leq 32$

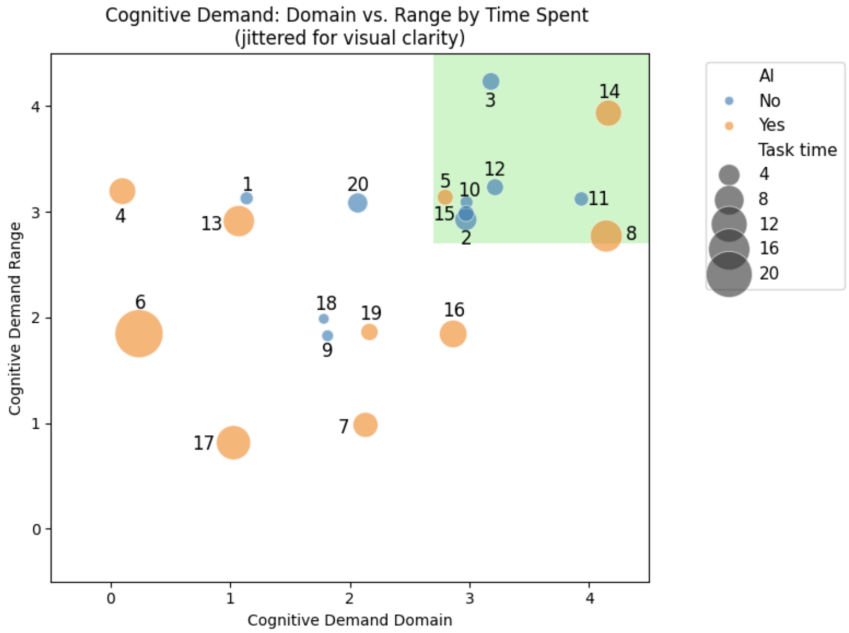

Figure 2. Cognitive demand (domain and range), time spent solving, and AI use of 20 student participants. The numbers in the figure indicate the student ID number (as listed in Table 2).

High Cognitive Demand

9 of 20 students maintained high cognitive demand for both domain and range (a 3 or 4 on the Mathematics Task Rubric, Stein & Smith, 1998), indicated by the green shaded region in Figure 2. A majority of these students (6 of 9) did not use ChatGPT to assist them with domain and range. Rather, they tended to remember what domain and range were and had ideas about how to apply them in the novel roller coaster setting. If they did use ChatGPT, it was typically a single prompt to remind themselves which axis domain or range corresponded to (e.g., Student_14 prompted, *"Does range measure the y axis?"*). They noticed at least one discrepancy between the plotted points (A-E) on the roller coaster track, the track visually continuing beyond the figure boundaries, and they generated questions pertaining to the domain's ambiguity about where the track ended (and *if* it ended). To illustrate, Student_8, a business management major who first used ChatGPT to recall domain and range concepts, said:

> "But you can see it continues this way. But [*in the problem statement*] it says consider point A to be the beginning of the roller coaster track. But this (*gestures to the track*) has to connect to the beginning eventually…come around to point A. So this makes me think that the domain is all real numbers. But at the same time, a roller coaster is not infinite."

Here, Student_8 explained her struggle to find a reasonable endpoint for the domain of the roller coaster. She knew it could not be positive infinity, because the roller coaster "has to connect eventually", yet she was uncertain what number would make sense, apart from numbers

visualized on the graph itself, which could not be the domain's endpoint because the roller coaster continued past them. The nature of her struggle showed high demand thinking (level 4, doing mathematics) because she grapples with non-algorithmic solution strategies, such as attempting to visualize the rest of the non-infinite roller coaster.

Student_8 and others struggled to generate a reasonable endpoint for the roller coaster's domain. As shown in Table 2, students created one of three responses: 55 (the x-coordinate of point E), 60-63 ("some point beyond 55"), or positive infinity, even though many students who wrote ∞ stated aloud that the roller coaster could not go to infinity. Student_16, a mechanical engineer, explained this discrepancy in terms of how she would approach it in her major:

> "I know that the roller coaster does not go on forever, but I have no information to suggest where it will end. So I mean, in the context of engineering, if this goes on for…65, 60 meters of it, and it's a 1000-meter roller coaster, you theoretically would consider that infinity, because it's so much higher. But I just don't have that information."

Low Cognitive Demand

11 of 20 students solved the task with low cognitive demand for domain, range, or both (typically it was domain - see Figure 2). Of these 11, 5 were STEM majors and 6 were not, suggesting that students with more math exposure through coursework did not appear to solve the task while maintaining higher cognitive demand than their non-STEM peers.

Students who solved with low cognitive demand tended to not grapple with the situated ambiguity presented by the roller coaster. For instance, Student_18 (an electrical engineering major) spent only 39 seconds on the task, reading the graph and immediately declaring, "So the domain is x, and it goes from 0-60 meters. The range is y, and it goes from 34? 32.5 meters. Because this is the maximum." He did not explain where 60 meters came from, but rather scanned the graph and selected domain values (level 2, procedures without connections). Student_13 (a biology major), on the other hand, spent almost nine minutes puzzling about the domain, before concluding, "Am I allowed to guess on this? My guess would be from negative infinity to infinity…it was 100% on the AP Calc test…if you were given a parabola and had to determine all these things about it." (level 1, memorization).

7 out of 11 students used ChatGPT to solve the task, but only three used it in ways that led them to generate a high demand answer for either domain or range (Student_4 and 13 for range, and Student_16 for domain). The others, and in particular Student_6, Student_17, and Student_7, struggled to obtain helpful information about the task via time intensive back-and-forth interactions with ChatGPT. Their struggle to use ChatGPT productively originated from one of three potential causes. First, they did not know how to make use of the information ChatGPT gave them, because it gave generic facts and examples about parabolas' domains and ranges in response to students' generic questions (Student_13's prompt: "determine domain and range on a parabola."). Student_13 struggled to relate ChatGPT's hints about utilizing a function in vertex form, to the roller coaster, which did not give a function equation:

> "It gave me the equation of a parabola, then it put it into vertex form…and then h and k is the vertex…And then it tells me the domain, based on, plugging in x and getting any real number. I mean, it's kind of clarifying, but I don't have the, like, function for it."

Other students, such as Student_7 (a food and nutrition major), interpreted ChatGPT's hints incorrectly. Student_7, reading from ChatGPT, inferred that domain is, "where it starts and where it finishes," but applied this definition in such a way that she obtained two answers, "and I

want to say that the domain would be x=5 and x=10." Her response reflects an understanding that a domain is discrete values, which she explained came from ChatGPT's illustrative example.

Finally, although hallucinations did not appear to occur frequently, Student_17 struggled when ChatGPT gave her negative range values after she prompted it with a screenshot of the roller coaster from the task. Student_17, a liberal studies major, realized that the graph visualization did not contain negative values, but did not know how to prompt ChatGPT in such a way that it would produce positive range values:

> (*reading AI output*) "y is the line that goes up and down, from the lowest point to the highest, drops as low as -5 meters and climbs to 35 meters. (*stops reading*). No it doesn't. Because, right here (*points to B, vertex*), looks like it's maybe 32. So, wrong, incorrect."

However, Student_17 was unsure how to find the domain and range absent a visually logical response from ChatGPT. After about 9 minutes and eight prompts, she resigned, "Okay, I'll just say what it tells me" (see Table 2), even though she suspected that ChatGPT's response was incorrect ("I don't know what -5 has to do with it") and had her own emerging ideas about how to find the range without AI (" *positive*) five is on this line, at the same place as zero").

Discussion

Consistent with prior work that has studied technology as a mediator of cognition (e.g., Hollebrands, 2003; Sherman, 2014), our findings suggest that AI tools do not, in many cases, deterministically lower or raise cognitive demand. Rather, how students solve the task depends on how they interpret it, construct prompts that bridge their understanding with what they need to learn, and evaluate AI output in response to the task's goals. Importantly, we observed that evaluating AI involved students' willingness and ability to challenge ChatGPT as a technological form of authority. Student_8 did so successfully, using it to remember domain and range then moving toward the demanding, ambiguous aspects of the task herself, while Student_17 did not, writing down ChatGPT's incorrect solution as her own even though she did not agree with it.

What students wrote down as their domain/range solution did not unilaterally represent their thinking during the task. Many students, for instance, did not know how to turn "this roller coaster cannot go on forever" into a domain statement even though they exhibited high demand thinking. Furthermore, ChatGPT did not tend to provide clarification because it gave canonical parabola domain examples that did not apply to the roller coaster. Rather than follow up with prompting that alluded to a need to *envision* a roller coaster as a function (Subramonyam et al., 2024), students with low demand thinking translated ChatGPT's generic output into ideas they believed were usable, often subverting qualities that made the task high demand in the first place.

These findings hold implications for the undergraduate mathematics education community. First, we hope that our findings illustrate that some students need to learn how to use AI tools productively to solve problems by becoming more attuned to their own sense-making and discernment. Second, educators must help students learn how to navigate open-ended, ambiguous problems, particularly as AI tools become more accurate in solving routine math problems (Pardos & Bhandari, 2024). Finally, as our study was conducted with individuals outside of any course they were enrolled in, future work should explore the nature of students' cognition and AI use within courses, where their AI use habits may have a stronger impact on their grades and eventual career trajectories. Future work might also consider how to design student-AI interactions, particularly with frontier AI models that students use on a regular basis, so that student thinking is amplified rather than automated.

Examining Novice and Experienced Programmers' Use of Python in a Combinatorial Context

Rebekah Kuss
Oregon State University

Elise Lockwood
Oregon State University

We explore the use of computational tools and techniques to enrich student's combinatorial reasoning by contrasting novice and experienced programmers in their exploration of combinatorial tasks in the context of Python. Drawing upon Lockwood's model of combinatorial thinking, we present data from interviews with students who were engaging with Python modules designed to help students solve counting problems. We contrast pairs of students who had different levels of prior experience with coding, and we highlight the experienced coders' solution that reflects how their experience with coding arose in their combinatorial solution.

Keywords: combinatorics, discrete mathematics, computing, programming.

Introduction

The use of computational tools and techniques has long supported mathematical activity (e.g., Papert, 1980), and there have been recent calls for studies that explore the role of computing in enriching students' mathematical reasoning (e.g., Geraniou et al., 2024; Lockwood & Morken, 2020). There is a growing body of work that highlights the potential of computational settings and activities to support student's mathematical thinking in a variety of contexts (e.g., Buteau et al., 2019; Sinclair & Patterson, 2018). In this report, we seek to add to this literature by contrasting novice and experienced programmers in their exploration of combinatorial tasks in the context of Python. The work in this report contributes by illuminating some aspects of programming that more experienced programmers may draw upon in such contexts.

Literature and Theoretical Perspectives

Counting Processes, Sets of Outcomes, and Formulas/Expressions

To characterize what we mean by combinatorial thinking, we draw on Lockwood's (2013) model of students' combinatorial thinking, which includes three main components of counting processes (the processes one engages with in solving a counting problem), formulas/expressions (the numbers, variables, and operations that often give the answer to a counting problem), and sets of outcomes (the set of objects being counted by a counting problem; the cardinality is the solution to the counting problem). In this model and in subsequent work, Lockwood and others (e.g., Soto et al., 2022) have made a case for the value of giving students experiences to connect counting processes they employ with the sets of outcomes those processes generate. It is desirable to us for students to make connections among these components, and the use of the computer is a motivation to foster connections between counting processes and outcomes.

Notably, in some prior work we have explored students' programming in the context of counting problems (e.g., De Chenne & Lockwood, 2022; Lockwood & De Chenne, 2020), but such work has focused mostly on novice programmers with no prior programming experience. Some work has examined an experienced coder with no combinatorial experience (De Chenne & Lockwood, 2023), but we have not yet reported on such tasks with students who had both combinatorial and coding experience. There is a need in this literature for more insights into the work of what more experienced coders bring to these combinatorial tasks.

Programming and Machine-based Computing

In this report, we focus on *machine-based computing*, as defined by Lockwood and Morken (2021): "the practice of developing and precisely articulating algorithms that may be run on a machine" (p. 405). We are interested in approaches that foreground the development of an algorithm as opposed to only its performance or implementation. In our study, this machine-based computing was programming, which entailed both creating code and editing existing code (in alignment with Weintrop et al., 2016). In the context of coding, we conceive of the programs as representing counting processes (in the sense of Lockwood 2013), as they are representative of the process of generating outcomes. The output that the computer then generates from that code represents the sets of outcomes. This is in line with other work (e.g., De Chenne & Lockwood, 2022; Lockwood & De Chenne, 2021) that has connected the computer to components of combinatorial thinking and activity in this way. We seek to answer the following research question: *What kinds of computational activity did experienced coders engage in as they solved counting problems in a computational context?*

Methods

Data Collection

The work described in this paper was part of data collected during a whole-class implementation of materials involving Python in the context of combinatorics. We developed a set of modules in which students engaged with Python and solved counting problems. These were implemented in a classroom setting of an upper-level mathematics course designed for pre-service teachers (the second author was also the instructor for the course). The modules covered six 80-minute class sessions, and they began with an introduction to Python and progressed to increasingly advanced combinatorics problems. The entire class worked through the modules, and we video- and audio-recorded two pairs of students for those six sessions. In those recordings, we both recorded the students as they worked, and we recorded their screens; we spliced together those inputs for analysis. As they worked in pairs, the instructor and another researcher would occasionally check in on how they were doing and would ask questions about their thinking and their work.

For this report, we focus particularly on one of the pairs of students we recorded, Zach and Levi (all names are pseudonyms). As a contrasting case, we briefly describe the solution of another pair Taylor and Kirk. Taylor, Kirk, and Levi were math majors enrolled in the secondary education program, Zach was a math major not enrolled in the secondary program. They were all senior-level mathematics majors with strong mathematics backgrounds. Taylor and Kirk had taken discrete mathematics but no advanced combinatorics; Zach and Levi students were taking an upper-division combinatorics class at the time of the interviews.

Taylor had no prior experience; Kirk had seen VPython, Matlab, and RStudio but said, "I don't remember how to do anything." Levi did not articulate prior experience with programming, and his work suggested he was a relative novice but felt comfortable trying to program. Zach had a strong background in programming, having coded previously in Python. At the time we did not ask what specific courses he had taken, but he talked about and demonstrated prior experience with coding in Python. This is borne out in their work, and we consider a relative comparison of *novice* for Taylor, Kirk, and Levi, and *experienced* for Zach; we are not making a claim about Zach's relative expertise to expert coders, but Zach was certainly more experienced than the other students and students we have reported on previously (e.g., Lockwood & De Chenne, 2021). Practically, this meant that he drew upon techniques (such as using functions and structures) that suggested familiarity with Python programming.

Data Analysis

For data analysis for this report, we began by examining Zach and Levi's work to investigate ways in which a pair of students that had more experience (in Zach) engaged with the problems. Specifically, the authors first watched the spliced videos of the interviews with Zach and Levi and regularly met to discuss broad themes that emerged from them. Then, the first author reviewed all of the interviews again and identified and collected episodes where the students specifically engaged with the code in a way that reflected their counting process. From these instances, the authors collaboratively wrote the episodes and together chose a representative example that highlighted an interesting solution to a counting problem that reflected the student's advanced knowledge of coding. The first author then reviewed the example and analyzed the students' thought processes. Finally, the first author analyzed Taylor and Kirk's solution to the same counting problem to see how they worked through the problem.

Results

We present data on the Language Books problem, which states: *There are 3 different French books, 4 different Norwegian books, and 5 Spanish different books. Create a computer program to list all of the possible book combinations of two books, both of which are not in the same language.* The students were asked to write code to solve the problem. We begin by only briefly (due to space) presenting Taylor and Kirk's solution, which is the solution we anticipated when we wrote the problem. We show this mainly to highlight a contrast with Zach and Levi's work, which we present in more detail. Then, we present Zach and Levi's solution, which demonstrates what the additional coding experience facilitated for their work. The point of the comparison is not to criticize the novice coders, but rather to give some sense of the kinds of tools and resources that might arise if such tasks are presented to more experienced students.

Novice Coders' Solution to the Language Books Problem

The first solution that Taylor and Kirk tried was a single nested for loop. This solution loops through all the French, Norwegian, and Spanish books, but it will repeat pairs causing the code to overcount. It appears in Figure 1a below, and the partial output shows some repeated pairs (such as F1 N1 appearing multiple times). The students were not sure how to fix their code in order to keep a single for loop and still avoid the overcounting that arose. In order to combat this overcounting, the novice coder group decided to use three separate for loops (Figure 1b). This code uses three separate, consecutive for loops that separately handle pairs of French and Norwegian, French and Spanish, and Spanish and Norwegian books. This case breakdown provides a cleaner way to organize the problem that avoids the overcounting that previously arose, without having to have the code check to see if there are repeats. As a result, Taylor and

```
French = ['F1','F2','F3']
Norwegian = ['N1','N2','N3','N4']
Spanish = ['S1','S2','S3','S4','S5']

books = 0
for i in French:
    for j in Norwegian:
        for k in Spanish:
            print(i,j)
            print(i,k)
            print(j,k)
            books = books+1
print(books)
```

```

F1 S3
N1 S3
F1 N1
F1 S4
N1 S4
F1 N1
F1 S5
N1 S5
```

```
French = ['F1','F2','F3']
Norwegian = ['N1','N2','N3','N4']
Spanish = ['S1','S2','S3','S4','S5']

books = 0
for i in French:
    for j in Norwegian:
        print(i,j)
        books = books+1
for i in French:
    for k in Spanish:
        print(i,k)
        books=books+1
for j in Norwegian:
    for k in Spanish:
        print(j,k)
        books=books+1
print(books)
```

Figure 1a and 1b. Figure 1a shows Kirk and Taylor's initial attempt at a single for loop. Figure 1b shows their solution for code that uses three consecutive for loops.

Kirk are utilizing sets of outcomes from Lockwood's model (2013). By thinking about how to do this process, they relied on knowing that the final set of outcomes would have pairs of French

and Norwegian, French and Spanish, and Spanish and Norwegian books. This is a correct answer to the problem, and indeed it was the solution we expected when we designed the task.

The output of the code in Figure 1b is shown in Figure 2. Note that each nested for loop creates one line of these lists (the first nested for loop created pairs of French and Norwegian books, the second created pairs of French and Spanish books, and the third created pairs of Spanish and Norwegian books). To reflect formulas/expressions of the model, we can consider an expression to reflect this process. For each nested for loop, we multiply the number of items in the outer array and the number of items in the inner array, which is also how Taylor and Kirk thought of it. Since we are counting up by one for each time the loop goes through, we end up adding up all the times each of the nested-for loops completes a loop, and so we sum up the products. This code thus reflects the sum of products, 3*4 + 3*5 + 5*4, which is a result that Taylor and Kirk found after they had written their code using the three consecutive loops.

```
F1 N1  F1 N2  F1 N3  F1 N4  F2 N1  F2 N2  F2 N3  F2 N4  F3 N1  F3 N2  F3 N3  F3 N4          12

F1 S1  F1 S2  F1 S3  F1 S4  F1 S5  F2 S1  F2 S2  F2 S3  F2 S4  F2 S5  F3 S1  F3 S2  F3 S3  F3 S4  F3 S5          15

S1 N1  S1 N2  S1 N3  S1 N4  S2 N1  S2 N2  S2 N3  S2 N4  S3 N1  S3 N2  S3 N3  S3 N4  S4 N1  S4 N2  S4 N3  S4 N4  S5 N1  S5 N2  S5 N3  S5 N4          20
```

Figure 2. The output of the code from Figure 1b. This was printed horizontally to save space.

Experienced Coder's Solution to the Language Books Problem

We now share results from Zach and Levi as they solved this problem. As noted, Zach especially was an experienced programmer. The students attempted a different solution than we had anticipated. Zach and Levi also attempted to create a single nested for loop, and we highlight what aspects of coding they needed to draw upon in order to do this successfully.

Zach and Levi create a single nested for loop. The first thing when creating their for loop was making sure that the code "looked forward" in the list; this was a term Zach used. By this, we infer that he meant that if X is the 5th item in the list, Y would only be the 5th or higher item in the list. The excerpt below shows Zach's reasoning about this, writing the code in Figure 3.

Zach: So, I was gonna do for X in range, uh, 1, 13.

Levi: Oh, yeah.

Zach: And then for, um... 'Cause I don't wanna have F1, R1, and then, uh, at... back at R1 go back to F1. So, I can actually do for Y in range X13. Right, so now if I'm... if I... so now if I start with like three- I'm not gonna look backwards. [...] It can only look forwards.

```
books = ['F1','F2','F3','R1','R2','R3','R4','S1','S2','S3','S4','S5']

for x in range(1,13):
    for y in range(x,13):
```

Figure 3. Zach's use of the range function in the code.

To do this, Zach used the range function so that the code would look at the first element of the list ("for x") and then the second element of the list ("for y") by putting an "x" into the range so that it would look at the number that the first for loop is on and only after that number. We suggest that this approach is indicative of someone who is more advanced in coding. While more novice coders may know that the range function can be used to create a list of numbers, we argue that Zach is using more advanced knowledge of coding here. In particular, he uses a nested for loop with range functions in order to force the second for loop to only look at the element that x is on and after that element. The use of range(x,13) suggests that he understood conceptually how the range function works, as well as understanding that this will use the x created in the outer for loop as a variable within the range function.

However, Levi and Zack recognized that this code would not ensure that they would not repeat the same language. As seen in the excerpt below, Levi recognizes that "F1, F2" is still a possibility. They discuss this below, and Zach tries to use nested indexing (which we would argue is a more advanced coding practice) to check that he can isolate the first elements of the string. In Figure 4 we see his initial work on comparing the first letters of each pair.

Levi: But then you can still get F1, F2.

Zach: Right. And then I can say, uh,

Levi: If-

Zach: If books at X at one is equal to... is... I'm sorry, is not equal to books at Y at one. All right, this should be a zero, shouldn't it? This is a zero.

Levi: Oh yeah, yeah, yeah.

Zach: So, this is like, the X inden- Uh, indices [...] Actually, this should be zero as well, shouldn't it? [...] So then it's gonna probably pull the first things of that string. So, when... if I pull F1 and F2-

```
books = ['F1','F2','F3','R1','R2','R3','R4','S1','S2','S3','S4','S5']

for x in range(0,12):
    for y in range(x,12):
        if books[x][0] != books[y][0]
```

Figure 4. Zach using nested indexing to look at the first letter of the x-th element of the array and making sure it is not the same as the first letter of the y-th element of the array.

Zach then checked this work to test whether the code is in fact isolating the first letter. He successfully "pulls" just the first element of the string, as seen in the column of Fs in Figure 5.

```
books = ['F1','F2','F3','R1','R2','R3','R4','S1','S2','S3','S4','S5']

for x in range(0,12):
    for y in range(x,12):
        print(books[x][0])

F
F
F
F
F
F
F
F
```

Figure 5. Zach testing the nested indexing function to see if it does what he thinks it does.

Zach: [...] It's gonna read it as, um, FF. So that... So, books... well, here. You could do like, print books at X at zero. Let me see what that does. So that- that's printing F. So that's seeing it as looking at the string- [...] First then look- so books X looks at the string and then zero pulls the first element of the string, which is just F.

Levi: Oh, okay.

Zach and Levi conclude their work on the problem in Figure 6, and in the following excerpt Zach explains his reasoning. Having successfully isolated the first letter, he can include a conditional if statement that only counts pairs where the first letter (the books[x][0] and books[y][0] are not equal). Here, they first make sure that the language of the books would not be the same by having the code look at the first letter and only keep going if the first letter of the first book selected and the second book selected were not the same, as Zach explains.

Zach: So, if we have book... so, as long as the letters aren't the same, books X-[...] at zero, as long as it's not equal to books, our yth component at zero... We gotta be careful with that one. I'll do plus one there I think […] Yeah. 'Cause like, as long as I have this, this is gonna say F1 and then for Y in range zero, it's gonna look at F1 again [...] It's gonna compare it to itself, but obviously it- it can't be the same as itself.

Then we do count equals, uh, zero. And then if they're not the same, the letters aren't the same […]

```
books = ['F1','F2','F3','R1','R2','R3','R4','S1','S2','S3','S4','S5']
count = 0
for x in range(0,12):
    for y in range(x+1,12):
        if books[x][0] != books[y][0]:
            count += 1
            print(books[x],books[y])
print(count)
```

Figure 6. Zach and Levi's final code.

In arriving at this final code, Zach also did a few fixes to make sure that the code was operating correctly. He first had to change the range to go from 0 to 12 instead of 1 to 13 since the indexing of the array starts at 0 and not 1. He then made the range for the y go from x+1 instead of starting at x so that it won't have a repeated book and it will just start at the next one. These practices highlight Zach's prior experience with coding. There are also examples of them utilizing the set of outcomes to obtain their final code. For example, they pay close attention to repeats like F1F2 and Zach utilizes a function of the code for reading the first letter to make sure that their set of outcomes does what they want it to do.

Zach and Levi's explanation of how the code works. In the excerpt below, Zach and Levi explain their work, and the explanations demonstrate how well that Zach understands how the code works. Notably, Levi also seems to agree and is able to articulate aspects of what the code is doing as well.

Levi: For X in range between 0 and 12 for Y and range X plus 1 to 12, and then, uh, that's just if that... if the F... if the letters don't match up.

Zach: Yeah.

Levi: Then you can continue [...].

Zach: If the letters aren't the same then they're the same... if they are the same then, they're like, the same language so I don't wanna count it.

Levi: Mm-hmm (affirmative).

Zach: And then the for range X plus 1 I'm not... I'm not gonna count, look behind me anymore, which you... it removes duplicates. So, I'm not gonna get R1 F1 and F1 R1 […]

Interviewer: Okay, good. And then what is making it so you don't get F1 R1 and also R1 F1?

Levi: The range on Y because once you... 'cause the range on Y is, it only looks farther down the line-[...] on the books, so...

Interviewer: I see, because you're just... you're in the same set. You have one set here. [...] So by looking at Y is only gonna be further down […]

Zach: Yep, so X picks like the fourth one and then my Y is only gonna be from the fifth on.

Relating the counting process to an expression. In terms of the model, we see the students connecting the code to expressions for the numerical total. In Figure 7, we see Zach wrote out the total of 27+20 = 47. To represent how the counting process was reflected in their code, they started with F being the first letter, and they noted that each of the "Fs" has 9. With 3 "Fs", there would be a total of 27. Then, looking at the "Rs", since we have already accounted for the pairs with French and Norwegian, each "R" is going to have 5 pairs. With 4 "Rs", there would be a total of 20. There are 47 combinations. In this way, they connected the process in their code to the outcomes being counted, and to mathematical expressions that reflected that code.

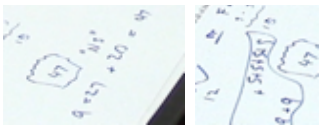

Figure 7. Zach's numerical solutions of how he counted the number of combinations of language books.

Discussion and Conclusion

By leveraging a couple of more advanced programming ideas (specifically, a sophisticated use of the range function and nested indexing), Zach arrived at a creative and efficient program that solved the Language Books problem in a single for loop. By using these techniques, Zach was able to account for making sure that they would not repeat the same language and ensured a complete list of desirable outcomes. We also highlight computational practices that Zach employed that suggest he drew upon his coding experience. Zach used the code to troubleshoot while making a prediction of what it would do. He wanted the code to specifically look at the first letter so that he could later compare the letters. To do this, he tested the code so that it would print out what he hoped was the first element of the code (this is reflected in Figure 5). We interpret that not only is the use of function itself using knowledge that an experienced coder would draw upon, but his testing of it to make sure that it does what he wants it to also highlights a practice of a more experienced programmer.

In comparing Taylor and Kirk's code and Zach and Levi's code, the overall structure of their sets of outcomes and final formula were different. Because Zach and Levi combined the code into one for loop, it forced French to be paired up with Spanish and Norwegian all at the same time, creating a group of where Spanish and Norwegian are almost like its own array. Meanwhile, Taylor's and Kirk's method forced French and Spanish and French and Norwegian to be completely separated groups. This is also reflected in their formulas, since Taylor and Kirk's group had three separate additions (3*4 + 3*5 + 5*4) while Zach and Levi's code had two separate additions (3*9+4*5). In all, they created the same result, but their Zach's experience as a programmer, they were able to see a different set of outcomes and formula/expressions.

In terms of components of the model of students' combinatorial thinking, both pairs of students were able to relate their counting processes with a structure of the set of outcomes and a corresponding mathematical expression. We note that their explanations suggest Zach and Levi understood the counting processes, and they ultimately expressed mathematical expressions that reflected the process of their creative, unconventional code. This highlights the fact that alternative approaches may meaningfully be connected to expressions that suggest a process.

In the undergraduate mathematics education literature, there is relatively little work on ways in which experienced programmers engage in mathematical tasks in computational settings. The episodes highlight ways that experienced coders may leverage certain advanced coding practices in their work. Both pairs successfully solved the problem, but the advanced techniques allowed for Zach to program the problem in one for loop, something Taylor and Kirk attempted but did not do. Zach's advanced coding practices emphasize why it is not surprising that Taylor and Kirk were not able to use a single for loop. Future research could explore whether there are mathematical implications for more advanced programmers, and subsequent studies could design tasks that could utilize certain computational tools that might not be available to novice coders.

Readers' Movement of Attention Through a Calculus Text

Emilie Wiesner
Ithaca College

Ellie Fitts Fulmer
Ithaca College

Aaron Weinberg
Ithaca College

Mathematics textbooks demand specialized forms of literacy, yet little research has examined how readers actually move through them. Drawing on the concepts of agency and didactical disciplinary literacy, this paper explores how readers allocate attention across textbook components and the reasons they give for doing so. We also propose an "attention continuum" in which shifting patterns of engagement represent agentive choices. These findings highlight how textbook reading intertwines literacy practices, disciplinary positioning, and agency, offering new insight into mathematics learning.

Keywords: Mathematics Textbooks, Agency, Didactical Disciplinary Literacy

Textbooks have long been a staple of college-level mathematics classes. Mathematics textbooks—dense combinations of technical prose, symbolic notation, graphs and figures, and examples—require students to engage with them in particular ways. Textbook authors offer instructions to students about how to read their textbooks, with exhortations to read closely and to attend to the various components of the textbook in particular ways and in a certain order (e.g., Stewart, 2016). Similarly, university learning centers advise students on reading strategies such as skimming and close reading for academic texts in general and scientific textbooks in particular (e.g., University of North Carolina, 2025). Yet, the mathematics education research community has paid relatively little attention to how students read mathematics textbooks.

Following Wiesner et al. (2020), we argue that literacy is central to disciplinary practice, and that textbooks are different from other disciplinary texts and deserve particular attention. Learning from reading a textbook depends both on the reader's background knowledge and the literacy practices they employ, including how they allocate their attention across the various components of the text. Moreover, these reading activities are situated within the disciplinary community and in relation to the reader's positioning within it.

To investigate these ideas, we present results from a study of undergraduate mathematics students and non-mathematics professors as they read an excerpt from a calculus textbook. Using a stimulated recall approach, assisted by eye-tracking software, we investigate how and why readers move their attention through the text. Specifically, we investigate the questions

- How do readers of a calculus textbook excerpt move their attention through the reading?
- What are the stated reasons and motivations for the choices that readers make about their movement through the text?

Literature Review

The concept of *disciplinary literacy* recognizes that disciplinary experts engage with texts in their field in ways that draw not only on their content knowledge, but also on their knowledge of the disciplinary community norms and concepts of knowledge and inquiry, and the reader's positioning within the community (Moje, 2007; Shanahan et al., 2011). *Didactical disciplinary literacy* extends this idea to didactical texts (texts whose principal purpose is didactical, such as textbooks); it encompasses "the habits of mind of the individual immersed in didactical practice and on the literacies of the discipline in which the text and reader are embedded" (Wiesner et al., 2020).

Agency emerges from an "individual's perception and enaction of control and choice" (Weinberg et al., 2024). The concept is a fundamental piece of disciplinary literacy (Moje, 2008) and has been highlighted as essential in both math education and literacy communities (Fulmer et al., 2022; Vaughn, 2014). We adopt the perspective put forward in Fulmer et al. (2022), who reconcile these perspectives by viewing agency as the "interplay of autonomy, identity, power, and knowledge" (p. 632). Agency in mathematics is naturally in tension with the structure and permanency of the discipline (e.g. Pickering, 1995); textbooks—"inherently hegemonic" (Fulmer et al., 2022, p. 633)—offer a particular challenge to the personal agency of the reader (Vaughn, 2014). In this context, we argue that the way a reader directs their attention through the reading offers an important opportunity to act agentively. In particular, as Weinberg et al. (2024), note, "actions that run counter to the status quo are evidence of agentive moments" (p. 669).

Theoretical Framework

The concept of *disciplinary literacy* recognizes that disciplinary experts engage with texts in their field in ways that draw not only on their content knowledge, but also on their knowledge of the disciplinary community norms and concepts of knowledge and inquiry, and the reader's positioning within the community (Moje, 2007; Shanahan et al., 2011). *Didactical disciplinary literacy* extends this idea to didactical texts (texts whose principal purpose is didactical, such as textbooks); it encompasses "the habits of mind of the individual immersed in didactical practice and on the literacies of the discipline in which the text and reader are embedded" (Wiesner et al., 2020).

Agency emerges from an "individual's perception and enaction of control and choice" (Weinberg et al., 2024). The concept is a fundamental piece of disciplinary literacy (Moje, 2008) and has been highlighted as essential in both math education and literacy communities (Fulmer et al., 2022; Vaughn, 2014). We adopt the perspective put forward in Fulmer et al. (2022), who reconcile these perspectives by viewing agency as the "interplay of autonomy, identity, power, and knowledge" (p. 632). Agency in mathematics is naturally in tension with the structure and permanency of the discipline (e.g. Pickering, 1995); textbooks—"inherently hegemonic" (Fulmer et al., 2022, p. 633)—offer a particular challenge to the personal agency of the reader (Vaughn, 2014). In this context, we argue that the way a reader directs their attention through the reading offers an important opportunity to act agentively. In particular, as Weinberg et al. (2024), note, "actions that run counter to the status quo are evidence of agentive moments" (p. 669).

Methods

Participants

We selected participants to capture a wide range of disciplinary and didactical disciplinary literacy practices. To recruit participants, we sent invitations to all math majors and minors who had not yet completed numerical analysis (where Newton's method is a standard topic); all students who had completed first-semester calculus with a grade of C- or better in the previous semester; and all (non-math) STEM faculty at our institution. All interested individuals who were available during interview times were included in the study. A total of 15 individuals particicpated in the study, five from each of the invited groups. We subsequently refer to participants by their group (MM for math major, NMM for non-math major, and NMF for non-math faculty) and a number.

Materials

Participants in the study read a four-page excerpt from a commonly used calculus textbook (Stewart, 2016) on Newton's method. The excerpt included introductory prose that attempted to motivate the need for Newton's method; a derivation of a general formula and description of the iterative process and associated limit; and three examples intermixed with text that elaborated on the examples. There were also seven figures that illustrated the ideas presented in the text. This organization of the excerpt reflects a common template in mathematics didactical texts; it informed the interviewer's questioning during the stimulated recall phase and served as a map for tracing readers' navigation through the text during data analysis.

The excerpt was chosen because it relied on knowledge that is generally taught in a first-semester calculus course, but Newton's method itself is often not taught in introductory semester calculus. Thus, we predicted that the topic itself would be novel to most participants but that they would possess the necessary background knowledge to engage mathematically with the reading.

Data Collection

Participants were each interviewed for a 75-minute session, conducted by the third author, a professor in the mathematics department. Following Schindler and Lilienthal (2019), the interview incorporated a stimulated recall of participants' reading. Participants were first asked to read the textbook excerpt for the purpose of learning Newton's method, reading an electronic version of the excerpt with an eye-tracker recording their gaze. After reading, the participant and interviewer jointly viewed a playback of their fixations. The participant was asked to narrate their fixation patterns and describe what they were thinking as they looked. In particular, if the participant's gaze was fixed on a particular component of the text for an extended period of time, if the participant skipped or skimmed over a component, or if the participant moved back to an earlier portion of the excerpt from a later portion, the interviewer prompted them to pause and describe their thinking and motivation.

Analytical Methods

We used a process of open and axial coding (Strauss & Corbin, 1994) to generate codes. Each author reviewed the interview transcripts and identified turns where the participant addressed how their attention moved throughout the text. Using both the turn itself and adjacent turns, the authors individually characterized each turn into an initial code, then worked collectively to refine the codes. This resulted in a collection of behavior codes and reason codes for each behavior code. The authors then individually coded the flagged turns (for both behavior and reason) and collaboratively reconciled differences.

Results

We identified five categories of behaviors–reading straight through, skimming, skipping, close reading, and reading order– and a classification of reasons the participants provided for each type of behavior. Between six and 17 turns were identified for each participant. Additionally, each participant was coded for at least two of the main behaviors we analyzed–skimming, increased attention, and reading order–and eight of the 15 participants were coded for all three.

Reading Straight Through

A turn was coded as *reading straight through* when the reader indicated that they had read the text in the order presented with no indication of more or less attention than expected. For

example, NMM1 stated, “I was locking in, reading straight through.” These moments were not elicited or probed by the interview protocol and were infrequent (five out of 146 turns were assigned this code.) In each case, the reader did not provide any justification for their behavior of reading straight through.

Skimming and Skipping

Turns were coded as *skimming* if the turn indicated rapid reading or reduced attention. For example NMF5 stated, “I just glossed over those formulas.” We classified reasons offered by participants for engaging in skimming as follows: efficiency, familiar, don’t understand, disciplinary reasons, overview, and no reason.

A skimming turn was coded as *efficiency* when the participant explicitly referred to moving through the text at increased speed. In all but one instance, turns that were coded as efficiency also received a secondary reason code. For example, NMM2 stated, “I think I probably read through this one quicker because I kind of understand more how the numbers plugged in.” This was coded as efficiency and familiar; in general, we identified skimming as *familiar* when the reader expressed that they already understood the material sufficiently. Other readers skimmed a portion of the text when they struggled to make sense of it, coded as *don’t understand*. For example, NMM3 explained their choice to move quickly through a segment of text: “I couldn’t figure it out.”

We used the code *disciplinary reasons* to identify turns where the reader justified skimming in terms of what they valued mathematically or based on disciplinary norms. For example, MM5 skimmed the first part of the reading–motivating Newton’s method–so that she could move on to the derivation of the method, explaining that she found the motivation section less important than the derivation section.

Skimming was classified as *overview* when participants indicated they were trying to get an overview or preview of the reading. For example, NMF5 stated, “Well, I was just trying to figure out, like, normally you don't know—in a textbook—you don't know what the best place to start is. So you're looking for a heading, or like, now we're going to learn about this and I guess that's at the top, I'm just seeing right now, so Newton's method.”

Skimming (as well as other behaviors) was coded as *no reason* when a participant did not offer a reason themselves and the interviewer did not prompt them for a reason, or authors could not identify a reason from the participant’s explanation of their behavior.

We coded separately as *skipping* instances where a participant gave an explicit indication that they did not look at a particular portion of text at all. For example, after being asked if they had looked at a figure, NMM2 stated that they had not noticed the figure. In each instance, the participant either did not supply a reason or indicated that they missed the piece or text or were not sure why they had skipped it; these were all coded as *no reason*.

Close Reading

The code *close reading* was applied to turns where the reader’s movement through the text appeared to slow or stop on a particular component of the text. We classified close reading using the reasoning codes understanding, familiar, disciplinary reasons, and no reason (defined as above).

The code *understanding* was applied when participants indicated they were working to make sense of part of the text that they found confusing or that they deemed needed additional time to

understand. For example, NMF1 said: “When you had that notation that's confusing, you look at it more and then—I don't want to go too fast.”

Similar to the skimming behavior, a close reading turn was coded as *familiar* when the participant indicated they were engaging in the behavior because a piece of text was familiar to them or a type of text that they felt comfortable with. This gave them greater access to or interest in the text, motivating their increased attention. For example, MM2 focused on Example 2, explaining the set-up of the problem (finding the sixth root of 2 using Newton’s method) reminded them of work he had done in a previous class.

Complementing the skimming-disciplinary reasons code, the close reading-*disciplinary reasons* code referred to turns where the reader indicated that their increased attention was motivated by what they valued mathematically or based on disciplinary norms. This happened in MM1’s report of close reading of the blue-boxed equation, stating that it was significant in understanding how and why Newton’s Method works.

Reading Order

The code *reading order* was used to categorize turns where the reader did something other than read in the intended order (as perceived by the paper authors). This included reading a piece of the text multiple times, jumping forward in the text (over a portion of the reading), jumping backward in the text, or moving back and forth between two different pieces of the text. We grouped these behaviors under one code as they often involved overlapping behaviors that were difficult to tease apart. For example, when a participant jumped backward in the text, they were likely rereading the earlier section but they may not have explicitly indicated this. Justifications for this behavior were classified as understanding, connections, disciplinary reasons, overview, zoning out, and no reason.

The code *understanding* was applied when participants indicated they were working to make sense of part of the text that they found unclear, to check their understanding, or to build understanding iteratively. For example, MM2 explained their choice to move back to an example earlier in the reading: "I wanted to make sure that like the x_1, that it was more of a choice of what to choose for x_1. You can choose one or something else, yeah I just wanted to make sure."

We coded reading order as *connections* when the reader was attempting to make connections between different pieces of text (such as graphs and text) without indicating they were attempting to resolve a confusion. For example, after starting to read Example 1, MM1 returned to the general equation earlier on the page to coordinate the calculation in the example with the general equation.

Participants also indicated that reading order was motivated by disciplinary norms and values, coded as *disciplinary reasons*. For example, NMF1 explicitly referenced her discipline when explaining her choice to look at the figure captions before looking at any of the text: “It’s how you read a [biology research] paper…. And when I read biology papers—and part of it is the method I was taught, and I like it—is you read the abstract and the figure legends, and then you go back and read the paper.”

Readers also engaged in reading order to get an overview or preview of the reading (coded *overview*). For example, NMF4 explained jumping around the text:“I wanted to see what came next.”

Finally, in three instances of reading order, a participant indicated that they reread a piece of the text because they had “*zoned out*”; this was coded as *zoning out*.

Discussion

This study highlights participants' movement of attention as a realized opportunity for agency. All readers employed a variety of reading behaviors. These movements demonstrated intentional choices about how to move through the excerpt, both through their own explanations and the authors' perceptions of the text ordering. Participant activity was constrained by the text itself and the goal of learning about Newton's Method. However, the participants' explanations for their choices reflected their own goals, understanding, and sense of themselves in relation to the text and interview context. This reflects the notion of agency as the "interplay of autonomy, identity, power, and knowledge" described in Fulmer et al. (2020, p. 632) .

In detailing participants' movement of attention, we have come to conceptualize the behaviors as having fuzzy and overlapping boundaries; and many of the behaviors can be viewed as existing along a continuum, as displayed in Figure 1.

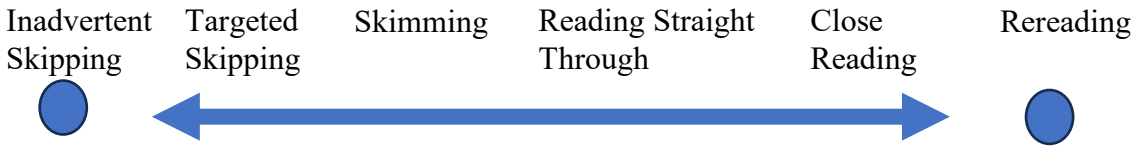

Figure 1. The attention continuum

Here the transition between skimming and close reading represents a dialing up and down of attention, reflecting the speed at which a person moves their attention and how much and what grain size of the text they give attention to. Moreover, skimming itself operates on a spectrum, where high-speed, large-grain size skimming might typically be described as skipping. In particular, we interpret instances when a reader identifies the intellectual/conceptual content of text component and make an active choice to not read it as skimming; this is labeled as "targeted skipping" in Figure 1 to highlight this extreme end of the continuum. We distinguish this from unintentional skipping, where a reader is not aware of the text they skipped. The turns in this study coded as skipping appear to fall into the category of unintentional skipping. The reading order-zoning out may also be a consequence of a lack of attention similar to unintentional skipping. At the other end of the model, rereading–while a different behavior from close reading–arises from similar motivations as close reading and represents a similar dialing up of attention. Not represented in this figure are other kinds of reading order behavior, namely jumping forward and backward. This type of behavior appears to arise, in part, from combining of skimming, reading straight through, and close reading.

The attention continuum contrasts with other research (for example, Phillips and Phillips, 2007) that presents skimming and close reading as in opposition to each other. We argue that viewing these behaviors as a continuum is useful for understanding a reader's movement through the text as a web of choices they make and coordinate throughout the reading. Moreover, this perspective positions all behavior other than reading straight through as inherently agentive, because it, "run[s] counter to the status quo" of reading straight through (Weinberg et al., 2024, p. 669).

The attention continuum can, potentially, be thought of in terms of various forms of attention. Posner and Petersen (1990) point to awareness of stimuli, planning, and goal-directed behaviors. For example, sustained attention, which enables an individual to concentrate on a particular stimulus for an extended time period (e.g., Chen & Wu, 2015; Roda, 2011), could be connected to close reading. Conversely, alternating attention, which supports rapid shifts among

a set of stimuli (Lezak et al., 2015; Parasuraman, 1998) could support behaviors like skimming and targeted skipping.

Participants' stated reasons for attentive behaviors reveal a variety of ways that readers used attentive movement to engage in a learning experience. Moreover, we believe that didactical disciplinary literacy provides a useful lens for understanding these reasons. While some of the readers' moves through the excerpt could be characterized in terms of general literacy strategies (such as skimming to get an overview), their explanations were often tied to the specific didactical structure of mathematics textbooks (for example, coordinating an example and general equation, as part of developing understanding). In some cases, we explicitly connected participants' reasons to disciplinary norms and values (via the disciplinary reasons code). Although this study focused on common themes among the participants, we also found considerable variation between participants in the particular ways that they engaged in behaviors and how these behaviors connected to their reasons. Although the small size and complexity of the dataset makes it difficult to draw clear distinctions between the three groups of participants, we believe the variation between participants suggests that the individual's positioning in the disciplinary community and as a learner may offer a useful perspective on how they move through a text.

The results of this study display a varied and nuanced set of behaviors that readers engaged in while reading a mathematics textbook. Readers' explanations for how they navigated the excerpt appear to be connected to their prior knowledge, their perceptions of the excerpt as a didactical text, their positioning in the discipline, and their understanding of disciplinary norms and values. While this study provides an initial description of reader's attentive movement and associated motivations, it also highlights this as an area for further investigation. In particular, additional research could reveal a richer description of how individuals organize their movement through a text, how this movement is guided by the text itself (as both a disciplinary object and a didactical text), the reader's background knowledge, and the reader's disciplinary positioning and identity.

Moving Beyond Total Scores With Skill-Proficiency Profiles on Concept Inventories

Kevin Roberge
University of Maine

Jayson M. Nissen
Montana State University

Vy Le

Ben Van Dusen
Iowa State University

Research-based assessments (RBAs) are widely used to evaluate student learning in STEM, yet most provide only total scores. We illustrate the value of moving beyond overall performance by applying a cognitive diagnostic (CD) model to student responses on the Precalculus Concept Assessment (PCA) and the Calculus Concept Inventory (CCI). Using 1,366 pre/post responses collected through the LASSO platform, we modeled five key calculus skills: prerequisites, limits, derivatives, applications of derivatives, and introductory integration. Traditional analyses revealed small but statistically significant score increases (d = 0.09 for PCA; d = 0.26 for CCI). CD modeling also showed limited shifts in skill proficiency profiles: students who lacked prerequisite skills did not gain those skills. These results underscore how CDs provide finer-grained evidence than total scores and motivate the development of a Calculus Cognitive Diagnostic to support timely instructional interventions.

Keywords: Calculus, Assessment, Learning, Cognitive Diagnostic

Research-Based Assessments (RBAs) have become foundational in DBER because they are developed through iterative qualitative and quantitative studies that build a cumulative validity argument aligned to field standards. This systematic approach positions RBAs to measure learning and to inform instructional decision-making at scale. In physics, RBAs enabled early demonstrations that interactive engagement markedly outperforms lecture (e.g., Hake, 1998), guided the design and evaluation of Modeling Instruction (Brewe, 2008), and later underpinned cross-disciplinary meta-analytic evidence that active learning improves achievement and lowers failure rates (Freeman et al, 2014). More recent work shows that although students *feel* they learn less during active engagement, they in fact learn more (Deslauriers et al., 2019), and that lecturing still predominates in undergraduate STEM (Stain et al., 2018). These results underscore the need for sustained, RBA-informed reform, and RBAs designed to meet the needs of educators and researchers pursuing those reform efforts.

Mathematics education researchers have developed at least six RBAs covering precalculus and calculus content (Epstein, 2006: Carlson et al., 2010; Carlson et al., 2015; Thompson et al., 2018; Lee et al., 2025). Researchers tend to use these fixed-length instruments to measure learning across a semester though they have played a smaller role in the RUME community than similar instruments have in physics (e.g. Hake, 1998). This limited use may result from subsequent studies that questioned the psychometric validity arguments of some of these instruments (Gleason et al., 2019; Jones, 2021; Lee et al., 2025).

We are developing a calculus cognitive diagnostic (CCD). Whereas current fixed length RBAs primarily assess overall ability, a cognitive diagnostic (CD) assessment measures student proficiency on individual skills and overall ability (Leighton & Gierl, 2007). The CD classifies students into skill profiles to provide instructors, researchers and students with finer grained information about student learning (de la Torre & Minchen, 2014). Unlike many fixed-length tests, CDs can assess a subset of skills and overall ability whenever needed, even multiple times

a semester, without compromising the instrument. By drawing from a larger item bank, CDs also prevent over exposure of items. Our CCD development uses a computerized adaptive testing platform (LASSO, 2025) that optimizes the information each question provides based on students' responses to earlier questions (Yasuda et al., 2021). Combining a CD with computerized adaptive testing ensures accurate and efficient measurement of each student's proficiency level (Morphew et al., 2018) with the fewest questions necessary.

In this paper, we apply a CD model to student responses on the Calculus Concept Inventory (CCI, Epstein, 2006) and the Precalculus Concept Assessment (PCA, Carlson et al., 2010). Prior work establishing acceptable fit for the CD student model used in this study (Roberge et al., 2025). This application illustrates the additional resolution provided by skill-level proficiency estimates. We contrast pre–post changes in total scores with changes in skill proficiency profiles, including transition patterns across skills, to show what these two outcomes reveal and obscure.

Research Questions

To that end, we asked the following research questions for the PCA and CCI:

1. How much do students' scores change (learning) from pre to post on each of the instruments using mean shifts?
2. Using the CD student model, what are students' pre- and post-instruction skill-proficiency profiles, and to what extent does instruction increase proficiency probabilities and transitions into proficiency for calculus skills?

Theoretical Framework

Building on prior work (Vy et al, 2025), we drew on Evidence Centered Design (Mislevy et al., 2003) to develop the CCD. The conceptual assessment framework within Evidence-Centered Design has five components: student model, evidence model, task model, assembly model, and delivery system. In this article, we focus on the student and evidence models, as these components shape the assessment output. The student model includes the skills that the instrument aims to assess. The evidence model establishes the criteria for evaluating the assessment and defines how to score the student's answers to the questions. For the evidence models, we applied a CD model to interpret performance in terms of skill proficiency. The task model defines the format of the items (multiple-choice questions in our case). The assembly model integrates the student models with task models to assemble the assessment and assess student's performance. The delivery system (LASSO, Van Dusen et al, 2021) administers the assessment online.

Literature Review

Calculus can function as a gatekeeper in STEM education (Seymour et al., 2019). In fact, Seymour et al. (2019) found that calculus was one of two of "…the first and second year courses with the highest numbers of students receiving a D, F or incomplete/withdrawal grades…" at a rate of 20% (p. 199). Other studies have found DFWI rates as high as 34.3% (Koch & Drake, 2018). Calculus failure rates may disproportionately affect women (Ellis et al., 2016) and students of color (Treisman, 1992) contributing to a lack of representation in STEM fields (Sanabria & Penner, 2017). Evidence based instruction can greatly improve learning outcomes (Kramer et al., 2023) and such methods require evidence to assess. To this end, researchers have developed at least six RBAs to assess student readiness for calculus or learning during first and second semester calculus and provide data for researchers to evaluate.

Beginning in 2006, Epstein created the Calculus Concept Inventory (CCI) to measure learning in a first semester calculus course. In 2018 Thompson and Ashbrook began developing the Calculus 1 Concept Inventory (C1CI) and the Calculus 2 Concept Inventory (C2CI). More recently Lee et al. (2025) have released the Revised Calculus Concept Inventory (RCCI) which combined the CCI and C1CI. Carlson et al (2010) developed the Pre-calculus Concept Assessment (PCA) to measure student learning in precalculus. She and collaborators would later extend this work to the Calculus Concept Readiness (CCR) in (2015) to measure student proficiency on prerequisite concepts important for calculus.

Because researchers use a wide range of instruments and inconsistent reporting practices, we found it difficult to characterize learning gains in calculus. Researchers sometimes use RBAs such as the CCI (Bagley, 2014; Villalobos-Camargo, 2021; Dagley et al, 2018; Epstein, 2007 Thomas & Lozano 2013) but often they create their own instruments for pre and post assessments (Adams and Dove, 2018; Cronhjort et al., 2013; Kramer et al., 2023; Young et al, 2011). Reporting of descriptive statistics varies across these studies. Normalized gains in lecture based courses tend to be small and range from 0.1 (Villalobos-Camargo, 2021) to 0.3 (Young et al., 2011; Adams and Dove, 2018). Normalized gains (Hake et al., 1998) are not without issues (Nissen et al., 2018).

We (Roberge et al., 2025) identified a list of calculus skills by examining the learning outcomes from the OpenStax first semester calculus textbook (Strang & Herman, 2016) and from the Advanced Placement AB calculus test (*AP Calculus AB and BC: Course and Exam Description*, 2020). We initially developed a list of 27 skills that we used to code the items from both RBAs. Each instrument had too few items to cover 27 skills. After several iterations, we decided to focus on five broader categories: Prerequisite skills, Limits, Derivatives, Applications of Derivatives and Introduction to Integration. Tallman et al. (2016), after analyzing 254 different final exams for post-secondary, first-semester calculus courses, came to a similar conclusion about common calculus content. Our results (Roberge et al., 2025) supported the student models of the five skills fitting the data well. Both fit characteristics (RMSEA and SRMSR) were well below cutoff values and classification accuracies were either acceptable or good for each learning outcome.

Methods and Materials

The data was supplied by the LASSO platform (LASSO, 2023). The data consisted of 1,366 college student responses to both a pre and a posttest from the PCA (25 items – 897 students) and CCI (22 items – 469 students). Data for the PCA came from six institutions across thirty-three unique math courses that ran between the fall of 2016 and the summer of 2018. Data for the CCI came from five institutions, eight instructors, and eighty-six courses taught between the Fall of 2021 and the Winter session of 2024. Following previous data cleaning processes on LASSO data (Morley, Nissen & Van Dusen, 2023; Van Dusen & Nissen, 2020) we excluded students who took less than five minutes to complete the assessment or attempted fewer than 80% of the questions.

Descriptive statistics on pre/post scores for the PCA and CCI suggest only small changes. These scores are on a 100 point percentage scale. The PCA pre and post score means were 44.4/46.0 with standard deviations 17.1/17.3 respectively. The CCI pre and post score means were 34.2/38.7 with standard deviations 15.8/18.2 respectively. The PCA effect size was $d = 0.09$ and the CCI effect size was $d = 0.26$.

To determine if the differences in mean scores were significant, research question 1, we used a hierarchical linear model. Pre and post scores are nested within students and students are nested

within courses. Neglecting nesting in data can violate the assumption of independence of many statistical methods such as multiple regression and ANOVA (Van Dusen & Nissen, 2019). For our models the intraclass correlation coefficients (ICCs) were, for PCA/CCI, students 0.54/0.56 and for courses was 0.18/0.069 respectively. Greater between group variance indicated we needed to treat groups (in this case: students and courses) separately and the hierarchical linear model accounts for both within-student variance and within-course variance.

To answer research question 2 we used CD models to produce finer grained information than traditional concept inventories. The model used test items, student responses, and a binary Q-matrix that codified item-skill dependencies. The Q-matrix is an $n \times m$ matrix for n items and m skills (Chen et al., 2015; Cui, Gierl & Chang, 2012). A one in the *ij-th* location means that skill j is required to correctly answer item i. An item may require more than one skill so its row in the Q-matrix will be a string of zeroes and ones. The resulting CD fitted to data categorized students into skill profiles and provided a variety of classification accuracies (Ravand & Robitzsch, 2015).

Skill profiles are binary vectors of length m (for m skills) where each '1' represents a proficiency and each '0' represents a missing proficiency. For example, a skill profile of 10100 for the CCI represents proficiency on prerequisite material and derivatives but missing proficiency on limits, applications of derivatives and introductory integration. We used alluvial plots to show how students transitioned from one skill profile to another from the pretest to the posttest. The quantity of students following any particular path from left to right is depicted by the size of the band connecting the left node to the right node. Additionally, when presenting alluvial plots of student proficiency groups we filtered to include only groups of ten or larger. For the PCA, this resulted in 24 students removed and six skill profiles removed. For the CCI this resulted in 39 students removed and fourteen skill profiles removed.

Table 1. The number of items and the classification accuracy (CA) for each skill for each RBA.

		Prerequisites	Limits	Derivatives	Apply Deriv.	Integration
PCA	items	20	3	0	5	1
	CA	0.92	0.68	-	0.87	0.91
CCI	items	6	3	6	6	1
	CA	0.94	0.91	0.94	0.95	0.98

Skill classification accuracy is a value between 0 and 1. Values between 0.8 and 0.9 are considered acceptable and values above 0.90 are considered high. For the five skill student model applied to the PCA and CCI data, Roberge et al. (2025) reported the results in Table 1. The reader may notice that the skill classification accuracy for Introductory Integration is considered high even though each RBA has only a single item coded for this skill. When a skill is represented by only one or two items, we may be skeptical of a high classification accuracy. On the PCA only 17% answered item 8 correctly on the pre-test (coded for integration) and only 18% on the post-test. On the CCI only 20% of students correctly answered item 18 (coded for integration) on the pre-test and only 24% on the post-test.

Findings

The results, shown in Table 2, indicate that post-test scores for both RBAs were larger than pre-test scores. The average post-test score on the PCA, accounting for student level and course level nesting of data, is 1.57 percentage points higher than the average pre-test score and this

difference is statistically significant at the level of $p < 0.001$. The average post-test score on the CCI, similarly accounting for nested data, is 4.54 percentage points higher than the average post-test score and this difference is statistically significant at a level of $p < 0.001$.

Table 2. Model summary for each of the hierarchical linear models

		coefficient	st. error	df	t	p
PCA	intercept	39.31	1.74	26.84	22.56	$p < 0.001$
	post-test	1.57	0.45	897.00	3.52	$p < 0.001$
CCI	intercept	34.52	0.95	107.03	36.40	$p < 0.001$
	post-test	4.54	0.66	474.11	6.92	$p < 0.001$

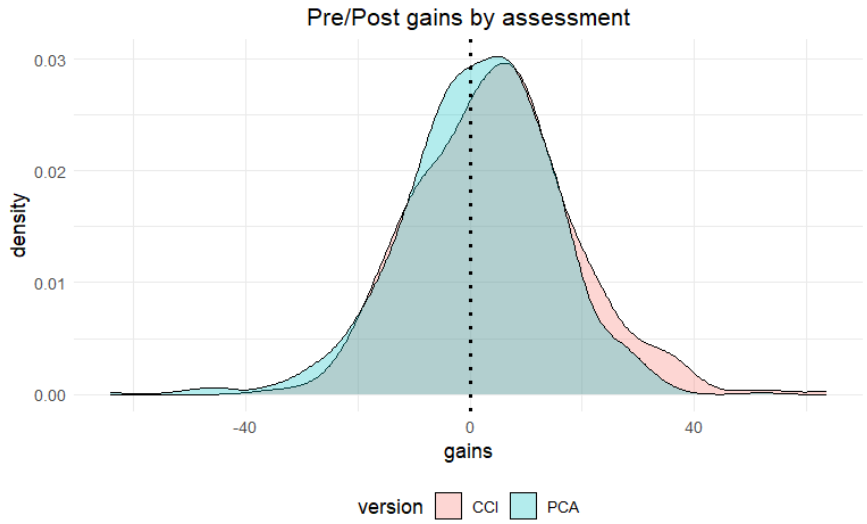

Figure 1. Density plots by gain (post score - pre score) for the CCI and PCA.

Addressing RQ2, Figure 2 depicts the changes in student skill profiles from pretest to posttest. The results for the PCA are located on the left and the results for the CCI are located on the right. Pretest skill profiles are depicted on the left-hand side of each alluvial plot and posttest skill profiles are depicted on the right-hand side of each plot. For example, in each alluvial plot the profiles 0000 or 00000 (we did not code any items from the PCA as assessing "Derivatives") would represent a lack of proficiency for all of the skills. Profiles 1111 or 11111 would represent proficiency in all the skills. The size of each rectangle represents the quantity of students in each group, for example in both the PCA and CCI the largest skill profile group on the pretest is 0000 or 00000.

The two figures portray overall similar trends of small changes in skills that were consistent with the results from research question 1. The PCA also differs because the size of the 0000 group decreased by more than half (51%) whereas for the CCI the 00000 group only decreased by 12%. Large chunks of the 0000, 1100, 1110, and 1111 groups on the pretest stayed at that same skill proficiency on the posttest. For the 0000, and 1100 groups, a notable number of students gained additional skill proficiency on the PCA posttest. This was much smaller for the transition from 1110 to 1111. Almost all of the students that ended with proficiency of all 4 skills, 1111, started there or with proficiency of the first three skills.

The shifts on the CCI were smaller than on the PCA and there were fewer skill proficiency profiles, which was likely due to the smaller sample size. We treat skill proficiency profiles of

00000 and 00001 as equivalent because that last skill is integration and the CCI only has one item that assesses integration. Only mastering integration is unlikely. When we equate skill profiles 00000 and 00001, out of the 378 students who start with no proficiency, 336 finish the course in the same situation. That's 89% of students acquiring no increased proficiency. Though enough students transitioned from 00000 to either 11110 or 11111 to make both of those groups increase in size. The total number of students who finished with proficiency in four or five of the skills was 17% (37) of the sample.

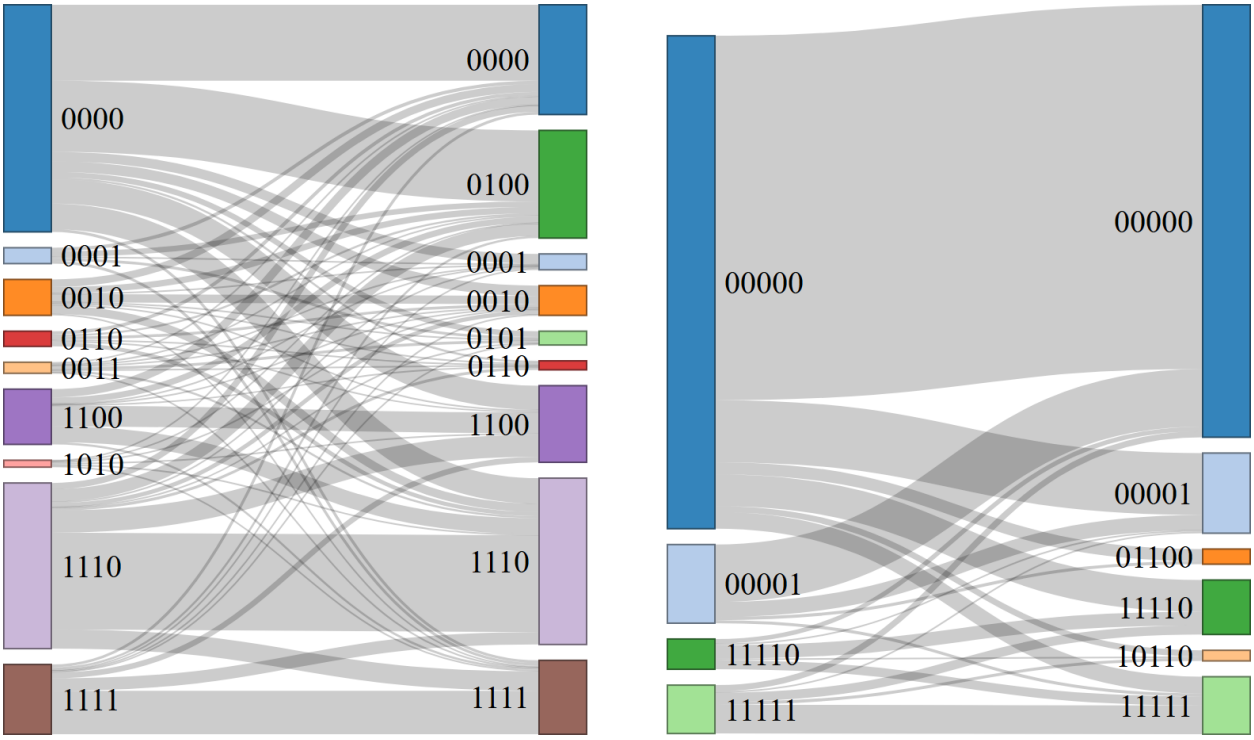

Figure 2. Sankey diagrams of pre-test and post-test data for the PCA (left) and CCI (right). Pre-test skill profiles are on the left of each plot and post-test skill profiles are on the right. For the PCA the binary 4-vector represents student proficiency on prerequisites, limits, applications of derivatives and introductory integration. For the CCI the binary 5-vector represents student proficiency on prerequisites, limits, derivatives, applications of derivatives and introductory integration. For example, on the CCI plot the skill profile 01100 would represent lacking proficiency in prerequisite concepts, proficient in limits and derivatives while lacking proficiency in applications of derivatives and introductory integration. Note: the data was filtered to include only skill profiles that contained at least ten students. Care should be taken when interpreting these plots as they do not represent individual courses but a population of students from many courses.

Limitations

These results represent the outcomes of students in the dataset and do not generalize to other courses or data. The contrast of skill proficiency profiles and overall scores, however, does generalize beyond this data. While binary skill proficiency profiles may seem to oversimplify student knowledge, they are a tradeoff of the finer grain measures that CDMs provide, and our development of the CCD seeks to better leverage this trait of CDMs. The timeframe of pre and post scores misses within-semester dynamics that CDAs can assess. Finally, neither RBA was designed as a cognitive diagnostic and the PCA was not designed with calculus content in mind though the retrofitting of a non-diagnostic assessment in this way is common practice (Ravand & Robitzsch, 2015) and serves to illustrate the information CDAs can provide.

Discussion

While both post-test scores were larger than the pre-test scores, the difference shows limited learning. The effect size on the PCA was d=0.09 and on the CCA was d=0.26. Kraft (2020) points out that a typical gain in secondary school is d=0.5 over an academic year and in introductory college physics the typical gain is closer to d=1.0 (Nissen et al., 2022). The density plots in Figure 1 rule out both floor and ceiling effects, which also indicates that the instruments did not grossly misalign with instruction. The results of the PCA and CCI data are consistent with existing literature on learning gains in calculus classrooms even though those gains are hard to compare given the variety of instruments. This points to a need to develop a standardized, yet flexible, instrument that can meet a broad range of teaching and research needs.

The CDM provides a finer grained perspective than the overall scores. Some students did make small gains in their skill proficiency. This is notable in the decrease of the no skill proficiency group from pre to posttest on the PCA and the increase in the 4 and 5 skill proficiency groups on the CCI. These small gains, however, sit within a larger picture of stagnation where instruction maintains proficiency for those who start with it and leaves those without proficiency in that state. It is particularly concerning that there does not seem to be a greater increase in the number of students gaining proficiency on prerequisite skills.

Consistent with the results from our first research question, either the instruction in these courses did not support the development of student proficiency or the RBA was not a good fit for the content of the course. Our five skills are consistent with commonly covered content areas in a first semester calculus course (Tallman et al. 2016) and most students who start with no proficiency (00000) end the course with no change to that skill profile. Most students who began with full proficiency retained that throughout the course, though some students transitioned from partial/no proficiency to full proficiency. This is consistent with Bressound's (2021) description of calculus classrooms in higher education having both students who are encountering these ideas for the first time and for whom this may be their last math course and those taking calculus again, after high school preparation who are building towards a math intensive STEM discipline.

Conclusion

The data for the PCA and CCI pre and post test scores are consistent with the literature that students experience relatively little learning in introductory calculus courses. Students who begin the course with low proficiency have minimal opportunity to improve while those who already possess high proficiency maintain that level.

The post-test score is too little too late to support teaching and learning. The CCD will support instruction by providing timely assessments that are fine grained enough to be acted upon. For example, instructors can use CCD results to inform what content they cover in their lectures or on their homework and to inform timely interventions to better ensure that students had the skills they needed before moving on. Student groups for in-class work could also be structured using CCD results to foster peer collaboration. The CCD, delivered with computerized adaptive technologies on the LASSO platform, has the capacity to support this vision.

"I think most of them would say they don't understand yet": Mathematicians' Views on the Benefits of In-class Time

Corinne Mitchell
Virginia Tech

Estrella Johnson
Virginia Tech

Tim Fukawa-Connelly
Temple University

Through analysis of 7 mathematicians' perspectives teaching proof-based linear algebra, we found that participants wanted to offer benefits to students during class which were analogous to the benefits documented in previous research that mathematicians have when attending and giving mathematics lectures at professional events (e.g., conferences, symposia, or workshops). Findings suggest that mathematicians may see attending mathematics lectures as an authentic mathematical practice in ways that education researchers have not previously attended to.

Keywords: teaching practices, proof-based courses, lecture, active learning

Efforts by the mathematics education research community to improve teaching have led to the development and testing of reform initiatives throughout the undergraduate mathematics curriculum. However, as documented by Fukawa-Connelly et al. (2016) and summarized by Artigue (2016), there has been "very limited influence of our research on university teaching practices. Reading recent publications… I find nearly the same description of standard university practices at undergraduate level as decades ago" (p. 12). One explanation for this is that "standard university practices" may be fulfilling the instructional goals of mathematicians in ways that reform initiatives championed by mathematics education researchers are not. By investigating what mathematicians see as valuable uses of class time, we gain insight that may allow us to propose pedagogical changes in ways that are better aligned with mathematicians' goals and have broader impacts at the practitioner level. To this end, we report on a collaboration between mathematics education research and mathematicians on the implementation of specific evidence-based active learning strategies (EBALS) in an advanced linear algebra course.

Background and Framing

Surveys on reports of how mathematicians structure their in-class time have consistently shown that lecture is the dominate form of instruction. For instance, Eagan (2016) found that about two-thirds of mathematics teachers use "extensive" lecturing in all or most of their courses, Johnson (2019) stated that "77% of pre-calculus courses, 82.3% of Calculus I courses, and 86.3% of Calculus II courses are taught as either 'lecturing and answering student questions' or 'lecture with some active learning techniques', and Fukawa-Connelly et al. (2016) found in their study that 85 percent of respondents reported using "lecture" to teach abstract algebra, as opposed to reporting that they use a "non-lecture pedagogy". Research on instructor's beliefs about teaching and learning, however, suggest that the predominance of lecture may not simply follow directly from their beliefs. For instance, in comparison to the 85% of respondents who reported that they lecture in their survey of abstract algebra instructors, Johnson et al.'s study (2019) only about 59% of the respondents agreed with the statement "*Lecture is the best way to teach*", whereas the overwhelm majority of them, 87%, agreed with the statement *"I think students learn better when they do mathematical work (in addition to taking notes and attending to the lecture) in class*". This raises a natural question: If instructors believe that students learn best when they are doing mathematical work in class, then what do mathematicians see as the benefit of lectures?

A similar question was the focus of a study conducted by Weber and Fukawa-Connelly (2022). Instead of looking at what mathematicians perceived as benefits of attending a lecture for their students, they instead investigated what benefits they perceived for themselves as lecture attendees in a workshop on inner-model theory. As mathematical learners in this setting, the mathematicians did not necessarily expect to learn everything they needed to know from watching a lecture. Rather, they saw key features of the lecture as beneficial to their own independent study of the content. Indeed, the benefits Weber and Fukawa-Connelly (2022) found belonged not only to those attending the workshop lectures, but also to those who provided them. It is natural to wonder whether the same benefits mathematicians see in attending lectures for themselves as learners are also considered by mathematicians as they think about how to spend class-time as teachers.

Analytic Framing, Methods, and Data

A key premise of the NSF funded *Collaborating with Mathematician's to Enhance Teaching (COMET)* project, of which this work is subsidiary, was that the reasons mathematicians have for rejecting or accepting EBALS provide insight into what they see as beneficial or valuable. Similar to Herbst and Chazan (2011), we aim to understand stable systems of practices by understanding how those systems react to perturbations. By proposing changes to mathematicians' face-to-face instructional practice, we created discussions focused on their considerations when planning class, revealing the reasoning behind and justification of their use of class-time. Here we analyze these reasonings and justifications to answer the research question*: When mathematicians are considering what is a valuable use of class time, do they attend the same benefits that they attribute to the mathematics lectures that they present and attend (e.g., at conference presentations, symposia, and workshops)?*

The data was collected over the course of two semesters at a large American university. Over the course of six semi-weekly meetings throughout each semester, three mathematics education researchers met with a group of mathematicians teaching a proof-based linear algebra course. The first group had four instructors and the other three. In this paper, the year one instructors are assigned pseudonyms A1, A2, and so on, and the year two instructors are assigned B5, B6, and so on. The goal of such meetings was to strategize about incorporating EBALS in the linear algebra course. The course presented an axiomatic treatment of abstract vector spaces and linear transformation on those spaces and covered topics such as eigenvectors and eigenvalues, the Jordan Canonical Form (JCF), its associated theorems, and inner product spaces. Prior to the start of regular meetings, the mathematicians were also interviewed about their current teaching practice. Each of the interviews and collaborative planning meetings were initially transcribed using Otter.ai. First, we conducted a thematic analysis (Braun & Clarke, 2006) to understand the mathematicians' considerations about how to spend their class time. Then, we analyzed how the themes we found relate to conventions of lecture in a professional context.

After editing the AI generated transcripts for accuracy, the first author made an initial pass through the data, identifying any excerpts where participants discussed the purpose of in-class time, either by describing what they wanted to do during class or by explaining why they would not want to do a particular activity. These excerpts were logged in a spreadsheet where the excerpt was described and initial comments about the content of the excerpt were made. Then, these initial descriptions became the focus as we sought commonalities between comments and then arranged them into larger themes. These themes became a codebook that was used to code each transcript during the second pass through the data. After collecting all instances of each theme into a single document, the first and second author met to resolve any disagreements.

Finally, we compared these inductive themes to the benefits of lecture identified in Weber and Fukawa-Connelly (2022). Specifically, we sought analogues to the benefits *exposing participants to interesting results, providing a big picture of the domain, highlighting results and techniques that are important,* and *illustrating how the lecturer thinks about a topic.* That is, we hypothesized that these mathematicians were attending to benefits analogous to those identified by Weber and Fukawa-Connelly when they considered how to spend class time, and then looked for confirming and disconfirming evidence in our thematically coded data.

Findings

When discussing their plans for class, these mathematicians did not expect that the students would develop deep understanding of the material based solely on what happened during class time. Instead, they often indicated that they believed that students needed to study the material outside of class to understand it thoroughly[1]. Six of the seven mathematicians made comments relating to this idea. When asked how students best learn in the course, A1 said,

> "By doing mathematics. . . **Watching me doing it a million times, I don't think has much of an effect and seems like a different skill**. You know, **they could watch me prove a theorem and be really amazed at it**, how clever that is, and so on. **And they will never know how to do that themselves**."

We note the distinction made by A1 between the skill of studying independently and the skill of watching a lecture. Students could be amazed by watching a lecture, but that is not enough for students to learn the mathematics themselves. A2 and A3 echoed this sentiment, with A2 noting that "30 seconds or one minute is not enough" to absorb complex ideas during class, and A3 saying that, if you asked students what they understood at the end of class for an *exit-ticket*, "I think most of them would say they don't understand yet". It makes sense that if you believe that significant time and effort are needed for students to develop a deep understanding of the content, then developing such an understanding would not be a reasonable goal for the few hours a week spent in class.

Instead, when we asked what was most important to do during class time, responses fell broadly into four categories. For instance, B7 stated:

> "The first thing is that **I give a very organized lecture so they know what is important**. The most important formulas, or theorems, and hopefully some of the arguments. And second, I think **hopefully it'll be a bit inspiring**, so that **they will find it interesting**. For example, in today's class, I did one example about the derivative for polynomials. So they can sort of relate differentiation and integration as linear operators to the matrix representation. So **this is some connection between calculus and analysis to algebra and matrix algebra, as well as how it's related to physics**. So I hope I try to be a little bit inspiring at times."

These mathematicians wanted to spend class time interesting, inspiring, and motivating their students; they wanted to provide an overview of the big ideas in linear algebra, including how they relate to other domains; to highlight important results and techniques; and to illustrate appropriate thinking about the content.

[1]While they expected students to follow along with calculations and proofs of lemmas or simpler theorems, these discussions were often referencing abstract concepts, or theorems which required more involved methods of proof.

Class Time Should Inspire Students

Inspiring students by discussing interesting results during lecture came up frequently during meetings. Furthermore, participants' commentary often focused on motivating the mathematical material presented in the course. Five of seven mathematicians made relevant comments.

A1 referenced wanting to "sell" the material to the students, as well as ways he generated student "buy-in" to the course, to "get [students] hooked" by explaining how a vector is an essential object with applications "not just to linear systems, but to differential equations, to probability and statistics, to game theory, [and] to particle physics . . ." Later, he argues, "the reason you can have all these different applications is that [a vector is] fundamentally an abstract mathematical thing. So that's how I actually put the hook in there. And I think students are buying it so far." Several mathematicians in our study prioritized showing students interesting results from linear algebra that apply to other sciences. We interpret A1's reference to "buy-in" as expressing a desire for students to be willing to engage in the more abstract reasoning required in proof-based linear algebra.

In addition to motivating students, these mathematicians also wanted to motivate the mathematics presented in class. Specifically, they prioritized discussions that developed intellectual need for the material they covered. All of the year 1 collaborators considered motivation when they discussed the lectures on the Jordan Canonical form, complaining that the textbook's treatment was inappropriate for presenting in class. A1 commented, "It's written in a very "mathematician" style: definition, theorem, proof . . . for twenty theorems." A2 echoed this sentiment and explained,

> "It's unfortunate that this book starts with proofs . . . so I also had to adjust this. But **for motivation**, what I told the students is that we always want to find the simplest possible matrix. So that's actually a good way to **explain why we need Jordan canonical form**."

B6, A1, and A2 all noted that motivation was an essential product of lecture that was often missing from the textbook. B6 even contended that this kind of motivation supported students' learning outside of class, saying, "Because students have a textbook that they can read for theorems, I think an important thing is to just motivate things because it's a lot easier for them to learn if they know why you would ever define these things." In short, the mathematicians prioritized motivation in two senses: inspiring students to be curious about the content, and discussing the origins and context of the material to create an intellectual need for learning it.

Class Time Should Provide an Overview of the Content

We found that the mathematicians in our collaborative planning meetings wanted to provide students with an overview of the high-level ideas of linear algebra; they did not intend to spend class time fleshing out every detail exhaustively, because they saw the details as time-consuming and students as unable to digest them in real time. All seven participants made comments in this theme. For example, A3 remarked, "I don't think that's an efficient use of class time to listen to someone prove very slowly this theorem, because I think **you just want to get the main idea**." He did see presenting material in class as communicating to students which content to account for on future assessments:

> "You have to spend time on the proof, because they're responsible for knowing that. You can't just say read the book. **That doesn't mean you have to go through every detail**, you know. I think you have to do the hard direction [of the biconditional], or **you have to introduce the main idea**, right?"

In addition to demonstrating which concepts students are "responsible for knowing", participants frequently commented that class time should be spent showing students how important concepts

are related to each other, as well as situating the course content within broader scientific contexts. A1 remarked, “Sometimes it's not fully connected in their minds, these different concepts. So maybe that's something that I could stress more in my lectures, try to make these connections clearer.” We see this attitude as analogous to the mathematicians interviewed in Weber and Fukawa-Connelly (2022) in that, for our participants, emphasizing the high-level ideas and their connections to each other was a benefit of lecture.

Class Time Should Highlight Important Concepts and Techniques

Participants frequently accepted or rejected a suggested EBAL based on whether it concerned content that was important enough to spend class time on, with five of seven making comments in this theme. What warranted importance often varied; content was “important” if it was worth understanding more deeply, introduced a new skill, or if it was seen as either more sophisticated than the prerequisite linear algebra course’s content or as necessary for the preparation of math majors. After accepting a task concerning the JCF, mathematician A1 commented,

> “I think in this case, you made the right choice. The theorem that you chose questions for here, that's actually the main important thing to get the block diagonal structure. That is a really important theorem. And it takes a long time [to prove], because it has several parts, and none of the parts are trivial to do. And then everything else kind of follows from that.”

B5, A2, and B6 often referenced wanting to spend class time on demonstrating new skills, with A2 commenting that he would not “give the full details” because “the main thing is to teach them how to do the calculations” which were new content for the course. We interpret the reference to “the main thing” to be synonymous with “the important thing.” He sees understanding how to find a linear transformation’s JCF as important enough to spend class time on because, in contrast to other calculations, this one is specific to the advanced linear algebra content.

That is, an activity was often considered important if it was appropriately sophisticated for the level of the course. A3 agreed, saying that the use of more abstract vector spaces of functions was “really important if they want to go into a differential equations class.” As well as attending to whether a task was appropriately sophisticated for the 350-level course, participants also weighed importance based on relevance to other courses in the math major, like differential equations. B5 added, “I think it just ties in with so many different courses in the math major that it's worth doing.” Finally, A3 commented, “I think in terms of the applications [math majors] are interested in, the inner product stuff is much more important.”

These participants wanted to show students “important results” that were conceptually rich, worth understanding deeply to use in practice later. The pedagogical context offered more nuance; a concept was also considered important if it was appropriately sophisticated for the level of the course, or if it was relevant to future courses in the math major.

Furthermore, this decision-making apparatus took the form of a biconditional statement. Not only did these mathematicians want to spend class time discussing important concepts, they warned that the amount of time spent on a concept during class *indicated to students* which content was important. When discussing whether he valued having students create their own conjectures during class, A3 commented that many theorems in linear algebra would not be appropriate for such an activity, noting the rank-nullity theorem as an exception. Then, he said, “But I don’t know, I don’t really feel like the rank-nullity theorem is that important. I don’t want to spend that much time on something that I don’t really care about that much.”

Time spent during class on a particular topic corresponded to its importance relative to the course content. Although A3 saw conjecturing as a valuable practice for students, he did not

wish to emphasize a theorem that was not important enough to spend that amount of class time on. A2 made similar comments:

> "Especially for some really, really important theorems, for example, the proof that every linear transformation has a Jordan canonical basis. The goal for the students to get these arguments, it's very good. But on the other hand, we cannot use it for all the theorems, because we do not have enough time for this course. We can only do it for the important theorems."

It is notable that these mathematicians sometimes saw active learning as having an undesirable potential to emphasize results or techniques which were not important enough to warrant the time expenditure.

Class Time Should Illustrate How to Think About the Content

The mathematicians in our study wanted to model how to do linear algebra according to the norms and values of the broader mathematical community, beyond showing how the lecturer as an individual approached the content. This included demonstrating appropriate rigor and precision, showing students which ways of thinking may be productive, and giving students the opportunity to have their misconceptions corrected by an expert. All seven mathematicians made comments in this theme.

A2 observed that "the nice thing" about class was the chance he got to show students how to express their correct ideas abstractly and rigorously, saying "I point out that okay, yes. Roughly, you're right. But see, this is not precise. The precise way is [this]." It was important for participants that time spent in class not only showed students appropriate rigor, but also focused on material that was sufficiently sophisticated for the course. For example, it was important that examples used vector spaces other than $\mathbb{R}^n$. A3 commented,

> "In things like signal processing, we really use vector spaces of functions that are usually not polynomials, polynomials very rarely come up in in applications. It's usually either periodic functions, or exponentials, or logarithms, things like that. I think this course is really an opportunity to talk a little bit more about those kinds of functions."

B5 and B6 both described tension regarding the use of notation aligned with the textbook that was unconventional in the mathematical community, with B6 saying "I'm really torn between whether to use the book's notation or to use the notation that everyone else uses." A1 was willing to spend time in class on tasks that developed productive ways of reasoning about the content, saying, "there should be a way of making that part of their habit of thinking."

Our participants wanted to spend class time demonstrating what it meant to do math at this more advanced level. We see this benefit as analogous to the benefit Weber & Fukawa-Connelly (2022) found that the mathematicians in their study valued observing the habits of mind of a professional, experienced practitioner of a niche subfield. Because the audience members our participants referred to were students, it is sensible that they felt a responsibility to include *informal content* (see Fukawa-Connelly et al. 2017) like attending to precision and rigor, or correcting misconceptions, where the lecturers in the former study may not have.

Conclusion and Implications

There are many motivations for mathematics education researchers to advocate for the use of EBALS, and many benefits of their use recognized by mathematicians. These motivations and benefits vary based on the specific strategy, and the implementation of these strategies may be more or less compatible with lecture. For instance, Johnson et al. (2025) distinguished between "two types of active learning pedagogy in advanced mathematics: pedagogy to *replace* lecturing

and pedagogy to *augment* lecturing" (pg. 147, emphasis in original). They go on to argue that, while there has been comparatively limited research in undergraduate proof-based mathematics courses on the use of EBALS that augment lecture, there has been substantial research in undergraduate mathematics education on initiatives designed to replace lecturing.

In this push to replace lecture, a common sentiment is that class time should be used to engage students in authentic mathematical activity. For instance, in providing a joint characterization of Inquiry Based Mathematics and Inquiry-Oriented Instruction, Laursen and Rasmussen (2019) state that a

> "distinguishing characteristic of inquiry is the nature of students' mathematical work. In inquiry classrooms students reinvent or create mathematics that is new to them. They do so by engaging in mathematical practices similar to those of practicing mathematicians: conjecturing and proving, defining, creating and using algorithms, and modeling" (p. 4).

However, this description of the practices of mathematicians leaves out some of the ways that mathematicians learn about new areas of mathematics, by attending lectures at workshops and studying the foundational texts of that area (Weber & Fukawa-Connelly, 2022). And indeed, we found that our mathematician collaborators attended to the similar benefits mathematicians attending – and giving – professional lectures when evaluating how to use class time.

We see two ways in which this finding can inform the work of mathematics education researchers looking to have a broader impact on undergraduate instructional practice. First, many mathematicians have goals like covering course content and improving students' abilities to write conventional proofs (e.g., Johnson et al., 2013; Johnson et al., 2025; Wu, 1999). Our findings add nuance to these goals. When we attending to the goal of providing students with a "big picture", we can make sense of content coverage as a priority for mathematicians regardless of department pressure (see Johnson et al., 2018). Content coverage may be seen as a prerequisite for situating the high-level ideas and techniques in relation to each other. Notably, active learning pedagogy designed to replace lecturing tends to prioritize depth over breadth in terms of content (Roth McDuffie & Graber, 2003). Additionally, demonstrating proof conventions like abstraction and rigor during class may be important to mathematicians not only because it prepares students to write formal proofs, but because it gives the audience access to the habits of mind of an expert. Modeling a formal proof by providing a lecture may be a more effective way of meeting that goal than active learning strategies that are designed with the intention that "the teacher must help transition the developing mathematics of the classroom, from that of informal student reasoning to that of formal mathematics" (Kuster et al., 2018). While we see the desire for more student-centered instruction as legitimate, it seems that there are places in which that desire may be at odds with some of the goals that mathematicians have for class time.

Second, in problematizing lecture-based instruction, we implicitly disavow a disciplinary practice that they themselves turn to when they want to learn (i.e., listening to lectures). This stance disavows a practice that is seen as beneficial by many in the community we are trying to reach. Further, we may be asking them to replace that practice with something that fails to provide them with those same benefits. This information not only allows mathematics education researchers to better understand why so many of our instructional innovations have failed to be adopted at scale, it also provides additional considerations for designers and disseminators of active-learning innovations as they think about how their products do (or can be adapted to) provide benefits more aligned with the goals of practitioners while preserving their own values.

Mathias Chacon-Perez
James Madison University

This study explores student-generated memes submitted as a part of a Calculus II homework assignment. Drawing on a twofold theoretical perspective that combines Bini et al.'s (2023) heuristic model for the creation of a mathematical meme and Bolman and Deal's (2008) Four Frames framework of an organizational culture, we analyzed 32 memes and corresponding reflections. We found that via memes, students reflect on and communicate their struggles with Calculus and draw connections between Calculus concepts. Memes also became a vehicle for reflecting and shaping the classroom culture, offering students an opportunity to "laugh back" at the course authority. Together, these findings illustrate how memes can serve as reflective artifacts that capture both cognitive and socio-cultural dimensions of learning. We argue that meme-based assignments hold promise for fostering higher-order thinking, humanizing instruction, and promoting engagement in a challenging Calculus course.

Keywords: memes, Calculus, assignments, classroom community and culture

The term *meme* was first introduced by Richard Dawkins in his book *The Selfish Gene* (1976) to describe a cultural unit transmitted between people in a manner analogous to genes. With the rise of the internet, memes initially appeared as simple captioned images circulating in online communities for humorous purposes. Today, they encompass a wide range of formats, including photographs, videos, and hashtags, and play an increasingly prominent role in modern digital culture. Beyond entertainment, memes now function as tools for communication, creativity, and self-expression, offering ways to comment on current events, challenge mainstream narratives, and participate in shared community life.

While research on memes in education is still emerging, scholars have increasingly recognized their significant educational potential. Studies demonstrate that memes can be a valuable and effective addition to higher education classrooms, fostering student engagement, critical thinking, and creativity across a range of disciplines, such as psychology (Kath et al., 2024), pharmacy (Brown, 2020), nursing (Bradley et al., 2022), and others.

Mathematics educators have likewise begun exploring the role of memes in teaching and learning. One line of work focuses on *mathematical memes* (memes containing a mathematical statement that can be validated) circulating in global online communities (e.g., Benoit & Salopek, 2023; Bini et al., 2022). For example, Benoit et al. (2025) found that engagement with mathematical memes can influence students' mathematical identity and their perceptions of who can become a mathematician. Another line of research examines *pedagogical memes* – memes intentionally integrated into mathematical instruction. Studies suggest that such memes support effective learning practices, enhance students' motivation, and reduce math anxiety (Akin et al., 2025; Sidekerskienė & Damaševičius, 2025). In particular, Sidekerskienė and Damaševičius (2025) presented a case study of a university Calculus instructor who incorporated a set of memes into her lessons as visual aids, thereby making complex Calculus concepts more accessible and engaging, which in turn improved student understanding and motivation.

The purpose of the present study is to extend the exploration of memes in undergraduate mathematics education by focusing on student-generated memes. Specifically, we analyze memes created by undergraduate students as a part of a homework assignment in one section of Calculus II, taught by the first author during the Spring 2025 semester. This study is guided by the following research questions:

1. How can undergraduate students use memes to reflect on and communicate their experiences with Calculus? In particular, what Calculus concepts and learning experiences do they reflect on and communicate through memes?
2. What pedagogical implications emerge from incorporating meme creation into a homework assignment in a Calculus course?

Theoretical Perspective

In answering these research questions, we adopt a twofold theoretical approach. First, we draw on Bini et al.'s (2023) heuristic model for the creation of a mathematical meme. This model views meme-making as an iterative process of linking between a specific meme template and a mathematical concept. According to Bini and colleagues, mathematical memes integrate three partial meanings: structural (the visual and textual conventions of meme formats), social (the cultural resonance of the chosen template), and specialized (the mathematical content to be expressed). The creative act lies in identifying a *linking idea* that bridges these domains. Although this model was originally developed for mathematical memes, we extend its application to encompass memes that capture both Calculus concepts and students' learning experiences.

As it was pointed out by Benoit and Salopek (2023), "… memes do not exist in a vacuum; they rely on a shared cultural and semiotic understanding for collective interpretations. They are entangled in their sociocultural environments and cannot exist outside of the events and practices in which they appear" (p. 45). In our study, memes were created by the members of a specific sociocultural environment with its own rules, practices, and shared meanings. Therefore, we adopt another framework that complements Bini et al.'s model by providing in-depth insights into classroom culture – the *Four Frames* perspective. Originally, this perspective was developed in organizational science (Bolman & Deal, 2008) and later adapted for undergraduate STEM department contexts (Reinholz & Apkarian, 2018). In this study, we extend its application to an even more local setting – a single classroom community.

In the Four Frames perspective, culture is defined as "a historical and evolving set of *structures* and *symbols*, and the resulting *power* relationship between *peopl*e" (Reinholz & Apkarian, 2018, p. 3). This definition highlights four interrelated dimensions of organizational culture. Table 1 summarizes the definitions of these dimensions and illustrates how they manifest in a mathematical classroom setting. Specifically, we view classroom *structures* as the syllabi, assignments, routines, and assessments; *symbols* as the cultural and humorous artifacts, informal rituals, and shared meanings; *people* as the permanent and temporal members of the classroom community (i.e., students, teacher, and the substitute teacher); and *power* as the authority and explicit (and implicit) hierarchy in a mathematical classroom.

Table 1. Definitions and aspects of the elements in the Four Frames framework, and their applications to a mathematical classroom setting.

Frame	Definition (adapted from Reinholz & Apkarian, 2018)	Application to a Mathematical Classroom
Structures	Formal arrangements, policies, and practices that organize how people work.	Syllabi, assignments, routines, and assessments.
Symbols	Cultural artifacts, language, rituals, stories, and meanings that community members use to guide their reasoning.	Cultural and humorous artifacts, informal rituals, and shared meanings.
People	Individuals and groups within the community.	Students, course instructor, and substitute teacher.
Power	Status, control, position, and political coalitions which mediate interactions between people.	Authority and explicit (and implicit) hierarchy in a mathematical classroom.

Methods

The data for this study stem from a second-semester Calculus course (Calculus II) taught by the first author in Spring 2025. The course enrolled 33 students, the majority of whom were STEM majors. Throughout the semester, the instructor regularly incorporated memes into his instruction, using them in lecture notes, handouts, online announcements, and a specific homework assignment called *Memengful Calculus*. This assignment, which accounted for 3% of the overall course grade, required students to submit a meme accompanied by a brief written reflection. In their reflections, students were asked to explain the choice of meme context, describe the Calculus concept or learning experience they were referring to, and elaborate on the connection between the two. By the time the assignment was due (around the middle of the semester), the following topics had been covered: Riemann Sums, volumes of solids of revolution, various integration techniques, and improper integrals.

The data corpus consisted of 32 submissions (32 memes and 32 corresponding reflections). All submissions were completely anonymized. The analysis proceeded in multiple iterations. In the first round, we conducted open coding, focusing on three dimensions of each submission: the context of the meme, the Calculus concept or learning experience it referenced, and the links between them. The submissions were divided into four equal sets, with each researcher coding the assigned set independently. During weekly research meetings, we reviewed and discussed all codes as a team, reaching consensus through the process of constant comparisons (Glaser & Strauss, 1967). Related codes were then grouped into categories, which served as the foundation for developing higher-level themes through thematic analysis (Braun & Clarke, 2006).

The final step of the analysis involved interpreting the resulting themes through the lens of the Four Frames framework. This allowed us to examine how students' submissions reflected their positioning within the social and cultural dynamics of the course.

Results

Our thematic analysis revealed four themes: two *cognitive themes* that captured students' engagement with mathematics and two themes related to different aspects of the *classroom community and culture*. In what follows, we describe each theme and illustrate it with the most salient examples from the students' memes and corresponding reflections.

Cognitive Themes

Through memes, our participants expressed their struggles with Calculus, particularly in relation to quizzes and exams. At the same time, the Memengful Calculus assignment provided a space for students to reflect on their mathematical knowledge by comparing various Calculus concepts and even making connections across different branches of Calculus.

Struggles with Calculus. A persistent myth surrounds mathematics–undergraduate mathematics, and Calculus in particular–that portrays it as "nightmarish, inherently difficult, and something to be avoided" (Darragh, 2018, p. 197). Many of our participants' memes echoed this characterization. Figure 1, for instance, illustrates students' struggles with two integration techniques – integration of rational functions by partial fractions and trigonometric substitution. As one student explained in their reflection, "Trig sub has been my biggest downfall in this class, so I would rather do any type of integration over that."

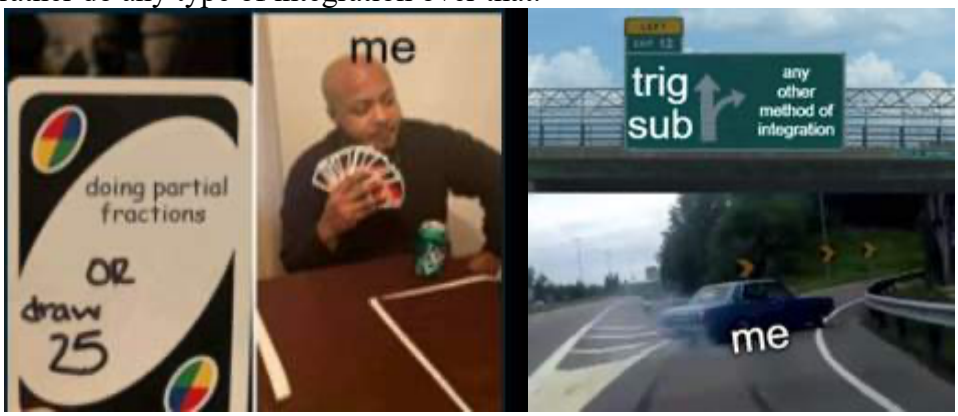

Figure 1. Students' memes illustrating struggles with two integration techniques.

In addition to communicating struggles with particular Calculus concepts, our participants' memes often conveyed the stress and frustration they and their peers experienced in relation to quizzes and exams. For example, one student described the discouraging experience of forgetting to adjust the bounds when applying the substitution rule in a definite integral on a midterm (Figure 2, left). Another student created a meme capturing their classmates' struggles with an in-class quiz on partial fraction decomposition (Figure 2, right). As they explained in their reflection, "I made this meme in the wake of the ***devastating*** news of quiz 5. While I personally did not struggle with the question, I know others who did and thought this would be a lighthearted representation of that struggle."

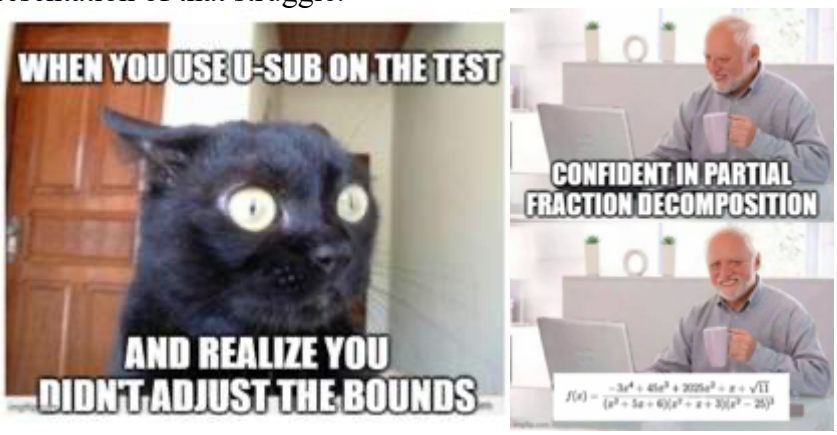

Figure 2. Students' memes illustrating struggles with quizzes and exams: forgetting to adjust bounds on a test (left) and the collective difficulty with the partial fractions problem on an in-class quiz (right).

Reflecting on conceptual connections. Some students used memes as an opportunity to reflect on and articulate conceptual connections between Calculus concepts, including drawing links between material previously learned in Calculus I and new content introduced in Calculus II. One student created a meme contrasting the processes of differentiation (Calculus I) and integration (Calculus II) of the same function, noting that the former was "easy to find," whereas the latter produced a lengthy and complicated formula (Figure 3, left). Another student used their meme to highlight a key distinction within Calculus II itself, focusing on the subtle differences between the proper and improper integrals (Figure 3, right). In their reflection, the student explained that their meme offered a playful way to emphasize the "improperness" of the latter, showing that a seemingly minor change in the integral bounds may result in a significant change in the type of integral – an idea humorously conveyed through the distorted appearance of Winnie the Pooh.

Figure 3. Students' memes illustrating conceptual connections: comparing differentiation and integration of the same function (left) and contrasting proper and improper integrals (right).

Classroom Community and Culture

When completing the Memengful Calculus assignment, many students went beyond interpreting Calculus solely as mathematics learned in this course and created memes that captured various aspects of the classroom community, which they were a part of. This aligns with the idea that a meme is strongly connected to its socio-cultural context (Benoit & Salopek, 2023; Bini et al., 2022), even when the overarching community is a single Calculus II class with its integral elements – students, instructor, rituals, shared meanings, and the power dynamics.

Classroom experiences. Many submissions reflected students' everyday experiences in a Calculus classroom. These experiences are shaped by many factors, such as the students' schedule, seating arrangements, interactions with their peers, inside jokes, and memorable sayings from the instructor. For example, one meme reproduced a recurring phrase the instructor used to close the class (Figure 4, left). As the student explained in their reflection, "Instead of saying just 'any questions?' like a normal teacher, [the instructor] adds a little spice to this saying by asking, 'any questions, comments, complaints, or compliments?" By humorously elevating this classroom ritual, this meme underscored how certain phrases and routines contributed to shaping the unique classroom community.

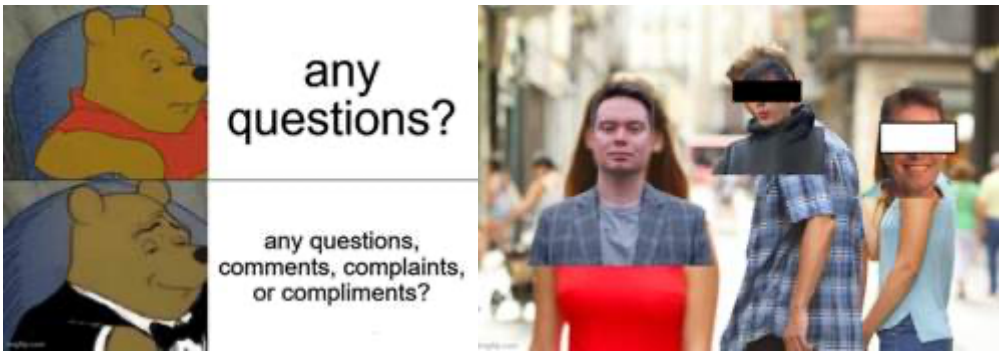

Figure 4. Students' memes illustrating aspects of the classroom experiences: recurring instructor's saying (left) and the student's reluctance to adjust to another instructor's new teaching style (right).

In some submissions, students positioned themselves as integral members and even gatekeepers of this community. The meme presented on the right side of Figure 4 illustrates a student in the role of a "distracted boyfriend" who turns away from his "girlfriend" (a substitute teacher) and directs his attention to "another girl" (regular course instructor). This meme reflects the student's experience of (an award-winning) teacher subbing for the regular instructor for several classes, humorously underscoring the student's loyalty to the familiar classroom culture and reluctance to adjust to a new one. The temporary disruption of the established classroom community thus induced the student's dissatisfaction that turned out to be memorable enough to be immortalized in their meme.

Memes as an opportunity for students to "laugh back." Several students also used pictures of the instructor found on the internet to create their memes. However, in these cases, the instructor's image carried structural meaning (a part of the meme's visual and social context), rather than a mathematical meaning tied to a particular Calculus concept or learning experience.

One student contrasted a German U-boat with the *u*-substitution technique, humorously modifying the famous *Drakeposting meme* by placing the instructor's image on top of Drake's face (Figure 5, left). This meme is typically used to express one's disdain and admiration for certain or different subjects. In the student's submission, the Calculus instructor is humorously positioned as "choosing" the integration technique over a submarine. Another meme depicted the instructor's face with a stern expression, captioned to suggest his reaction to students resisting "to do the hardest integration problem known to man" at the end of a Friday class (Figure 5, center). The student learning experience referenced here is their mental exhaustion that builds up at the end of the week, with the instructor's face serving as a humorous foil for this frustration.

Figure 5. Students' memes utilizing the instructor's image: the instructor choosing u-substitution over a German U-boat (left), depicting the instructor's stern reaction to students resisting "to do the hardest integration problem" at the end of a Friday class (center), and students' productive struggle with irreducible quadratics (right).

Perhaps the quintessential illustration of this theme is presented in the meme on the right side of Figure 5. Similar to one of the cognitive themes described in the previous section, this meme references the students' (productive) struggle with a challenging Calculus concept – integrating irreducible quadratics. However, the context for this meme was shaped by the instructor's picture, which anchored the meme's humor. The student even added a playful nod to the instructor's accent through the tiny caption "I'm smort" embedded in the image. Taken together, these three memes demonstrate how the Memengful Calculus assignment created space for students to "laugh back" at the course authority, humorously re-negotiating classroom power.

Discussion and Conclusion

This study set out to explore how students can use memes to reflect on and communicate their experiences with Calculus and what pedagogical implications this type of assignment might have. Our analysis revealed that memes provided a flexible medium through which students expressed both cognitive and socio-cultural dimensions of learning.

With respect to our first research question, we found that memes allowed students to both articulate their struggles learning Calculus and reflect on conceptual connections across different topics. The former echoes a popular societal perception of mathematics as "nightmarish" and "inherently difficult" (Darragh, 2018), while the latter suggests that the Memengful Calculus assignment encouraged engagement in higher-order cognitive processes, such as creation and metacognition (Bloom, 2010). In this sense, memes functioned not only as humorous artifacts but also as learning tools. This finding contributes to the growing body of research suggesting that memes can promote students' learning across disciplinary domains (e.g., Bradley et al., 2022; Brown, 2020; Kath et al., 2022).

We also found that students reflected on and communicated about the classroom experiences and various aspects of the classroom community and culture. Students' submissions captured each of the Four Frames of Bolman and Deal's (2008) framework. Specifically, memes aligned with the *structural* frame by highlighting students' struggles during course assessments and the necessity to work on a challenging mathematical task at the end of a Friday class. They reflected the *symbolic* frame through inside jokes and the instructor's recurring catchphrases. The *people* frame emerged in memes that incorporated images of the community members, emphasizing the personal and relational aspects of classroom life. Finally, the *power* frame was evident in students "laughing back" at the course authority by using the instructor's images as the memes' contexts. Taken together, these findings further shed light on how memes reflect and contribute to the development of the epistemic culture of overarching communities (e.g., Bini et al., 2022, 2023) – in our case, the classroom community – thus addressing our second research question.

Finally, as became evident in our last theme, this assignment has further pedagogical implications not previously documented in the mathematics education literature. Iloh (2021) discussed the utility of memes in qualitative research, highlighting their potential for building rapport between researchers and participants. Our findings extend this argument to a mathematical classroom, suggesting that meme-based assignments can also foster rapport between instructors and students by creating space for students to "laugh back." In this way, this assignment allowed the instructor to humanize his teaching practice, while the students were empowered to infuse humor into their mathematical learning experiences. Therefore, incorporating student-generated memes in a mathematical course can reduce the traditional power distance, foster a more collaborative learning environment, and support student engagement in a challenging Calculus course.

Assessment of Student Understanding: Exploring Faculty Optimization Problem Grading

David Miller
West Virginia University

Jesse Cook
West Virginia University

Kaitlyn Roxby
West Virginia University

William Robertson
West Virginia University

Edwin (Ted) Townsend
West Virginia University

In this study we examine how faculty members grade optimization problems from calculus. Eight faculty members were interviewed and asked to grade three student solutions for three different optimization problems. In addition, faculty members also discussed their grading philosophies and practices for both optimization problems and in general. We used open thematic analysis to analyze all faculty interviews and two major themes of reflection of understanding and key steps in optimization solutions emerged from the data. These themes that was supported by faculty were further analyzed for the interplay between them. In addition, we delve deeper into reflection of understanding using Skemp's instrumental and relational understanding to establish when faculty assessed good student understanding of optimization problems. Our results provide insight into how mathematics faculty grade student solutions for optimization problems, how they emphasize student understanding, and offer possible insights into the variations in scores we observed in this study.

Keywords: Assessment, Calculus, Optimization, Understanding

Faculty in many mathematics departments are needed to teach calculus courses so they can cover all mathematics courses they offer each semester. As part of their teaching, faculty normally grade homework, quizzes, and exams. Computerized homework that is graded automatically is commonly used, but faculty is still responsible for grading paper and pencil assignments such as quizzes and exams. Grading student solutions is important and crucial as grading communicates instructor's anticipated standards to students (Stiggins & Chappuis, 2005; Yerushalmi et al., 2015), as well as guiding students on how to enhance their work to improve their understanding of the subject material. Black and Wiliam (1998) noted that "feedback on tests, seatwork, and homework should give each pupil guidance on how to improve" (p. 144). Further, effective grading practices can provide feedback that can foster learning, communicate to students what practices and skills help them: learn a discipline, develop problem-solving skills, prepare for formative and summative assessments, and communicate to students about what to focus on to better prepare for future activities (Black and Wiliam, 2009; Marshman et al., 2018; Hattie & Timperley, 2007; Mulliner & Tucker, 2015; Wiliam, 2006). Having consistent grading is also important for ensuring fairness among students. Thus, the feedback and grading provided to students by instructors on their solutions plays an essential role in shaping their learning experiences.

Despite the importance of grading practices of instructors, there have been few studies on the topic. Several prior studies have focused on the evaluations of students' proof in theoretical mathematics classes by professors (e.g., Moore, 2016; Miller et al., 2018) as well as the grading practices of physics professors on students' problem solutions in calculus-based introduction to physics classes (e.g., Docktor et al., 2016; Henderson et al., 2004). None of these studies investigated the grading practices of mathematics faculty in calculus. Thus, our study will specifically investigate the grading practices of mathematics faculty, and in particular, how they

grade calculus students' solutions to optimization problems. The following questions in the context of optimization problems in calculus guide our research: 1) How do mathematics faculty assign points to student solutions?, 2) What features or details do mathematics faculty value when grading?, and 3) How do mathematics faculty assess student understanding when grading?

Literature Review and Theoretical Framework

While studies regarding the grading of student solutions have been on the rise, most prior research lies in the realm of physics (Docktor et al., 2016; Henderson et al., 2004; Marshman et al., 2020). One of the earliest such studies by Henderson et al. (2004) tasked 30 collegiate physics instructors to evaluate two student solutions resulting in the same (correct) answer. This study indicated that instructors were apt to deduct points for flawed intermediate logic with minimal supporting work, while graders may be reluctant to deduct points from a student solution that might be correct. Further, it was noted graders tend to project correct thought processes, indicating that the graders were placing the 'burden of proof' on themselves rather than the student. Of the six graders interviewed in depth in the Henderson et al. (2004) study, only one grader placed the 'burden of proof' on the student and awarded points to a student solution when the student showed explicit evidence of understanding. The other graders placed the 'burden of proof' on themselves and only deducted points when there was clear evidence the student did not understand. Thus, it was observed that clear evidence of understanding was not always needed to award points.

To obtain more consistency in grading solutions, Docktor et al. (2016) developed a problem-solving rubric encompassing five aspects of a desired student solution including descriptions of the problem, mathematical procedures, and appropriate logical progression. Such a rubric provides a solid foundation for other practitioners to implement either holistically or analytically.

In a similar vein, Marshman et al. (2020) implemented a professional development seminar for GTAs enrolled in physics doctoral programs. During their first semester, new GTAs met with each other and the authors of the study to discuss grading strategies and philosophies. Interestingly, the GTAs involved in this seminar believed grading was a formative assessment designed to enhance student learning with feedback. As the seminar progressed, however, it became evident that the GTAs focused on the correctness of a solution rather than treating the assignment as a learning experience. This result corroborates the study by Henderson et al. (2004) who found that graders can experience internal conflict when assigning grades.

Another study conducted by Marshman et al. (2017) implemented a similar professional development seminar as Marshman et al. (2020). The Marshman et al. (2017) study focused on how GTAs developed teaching examples, and if the assistants valued the students implementing the same problem-solving strategies found within the teaching examples when grading student solutions. In addition, they investigated if the GTAs' grading strategies differed between introductory physics and quantum mechanics. They found that the GTAs valued correct answers over explicit problem-solving strategies when grading introductory physics, but the reverse was true for quantum mechanics. Moreover, the GTAs graded the quantum mechanics solutions harsher than the introductory students (Marshman et al., 2017). The GTAs stated that they graded this way because the students in quantum mechanics were more experienced and should know the basic physics concepts. Echoing the findings previously discussed, the GTAs viewed grading as a summative assessment and not a formative teaching tool (Marshman et al., 2017). Therefore, it appears important to investigate if mathematics instructors grade calculus students for correct answers or provide formative feedback.

Other studies researched how professional mathematicians grade students' proof-writing skills. Moore (2016) interviewed four professors and noted remarkable variation in scores contingent upon the perceived student's intent within the proof. The four professors discussed the importance of logical correctness, clarity, and fluency in good proof writing and differed in their evaluations due to seriousness of errors, the students' demonstration of understanding of the proof, the validity of the proof and the associated mathematical concepts. Similarly, Miller et al. (2018) presented nine mathematicians with sample proofs from a transition-to-proof course. This study indicated that professors offer 'the benefit of the doubt' to student proofs that exhibit logical gaps. This 'benefit of the doubt' extended to instances where generic proofs would be accepted as full proofs, and proofs deemed "correct" received less than full credit. Such results indicate inconsistency in how professional mathematicians grade in proof level courses, so it would be prudent to investigate how instructors grade problems in calculus.

We use a theoretical framework of understanding by Skemp (1976), where student understanding is broken down into two categories, 'instrumental' and 'relational'. Instrumental understanding refers to students having certain rules or facts in mind, such as specific formulae or procedures, without having the underlying knowledge or understanding of why these rules work. Conversely, relational understanding refers to a deeper type of understanding, where the underlying connections and rationale behind knowledge is known, allowing students to be able to more easily and appropriately apply their knowledge to new situations. Skemp maintains that students gaining relational understanding is preferred over students only having an instrumental understanding. However, many students only acquire instrumental understanding as many classroom environments do not promote relational understanding. We will use this framework to analyze the participant's grading of the optimization problems and their interpretations of student understanding of these solutions.

Methodology

Participants

For this study, eight mathematics faculty members from a large state university in the United States consented to participate in this study during the Spring of 2024. The participants all had experience teaching calculus for the university that included grading exams and other assignments. The participants were representative of all the levels of tenure-track faculty and the assistant and associate levels for teaching professors. Also, one participant was a postdoctoral researcher with three years' experience teaching calculus, along with additional experience as a graduate student at a large state university. Participants were from a variety of fields in mathematics such as Algebra, Graph Theory, Discrete Mathematics, Partial Differential Equations, and Undergraduate Mathematics Education.

Procedure

The eight participants were interviewed in the spring of 2024. They are listed as F1 to F8 in this study and referred as a neutral gender to mask their identity. The interviews were conducted via Zoom. Each participant was presented with three optimization problems to grade, with three solutions (labeled S1, S2, and S3) per problem. The interviews were conducted in two sessions, each taking approximately an hour, depending on the length it took for the participants to grade the papers. A draft of the interview transcripts was automatically generated via software using the recorded video and then polished up by the researchers after reviewing each recorded interview. The solutions for the problems were generated by the authors and the prior studies in

physics, and the participants were asked to grade them as if they were grading a calculus assignment in the online grading system called Crowdmark. While they were grading the questions, the participants were encouraged to provide justifications on what they were doing, how the grade was determined, and their final score. Additionally, before the participants graded the student solutions to the three optimization problems, they were asked semi-structured open-ended general interview questions about their grading philosophies and practices, as well as specific approaches when grading optimization problems.

Materials

The nine solutions we devised for the interviews consisted of three problems with three solutions S1, S2, and S3 (see Figure 1 for an example solution of the rectangle problem). One of these problems, the Rectangle Problem, is a standard problem asking how to minimize the cost of a fence enclosing a rectangular, partitioned area. The other two optimization problems were the Barrel Problem and the Pipeline Problem, from a previous Calculus exam conducted at the university and are common types of problems in Calculus textbooks. The Barrel problem dealt with optimizing the volume of a cylinder with specific surface area and the pipeline was about building the minimum cost pipeline to a refinery over land and across a river. While the fundamental structure of all three problems is similar, the difficulty in understanding the scenarios and the algebra involved varies between the problems, with the Rectangle Problem being the easiest, followed by the Barrel and Pipeline problems. The problems and their solutions can be shared upon request.

The solutions were designed to highlight the issue of how the faculty members would assign partial credit and motivated by the Physics Education research of how GTAs and faculty grade calculus-based physics problems (Henderson et al., 2004). For the Rectangle and the Pipeline problems, all the final solutions are accurate, however the amount of work shown varies between the solutions, with many of the solutions having what the authors deemed as an insufficient amount of work. The solutions for the Barrel problem on the other hand has a variety of errors and different answers due to those errors. Note that all solutions have approaches which are generally correct. They each find a formula for the quantity to be optimized as a function, compute the derivative, and then determine where the derivative is equal to zero to find the critical points. However, further steps such as verification of the solution and showing appropriate algebra or calculations to justify the work are sometimes brief or omitted. The variety in the amount of work shown and correctness was done to mimic real student work on optimization problems in order to provide the graders with authentic, realistic grading scenarios they are likely to encounter with optimization problems.

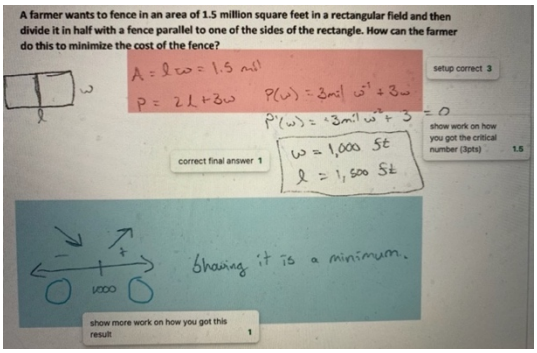

Figure 2. Solution S2 on the rectangle problem

Analysis

The authors engaged in open thematic analysis (Corbin & Strauss, 2014) in the following way. First, all authors individually read over all the transcribed data while identifying and highlighting passages that might be of theoretical interest concerning grading. All authors met to discuss and compare their findings and developed a list of codes for further study. Next, each author reread the transcripts again, searching for each topic of interest; we then put these excerpts into a file of comments related to that code. Through this process, we developed criteria and descriptions of these themes. Finally, the authors individually went back through the data one last time to identify passages that would satisfy the criteria for each of these themes.

Results

Quantitative Data

Table 1 below shows the scores that the eight-mathematics faculty assigned for the three different optimization problems solutions, S1, S2, and S3, on the three optimization problems. In addition, the average, median, and variances for each solution are shown at the bottom of the table. We can see that the largest variances occurred on the rectangle optimization problem with student solutions 1 and 3 and the smallest variances occurred on the barrel and pipeline problems with student solution 3. The rest of the variances were somewhere in between. Furthermore, four of nine solutions typically scored high with an average of over 8, two were more problematic solutions with an average score below 5.5, and the remaining three of nine solutions were somewhere between.

Table 1. Faculty Member Scores for the 3 Optimization Problems and 3 Solutions S1, S2, and S3.

	Question 1 (Rectangle)			Question 2 (Barrel)			Question 3 (Pipeline)		
Grader	S1	S2	S3	S1	S2	S3	S1	S2	S3
F1	4.5	7	6.5	8	9	9.5	4	10	7.5
F2	5	6	8	7	10	8	5	10	8
F3	4	8	7.5	9	9	9	4	10	7
F4	6	9	9	9.25	9.5	9.5	6	10	7.5
F5	4.5	8	9.5	9	10	9	7	8	8
F6	7	7.5	7	6.5	8	8	4	8.5	7
F7	4	7	5	7	8	8	4	7	6
F8	9	10	9	9	10	9	6	10	8
Average	5.5	7.813	7.688	8.094	9.188	8.75	5	9.188	7.375
Median	4.75	7.75	7.75	8.5	9.25	9	4.5	10	7.5
Variance	3.071	1.567	2.281	1.249	0.710	0.429	1.423	1.424	0.482

Qualitative Data

We report on two major themes that emerged from the data: 1) Key steps in Optimization Solutions and 2) Reflection of Understanding. These themes were supported by all participants, and we will show support for the themes with excerpts from the faculty interviews.

Key Steps in an Optimization Solution. All participants talked about key step(s) while grading the optimization problems. While grading the optimization problems, one of the first things that most participants mentioned were checking the key steps of the solution that consisted of constructing the optimizing function, finding the derivative, solving for the critical points, and

verifying which critical point solves the problem for the maximum or minimum. For example, F9 states while they are grading, "there are kind of key steps that I look for along the way" and

> "they're setting up the problem which typically has an optimizing function and a constraint. I don't like the word constraint, but because really it helps us to put the optimizing function into one variable. And then I want to see them take the derivative of the optimizing function, find the critical points, and then I want to see them determine whether or not those critical points really are the things we're looking for."

Therefore, checking key steps served as signposts to quickly assess if the solution is correct.

Some participants went further by combining key steps into chunks. They would look at the chunks as important pieces and would determine the number of points they designated to each chunk depending on their views on the importance of the chunk. For example, F10 comments that *"I solve the problem, show all the steps, and then I just go through and block off each little piece of what they do, and decide… How much does knowing this part account for? How much does knowing this part account for? So, I kind of block it off into pieces*" and F7 also states *"in an optimization problem they set up the function, right? That's one batch of stuff. They take the derivative and find the critical numbers. That's one batch of stuff. They test the critical numbers in the first or second derivative test. That's a batch of stuff, and then they answer the problem. That's a batch of stuff."* This ensures the appropriate allocation of points for important work in the student solutions and assists them when grading. However, not all participants grouped key steps in chunks and just developed their rubrics around the key steps. This is illustrated by F8 with *"[I] break my solution into steps depending on how important it is, and I usually have in mind that this step they should get 2 points. And this step has these points."*

At that point and to varying degrees, the majority would assess the details of the solution to further assess the student solutions and determine how many points they earn on key steps as well as overall. It is during this stage that participants expected the solutions to provide more detail to justify the work (see the next section of reflection of understanding).

Therefore, key steps and key chunks played an important role for participants when building their grading rubrics and while they were grading student solutions for the optimization problems. This ensured each participant graded consistently and fairly on each of the three solutions for the three optimization problems. Although this result was in the context of optimization problems, participants discussed this is how they grade on most topics.

Reflection of Understanding. We now use Skemp's (1976) relational and instrumental understanding to further explore how participants assess whether students understand the mathematics for the optimization solutions. We first discuss participants assessment of instrumental understanding and then move to the assessment of relational understanding.

Reflection of Instrumental Understanding. When analyzing the participant's optimization grading, we found instances where participants assessed the solution for instrumental understanding by not expecting any justification in the solution. They were assessing the solution based on formulas, rules, or facts, without displaying any further underlying understanding.

For example, all participants did not need to see justification for the calculation of the derivative for at least the optimizing function on these three solutions. For example, when F9 is grading the rectangle optimization problem, she states as she reads the solution*, "And then we're taking the derivative, which I think is good." For another example,* F10 states *"I think it can be common for students to just write something down because they know it's supposed to be a minimum, and so they just draw the picture like they know it's supposed to be without doing any actual thinking at all."*

Reflection of Relational Understanding. When analyzing the participant's optimization problem grading, we found many instances where participants assessed specific steps of the solution for relational understanding by expecting justification in that step. That is, they were looking for a reflection of relational understanding in a step that showed a deeper understanding of the rationale and underlying reasons for the mathematics. One prime example of the reflection of relational understanding occurred on the verification key step for the maximum or the minimum. For example, on S2 for the rectangle problem (see Figure 2), F7 states

> "… let's call this the next batch of stuff [boxes verification work in blue] which I think is the most important batch. I still would not call that enough work. If you want it to be a minimum, you know you want it to go down and then up. So, you're not showing me that you actually checked that. You're just showing me that you know what it's supposed to be so, I would imagine that there would need to be like, in my opinion, what I would call enough work, would be put a number over here [draws circles on both sides of sign chart].Put a number over here, you know, like 10 or one, or whatever, and then like 1,500, or whatever over here, and show me that you plugged it back into the first derivative and got this decreasing increasing. So, I would say, show more work on how you got this result."

For another example, F12 wants the hypothetical student to explain why there is a maximum or minimum at the critical point instead of just saying the $V''(r) < 0$, "My concern when there's just so little is that they're just regurgitating a fact. Like, 'Oh, it's less than 0, so that means it's a maximum.' Like, well, do you actually understand why it's a maximum." Therefore, F7, as other participants, expected the solution to display justification for key steps in the solution to show a reflection of relational understanding.

Discussion

In this paper we investigated how faculty assess student understanding on three optimization problems and found three main results. The first result was that for the most part, professors assigned points consistently, except on the rectangle problem. The second result was that professors wanted to see key steps in the solution. When a key step or steps were missing from a solution or there was insufficient work, professors would assess a lack of understanding and deduct points. This parallels the results of Raman (2003) for mathematical proofs where she found that mathematicians valued key ideas in a proof. The key idea is the big picture of why the proof works and can be used to construct the final written proof. Likewise, key steps give an outline or big picture of what needs to be produced to solve an optimization problem.

The third result was that professors wanted to see a reflection of understanding in the student solutions. They interpreted that students did not have a complete understanding when the solution did not include key step(s) or there were errors in between key steps. Prior research in proofs by Miller (2018) and Moore (2016) found a similar result when professors graded mathematical proofs. In contrast, Henderson et al. (2004) found that this was not the case with physics graduate students. This reflection of understanding further evolved into the final result where professors were interested in seeing that students were fluent with the mathematical rules (instrumental understanding) but also wanted to see students providing justification to show they understood the mathematical concepts involved in their solutions (relational understanding).

Using Expectancy-Value Theory to Explore Motivations in Inquiry-Oriented Linear Algebra

Lauren Janda
Arizona State University

This study examines undergraduate student motivation in an inquiry-oriented linear algebra course using expectancy-value theory (EVT). While EVT has more frequently been applied in K–12 settings, its use in undergraduate mathematics remains limited. Through interviews with four students, this study explores how components of EVT—expectation for success, attainment value, intrinsic value, utility value, and cost—relate to students' engagement. Findings show that the expectancy-value theory can be helpful in making sense of the motivations of undergraduate students. Students were motivated in different ways, with many citing their key influences as collaboration, real-world applications, and classroom expectations that promote a novel definition of success. Inquiry-oriented instruction appeared to support positive motivational outcomes by normalizing struggle and promoting group-based problem solving. This suggests EVT is a useful framework for understanding motivations in undergraduate mathematics, particularly in the context of inquiry-oriented instruction.

Keywords: motivation, expectancy-value theory, inquiry-oriented instruction

Introduction and Literature Review

Students' motivations have been a topic of mathematics education research for decades, with a particular focus in the last 20 years (Schukajlow et al., 2023). Several studies have been conducted looking at the motivations of primary or secondary school students (e.g., Middleton et al., 2023; Fielding-Wells et al., 2017; Eccles et al., 1993). Middleton and collaborators (2023) analyzed different aspects of mathematics engagement in high school students and found that, related to motivations, social support in class improved student interest in the situation as well as their beliefs in their competence. Of particular relevance to this study, Fielding-Wells and collaborators (2017) explored motivations in an inquiry-based mathematics classroom of 9-10-year-olds using the expectancy-value theoretical framework. They found that this framework was helpful to make sense of student motivation in an inquiry-based classroom, and aspects of this instructional design could be positively influential on student motivation (Fielding-Wells et al., 2017). However, less research has been done studying the motivations of undergraduate students, with or without the use of the expectancy-value theory (e.g., Weber et al., 2020).

One possible explanation for this is that motivations towards mathematics are developed early in life and maintain relative stability throughout (Middleton & Spanias, 1999). However, motivating undergraduate students should not be dismissed. Eccles and collaborators (1993) found that beliefs of confidence lower with age, which may reflect increasing pessimism with age. As a result, it is worthwhile to analyze why older students have lower competence beliefs and what can be done to support their motivation. Additionally, according to Middleton and Spanias (1999), different instructional designs can alter students' motivations, so there may be merit in examining the ways that instructors at an undergraduate level can affect students' motivations in their math courses. As a necessary first step to that, the results of this contributed report will work to identify common motivations that students are expressing from a particular population.

Specifically, I am interested in looking at the motivations of students in an inquiry-oriented linear algebra course, because I hypothesize that this instructional design may have positive

effects on undergraduate student motivation. It has been noted that inquiry-oriented instruction (IOI) is closed related to inquiry-based learning (IBL; Laursen & Rasmussen, 2019), which has been found to have positive student outcomes in many regards: cognitive, affective, and collaborative benefits (Laursen et al., 2014). Because Fielding-Wells and collaborators (2017) found aspects of an IBL environment to have positive outcomes, and IBL has been found to benefit student outcomes (Laursen et al., 2014), I hypothesize that IOI may have positive effects on undergraduate motivations. This paper aims to explore the motivations of undergraduate students in an inquiry-oriented linear algebra course using the expectancy-value theory of achievement motivation.

Theoretical Framework

The expectancy-value theory of achievement motivation, also commonly referred to as just the expectancy-value theory (EVT), is a well-established theory in the field of psychology (Wigfield et al., 2021). This theory was initially developed by inquiring into why women are less likely to pursue STEM-related careers than men (Eccles, 1983). Findings from that large-scale, longitudinal study emphasized that the few sex differences that did emerge indicated that females had a less positive perception of their math ability along with a lower value of the subject than males (Eccles, 1983). EVT declares that individuals make decisions in achievement settings based on (a) their expectations of success on the task and (b) how much they value the task (Wigfield & Eccles, 2000). Mathematics courses are considered achievement settings, because there are opportunities to attain specific goals, such as demonstrating understanding of the content on assessments or passing the course. We will be discussing the constructs here in the order they are listed in Figure 1, which is the order they are presented in Wigfield and Eccles (2000).

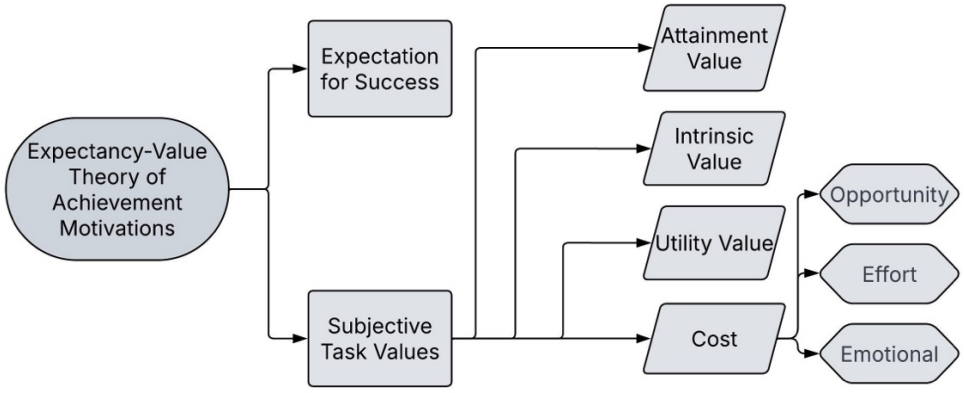

Figure 1. Expectancy-Value Theory of Achievement Motivation Components

The *expectation for success* portion of this theory refers to how much an individual believes that they are able to attain success at a given task (Schukajlow et al., 2023). If a student believes a task is too difficult for them to complete (i.e., they don't think they are smart enough, they don't think they were given enough resources by their instructor, etc.), they will generally be unmotivated to complete that task. Additionally, four types of *subjective task values* are distinguished: attainment value, intrinsic value, utility value, and cost. *Attainment value* is how important doing well on a task is to that individual; this task value is usually tied closely with one's self-concept or identity (Wigfield & Eccles, 2000; Schukajlow et al., 2023). *Intrinsic value* is how interested that individual is in the task or how much they enjoy it (Wigfield & Eccles,

2000). *Utility value* is how much the individual sees the task fitting into their future goals (Wigfield & Eccles, 2000). It is important to note that these task values are subjective, varying by the individual and their experiences. For example, a student who is not particularly interested in mathematics (low intrinsic value) and doesn't care about what grade they get in their math class (low attainment value) can still be motivated to do well in their math course if they view mathematics as something that can help them understand necessary concepts for their job as, say, an electrician (high utility value). *Cost*, which is a factor of decision-making in this theory in line with the subjective task values, is the other end of the scale. Cost may be accounting for how much engaging in the task restricts one's ability to engage in higher valued activities (*opportunity cost*). For example, if I do my homework, that gets in the way of my ability to chat with friends. Cost could also account for how much effort goes into engaging in the activity (*effort cost*), or how much emotional labor goes into the task (*emotional cost*). When people make decisions, they gauge how much it costs and see if that outweighs their values and expectations for success.

I am using this theoretical framework to answer the following research question: *How do students characterize their motivations related to their engagement in an inquiry-oriented linear algebra course?*

Methods

This study investigated the experiences of four undergraduate students from two sections of inquiry-oriented linear algebra at a large public university in the southwest United States. A general day in this course involved the students working on a mathematical task in groups of two to four students, while the instructor and TA circulated the classroom and supported student discussions. The instructor would ask students to share their thought processes with the whole class. The tasks generally had scenarios associated with them and asked students to collaborate with one another and provide reasoning for their answers. An example of the kinds of mathematical tasks provided in this class can be seen in Wawro et al. (2012).

Due to the complexity of students' engagement, multiple data methods were used (as suggested by Middleton et al., 2017): observations, participation surveys (self-report), and interviews. Classroom observations were conducted for the three weeks of class that occurred after the first exam. Additionally, students reported on their participation for one day of each week of the semester by responding to questions in a Google form. One week after the conclusion of the observations, four students participated in an interview with questions asking about their experiences in the class. The interview questions were intended to reveal information about their motivations for engaging with the course material. Note that, for the purpose of this contributed report, only analysis from the interview data will be presented.

To answer the research question, I first familiarized myself with the data by transcribing the interview data and reading through it. Next, I highlighted excerpts based on whether they addressed the students' motivations to engage in a task. Excerpts were identified as *motivations* if they indicated the reasons why someone engaged with the course content (Middleton & Spanias, 1999). From here, I used the constructs from the expectancy-value theory to classify the various motivations as either *expectation for success, attainment value, intrinsic value, utility value,* and *cost* (Wigfield & Eccles, 2000).

Results

In total, 63 excerpts were identified as containing motivations among the four participants. The classifications for these motivations can be seen in Figure 2. Of note, expectation for success

was coded 18 times among three participants. Of the four types of subjective task values, attainment value showed up five times among two participants. Intrinsic value showed up six times among three participants, four of those occurrences were all from one participant. Utility value showed up 22 times among all four participants. Finally, cost was coded 12 times among all participants.

EVT Component	Olivia	Payton	Quincy	Romeo
Expectation for Success	7	1	10	0
Attainment Value	0	1	0	4
Intrinsic Value	1	4	1	0
Utility Value	3	8	8	3
Cost	2	3	6	1

Figure 2. Counts of Student Motivation Excerpts by EVT Component

Expectation for Success

Expectation for success was coded particularly strongly with Olivia and Quincy, in addition to a single time with Payton, with these excerpts generally noting that what counts as 'success' in this class is varied compared to their other classes. For example, Payton compared the differences between the homework expectations and resources provided in this course, stating that, "the homework throws it at you like it expects that you've already learned it, because it just, it presents the problem and you should have the knowledge of the techniques used to solve it, versus the in-class activities are very much presented to us where we're not assumed to have that understanding." Here, Payton is describing that in-class activities provide more support and resources than the homework activities, because for in-class activities, the students are not expected to know how to solve the new material. Overall, Payton demonstrated a high expectation for success in this course, but had a lower expectation for success on the homework because there was not as much support if he got stuck.

Olivia and Quincy also displayed high expectations for success in this course, but associated those expectations with different components of the course than Payton. For example, instead of comparing the homework's expectations to the in-class expectations, Olivia compared this course to her experiences in other courses, stating that "the frustrations I feel in those classes are like [...] 'I plugged in the numbers I'm supposed to and it's not working, so like, what am I doing wrong?' [...] I feel better when my whole team doesn't understand it, or even if they do understand it, I feel better because they're gonna explain it to me." Later, she shared that when she does not understand in this class, she feels as though it is "definitely, not as like personal towards me. [...] We don't really know what we're supposed to be doing yet mathematically, so if you don't understand, like the bigger picture, it's okay." Here, and generally, Olivia understands that there is an expectation for students to struggle initially with concepts in this course, and so even if she does not immediately solve the problem, she still expects to succeed by struggling through the problem with her group. Quincy shares the same kind of opinion, stating that in other classes he gets frustrated and can take it personally when he doesn't understand, but he said he is

able to “kind of just like trust the process with this class.” Each of these students shares that the course expectation of students figuring out the mathematics for themselves in groups helps them to feel less pressure to immediately know how to approach the problem, making the idea of what counts as successful more accessible for students.

Attainment Value

Attainment value showed up for Romeo the most, specifically as he shared about his work ethic and how that shapes his identity. When asked how Romeo pushes through days when he is tired or has low energy levels, he said, “you gotta push yourself to do hard things, you know. That's like my mentality always, you know, just everything's gonna be -- well, there's gonna be challenges, and you're just gonna have to, you know do your best.” In this sense, Romeo would likely have a strong attainment value in any of his courses, as they are all simply “hard things” that he has to push through. Payton shared a bit less explicitly about his work ethic, stating that “whenever I’m trying to learn something new, I always try and get it as much as I can, just through my own understanding” before he uses any other resources such as Google. Generally, attainment value did not show up much in these interviews, which may be because, before conducting the interviews, I was not using the expectancy-value theory to analyze the data, so there were not interview questions aimed at exploring a students’ desire to do well on the in-class activities.

Intrinsic Value

Intrinsic value usually presented as the participant expressing that they enjoyed a specific activity. For three participants in this study, they shared their interest or enjoyment in a specific task in response to the interview question “What is your favorite task we’ve done so far in class?” The reason for the interest was different for each participant, demonstrating some of the different ways that this code can show up for people. Although Romeo did answer this interview question, he did not express particular interest or engagement in the task, attributing his choice of favorite task to how “clear-cut” the solution was for him, so his response was not coded as intrinsic value. Quincy picked his favorite task based on which task provided the best example. Olivia picked her favorite based on what activity she could visualize best. Payton picked his favorite task based on which task introduced new math content. Additionally, for Payton, he expressed interest in the course content without being prompted. He finished his interview saying, “this is probably one of the more enjoyable math courses that I’ve had in a long while [...] it’s a lot of collaborative work too, so it’s very much more social and fun to do which I enjoy.” Payton also shared that he enjoyed teaching or leading his group. Overall, the intrinsic value code was particularly subjective, showing up in a few different ways depending on the participant and depending on the various things each participant enjoys.

Utility Value

For these participants, utility value usually showed up as engaging in a particular way as a means to an end. Payton expressed that he will sometimes take the back seat in his group’s work and work on the problem on his own for the sake of seeing how his groupmates do it and if they find more efficient solving methods. Specifically, Payton said, “I’d like to see how it’s done to see how it compares to how I do it, cuz I am very set in how I solve a lot of these problems and I definitely have done some like inefficient ways of solving them.” Romeo shared the same reasoning, but instead of taking a back seat in his group, he asks his group a lot of questions to gain the perspective of more efficient solving methods. Romeo said, “So to be honest, I'm the

one asking a lot of questions, because you know, everybody has their own process, and I'm trying to understand how they solve it through." For Olivia, she saw the utility value in tasks through the real life applications that these tasks can be used for, when asked to share about her favorite task she said "This whole class feels like just like trying to solve puzzles and so like this was the more helpful puzzle to solve because I'm like, okay, like people do this to actually like... in real life, if that makes sense?" All of Quincy's utility value codes were related to him viewing his engagement with the material as a means to the end of passing quizzes and exams. In one instance, Quincy said "even if I'm focusing for like 20%, I come out of the class ready for the next exam." Overall, utility value showed up as the participants trying to do what helps them learn the material best, as in Payton and Romeo's case, appreciating the real-life applications of the activities, like Olivia's case, or doing what they need to perform on assessments, as in Quincy's case.

Cost

Cost showed up in a few different ways as well. For Payton and Romeo, cost showed up as continuing to work on their board work during whole-class discussions when people are presenting. Payton explained that "my group very often tries to continue working on whatever our brain was still doing." This demonstrated the opportunity cost: fully engaging with the whole class discussion would get in the way of them continuing their work on the board. This opportunity cost also showed up when the participants talked about the hypothetical of people working on an assignment for another class. For example, Quincy said "my kind of reasoning is that maybe, like you got […] something due that day and we just like need to finish that, so […] you kind of set it [the in-class activity] aside because it's like, whatever you're doing at that moment is not gonna matter up until, like the quiz." To Quincy, it is understandable that someone may work on an assignment that they feel is more pressing for another class because whatever is currently being worked on in class will always be less pressing until the assessments.

Another aspect of cost mentioned is the energy levels or 'moods' that the participants were feeling during class. Three of the four participants shared the sentiment that if they are tired, "it's easier to get derailed because I'm not as focused" (excerpt from Payton's interview). Additionally, participants shared that if they are having personal issues, it makes it more challenging for them to engage fully with the in-class activities. I would consider this an effort cost: these students perceive that they do not have the energy to continue engaging because of physical energy levels.

The final way that cost showed up is related to the participant's expectation for success. When Olivia and Quincy felt that even if they fully engaged with the material, they still would not understand it, they would disengage and usually distract themselves with activities on their phones. Quincy said that if he doesn't understand what is happening in class, then:

> I'm just gonna immediately just put my AirPods in like, listen to music, or like, watch a video or like, do something else that, that is well, honestly, that's what I would do now like, even if I have, I told my full attention to this, I'm not gonna understand it. So why, why should I waste my time, or why should I waste my effort..?

These participants did not expect success from engaging with the activity: to them, the cost was too high, and they did not expect to get payoff of understanding.

Discussion

The ways that the expectation for success code presented for these participants was particularly interesting because their perception of what counted as success and the resources available to reach it shifted given the classroom expectations for this course. Generally, being successful in this course became more accessible to these students compared to other courses, because they believed there were ways to be successful in this course outside of completing a problem successfully. I conjecture that this increased accessibility of success may be attributed to the classroom expectations of an inquiry-oriented linear algebra course, but more investigation is required to validate that claim. For example, according to Rasmussen and Kwon (2007) teacher inquiry into student thinking is one of the defining aspects of an inquiry-oriented classroom. One of the participants in this study stated that he felt motivated when the instructor, instead of saying that answers were "bad or wrong," would say "that's one way of looking at it." This student found it motivating that the instructor would interpret students' perspectives instead of dismissing the student contribution because it was incorrect.

Additionally, the fact that this was an inquiry-oriented classroom being studied provided another unique aspect: student reinvention (Kuster et al., 2018). Student reinvention means the students are making sense of the mathematical concepts for themselves, instead of adopting another's reasoning. For an inquiry-oriented classroom, the tasks are designed to support student reinvention by building on student reasoning before formal reasoning is introduced (Kuster et al., 2018). Although these participants never mentioned student reinvention explicitly, Olivia did mention that she thought in group work that "going off of each other's ideas is really cool to see because I'm like, 'Okay, this is what people were doing when they were inventing this math.'" A potential contributor to this shifted expectation for success for these participants is the instructor inquiry and student reinvention, two aspects unique to inquiry-oriented courses. While the results of this study demonstrate that the expectancy-value theory is suitable to make sense of the motivations of undergraduate students in an inquiry-oriented course, it is worthwhile to consider whether this shifted expectation for success can be most directly attributed to the fact that this is an inquiry-oriented course.

Multiples of these components of the expectancy-value theory of achievement motivation (*expectation for success, attainment value, intrinsic value, utility value,* and *cost*) can play a role in any one instance of an individual's decision-making. In this study, we saw instances of students making decisions based on how much they expected to succeed at a task, weighed against how much effort they would need to put in to reach that success. As such, classrooms implementing inquiry-oriented instruction may provide unique environments to explore students' motivations, because the expectations of what is considered success may change for students based on the overall expectations of the class.

Subjective Combinatorics: A Case of Set Partition Problems

Niusha Modabbernia
Simon Fraser University

Research in combinatorics education highlights the importance of examining how students think about counting problems to gain deeper insight into their conceptualizations. Such an examination involves attending to students' interpretations of counting problems, particularly the subjective elements that influence their combinatorial thinking. Subjective combinatorics has recently been introduced to account for these elements in how students interpret counting problems and engage in counting activity. This paper refines the construct and demonstrates its usefulness as a lens for analyzing students' engagement with counting problems through an examination of student work on a set-partition task.

Keywords: combinatorics, conceptual analysis, counting problems, subjective combinatorics.

Enumerative combinatorics, the study of counting problems, is part of many school and undergraduate curricula. Its presence in curricula reflects both its practical relevance in fields such as probability and computer science (e.g., Abrahamson, Janusz, & Wilensky, 2006; Shaughnessy, 1977) and its potential to engage students in critical mathematical thinking (e.g., Kapur, 1970; Martin, 2001; Tucker, 2002). A growing body of research in the mathematics education community has examined how students think about counting problems, identifying common strategies and sources of difficulty (e.g., Batanero, Navarro-Pelayo, & Godino, 1997; English, 1991, 2005; Lockwood, 2013; Lockwood, Swinyard, & Caughman, 2015; Tillema, 2013). Building on this work, it is important to investigate how students interpret counting problems, with particular attention to the subjective elements that influence their combinatorial thinking. To this end, *subjective combinatorics* (Modabbernia, 2025) has been introduced as a lens to examine such subjective interpretations of counting problems, building on ideas developed in the study of *subjective probability* (Chernoff & Zazkis, 2011; Jones, Langrall, & Mooney, 2007). This study situates *subjective combinatorics* within a broader body of mathematics education research and refines the construct by focusing on subjective interpretations of outcomes, illustrating its usefulness through an analysis of student work on a set partition problem.

Brief Background and Contextual Insights

Subjective combinatorics was originally introduced with ideas drawn from subjective probability (Modabbernia, 2025). In this paper, I situate the construct within a broader body of mathematics education research that addresses subjectivity in mathematical reasoning and students' combinatorial thinking. I begin with studies in mathematics education that foreground the interpretive and experiential dimensions of reasoning, followed by research in combinatorics education that has highlighted subjective elements in students' combinatorial thinking.

Mathematical reasoning cannot be separated from students' personal perspectives. As Johnson (1987) observed, "without imagination, we could never reason toward knowledge of reality" (p. ix). This view underscores the centrality of imagination for making sense of experience and highlights how reasoning is inherently interpretive. Speiser and Walter (1996) extend this idea, emphasizing that embodiment and personal experience shape what and how things can be meaningful, and therefore, personal experience is part of how we understand and

use our mathematics. Empirical research further illustrates this interpretive dimension. Tourniaire and Pulos (1985), in their review of proportional reasoning, noted that "studies using problems with different contexts yielded unequal success rates, which suggests that context has an important influence on performance" (p.190). Prior experiences also play a critical role. In the study of students' conceptualizations of calculus, Marrongelle (2004) emphasized that students often drew upon earlier experiences to reason through mathematical tasks. Van den Heuvel-Panhuizen (2005) reinforced the interpretive role of context by demonstrating that students were more willing to generate meaningful responses when problems were situated in contexts they experienced as real. By imagining themselves in such situations, students engaged in sense-making that was directly inspired by the task. At the same time, contexts could also hinder reasoning if they conflicted with students' personal experiences, as in Mack's (1993) finding that a child rejected a pizza-sharing problem because she disliked pizza and would have found the problem more sensible if framed in terms of ice cream. Research in probability has also highlighted subjectivity, where interpretations of outcomes are shaped by personal judgment and belief (Jones et al., 2007). As Batanero et al. (2005) noted, "what is random for one person might be nonrandom for another" (p. 24), reflecting uncertainty specific to each individual. Collectively, these perspectives show that students' interpretations of mathematical problems are shaped by imagination, embodiment, context, and personal experience, providing a foundation for viewing mathematical reasoning as inherently subjective.

These findings, while not situated in combinatorics, emphasize that mathematical reasoning could be subjective. This subjectivity is particularly evident in combinatorics, where many problems are presented through contextual scenarios rather than in purely abstract form. While such presentations enhance accessibility, they also increase the potential for varied interpretations of the problem itself. To consider subjectivity in combinatorics, it is helpful to begin with the way counting problems are stated. A counting problem highlights specific restrictions for representing a set of outcomes and tasks students with determining the cardinality of that set. Prior research in combinatorics education has already drawn attention to interpretive elements in students' reasoning. At the elementary level, English (1993) found that children's understanding of the word "different" shaped the way they constructed outcomes. In her study, "children interpret *different* to mean *different in all ways* and thus see the goal of *all different outfits* as an indication to make each new outfit completely different from the previous outfit(s)" (p. 260). Such findings highlight how students' interpretations of task wording can influence what they count as valid outcomes, underscoring the role of subjectivity in combinatorial reasoning. At the middle-grades level, Fischbein (1987) described intuitions as behaviorally grounded, shaped by prior experiences, and directed toward meeting adaptive demands, even if they sometimes lead to errors. Extending this view to combinatorics, Fischbein and Grossman (1997) showed that students' reasoning was shaped by the interpretive schemata they brought to a task: "Their reactions are different because their intuitions express different schemata, different programs of interpretation related to their age" (p. 28). These findings highlight how students' interpretations of combinatorial problems are grounded in prior experience and the schemata that guide their intuitions, reinforcing the role of subjectivity in their combinatorial reasoning. At the high school level, studies further suggest that students' interpretations of problem statements can strongly influence their combinatorial reasoning. Batanero, et. al. (1997), drawing on Dubois's (1984) classification, showed that students often did not regard structurally isomorphic problems as equivalent when different objects were involved, instead applying different methods depending on the structures they perceived. They also documented how wording could shift

students' reasoning, as in a distribution problem involving four cars and three children where one student reasoned arithmetically: "4/3 = 1; one car for each brother and there is a car left" (p. 191). Such findings illustrate how both the objects embedded in a task and the everyday meanings of words such as "distribute," "divide," or "share" can shape students' subjective interpretations. At the undergraduate level, Antonides and Battista (2022) explained that structuring "is not a form of abstraction, but rather is a process that can be abstracted at various levels and that can build on previous abstractions. Abstraction of structuring leads to mental models of objects, which are integrated sets of abstractions activated to make sense of, reason about, and operate within experiential situations" (p. 798). This perspective aligns with subjectivity, as it highlights how students' reasoning depends on the mental models they construct when interpreting combinatorial tasks.

Taken together, this literature illustrates that students' mathematical reasoning is deeply shaped by subjective dimensions such as imagination, embodiment, context, and personal experience. Within combinatorics specifically, subjectivity emerges through factors including task wording, prior experience, interpretive schemata, and the mental models students construct. These insights highlight subjectivity as a central feature of how students engage with counting problems, providing the foundation for refining subjective combinatorics in the present study. To this end, this study aims to refine the construct of subjective combinatorics and examines its usefulness for analyzing students' engagement with counting problems. In particular, this study attempts to address the following research questions: *What factors contribute to students' subjective interpretations of combinatorics problems? What factors contribute to students' generation of restrictions when solving and evaluating combinatorics problems that are susceptible to subjective consideration?*

Theoretical Framework: Subjective Combinatorics

In an earlier study (Modabbernia, 2025), *subjective combinatorics* was introduced as a construct, viewing combinatorics as shaped by personal judgment and information about outcomes. This perspective highlights how individuals may approach the same counting problem with different assumptions, leading to varied yet reasonable interpretations of sets of outcomes. For instance, in a problem asking for the number of possible outfits from two shirts, five pairs of pants, and three hats, some students may consider an outfit incomplete without a hat, while others may view a shirt and pants as sufficient. In such cases, differences in interpretation lead to different sets of outcomes, and thus to different final answers. In this example, the restrictions could be made explicit by defining an outfit as one hat, one shirt, and one pair of pants, giving the problem a determinate answer. More broadly, while some counting problems are fully specified, others remain open to interpretation; this study focuses on the latter. Such openness can even give rise to more than one plausible set of outcomes, depending on how students interpret what the problem is asking. I refer to this interpretive flexibility as a *multiplicity of plausible sets of outcomes*. This idea supports the broader construct of subjective combinatorics, in which different yet reasonable interpretations lead students to envision different sets of outcomes to count. This interpretive flexibility is evident in a classroom example (not part of the study data), where a student approached the problem: *"In how many ways can a committee of 5 people be selected from a group of 12, if two specific people must be included?"* The student treated the version without the condition as an ordered selection (using P(12, 5)) and the version with the condition as unordered (using C(10, 3)). This shift may reflect the effect of the condition in prompting a different interpretation of what needs to be counted, rather than a mistake. It illustrates how conditions of the task itself can cue a particular structure of the set of outcomes.

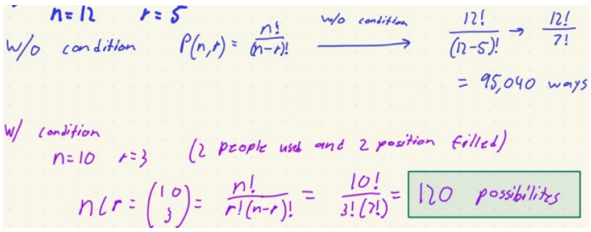

Figure 1. An example drawn from classroom experience (not study data) showing a student navigating different sets of outcomes.

This interpretive variation highlights the role of subjective interpretation not just in the process of counting, but in defining the set of outcomes itself. By situating subjective combinatorics within a broader body of research and highlighting the multiplicity of plausible sets of outcomes, this study refines the construct and extends its usefulness for analyzing students' thinking. Building on this refinement, I now define this construct more precisely.

For problems that allow *multiple plausible sets of outcomes*, *subjective combinatorics* views combinatorics as a matter of belief, shaped by personal judgment and information about outcomes. These are influenced by (1) *student-related factors* such as imagination, embodiment, personal experience, interpretive schemata, and the mental models they construct, and (2) *problem-related factors* such as the context in which the problem is posed and the wording of its conditions. Through this lens, differences in students' reasoning may reflect the interplay of these influences, giving rise to diverse yet reasonable framings of what counts as an outcome.

Method

At the time of data collection, 35 participants were enrolled in a secondary mathematics methods course within a professional development program in mathematics education. All held degrees in mathematics or science, though their academic backgrounds varied. The course, typically completed in the final semester of teacher certification studies, is designed to strengthen mathematical knowledge, foster investigative skills, and explore pedagogical approaches to secondary mathematics, with an emphasis on topics underrepresented in school curricula.

The topic of counting problems was addressed as the final area of exploration. In class sessions, the participants revisited the multiplication and addition principles from their secondary school studies and examined combinations, permutations, the binomial theorem, and combinations with and without repetition. They engaged with a range of counting problems, discussed potential sources of error, and concluded the unit by completing the following task.

You work with a class on counting problems. One of the problems asks students to solve the *Committees Problem*: There are 16 students. How many ways can we organize them in 4 committees of 4 people?
Three students suggest three different answers.

Alex's answer: $\binom{16}{4}\binom{12}{4}\binom{8}{4}\binom{4}{4}$

Ben's answer: $\frac{\binom{16}{4}\binom{12}{4}\binom{8}{4}\binom{4}{4}}{4!}$

Nikki's answer: $\binom{16}{4}4!\,\binom{12}{4}4!\,\binom{8}{4}4!\,\binom{4}{4}4!$

1) Which answer do you agree with? Explain your reasoning. If you disagree with all, please provide your own answer and justify your reasoning. 2) What do you think was implicitly assumed in each answer? 3) Why do you think the students made these assumptions? The suggested length for responding to each question is about 150 words.

Figure 2.The Task

The *Committees problem* was adapted from a standard combinatorics problem that allows varied interpretations, particularly around grouping. The task encouraged interpretations grounded in students' assumptions about what is being counted. One key source of subjectivity

lies in whether the committees are labeled or unlabeled. Additionally, students may or may not attend to the fact that committees are typically unordered collections of individuals, which affects whether orderings within each group are considered meaningful. The three suggested responses reflect different assumptions about what is being counted. Alex's answer treats the committees as labeled and distinct, assuming the order of group formation matters. Ben's response views them as unlabeled. The inclusion of 4! in the denominator suggests that arrangements of the same four groups represent the same outcome. Nikki's response builds on Alex's by assuming that the order of students within each committee matters, multiplying each binomial coefficient by 4! and treating each group as an ordered list. These responses illustrate how combinatorial reasoning can be shaped by assumptions about grouping and distinguishability. The data consisted of participants' written responses. Instances reflected subjective interpretations served as the unit of analysis. Having repeatedly read the data, I looked for common themes by highlighting noteworthy explanations.

Results

In the following analysis, participants' interpretations of the Committees problem, particularly whether the committees and their members were treated as ordered or unordered, are presented alongside their reasoning. The excerpts illustrate the assumptions participants brought to the task, revealing how they interpreted what needed to be counted. These interpretations played a central role in shaping their combinatorial thinking, influencing how they envisioned the set of outcomes and, in turn, the counting processes they considered appropriate. Among the 35 participants, 9 agreed with Alex's solution, 22 with Ben's, and 2 with Nikki's. One participant supported both Alex and Ben's solutions, and one found all three responses plausible. These interpretations were influenced by a range of factors, including wording, real-world experience, and unconscious implicit ordering—each of which is explored below.

Interpretation 1: The Committees Are Distinct

The role of wording. In counting problems, the language used in the problem statement can strongly shape students' interpretations. Certain words may prompt assumptions about the nature of the outcomes, such as whether elements are distinct or interchangeable, which in turn influences how students conceptualize the set of outcomes. The following excerpt illustrates.

> *Tara:* The committees are likely to have specific roles to fill, so they aren't all the same, if the question wanted the partitioning to be into indistinct groups then it would have used a more general word, like "group" or "team."

Tara's explanation highlights how the specific wording of a counting problem can guide students toward particular interpretations. Her reflection on the difference between terms like "committee," "group," or "team" suggests that certain words may prompt students to interpret the set of outcomes in particular ways. In this case, the word "committee" led Tara to assume that the groups were distinct, revealing how subtle differences in phrasing can shape how students interpret the set of outcomes. Consistent with this interpretation, Tara chose Alex's solution, which reflects the assumption that the committees are distinct.

Real-world experience. Students' interpretations were also shaped by how they connected the counting problem to real-life contexts. The following excerpt illustrates how Tara drew on her everyday experience with committees to interpret the structure of the outcomes.

> *Tara*: A committee generally is made with a specific intent, so creating the 4 committees are likely to have different goals, therefore, it matters which one each student got placed in.

Tara relied on her real-world interpretation of committees, typically tied to distinct roles, to infer that each group served a specific purpose. This led her to treat the committees as distinct and the arrangement as ordered, where assigning students to different committees resulted in different outcomes even if the group compositions remained the same. Tara's reasoning illustrates how real-life associations can shape students' assumptions about what distinctions matter in a counting context and how they conceptualize outcomes. Reflecting this interpretation, Tara selected Alex's solution, which treats all four committees as distinct.

Unconscious implicit ordering. Sequential thinking is a common cognitive pattern in daily life, where actions are broken into manageable steps. In many real-life situations, we approach tasks this way simply because it feels intuitive. When carried into counting problems, this natural tendency can introduce an implicit structure and lead to assumptions about how elements should be selected or grouped. The following excerpt exemplifies how such ordering emerged naturally.

> *Ana*: we want to create 4 groups of 4 students, out of a total of 16. To make it easier, let us do it one at a time: First, we will choose a group of 4 from 16 people, that is, C (16,4). Now, we want another group of 4, but now, out of twelve total people, since four of the previous sixteen have already been chosen. That makes it C (12,4). We have to repeat next step like that for the remaining 8 people to get C (8, 4) and then Finally, we have to create the last group of 4, but now we have only 4 students to choose from. Since the order of choice does not matter, it is rather intuitive that our C (4,4) is equal to 1. Therefore, all we must do is join all those combinations.

Ana's explanation reflects how a step-by-step approach, while intended to simplify the task, can introduce an ordering structure. Although she explicitly stated that the order of choice does not matter, likely referring to the order of students within each group, her sequential construction suggests an implicit assumption of ordering among the groups themselves. Based on this interpretation, Ana supported Alex's solution. This example illustrates how the structure of a counting process can shape the interpretation of the set of outcomes.

Interpretation 2: The Committees Are Indistinct

The role of wording. In some cases, students viewed the committees as indistinct based on how they made sense of the term *committee*. They viewed the term as describing a set of equivalent groupings. This perspective is reflected in the following excerpt.

> *Sarah*: The committees are 4 random groups, so it doesn't matter which group anyone is in.

Sarah's response suggests she treated "committee" as a neutral term, viewing the groups as interchangeable. By referring to them as "random groups," she overlooked any functional distinction, leading her to interpret the committees as indistinct and disregard ordering among them. This interpretation prompted Sarah to select Ben's solution.

Mathematical experience. Some participants approached the problem with expectations shaped by their prior encounters with combinatorics. Their interpretations reflected the distinctions they had experienced in earlier tasks, including how such distinctions were stated. The excerpt below shows how students' mathematical experience can inform their assumptions.

> *Madison*: Because there was no specific indication that the committees are distinct, there was no reason to think that they were. If the question wanted to imply that each committee is distinct then the question would have indicated that in some way.

Madison's reasoning highlights how the absence of explicit wording led to the assumption that no distinction between the committees was intended. Her interpretation was shaped by prior experience with combinatorics tasks and the ways distinctions had been communicated in those

settings. In this way, Madison's explanation illustrates how students draw interpretive meaning not just from what is stated in a problem, but also from what is left unsaid.

Interpretation 3: Committee Members Are Ordered

Real-world experience. Some participants considered not only the distinctness of the committees but also whether members within each committee should be treated as ordered. These interpretations often reflected real-world contexts where roles, positions, or functions within a group are assigned. The following excerpt illustrates how a participant invoked a familiar setting, a sports tournament, to justify why the order of members might matter.

> *Simon:* Imagine we have 16 students and we want to make 4 teams of 4 for a soccer tournament … There might be specific positions we can fill on a soccer team, and if there's a tournament bracket so it might matter what team we end up on.

Simon's response reflects how his familiarity with structured team settings informed his assumptions about the task. By relating the scenario to a soccer tournament, he drew on the idea that individuals in a group may have assigned roles or positions. This connection to real-life experiences introduced distinctions that might not have been explicitly required by the problem but felt natural within the imagined context. Simon's interpretation guided him toward Nikki's solution, which reflects the view that both the committees and their members are ordered.

Interpretation 4: Committee Members Are Unordered

Real-world experience. Some participants drew from real-life contexts to justify that the arrangement of members should not matter. Their reasoning emphasized that a group's identity is determined by its members, not their arrangement. The following excerpt illustrates this view.

> *Sam*: It does not matter whether you think about your committee as Sherry, Joseph and Timmy or as Joseph, Sherry, and Timmy. In either case, the same three people are in the committee. It might also be helpful to contrast this with something like a smartphone passcode (where the order of digits matters), and 1234 is not the same as 4321. One of these will unlock your phone, and the other will not.

Sam emphasizes that a group's composition remains unchanged regardless of member order. Comparing committee formation to a passcode, she noted that in one case, reordering does not affect the group, whereas in another, it fundamentally changes the outcome. This contrast shows how real-world reasoning shaped her interpretation of when order matters.

The interpretations discussed in this section reveal that students' combinatorial reasoning is influenced not only by the explicit conditions of the task but also by subjective assumptions tied to language, context, and structural framing. These factors play a central role in how students construct sets of outcomes and determine appropriate counting strategies.

Conclusion

This study refines the construct of *subjective combinatorics* by emphasizing the *multiplicity of plausible sets of outcomes* and clarifying the roles of *student-related factors* (such as imagination, embodiment, personal experience, and mental models) and *problem-related factors* (such as context and wording). These refinements provide a sharper account of how subjectivity shapes combinatorial reasoning, illustrating that different yet reasonable interpretations of sets of outcomes can emerge from the same task. In doing so, the study demonstrates the usefulness of subjective combinatorics as a lens for analyzing students' engagement with counting problems and points toward future research on how subjectivity shapes mathematical reasoning more broadly.

STEM Teaching Practices: Before, During, and After Pandemic Response Teaching

Naneh Apkarian
San Diego State University

Estrella Johnson
Virginia Tech

Spring 2020 marked the start of a national pandemic response teaching (PRT) period as colleges and universities responded to the public health emergency and associated upheavals and restrictions. Instructional practices and delivery modalities changed during this period, but there have been lingering questions about any lasting impact on pedagogy. In 2025, we conducted a national survey, following up with instructors of undergraduate chemistry, mathematics, and physics courses who had reported on their teaching in 2019, to explore this question. This paper focuses on questions about modality of instruction, distribution of class time between lecture and more active practices, and a set of other common instructional practices. In general, we find an aggregate return to pre-PRT practices, although there has been uptake of certain auxiliary digital practices (e.g., online office hours).

Keywords: introductory courses; teaching practices; pandemic; instructional change

Instructional practices in introductory STEM courses vary across disciplines, campuses, courses, and individual instructors. Over the last several decades in the US, there has been a push to incorporate research-based instructional strategies (RBIS) in these courses, with a particular emphasis on "active learning," an umbrella term used to describe pedagogical approaches that incorporate doing and discussing mathematics during regular class meetings. Despite some shifts, the majority of introductory STEM students still spend the majority of time in class listening to an instructor lecture or solve problems, something which has been repeatedly documented in large studies across the USA (Apkarian et al., 2021; Dancy et al., 2024; Johnson et al., 2022; Wang et al., 2024; Smith et al., 2021; Stains et al., 2018; Yik et al. 2022b).

Since then, higher education experienced a massive disruption. In particular, the global COVID-19 pandemic caused many institutions to move online in Spring 2020, and to incorporate modified practices due to public health concerns and local policies (Johnson et al., 2020). Across states and institutions, these modifications varied both in their nature and duration, though most colleges and universities returned to "normal" by the end of the 2021-22 academic year. Questions have persisted about any lasting effects of instructors' pandemic response teaching (PRT), particularly in the aggregate (Engelbrecht et al., 2020; 2023). These questions affect both our understanding of the current STEM instructional landscape and our ability to leverage research conducted prior to the pandemic.

This paper is part of an ongoing study aiming to answer those questions with particular attention to practices used in introductory general chemistry, single-variable calculus, and physics at undergraduate institutions. We re-surveyed instructors of these courses who had previously reported on their practices in 2019, giving us a unique ability to report on shifts (or lack thereof) in pedagogy. This paper specifically focuses on two research questions:

1. Has the time distribution of in-class practices, across lecture, individual work, group work, and whole class discussion, changed since 2019?
2. What common practices did instructors use before, during, and after PRT? Which, if any, were more likely to be abandoned, paused, or adopted throughout this period?

Background & Theory

Pandemic Response

On March 11, 2020, after months of monitoring the spread of disease, the World Health Organization officially declared COVID-19 a pandemic (World Health Organization, 2025), sparking international public health policies which included school closures around the world, including most higher education institutions in the United States – at least temporarily (Nurunnabi & Almusharraf, 2020). This generally meant a rapid shift to online remote instruction without significant prior preparation, previous experience, or professional development (Johnson et al., 2020; Kirkman et al., 2021; Skliarova, 2022).

Pedagogy in Spring 2020 is sometimes referred to as *emergency remote teaching* or *emergency response teaching*; we refer to the entire period of Spring 2020 through the end of the 2021-22 academic year as *pandemic response teaching* (PRT), including both the immediate response and more planned instruction as policies shifted and restrictions eased. We note that, while instructors had more time to prepare for teaching under extenuating circumstances for the 2020-21 and 2021-22 academic years, it was broadly understood that the policies in place to ensure public health would be in place for an unknown, but finite, period – as opposed to a permanent adjustment.

Since the shift to PRT, there have been questions about the extent to which those practices will have some lasting impact on college instruction (e.g., Engelbrecht et al., 2020; 2023). Optimists noted many examples of instructors around the world taking the pandemic as an opportunity to examine and reflect upon their teaching practices and experiment with new ideas as alternatives to standard practice became a necessity (e.g., Albano et al., 2020; Gosztonyi, 2021; Maciejewski, 2021; Rapanta et al., 2020) and hoped that change would be widespread, and positive (Engelbrecht et al., 2023). Others urged caution, in particular noting that the emergency-response online teaching enacted in Spring 2020 was distinct in design and implementation from purposefully developed online learning programs (Hodges et al., 2020). There can be no doubt that human experiences through the pandemic impacted individual instructors, but the question of how those experiences impacted teaching practices at scale remains open.

Choosing Practices

One consistent result found across many studies of instructors' practice is that their personal experiences influence their instructional approach (Andrews & Lemon, 2015; Apkarian et al., 2021; Emery et al., 2021; Oleson & Hora, 2014; Yik et al., 2022ab). Thus, we assume that how instructors thought and taught prior to PRT influenced the decisions they made during PRT, and that their experiences during PRT now also influence their current decisions and practices. Figure 1 shows a toy model of this theorized influence: prior practices and beliefs contribute to current practices and beliefs, mediated by PRT experiences. We cannot say, *a priori*, however, in what direction(s) these changes might have occurred.

In higher education contexts, most theories of change focus on guided change (with identifiable change agents and premeditated, though flexible goals) or long-term unguided evolution. The unique conditions of the COVID-19 pandemic with regards to higher education mean that many change theories are not entirely satisfactory in terms of predicting outcomes across the country - hence the need for empirical work such as that presented in this paper.

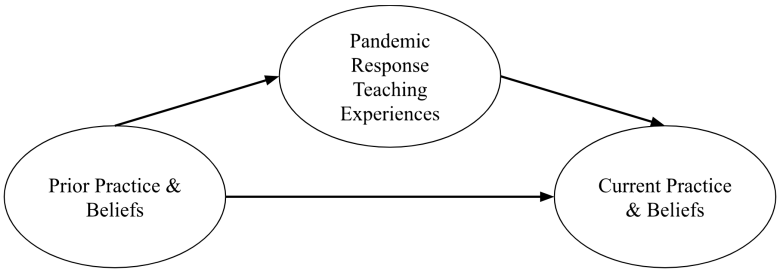

Figure 1. Toy model of theorized influence of prior practice and beliefs, mediated by PRT experiences, on instructors' current practices and beliefs.

The CACAO model (Dormant, 2011; Viskupic et al., 2022) draws on many change theories and is intended to help people plan changes, drawing focus to four elements: the *change* itself, the *change agents* who support the intended *adopters* through the change process, and the *organization* in which they reside. This model outlines five stages of the adoption process for new practices: awareness, curiosity, mental tryout, hands-on tryout, and adoption. Viewed through this lens, we can say that the pandemic forced many instructors to skip directly to the "hands-on tryout" stage, without prior preparation or the support that might be provided by deliberate agents of change. We note that there was not a unitary "change" being tried out, but rather a constellation of strategies, techniques, and technologies being engaged across different and evolving contexts. As such, we explore which aspects (if any) of instructors' PRT were adopted after the crisis had passed and mandates were lifted.

Research Methods

Participants & Data Collection

We leveraged the roster from a previous research study, conducted in 2019, to recruit participants to the study. The initial roster consisted of roughly 17,000 names gathered from publicly available information on university websites and targeted those who had taught introductory chemistry, physics, or single-variable calculus at colleges and universities across the country in the 2017-18 or 2018-19 academic year; 3,679 of these met the desired criteria and participated in the original study.

The entire original roster was contacted again to capture those who taught before *and* after the pandemic-induced disruption c. 2020-2023. To be eligible, instructors must have taught one of the target introductory courses in the 2023-24 and/or 2024-25 academic year. In total, 933 participants provided usable responses to our survey: 339 chemistry, 279 mathematics, and 315 physics; roughly two-thirds of responses in each discipline came from individuals who completed the 2019 survey, allowing for direct comparison. Instructors who participated in both surveys can be linked via an anonymous identifier, allowing for direct comparison.

Data was collected via web-based survey using the Qualtrics platform. The majority of the survey questions were copied from the survey used in 2019 (Apkarian et al., 2021; Yik et al., 2022ab), and asked instructors about their course structure (e.g., class size, classroom setup), department context (e.g., coordination of course content), instructional practices, experiences with research-based instructional strategies, professional context, and personal identity questions. New items were developed to capture instructors' experience during the pandemic response teaching period, including questions about how many terms they taught online, which (if any) RBIS they tried, and the resources and support they had access to in that period.

Data Analysis

This paper reports on three sets of survey items. The first captured instructors' experience teaching undergraduate courses in four different modalities (face-to-face; online synchronous; online asynchronous; hybrid) before, during, and after PRT. The second set asked instructors to estimate the percentage of class time, in a typical week, that students spend (a) listening to the instructor lecture or solve problems; (b) work on tasks individually; (c) work on tasks in small groups; and (d) engage in whole class discussion (these were required to total 100). The third set of questions presented instructors with a list of eight teaching-related practices and asked instructors to indicate if they had used the practice before, during, and/or after the pandemic response period; "never" was also an option, to distinguish between those who skipped the item and those who had never used a practice.

Analyses were conducted on complete cases (by focal item) and so the *N* size varies. We present descriptive statistics leveraging both the earlier data set (collected in fall 2019) and the new data set (collected in spring 2025). We leverage *t*-testing to compare data from 2019 and 2025, both in the aggregate using the entire sample and paired t-tests to directly compare repeat participants and applied a Bonferroni-corrected threshold to account for the increased rate of Type I errors when engaged in multiple hypothesis testing.

Results

Instructional Modality

As expected, instructors in our study were predominantly teaching face-to-face courses until partway through the spring of 2020, when public health led to widespread social distancing policies. In the later part of the spring, online synchronous and online asynchronous were the most common modality in the emergency situation. In the first full academic year of pandemic response teaching (2020-21), with some additional time for preparation but before vaccines were widely available, these four modalities were almost equally in use. The following year (2021-22) saw an increasing return to face-to-face teaching, and by 2025 when the more recent data was collected, the pattern of instruction was back to pre-PRT levels, closely matching reports about teaching modalities early in the Spring of 2020 (see Figure 2).

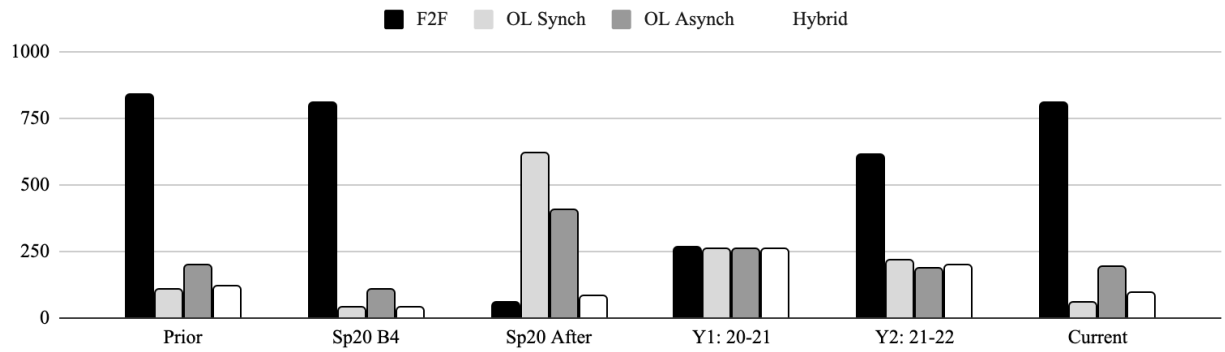

Figure 2. Chart showing number of respondents reporting using each of four modalities, for any course, from before Spring 2020 through Spring 2025 (current).

Distribution of Class Time

One outcome measure used in the first study was the reported percentage of class time, in a typical week, that students spend listening to the instructor lecture or solve problems, as opposed

to working individually, working in small groups, or engaged in whole class discussion. Instructors' averages, disaggregated by discipline, are presented in Table 1.

Table 1. Average reports of the percent of class time students spend in different learning activities.

	Chemistry		Mathematics		Physics	
	2019 *N*=1207	2025 *N*=339	2019 *N*=1293	2025 *N*=279	2019 *N*=1141	2025 *N*=315
Listening	59.01 (24.70)	54.66 (25.98)	56.48 (25.15)	54.36 (25.53)	53.94 (25.59)	53.16 (26.63)
Individual Work	11.69 (11.61)	14.20 (15.37)	11.31 (11.80)	13.04 (13.95)	10.60 (11.68)	11.21 (14.31)
Small Group Work	18.40 (19.43)	20.79 (21.38)	17.14 (17.90)	19.27 (19.10)	22.45 (20.53)	23.99 (21.43)
Discussion	10.89 (11.76)	10.35 (11.37)	15.07 (14.56)	13.33 (14.18)	13.01 (11.64)	11.64 (10.84)

Note: table entries give cell mean (standard deviation). For 2025 data, N=933; for 2019, N=3641.

In general, we see very small changes in the direction of slightly less lecturing and discussion being reported, and slightly more individual and small group work on mathematical tasks. We consider these slight differences to be of no practical significance, well within what we might accept as rounding error on the part of participants. We additionally conducted paired *t*-tests with the 2019 and 2025 data for the 588 individuals who responded to both surveys and filled out this item completely. With an adjusted *p*-value to account for multiple testing, none of the differences were statistically significant.

Note that this is not equivalent to saying that *no* instructors changed their practices over the previous six years. However, those changes average out to zero. As shown in Figure 3, across all three disciplines instructors reported balanced changes toward and away from lecture - both in number of instructors and the magnitude of the reported shifts.

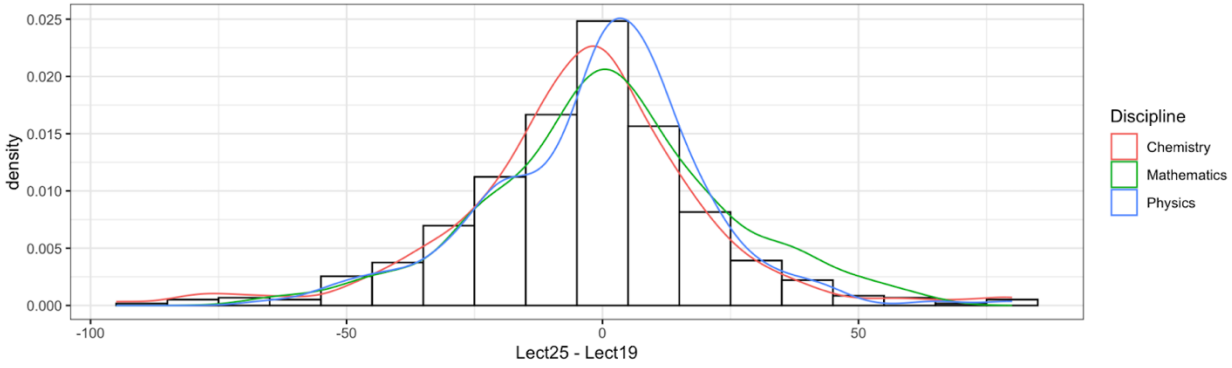

Figure 3. Chart showing density of reported changes in the percentage of class time spent in lecture from 2019 to 2025. Histogram shows aggregate responses, while colored lines show density distribution by discipline.

Usage of Instructional Practices Pre/Post

Looking across all instructors (chemistry, mathematics, and physics) certain patterns emerge from instructors' usage of certain practices before, during, and after the pandemic response teaching period (PRT). Table 2 shows the proportion of respondents who indicated that they had never used a particular practice, and the proportions (of the rest) who indicated each *pattern* of usage for that practice. That is, "only before" refers to those who used a practice before PRT, but not during or after; "during and after" refers to people who did not use the practice before PRT but used it during and after that time. For example, 40% of respondents indicated that they had

never used live polling in their class; of the 60% who *have* used polling, 20% did so only before PRT while 42% used it consistently before, during, and after PRT.

In terms of the CACAO change model, we are particularly interested in practices which instructors started or stopped using during PRT. With regards to the former, the "only during" pattern is indicative of trying out a new practice during PRT and discontinuing usage afterward; the "during and after" pattern is indicative of trying out a new practice and then adopting it. With regards to the latter, the "only before" pattern can be interpreted as trying out *not* doing something (e.g., trying teaching without live polling) and adopting that non-practice afterward; "before and after" discontinues that absence, returning to previously adopted practices. These patterns are the focus of our queries regarding changes to instructional practice which might have been catalyzed by the pandemic response, despite the unplanned nature of these changes.

Table 2. Proportion of instructors who used practices by pattern of usage.

	N_1	Never	N_2	Only Before	Before & During	Only During	During & After	Only After	Before & After	Always
Online office hours	838	-	808	-	-	0.39	**0.42**	-	-	0.15
Recorded lectures	831	0.14	711	-	-	0.30	0.37	-	-	0.26
Supplemental videos	824	0.16	691	-	-	0.15	0.25	-	-	**0.50**
Group work	829	0.14	715	0.08	-	-	-	-	0.29	**0.52**
Think pair share	807	**0.41**	477	0.13	-	-	-	-	0.31	**0.46**
Live polling/clickers	816	**0.40**	489	0.20	0.06	0.12	-	-	0.11	**0.42**
Online exam proctoring	821	0.31	568	-	-	**0.69**	0.14	-	-	0.11
Online HW system	834	0.11	746	-	-	-	0.07	-	-	**0.78**

*Note: Values ≤ 0.05 are omitted for clarity; no cell is truly zero (minimum 2); values ≥ 0.4 are **bold**. Individuals who skipped all possible answers for a particular practice are not included. N_1 refers to the total number of people who responded to the item at all; N_2 refers to the number of people who answered the question and at some point used the practice.*

Fewer than 5% of respondents indicated using any of these practices after PRT without prior usage. Online homework systems were the most consistently used, with 78% of people who ever used such a system reporting that they *always* used such a system. Online exam proctoring, on the other hand, was primarily a PRT-exclusive practice: of the 489 instructors who ever used online exam proctoring, 69% report only using it during PRT, with another 14% reporting that they adopted the practice during PRT and continued to use it afterward.

Practices which were "picked up" during PRT and maintained afterward include online office hours (42% of users), recorded lectures (37%), and supplemental videos (25%). Instructors not in this category were most likely to report using online office hours and recorded lectures exclusively during PRT (39% and 30%, respectively), and to report using supplemental videos throughout (50%).

To summarize the highlights: online/digital resources (office hours, recorded lectures, supplemental videos) were broadly adopted during PRT and maintained afterward; practices related to student-student interaction (group work, think pair share) were consistently used by many instructors, though a sizable group paused their use during PRT; live polling was also used fairly consistently, with a few instructors using it only during PRT and a few pausing their usage in that period; for those who used online exam proctoring, it was primarily consigned to PRT; online homework systems were already broadly in use and were used consistently throughout.

Discussion

We did not identify significant changes in reports of how class time is spent across any of the three disciplines with regards to the four major categories reported: listening to the instructor lecture or solve problems, working individually, working in small groups, engaged in whole class discussion. However, we did identify several changes between 2019 and 2025 in calculus instructors' usage of RBIS. While some change is expected due to an additional five years of teaching experience, we conjecture that some of these changes may have been accelerated by instructors' experiences during the pandemic response period. Note that this discussion is heavily conjectural, and further analysis of the quantitative and qualitative data is needed to support these conjectures.

Increased usage of online office hours, supplemental videos, and recorded lectures starting during PRT and continuing afterward suggests that once instructors had "figured out" these strategies, they maintained their usage. That is, PRT prompted instructors to take certain actions which were relatively straightforward to maintain, and they saw enough value in those practices to continue using them. In comparison, the interactive practices of think-pair-share and group work were used less frequently during PRT than before/after, although some maintained usage throughout. This is perhaps unsurprising, given the logistic difficulties of having students talk in small groups on web-based platforms that were widely in use. That think-pair-share saw a greater drop than group work may again be due to logistical considerations: putting students into breakout rooms to work on a task for 5-10 minutes may have been more manageable than quickly separating students into pairs for just a minute or two.

Online exam proctoring was fraught with considerations of integrity, logistics, privacy, and so on; upon the return to in-person teaching, it is therefore not surprising that it went back to being sparsely used, though it does appear that it had some uptake - perhaps allowing instructors to move examinations out of regular class meetings and save that time for additional instruction. Perhaps more surprising is that there was not an uptick in usage of live polling, since this is a built-in feature of many web-conferencing platforms and might have been easily employed by instructors. Overall, we see no major shifts to in-class instructional practices, although some auxiliary resources were adopted during PRT and remain in usage. This suggests two main conclusions: (1) there has been little lasting pedagogical change since the pandemic response teaching period; and (2) large-scale studies conducted prior to 2020 are likely still valid descriptions of undergraduate STEM instruction.

Parsing Students' Decision-Making During Analogical Reasoning: A Multi-Constraint Approach

Michael D. Hicks
Middle Tennessee State University

General theories of analogy dictate that connections can be made between virtually any two domains, thus suggesting an extremely large number of analogies that one might observe. Unsurprisingly, some analogies are of course more useful than others. How then do students come to observe "useful" analogies? Multi-constraint theory is one such avenue for exploring questions such as these. In this contributed report, I adopt a multi-constraint approach to parsing students' analogical reasoning with the goal of uncovering how certain choices are made when developing ring-theoretic analogies to group-theoretic structures. Analysis revealed that the participants exhibited variations in emphasis of analogical constraints during their reasoning in three ways: (a) adhering to basic structure, (b) adhering to conceptual structure, and (c) flouting constraints to advance exploration. Implications for the teaching and learning of abstract algebra and curriculum development are discussed.

Keywords: Abstract algebra, Analogy, Multi-constraint theory, Similarity-based reasoning

What are all the possible similarities and differences might students observe between a group and a ring? One student might focus on simple aspects of their definition, such as the number of operations each structure possesses. Another might focus on deeper features of the objects, such as recognizing both as being general examples of abstract structures that replace the need to focus on specific objects when writing proofs. Yet, it might be strange to hear a student suggest that groups and rings are similar because they are both spelled with letters from the English alphabet, or that they are different because one describes a collection of things, while the other describes an object you might wear on your finger. While such connections may not be considered all that valuable from an educational perspective, some would still count them as examples of analogies. In fact, highly general theories of analogy dictate that connections can be made between any two domains, thus suggesting an extremely large number of analogies that one might observe between any two situations (e.g., Faulkenhainer, Forbus & Gentner, 1983). A question then arises as to why some connections are more commonly observed over others.

To begin answering questions such as these in the context of mathematical thinking, I adopt a prominent theory of analogical reasoning that delineates types of constraints that occur naturally when reasoning by analogy. In this contributed report, I present an analysis of four students' thinking during their construction of (and reflection upon) ring-theoretic analogues to group-theoretic structures. Unlike previous investigations that focused more-so on *what* students created (e.g., Hejný, 2002; Hicks, 2024; Stehlíková & Jirotková, 2002), this report focuses on exploring underlying reasons for *how* certain choices were made over others when reasoning by analogy (e.g., Lee & Sriraman, 2011)

Theoretical Background: Multi-Constraint Theory

The approach to parsing students' thinking presented in this study relies on a theory of analogical reasoning known as *multi-constraint theory* (Holyoak & Thagard, 1989). This theory posits that the development of analogies is inherently guided by sets of constraints that serve as the foundation for coherent analogy formation. While it can be argued that analogies might be generated between any two given situations, it is rarely the case that a person randomly generates

analogies between any two situations as they go about their day-to-day activities. Instead, individuals tend to select particular mappings when generating an analogy. Multi-constraint theory takes as its premise the idea that adherence to a set of constraints leads individuals to develop analogies that satisfy their personal sense of rationality, thus greatly reducing the overall number of analogies that might be created to a smaller subset of "reasonable" analogies as opposed to creating analogies at random. I describe three broad categories of constraints below, all of which serve different purposes in dictating the construction of analogy from an individual's perspective.

Three Types of Constraints

The first constraint is known as *structural consistency*. This constraint suggests that in the course of analogy formation, there is an implicit desire to create, to as great of an extent as possible, a one-to-one mapping between the source and target domains. For example, consider possible analogical comparisons the following statements: (1) *Oliver is taller than Paul*, and (2) *the Sun is more massive than the Earth*. Each of these statements successfully establishes a relation of order between two objects, displaying that there is consistency of a basic structure between the two situations. As such, there is a clear structural mapping between these two domains through a form of proportional reasoning (e.g., Modestou & Gagatsis, 2010).
